2430.1	round 1	Gitxaala Nation	Air Quality Technical Data Report	Air Quality	End of second paragraph states "most effects to community receptors are attributed to future regional sources." As stated in the TDR, there are multiple future regional sources, and so it is not clear whether one of those sources or the Project itself is the largest contributor to effects on community receptors. All future regional sources are bunched into one group. We would like to know the relative importance of the Project relative to other individual projects.	The relative importance of the Project compared with other individual projects is described in detail in Section 7.4.2 of Appendix A (Air Quality TDR). The CEA Case Attribution section breaks down the contribution of the CEA case at eight locations by 1) the Base Case, 2) the Project Alone Case, and 3) Other Future Sources. Determining which future project is responsible at each receptor is a matter of reviewing the isopleth maps for the parameter in question and studying Table 15 (to determine which project was included in the modelling) and Figure 3 (to determine the included projects location). For example, studying Figure 5-49 shows the SO2 maxima for the CEA Case is at Fairview Terminal.
2431.1	round 1	Gitxaala Nation	Air Quality Technical Data Report	Air Quality	No frequency of exceedance plots. Only one reference to FOE values on page 42 of TDR. Statement on page 49 that characterizes exceedances of PM10 and NO2 as "short term in duration, infrequent" are not backed up by actual published values. In Appendix 1 page 22 is states that "frequency counts of hourly exceedance will be reported". This is not done in the TDR. On page 4.2-37 of EA FOE for PM10 and NO2 are mentioned in the text for CEA case and Application case only. There needs to be a more explicit discussion of frequency of exceedance.	The dispersion modelling indicated that there are predicted exceedances of PM10 and NO2 adjacent to, and primarily attributable to emissions from, facilities other than the Aurora LNG Project. Frequency of exceedance plots for PM10 for Base Case, Application Case and CEA Case have been provided as Figures 1, 2, and 3 of the "Air Quality Figures (#1270.1)" technical memo. The maximum PM10 concentrations for the Base Case, Application Case and CEA Case (i.e. where exceedances are shown to occur) are predicted adjacent to the Prince Rupert Grain Terminal. The maximum frequency of exceedance for the Base Case, Application Case and CEA Case is 7.5%, 7.6% and 7.8% of the time, respectively. A frequency of exceedance plot for 1-hour NO2 for the CEA Case has been provided as Figure 4 of the "Air Quality Figures (#1270.1)" technical memo. The maximum NO2 concentration for the CEA Case (i.e. where exceedances are shown to occur) is predicted adjacent to the Fairview Terminal. The maximum frequency of exceedance for the CEA Case is 7.9% of the time (28.7 days where the daily hourly maximum exceeds the AQO of 188 ug/m3). The "Air Quality Figures (#1270.1)" technical memo will be filed with the BC EAO.
2432.1	round 1	Gitxaala Nation	Air Quality Technical Data Report	Air Quality	The scale of the figures does not allow the reader to see isopleths close to the Project or close to CAC maxima. Would be helpful to see some zoomed in figures to see these areas more clearly.	The scale of the figures and the selected isopleth interval is chosen to balance the need for detail over a large area without cluttering the figure with unnecessary detail. There are 71 isopleth maps in the Air Quality Technical Data Report (Appendix A of the Application). If the Gitxaala Nationwould like to provide a list of figures and specific geographic areas of interest, some revised maps with a larger scale can be provided.
2433.1	round 1	Gitxaala Nation	Air Quality Technical Data Report, Appendix 1	Air Quality	This Table shows that precipitation values derived from WRF were low compared to normal precipitation. Appendix 3 Table 7-2 also shows that WRF precipitation is ~25-30% too low compared to actual precipitation over the modelled years. This will have effects on deposition rates and ambient concentrations. Why not use precipitation data from Prince Rupert Airport and convert daily values to hourly? What is the effect on calculated deposition rates that are used to assess acidification and eutrophication of using precipitation rates that are too low?	Table 7.2 shows that precipitation at Prince Rupert Airport and Prince Rupert Mont Circle are under-predicted by 25% and 30% respectively. Experience with like projects in a similar setting shows that this range of under/over prediction are common and expected. This information has no meaningful effect on the spatial pattern shown in Figure 7-9. The overall effect of this discrepancy on the effects assessment regarding acidic deposition is small. Prince Rupert Airport precipitation was not used as input to the CALMET model as the final approved Detailed Model Plan stated that precipitation from the WRF model would be used. The WRF precipitation data was determined to be representative and have the advantages of spatial variation and accounting for orographic effects (increased precipitation at high elevations).
2434.1	round 1	Gitxaala Nation	EA Certificate Application	Air Quality	A commitment by the proponent is made to participate and contribute to regional ambient air quality monitoring programs. In our opinion it is very important to have ongoing continuous monitoring of CACs considering the modelling suggests that exceedances of PM10 and NO2 are likely. The details of this monitoring need to be established.	Details of Aurora LNG's participation in regional ambient air quality monitoring programs will be established prior to the commencement of operation of the Project. It is expected that the program will be consistent with any requirements that may be outlined in potential EAC conditions and in the process of obtaining a Permit under the Environmental Management Act, Waste Discharge Regulation.
2435.1	round 1	Gitxaala Nation	Air Quality Technical Data Report, Appendix 2	Air Quality	Fugitive dust from construction activities are considerable from the handling and processing of materials, but was determined negligible based on precipitation data and peat moss composition of the materials moved. More clarification should be given on the precipitation in the area and its contribution to eliminating fugitive dust emissions. There is a potential for dust events during periods of no precipitation especially during the summer. As most emission factors for fugitive dust are based on moisture content and silt content, these parameters should be determined to support the exclusion of fugitive dust during construction.	Measures are proposed to reduce, avoid, or mitigate coarse fugitive particulate emissions from construction. They are contained in Table 4.2-10 of part 4.2 of the Application (Mitigation Measures Proposed to Avoid or Reduce Air Emissions). Measures are proposed such as limiting vehicle speed, and dust suppression. Coarse particulate matter emissions are easily managed in this setting, and are generally not an issue. Consistent with the final approved Detailed Model Plan (Appendix 1, Air Quality - TDR: Appendix A of the Application), the assessment focuses instead on fine particulate matter (PM2.5) from combustion sources.
2436.1	round 1	Gitxaala Nation	Air Quality Technical Data Report, Appendix 2	Air Quality	The load factor was described as the ratio of actual engine fuel consumption to maximum rated output. It is unclear how the load factor for each equipment was calculated based on the engine power in horsepower (hp) and fuel consumption in litres per hour per unit (L/hr/unit).	The load factor for each engine was calculated based upon the ratio of actual engine power output to maximum rated engine output. The average engine power output was calculated based upon the fuel consumed, energy content of the fuel, and thermodynamic efficiency of a typical engine, assumed to be 35%. Load Factor = (average power output / maximum power output) Average power output of the engine was calculated as: Average Power Output (bhp) = (L/h of diesel) * (1 USG/3.785 L) * (137,000 BTU/USG of diesel) * (0.000393 bhp-h/BTU) * (thermodynamic efficiency of 0.35)
2437.1	round 1	Gitxaala Nation	Air Quality Technical Data Report, Appendix 2	Air Quality	"The emission factor for NOx is 2.6 g/hp-hr for all diesel equipment in Table 3-2 and Table 3-5 of the TAR. While there was no clear indication on the origin of the emission factor, NOx emission factors for equipment with power rating from 100 hp to 750 hp appears to be consistent with Table A4. in the US EPA publication ""Exhaust and Crankcase Emission Factors for Nonroad Engine Modeling - Compression-Ignition, NR-009d"" and accounting for the Transient Adjustment Factors (TAFs) provided in Table A5 of the same document. However, equipment with power rating less than 100 hp would have a higher emission factor based on Table A4. The emission factor for CO is either 3.7 g/hp-hr or 2.6 g/hp-hr for all diesel equipment. It is not clear how the CO emission factors were derived as they are not comparable to CO emission factors provided in Table A4 and TAFs provided in Table A5. "	The emission factors that were used for estimating emissions from the construction equipment are obtained from the emission limits in The Off-Road Compression-Ignition Engine Emission Regulations (SOR/2011-261, SOR/2005-32). As more than 90% of diesel consumption (based upon total hp-hours) is associated with diesel equipment with engines larger than 100 hp, the emission calculations were simplified and only adopted emission standards for engines greater than 100 hp. Aurora LNG has not yet started detailed construction planning and the exact composition and engine size of the construction fleet has not yet been determined. Based upon the estimated construction period for the Project and the typical lifetime of heavy duty construction equipment, it is anticipated that the construction fleet would consist of primarily Tier 4 compliant construction vehicles (i.e. better than Tier 3 assumed for calculation purposes) but may also contain some Tier 3 or Tier 2 compliant engines for select specialized equipment. The actual emissions from the diesel construction equipment are anticipated to be less than the estimate presented in Appendix 2 of the Air Quality TDR (Appendix A of the Application).
2438.1	round 1	Gitxaala Nation	Air Quality Technical Data Report, Appendix 2	Air Quality	Manufacturer performance data was used to estimate NOx emissions from compressor gas turbine drivers. Although the accuracy of the data maybe higher, there is a potential for underestimating NOx emissions as manufacturer data maybe based on optimal operation of equipment. Emission factors are recommended to provide a more conservative estimate of emissions.	The manufacturer performance data are in fact performance guarantees warranted by the various turbine manufactures. The manufacturer guarantees are a conservative representation of NOx emissions from Project gas turbines as actual emissions are typically less than the guaranteed upper limit. Project NOx emission estimates from the proposed gas turbines are conservative as they are based upon the adoption of manufacturer guarantees and the assumption that all turbines operate continuously at 100% of their maximum rated capacity.
2439.1	round 1	Gitxaala Nation	Air Quality Technical Data Report, Appendix 2	Air Quality	The estimated emissions in tonnes per day of PM10 is less than PM2.5 in Table 4-8. How is this possible?	In Table 4-8, PM10 is listed as 0.004 t/d, and PM2.5 is listed as 0.0044 t/d. In fact, all PM emitted by gas turbines is <2.5 um in diameter, and therefore PM2.5 is equal to PM10. The discrepancy is owing to the PM10 emission number being rounded to three decimal places, and the PM2.5 being rounded to 4 decimal places.
2440.1	round 1	Gitxaala Nation	Air Quality Technical Data Report, Appendix 2	Air Quality	The text in section 4.7 indicated 206 Q-Flex LNG carriers will visit the terminal per year, which is contrary to 256 carrier visits indicated in Table 4-29. Clarification in which number was used in the calculation is required.	The correct number of Q-Flex LNG carriers that were assumed to visit the terminal per year is 256. The value of 206 noted in the text in section 4.7 of the Air Quality Technical Data Report is a typographic error. The calculations were correctly completed using 256 Q-Flex LNG carrier visits per year. An errata document is being prepared that will capture this correction and it will be filed with the BC EAO.
2441.1	round 1	Gitxaala Nation	Air Quality Technical Data Report, Appendix 2	Air Quality	The load factor was calculated based on actual speed and maximum speed rather than engine output. The calculation is likely not an accurate estimate of the vessels' load factor, and updating the calculation is recommended.	The required power output for the main engine of the vessel is a function of vessel speed. The calculated load factor for the main engine is correctly calculated as the ratio of actual speed to maximum speed to the power of 3. The equation is obtained from Section 2.5 (page 2-11) of ICF International (ICF) report titled "Current Methodologies in Preparing Mobile Source Port-Related Emission Inventories, Final Report. April 2009.". Revised calculations are not required.
2442.1	round 1	Gitxaala Nation	Air Quality Technical Data Report, Appendix 2	Air Quality	The emission factors of NOx, SO2 and PM2.5 were recommended by the BC MOE. Clarification and reference should be included for these emission factors.	During consultation with the BC MOE, Aurora LNG were advised of the MOE's preference that Aurora LNG adopt the same emission factors for LNG vessel emissions as used in the Prince Rupert Airshed Study (PRAS). The emission factors presented in Table 4-30 of Appendix 2 (Air Quality TDR) were selected based upon MOE recommendations to ensure consistency with the PRAS.
2443.1	round 1	Gitga'at First Nation	4.2	Air Quality	The LAA is inaccurate and must be extended to include the shipping lane, and as such, Project effects must be assessed for the entire shipping lane.	The approved Application Information Requirements (Section 4.2.2) notes that air quality will be assessed through dispersion modeling to determine the effects of Project marine vessels and Project facility equipment on air quality for activities near the LNG facility. This includes the LNG and support vessels when maneuvering and at berth which is considered the worst case for marine vessel emissions. The study areas including the LAA and RAA are the same as those approved by the BC MOE in the final Detailed Model Plant (Appendix 1, Air Quality - TDR). The AIR and the Detailed Model plan excluded modelling of Project LNG vessels when underway. The request to revise the study areas and include Project marine vessels while underway is therefore not in the scope of this assessment.

2444.1	round 1	Gitga'at First Nation	4.2	Air Quality	Please provide rationale for excluding trace air contaminants (e.g., PAHs and metals).	The Application focused on criteria air contaminants that the Project could produce in sufficient amounts to reasonably pose a risk to human health. The scope of the assessment was determined in collaboration with federal and provincial regulators and other stakeholders. Polycyclic aromatic hydrocarbons, volatile organiccompounds and metals were not included in the Application Information Requirementsunder Section 8 for the assessment of human health. Volatile organic compounds in LNG are predominantly methane, ethane, propane and other short chained hydrocarbons which are not toxic when inhaled. Refer to the technical memo, "Volatile Organic Compounds and Human Health Assessment" which will be filed with the BC EAO. The "Volatile Organic Compounds and Human Health Assessment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting. There is no pathway for the Project to contribute metals in the air. The assessment of metals in air are typical of mine projects, which produce mineralized dust.
2445.1	round 1	Gitga'at First Nation	4.2	Air Quality	Also see Air Quality comments submitted by TESA.	Aurora LNG acknowledges this comment from Gitga'at First Nation.
2446.1	round 1	Gitga'at First Nation	4.3	Greenhouse Gases	As it is clear that the Aurora LNG Project will not be in compliance with the provincial intensity benchmark of 0.16 tonnes of C02e/tonne of LNG, and may or may not reach within the intensity limits of 0.16-0.23 tonnes of C02e/tonne of LNG (for reduction in carbon tax levy), it is not clear how Nexen will offset the non-compliance. As with other VCs where offsetting is required these offsetting plans (even if preliminary) are presented in the assessment to understand how significant effects can be balanced. Although a Condition of the potential EAC will be the submission of a GHG Management Plan to the EAO (and other relevant agencies), again the contents of this plan are unknown and it is difficult to understand the true significance of the effects of GHG emissions. Suggest, at minimum, that GHG Management Plan include an GHG emissions offsetting plan and the development of these plans be a transparent process among all affected stakeholders.	Section 4.3.5.2 of the Application states "A GHG Management Plan will be prepared to identify the requirements of relevant GHG reporting legislation and will contain continuous assessment of monitoring and management requirements applicable to the mitigations listed in Table 4.3-12 (e.g., requirements of a fugitive emission survey program). The management plan will also contain a Best Achievable Technology analysis." Compliance with the provincial intensity benchmark of 0.16 tonnes of CO2e/tonne of LNG produced will be clarified in the annual reports submitted to the Climate Action Secretariat during the operation phase of the project. Each year, the project will be able to choose if it will purchasing credits, offsets or investing in a technology fund.
2447.1	round 1	Gitga'at First Nation	4.3 (Talbe 4.3-9)	Greenhouse Gases	As stated in the responses from the proponent to WG members associated with the screening review: "As indicated in the Application, it is not anticipated that waste management will interact with GHGs in a substantial manner. The primary basis for this conclusion is that Aurora LNG intends to avoid open burning of accumulated waste during all phases of the Project. Therefore, based on the avoidance and minimization of burning of accumulated waste, it is not anticipated that waste management contribute to GHGs in substantial manner. To reflect this commitment, the list of GHG mitigations has included a mitigation to "Minimize open burning of accumulated waste materials from the construction camp" (Mitigation 4.2.6) which will be managed through the Solid Waste Management Plan. This indicates that burning of waste during the construction phase may occur, but Aurora LNG plans to minimize this activity, where possible and safe to do so." Even with a timber salvage plan, how does Nexen propose to eliminate the wood waste from clearing 773 ha if burning will not take place?	The construction GHG inventory conservatively includes burning of biomass to account for debris, stumps, and unused portions of the salvaged timber. However, the Project intends to avoid the burning of biomass where practical and safe to do so.
2448.1	round 1	Gitga'at First Nation	4.3 (page 4.3-20	Greenhouse Gases	Gitga'at does not agree with the exclusion of LNG carrier emissions from the Project's operational total (emissions). The proponent should calculate the percentage of emissions attributable to their LNG carriers transiting, at minimum, from Triple island to the berth and assess this as part of the total project GHG emissions and operational intensity calculation.	Shipping activities are quantified and presented in Table 4.3-14 of Section 4.3 of the Application. These totals include emissions from LNG carriers (international) and domestic boats. In the GHG assessment, Project operation emissions are compared to PIR and NIR totals to determine the impact or percent contribution. However, the PIR and NIR totals do not include international shipping activities. Therefore, this assessment has excluded them in this comparison. Further, the GHG emission intensity presented in the Application does not include international shipping emissions as these would not be included in future compliance reporting obligations and would not be included in annual operation GHG intensity calculations.
2449.1	round 1	Gitga'at First Nation	4.3 (Table4.3-12	Greenhouse Gases	Gitga'at would like to participate in the development of the GHG Management Plan. As proposed in Table 4.3-12 many of the proposed mitigations that are to be a part of the GHG Management Plan are standard best practices; however, Gitga'at is looking for innovative and adaptive management strategies such that Nexen will be viewed as taking steps above and beyond industry standards to reduce their GHG footprint (as was done with other LNG companies in BC).	Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Greenhouse Gas Management Plan.
2450.1	round 1	Gitga'at First Nation	4.3	Greenhouse Gases	Gitga'at agrees with screening comments from WG members regarding the need to quantify the GHG emissions associated with Project decommissioning. Generally, and without FEED information, many of the emission rates / quantities associated with construction activities are but estimates. Estimates for decommissioning activities could be made.	The construction emission inventory was prepared based on Project estimates of equipment usage in conjunction with emission factors that apply to current mobile equipment. The decommissioning phase will be more than 30 years in the future. Therefore, not only are Project equipment estimates more difficult but emission factors for equipment that will operate at the time of decommissioning are currently unknown (i.e., current generation of equipment will be retired). Emissions calculations for the decommissioning phase are therefore not possible at this time. Given the nature of the decommissioning phase activities, it is expected that equipment usage will be for a shorter period of time and less intensive than the construction phase. However, future decommissioning requirements are unknown so this may be incorrect. Mobile equipment will likely consume fuel more efficiently and emissions may differ from current depending on technologies employed. These factors suggest that during the decommissioning phase of the Project, GHG emissions should be less than the construction phase.
2451.1	round 1	Gitga'at First Nation	4.3 (Table 4.3-15)	Greenhouse Gases	It is unclear how a Project Residual Effects on GHG Emissions can have a negligible magnitude from decommissioning activities if GHG emissions have not be quantified for those effects. Please provide more information.	Based on the assessment conclusion that construction emissions will have a "low" magnitude of GHG emissions and that decommissioning activity is expected to be a shorter period with less GHG emissions than the construction phase, it was qualitatively determined that decommissioning will have a negligible magnitude of GHG emissions. As identified in the Application, only land clearing emissions during the construction phase will impact the PIR and NIR emission totals. During the decommissioning phase, little-to-no land clearing is expected. Therefore, the decommissioning phase will have limited impact to the PIR and NIR emission totals.
2452.1	round 1	Gitga'at First Nation	4.3	Greenhouse Gases	Gitga'at would like to see a commitment from the Proponent to assess every five years (or less) the feasibility of using electricity for LNG production activities with the objective to move away from natural gas to electric drive power. This would also include a commitment to develop and build power drives such that they may be switched from natural gas drives to electric drive.	Aurora LNG acknowledges the intent of this comment. The Aurora LNG project is proposed in phases with two LNG trains planned for the first phase and subsequent phases based on market demand. If there are no power options available and the facility design is based on the current gas turbine scenario and the Project takes a final investment decision to move forward, it is very unlikely that Aurora LNG would consider retrofitting the constructed portions of the facility with e-LNG at a later date. Given the very high capital costs, very long lead order time, and the numerous linked aspects of changes in design involved and that all of the facility plans and operations procedures would be based on a defined set of hardware. However, it may be feasible to consider e-LNG for subsequent phases of the Project. This would need to be reviewed at that time based on the latest information available. The current Project design proposes the use of gas turbines for both LNG trains and onsite power generation. At this time, this is the only technically feasible option given the limitations of the BC Hydro grid to accommodate new industrial power demand. Aurora LNG is continuing discussions with BC Hydro and other potential power providers to determine if "e-LNG" is a feasible option. If Aurora LNG is able to secure sufficient reliable power for e-LNG in advance of detailed design, then this option will be reviewed in detail and may be considered a viable option at that time.
2453.1	round 1	Gitga'at First Nation	4.3	Greenhouse Gases	It is not clear if the Application calculated the GHG emissions resulting from peatland destruction. This is essential to calculate given the large amount of peatlands that will be destroyed from the Project.	GHG emissions specific to land clearing activities on peatlands is not specifed in the GHG Assessment. However, to estimate CO2e emissions related to land clearing, average emission and decay factors for the Skeena ecoregion from Dymond (2014) are used. These emission factors have been derived for ecoregions in BC and consider the types of biomass that may be handled in those regions.
2454.1	round 1	Gitga'at First Nation	4.3	Greenhouse Gases	Also see Greenhouse Gas comments submitted by TESA.	Aurora LNG acknowledges this comment to see additional Greenhouse Gas comments submitted by TESA.
2455.1	round 1	Gitga'at First Nation	9.2.2	Accidents or Malfunctions	The assessment of the potential risk of effects from an accident or malfunction is based on a risk matrix that combines the likelihood of a residual effect after mitigation and response measures and the consequence (i.e., severity or magnitude) of the residual effect after mitigation and response measures. Since the mitigation and response measures relevant to accidents that have the potential to affect marine water quality are not described in detail, it is difficult to evaluate the appropriateness of the conclusions made about the risk of an accident and whether that accident will have significant effects. More detail is required.	Mitigation measures for on-shore or marine spill events are provided in section 9.8.2. and 9.9.2, respectively, and will be further detailed in the Emergency Response Plan (described in Section 14.16).Aurora LNG will engage with regulators, Aboriginal Groups, and interested stakeholders in the development of the Emergency Response Plan.
2456.1	round 1	Gitga'at First Nation	9.8.3, 9.8.4	Accidents or Malfunctions	The Proponent has stated, "After mitigation and response measures have been implemented following an on-shore hazardous spill, the likelihood and consequence of residual effects to water quality from both small-scale and large-scale spills are very low. Based on these factors, the risk matrix ranking is remote and the residual effects are not significant." However, a large-scale spill of diesel oil into the marine environment would be difficult to clean up, making the consequence (i.e., severity of effects) and likelihood of residual effects both moderate or high (not “very low”) and resulting in residual effects that are significant. A fact sheet cited in Chapter 9 of the EAC application (US FWS 2004) states that "light oils [including diesel] leave a film on intertidal resources and have the potential to cause long-term contamination." In addition, an expert report on oil spill response prepared for the City of Vancouver and the Tsleil-Waututh and Tsawout First Nations stated that “collecting and removing oil from the sea surface is a challenging, time-sensitive, and often ineffective process, even under the most favourable conditions” (Nuka Research and Planning Group, LLC 2015). Therefore, spilled oil is likely to remain in the environment after mitigation and response measures, meaning there could be a determination of significant effects according to the definition provided in Section 4.5.12.8: "A significant residual adverse environmental effect on marine water quality is one that is predicted to result in a change in sediment or water quality that would result in a health risk to a local population of marine biota (toxicity for contaminants, habitat and physical damage to fish for suspended sediments). A health risk is identified considering the water and sediment quality guidelines, the conservatism built into those guidelines, and spatial extent and duration of exposure to altered water quality." The Application must be updated with realistic evaluations of hydrocarbon spills. Nuka Research and Planning Group, LLC. 2015. Oil Spill Response Analysis: Technical Analysis of Oil Spill Response Capabilities and Limitations for Trans Mountain Expansion Project. Expert Report prepared for Tsleil-Waututh Nation, City of Vancouver, and Tsawout First Nation. Available at: http://vancouver.ca/images/web/pipeline/NUKA-oil-spill-response-capabilities-and-limitations.pdf. Accessed: February 2017.	Following a release of diesel, natural attenuation by evaporation and dispersal are expected to reduce the hydrocarbons toxicity to marine organisms over the short term. If unrecovered following containment and recovery operations, and not cleaned up from shorelines, heavier hydrocarbon fractions may persist in shoreline sediments; however, the toxicity and bioavailability of these heavier fractions is expected to be rapidly reduced through weathering processes (including physical losses and biodegradation) (Lee et al. 2003; Page et al. 2002). Considering the elements of the significance threshold (e.g.,..spatial extent and duration of exposure to altered water quality) the characterization of residual effects from an onshore spill with respect to water quality, remains valid. References Lee, K., R.C. Prince, C.W. Greer, K.G. Doe, J.E.H. Wilson, S.E. Cobanli, G.D. Wohlgeschaffen, D. Alroumi, T. King and G.H. Tremblay. 2003. Composition and toxicity of bunker C fuel oil in intertidal sediments after 30 years. Spill Science & Technology Bulletin, 8(2):187-199. Page, D.S. Page, P.D. Boehm, G.S. Douglas and A.E. Bence. 2002. Identification of hydrocarbon sources in the benthic sediments of Prince William Sound and the Gulf of Alaska following the Exxon Valdez oil spill. In P.G. Wells, J.N. Butler, J.S. Hughes (Eds.), Exxon Valdez Oil Spill: Fate and Effects in Alaskan Waters. ASTM STP1219, American Society for Testing and Materials, Philadelphia, PA (1995), pp. 41–83.
2457.1	round 1	Gitga'at First Nation	9.9.2	Accidents or Malfunctions	While response measures to a vessel grounding or collision are outlined briefly in this section, a full oil spill response plan should be included as part of the EAC application. It appears that a spill response plan will be included in the Emergency Response Plan (Section 14.16), but this plan is currently under development, and this information is required during the Application Review Stage.	Emergency response plans are typically prepared during a project's detailed design phase when more information is available to identify appropriate emergency response countermeasures and site-specific emergency response resources.
2458.1	round 1	Gitga'at First Nation	Section 9.9.3, 9.9.4	Accidents or Malfunctions	The Proponent has stated, "After mitigation and response measures have been implemented following a vessel grounding or collision event with a spill of diesel or LNG, the likelihood and consequence of residual effects to water quality is low. Based on these factors, the risk matrix ranking is low. Residual effects on marine water quality from a release of diesel or LNG due to a vessel grounding or collision event are predicted to be not significant." However, while a website cited in Chapter 9 of the EAC application (NOAA 2014) states that "Small diesel spills will usually evaporate and disperse naturally within a day or less," it also states that "what is commonly referred to as "marine diesel" is often a heavier intermediate fuel oil that will persist longer when spilled. When spilled on water, diesel oil spreads very quickly to a thin film of rainbow and silver sheens, except for marine diesel, which may form a thicker film of dull or dark colors." In addition, "it is possible for the diesel oil that is dispersed by wave action to form droplets that are small enough [to] be kept in suspension and moved by the currents" (NOAA 2014). Therefore, dispersed oil droplets could have an ongoing effect on marine water quality. Furthermore, in October 2016 a tug boat carrying almost 60,000 gallons (> 200,000 litres) of diesel fuel ran aground near Bella Bella and the spill response was hampered by bad weather. The diesel spread across the water and contaminated the clam beds used by the Heiltsuk First Nation (CBC 2016). The Final Situation Report on this incident from Spill Response BC states that 107,552 litres of the 237,262 litres of diesel fuel (45%) on board the tug was recovered (Seaforth Channel Incident Unified Command 2016). In addition, it took over a month to complete the spill cleanup efforts on the water (Seaforth Channel Incident Unified Command 2016). This is evidence that diesel oil can remain in the water during and after a spill response. Therefore, the consequence (i.e., severity of effects) and likelihood of residual effects could both be moderate or high (not “low”) and result in residual effects that are significant. Since tug boats will be escorting the LNG vessels, there is the potential for a large diesel spill having lasting significant adverse environmental effects on marine water quality. The Application must be updated with realistic evaluations of hydrocarbon spills. CBC (Canadian Broadcasting Corporation). 2016. Bella Bella diesel spill cleanup complicated by severe weather. Available at: http://www.cbc.ca/news/canada/british-columbia/bella-bella-diesel-spill-cleanup-complicated-by-severe-weather-1.3806058. Accessed: January 2017. Seaforth Channel Incident Unified Command. 2016. Final Situation Report – Nov 21. Seaforth Channel Incident Unified Command Information Site. Available at: http://spillresponsebc.ca/2016/11/22/final-situation-report-nov-21/. Accessed: February 2017.	As noted in this comment, 107,552 litres of diesel were recovered out of the total tug fuel volume of 237,262 litre following tug Nathan E. Stewart grounding. It is important to note that the reported recovered volume does not account for any evaporative loss in volume (i.e., only a portion of the total 237,262 litres would have been potentially recoverable). Further, the referenced Final Situation Report (November 21, 2016) does not appear to suggest that spill clean up, that was specifically on-water, took one month. Shoreline cleanup assessment technique surveys (SCAT) were conducted between October 14 and November 20, 2016 (Seaforth Channel Incident Unified Command 2016), but involved the assessment of oiling on potentially affected shorelines. The potential persistence of heavier, weathered, hydrocarbon fractions in the marine environment is not expected to be synonymous with an increase in consequence ranking for water quality because toxicity, concentration and bioavailability of these fractions is expected to be reduced through weathering in the short term (e.g., by evaporation, dispersal, dissolution, spreading). Reference Seaforth Channel Incident Unified Command. 2016. Final Situation Report – Nov 21. Seaforth Channel Incident Unified Command Information Site. Available at: http://spillresponsebc.ca/2016/11/22/final-situation-report-nov-21/. Accessed: February 2017.

2459.1	round 1	Gitga'at First Nation	9.9.3, 9.9.4	Accidents or Malfunctions	The Proponent has stated, "After mitigation and response measures have been implemented following a vessel grounding or collision event with a spill of bunker oil, the likelihood of residual effects to water quality is low, while the consequence is moderate. Based on these factors, the risk matrix ranking is low. Residual effects on marine water quality from a release [of] bunker oil due to a vessel grounding or collision event are predicted to be not significant." While admitting that a bunker oil spill would have a larger consequence on marine water quality than an LNG or diesel spill, the Proponent still concludes that the risk is low and effects are not significant. However, bunker C oil is persistent. A website discussing bunker C spills (NOAA 2017) says "the oil can be carried hundreds of miles in the form of scattered tarballs by winds and currents. The tarballs will vary in diameter from several yards to a few inches and may be very difficult to detect visually or with remote sensing techniques." In addition, an expert report on oil spill response prepared for the City of Vancouver and the Tsleil-Waututh and Tsawout First Nations stated that "collecting and removing oil from the sea surface is a challenging, time-sensitive, and often ineffective process, even under the most favourable conditions" (Nuka Research and Planning Group, LLC 2015). Therefore, spilled oil is likely to remain in the environment after mitigation and response measures and there could be a health risk to a local population of marine biota, meaning that a vessel grounding or collision resulting in a spill of bunker oil could have a significant residual adverse environmental effect on marine water quality. NOAA (National Oceanic and Atmospheric Administration). 2017. No. 6 Fuel oil (Bunker C) Spills. Available at: http://response.restoration.noaa.gov/oil-and-chemical-spills/oil-spills/resources/no-6-fuel-oil-spills.html. Accessed: January 2017.	In the unlikely scenario that portions of released bunker fuel are not recovered through containment and recovery operations and are not cleaned up from shorelines, heavier hydrocarbon fractions may persist in shoreline sediments or on the water surface. The toxicity of these fractions to marine organisms is, however, expected to be rapidly reduced through weathering processes (including physical losses and biodegradation) (Lee et al. 2003; Page et al. 2002). Floating tar balls may be transported by winds and currents. The hard crust-like surface of tar balls, formed through the oxidation of high-viscosity unrecovered hydrocarbons floating on the sea surface, reduces the bioavailability of contaminants of potential concern (Martin 2011). The prediction for the significance of residual effects remains valid. References Lee, K., R.C. Prince, C.W. Greer, K.G. Doe, J.E.H. Wilson, S.E. Cobanli, G.D. Wohlgeschaffen, D. Alroumi, T. Hughes (Eds.), Exxon Valdez Oil Spill: Fate and Effects in Alaskan Waters. ASTM STP1219, American Society for Testing and Materials, Philadelphia, PA (1995), pp. 41–83.
2460.1	round 1	Gitga'at First Nation	Section 9.10.3	Accidents or Malfunctions	There appears to be a typo in the Water Quality Section on p. 9-46. The text states "Consequently, the magnitude of residual effect to air quality is negligible and within the geographic extent of the LAA." Since this is in the Water Quality section it is assumed the words "air quality" should be replaced with "water quality."	Aurora LNG acknowledges this is a wording error. The word 'air' in the sentence on p. 9-46 should be 'water' and this correction will be included in an erratum. An errata document is being created that will capture these corrections and it will be filed with the BC EAO.
2461.1	round 1	Gitga'at First Nation	Section 4.5.13.1	Water Quality	The Canadian Council of Ministers of the Environment (CCME) has not established interim sediment quality guidelines (ISQGs) and probable effects levels (PELs) for Total PAHs in sediments; however, ISQGs and PELs are available for 18 individual PAHs. These benchmarks should be used in Table 4.5-22 and carried forward to the effects assessment.	In the Marine Sediment and Water Quality Technical Report (Appendix F of the Application), sediment data were screened against the CCME guidelines for individual PAHs. Of the 192 samples tested, all were below the Disposal at Sea total PAH screening criterion, and only four samples had individual PAH concentrations above CCME ISQG. Given the limited number of individual PAH exceedences, the total PAH criterion, which encompasses 16 high priority PAHs was considered more appropriate for the effects assessment.
2462.1	round 1	Gitga'at First Nation	Section 4.5.13.1	Water Quality	The CCME has not established ISQGs and PELs for Total PAHs in sediments; however, other sources of "threshold effects" and "probable effects" type benchmarks have been developed for use in risk and/or impact assessments. For example, MacDonald *et al.* (1996) provides threshold effects levels (TELs) and probable effects levels (PELs) of 1.684 and 16.77 mg/kg dry weight, respectively. These benchmarks should be considered for use in the effects assessment. MacDonald, D.D., R.S. Carr, F.D. Calder, E.R. Long, C.G. Ingersoll. 1996. Development and evaluation of sediment quality guidelines for Florida coastal waters. Ecotoxicology. 5: 253-278.	The Disposal at Sea total PAH screening criterion encompasses 16 individual PAHs considered relevant to environmental effects in the marine environment. Therefore this criterion was considered the most appropriate for total PAH screening in the effects assessment.
2463.1	round 1	Gitga'at First Nation	Appendix F (5.3)	Water Quality	It is stated that concentrations of arsenic and copper were routinely above ISQGs, but at naturally occurring concentrations for the area. This statement should be verified by comparing to the distribution of concentrations in reference areas within the RAA.	The assessment of dredge material focused on sediment sampling within the dredge footprint and followed the Disposal at Sea evaluation criteria for characterizing sediments. Elevated arsenic and copper levels in soils of the Skeena Region are documented in the Ministry of Environment Protocol 4: Determining Background Soil Quality. These documented levels are similar to those found in sediment from the assessment area. Elevated levels of copper and arsenic were found at all depths sampled, (down to 15 m below seabed), indicating that these metal concentrations predate industrial activity.
2464.1	round 1	Gitga'at First Nation	4.9.5.1	Marine Fish and Fish Habitat	The Marine Fish and Fish Habitat VC was reviewed alongside the Marine Water Quality VC in order to understand whether effects related to exposure to TSS were addressed. Section 4.9.5.1 lists the assumptions underlying the effects assessment. To assess effects related to TSS exposure, factors including dredge volume, disposal volume, and dredge rate were used to predict concentrations and spatial extent of TSS exposure. However, assumptions around exposure duration were not explicitly stated here and need to be provided.	The amount of time TSS levels are anticipated to exceed guidelines for the protection of aquatic life associated with dredging and disposal at sea activities was included in the model as part of the sediment dispersion modeling exercises. As described in Appendix G (Technical Data Report - Aurora LNG: MOF and Terminal Dredge Modelling), elevated TSS levels are expected to persist in Casey Cove for the duration of dredging activities (dredging in Casey Cove is anticipated to run for approximately 20 hours per day for approximately 48 days), with levels returning quickly to baseline conditions upon cessation of dredging activities. At South Digby Island, elevated TSS levels are expected to persist for the duration of dredging activities (dredging is anticipated to occur for ten hours per day for approximately 13 days at Berth 1 North, 17 days at Berth 1 South, and 11 days at Berth 2), with levels returning quickly to baseline conditions upon cessation of dredging activities. As described in Appendix H (Technical Data Report - Aurora LNG: Disposal at Sea Modelling), elevated TSS levels are expected to persist at Brown Passage during and immediately following each disposal event, with levels returning to baseline conditions relatively faster in shallower waters than in deeper waters. Disposal of dredged materials from the MOF is anticipated to require 124 disposal events (once every 8 hours, for approximately 41 days); disposal of dredged materials from Berth 1 North is anticipated to require 18 disposal events (once every 16 hours, for approximately 11 days); disposal of dredged materials from Berth 1 South is anticipated to require 23 disposal events (once every 16 hours, for approximately 15 days); disposal of dredged materials from Berth 2 is anticipated to require 15 disposal events (once every 16 hours for approximately 9 days). Dredging and disposal at sea activities will be limited to the DFO least risk timing window (November 30 to February 15) and will take place over two years. The amount of time marine fish may be exposed to elevated levels of TSS during dredging and disposal at sea activities was considered in the assessment of potential changes in marine fish health (Section 4.9.5.5 of the Marine Fish and Fish Habitat VC). In addition to the duration of dredging and disposal at sea activities themselves, and associated TSS levels, other factors such as species, life stage, and the behaviour of the individual may also influence exposure duration. For example, some species (such as pelagic fish), may choose to move away from or avoid areas of elevated TSS (Kjelland et al. 2015), resulting in relatively short-duration exposure. Other species (such as demersal fish, species with lower motility, or sessile invertebrates) may remain near the dredge or disposal areas, resulting in exposure to elevated TSS for relatively longer duration (up to a maximum of approximately 2.5 months, the length of the DFO least risk timing window). Reference: Kjelland, M.E., Woodley, C.M., Swannack, T.M. and D.L. Smith. 2015. A review of the potential effects of suspended sediments on fishes: potential dredging-related physiological, behavioral, and transgenerational implications. Environment Systems and Decisions, 35(3): 334-350.
2465.1	round 1	Gitga'at First Nation	4.5.15	Water Quality	Residual effects of re-deposition on benthic invertebrates during and post- dredging activities have not been included in the effects assessment. This information needs to be provided and assessed.	The potential for marine fish and invertebrates to be crushed or buried by marine sediment associated with dredging activities is assessed under the 'change in mortality risk' effect (Section 4.9.5.4 of the Application). The potential for health effects to marine fish and invertebrates due to exposure to elevated TSS concentrations associated with dredging activities is assessed under the 'change in health' effect (Section 4.9.5.5 of the Application).
2466.1	round 1	Gitga'at First Nation	4.5.15.3	Water Quality	It appears that the proponent did not conduct an effects assessment for the discharge of wastewater effluent to the receiving environment. For a project of this nature where seawater is proposed to be used for several project operations, we would have expected a more in depth and quantitative assessment of potential effects on marine water quality and marine resources, at both intake and discharge locations. Furthermore, limited information on the proposed mitigation for sanitary wastewater effluent management during construction and operations was provided in the Application. For example, details on the expected capacity or treatment level of the wastewater facility were not provided. More detailed information is required. A comprehensive description of water management and associated environmental effects should be undertaken.	As stated in Section 4.5.15.3 of the Application (Characterization of Residual Effects – Waste Management), waste water outfall designs and locations will comply with federal and provincial legislation designed to protect water quality. Sanitary wastewater will meet effluent permit requirements, including dechlorination of any chlorinated wastewater. Mitigation 4.5.8, Table 4.5-26 also states that waste discharges to the marine environment will comply with the Fisheries Act, Canadian Environmental Protection Act, Canada Shipping Act 2001, and the BC Environmental Management Act (Waste Discharge Regulation). Specific details on waste volumes and contaminant concentrations are not yet available and will be determined during Front End Engineering Design. However, Aurora LNG is legally obliged to abide by all waste discharge regulations, designed to protect the marine environment. Environmental effects from waste discharge are therefore predicted to be not significant. Further details on Project waste discharges and associated regulations, are provided in the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2467.1	round 1	Gitga'at First Nation	4.5.15.3	Water Quality	It appears that the proponent did not conduct an effects assessment for the discharge of desalination effluent to the receiving environment. For a project of this nature where seawater is proposed to be used for several project operations, we would have expected a more in depth and quantitative assessment of potential effects on marine water quality and marine resources, at both intake and discharge locations. Furthermore, limited information on the proposed mitigation for desalination wastewater effluent management during operations was provided in the Application. For example, details on the volumes of effluent generated and the feasibility of meeting water quality guidelines (WQGs) were not provided. More detailed information is required. A comprehensive description of water management and associated environmental effects should be undertaken.	Desalination waste water will meet CCME and BC regulatory water quality guidelines (WQG) outside of the initial dilution zone. These guidelines allow a maximum temperature change of $\pm 1^{0}$C from ambient at any time, location, or depth and a maximum rate of change <0.5^{0}C per hour. The CCME interim WQG for salinity limits the change of salinity to 10% from background conditions for a given time and depth. The residual chlorine concentration at the edge of the initial dilution zone, will be below the CCME WQG (0.5 µg/L). The exact size of the initial dilution zone is not yet known, and will be determined through modelling in the permitting phase. However, under the Fisheries Act, waste discharges within and outside the initial dilution zone, cannot be acutely toxic to fish. The effect of desalination waste discharge was assessed based on adherence to legally-binding legislation, designed to protect aquatic life. Further details on Project waste discharges and associated regulations, are provided in the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2468.1	round 1	Gitga'at First Nation	Section 4.5.15.3	Water Quality	It appears that the proponent did not conduct an effects assessment for the discharge of cooling water effluent to the receiving environment. For a project of this nature where seawater is proposed to be used for several of project operations, we would have expected a more in depth and quantitative assessment of potential effects on marine water quality and marine resources, at both intake and discharge locations. Furthermore, limited information on the proposed mitigation for cooling water effluent management during operations was provided in the Application. For example, details on the volumes of effluent generated and the feasibility of meeting water quality guidelines (WQGs) were not provided. More detailed information is required. A comprehensive description of water management and associated environmental effects should be undertaken.	Cooling water discharge will meet CCME and BC regulatory water quality guidelines for temperature, outside of the initial dilution zone. These guidelines allow a maximum change of $\pm 1^{0}$C from ambient at any time, location, or depth and a maximum rate of change <0.5^{0}C per hour. The exact size of the initial dilution zone is not yet known, and will be determined through modelling in the permitting phase. However,under the Fisheries Act, waste discharges within and outside the initial dilution zone, cannot be acutely toxic to fish. The effect of cooling water discharge was assessed based on adherence to legally-binding legislation, designed to protect aquatic life. Further details on Project waste discharges and associated regulations, are provided in the "Discharges to the Marine Environment" technical memo, which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2469.1	round 1	Gitga'at First Nation	Table 4.5-26	Water Quality	Mitigation measure 4.5.5 is to use silt curtains, "where practicable, to reduce the spatial extent of suspended sediments in the water column during dredging activities." The description of how the silt curtains will be implemented is very brief. The use of silt curtains for mitigating the effects of elevated TSS on marine water quality should be described in more detail.	The manner in which silt curtains are employed is dependent on numerous factors, including water depth, currents, tides, wave height, wind direction and speed, and the nature of the work conducted within the curtains. As such, specific details on silt curtain use cannot be provided until these factors are established on a site-specific basis. Silt curtains will be used, where practicable, to isolate the work site from the surrounding marine environment, during dredging. Strong currents, high winds and waves, and frequency of marine traffic into/out of the work site may prevent placement of silt curtains, and or limit their effectiveness. Fluctuating water depth due to tidal patterns may also alter the area over which silt curtains can be employed. Use of silt curtains was classed as having a moderate likelihood of success due to the limiting factors listed above. The classification of "effective in the short-term" refers to the duration over which the measure is employed, and not the likelihood of success. The modelling of TSS plumes does not incorporate the use of silt curtains.
2470.1	round 1	Gitga'at First Nation	Table 4.5-26	Water Quality	There appears to be a contradiction between the statements in Table 4.5-26 that "there is a moderate likelihood of success" with mitigation measure 4.5.5 and "this mitigation measure is effective in the short-term." If success is only moderately likely than the mitigation measure will not always be effective, so further mitigations are required. Please describe additional effective mitigations.	The manner in which silt curtains are employed is dependent on numerous factors, including water depth, currents, tides, wave height, wind direction and speed, and the nature of the work conducted within the curtains. As such, specific details on silt curtain use cannot be provided until these factors are established on a site-specific basis. Silt curtains will be used, where practicable, to isolate the work site from the surrounding marine environment, during dredging. Strong currents, high winds and waves, and frequency of marine traffic into/out of the work site may prevent placement of silt curtains, and or limit their effectiveness. Fluctuating water depth due to tidal patterns may also alter the area over which silt curtains can be employed. Use of silt curtains was classed as having a moderate likelihood of success due to the limiting factors listed above. The classification of "effective in the short-term" refers to the duration over which the measure is employed, and not the likelihood of success. The modelling of TSS plumes does not incorporate the use of silt curtains.
2471.1	round 1	Gitga'at First Nation	Table 4.5-26	Water Quality	Mitigation of TSS dispersion during infrastructure (i.e., non-dredging) construction is not discussed in the table of mitigation measures proposed to avoid or reduce change in physical or chemical composition of marine waters. An assessment of mitigation during infrastructure construction is required.	In Section 4.5.15.3 of the Application, under Characterization of Residual Effects - General Construction Activities, it is stated that "The volume of sediment disturbed by marine construction will be much lower than for dredging, and mitigation measures (e.g., silt curtains) will be used where practical to limit sediment dispersion"
2472.1	round 1	Gitga'at First Nation	Section 14.9	Environmental and Operational Management Plans	The information on the Marine and Freshwater Resources Management Plan in Section 14.9 (approximately half a page) is insufficient to evaluate the adequacy of the plan. For example, the frequency and locations of water quality monitoring have not been provided. Please provide more information.	The intent of Section 14.9 of the Application was to identify the components of the Marine and Freshwater Resources Management Plan. Aurora LNG recognizes that the details of these management plans, such as monitoring intensity, frequency and location, are important to the success of the programs. Aurora LNG will engage with the appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the environmental management plans. Typically these plans include details on the drivers, objectives, methods, and reporting requirements. Please note that for water quality specifically, as per mitigation measure 4.5.8, Aurora LNG is committed to meeting all regulatory requirements, including compliance with CCME and BC water quality guidelines.
2473.1	round 1	Gitga'at First Nation	14.9	Environmental and Operational Management Plans	The Marine and Freshwater Resources Management Plan does not include any information regarding post-dredging sediment characterization. Considering that some contaminants of concern (COCs; e.g., dioxins/furans) are present in dredged sediments, it is recommended that a follow-up sediment characterization monitoring program is implemented to analyze deposited sediments within the MOF, Berth 1, and Berth 2 areas. Please outline a follow-up monitoring program for this activity.	Section 4.5.15 of the Application concluded that contaminant re-settling will be limited at and around the dredge pockets. Baseline sediment sampling indicated that dioxins and furan levels above CCME ISQG were contained in the upper 0.2 m of sediment. As such, the upper 0.5 m of sediment will be removed during dredging and disposed of on land. A small amount of sediment containing elevated dioxins and furans will re-settle in and around the dredge site, likely at reduced concentrations. Much of this re-settled sediment will be removed in subsequent dredging (down to -15 m chart datum) or covered subsequently with dispersed sediment of lower PCDD/F concentrations. Therefore, it is expected that surface sediment contaminant levels will decrease relative to existing conditions and that post-dredging sediment monitoring is not necessary.
2474.1	round 1	Gitga'at First Nation	4.5	Water Quality	Mitigation measures included meeting water quality guidelines; however, insufficient detail is included in the Application to assess the feasibility of meeting guidelines. Please provide more information and evidence that water quality guidelines can be met.	Details on how water quality guidelines will be met are provided in the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.

2475.1	round 1	Gitga'at First Nation	4.5	Water Quality	A TSS monitoring plan should be provided that includes suggestions for a station array around the constructions site and whether TSS will be monitored in real time. In the same context, a TSS exceedance response plan needs to be provided that entails how TSS is going to be reduced in case of exceedances.	As noted in mitigation measure 4.5.3, (Table 4.5-26: Section 4.5.15.3 of the Application), water quality will be monitored during dredging. This will consist of real-time turbidity measurements. The actual station array used during dredging will depend on various factors such as the nature and extent of in-water construction activity, weather and tidal conditions, and vessel traffic. Therefore, it is not possible to provide sampling arrangement details at this time. Mitigation measures to address water quality exceedences are also site and condition dependent, and will be determined on-site, with input from the environmental monitor, and the dredging contractor. This may include slowing or temporarily stopping some of the dredging activities in areas of high turbidity.
2476.1	round 1	Gitga'at First Nation	4.5	Water Quality	A safe storage and run-off containment plan is needed for the PCDD and Furan contaminated marine sediment site storage site on land.	As noted in mitigation 4.5-10 (Table 4.5-26, Section 4.5.15.3), the land disposal site will be designed and managed to meet BC Contaminated Sites Regulations (CSR) standards for sediment storage. It should also be noted that under BC Contaminated Sites Regulations, the dioxin and furan limit for disposal of sediment on non-agricultural land is 350 µg/g, more than 100 times higher than the maximum concentration recorded in the proposed dredgeate. The sediment will not be considered contaminated, as defined under the CSR. Consider the following: 1. The maximum concentration of PCDD/F in the sediment was 2.86 picograms per gram of sediment, based on mammalian toxic equivalency (pg-TEQ/g). 2. The BC Contaminated Sites Regulations for PCDD/Fs in sediment for marine and estuarine waters are: - Sensitive Contaminated Site - 130 pg-TEQ/g - Typical Contaminated Site - 260 pg-TEQ/g http://www2.gov.bc.ca/assets/gov/environment/air-land-water/site-remediation/docs/policies-and-standards/sed_criteria_tech_app.pdf 3. When sediments are disposed on land, they are managed as soils. The BC Contaminated Sites Regulations for PCDD/Fs in soil are: - Agriculutral/Parkland/Residential Land - 350 pg-TEQ/g - Commercial Land Use - 1,000 pg-TEQ/g - Industrial Land Use - 70,000 pg-TEQ/g http://www.bclaws.ca/EPLibraries/bclaws_new/document/ID/freeside/375_96_07 4. The BC Contaminated Sites Regulations - Schedule 7 for soil relocation to non-agricultural land for PCDD/Fs are: - 350 pg-TEQ/g http://www.bclaws.ca/civix/document/id/loo78/loo78/375_96_09 5. The Canadian Food Inspection Agency dioxin limit for all fish products is 20 parts per trillion (ppt), measured as TEQ. In comparison, the dioxin concentrations in sampled marine foods were: - Dungeness crab meat - 0.273 ppt - Dungeness crab hepatopancreas - 1.4 ppt - Clam - 0.811 ppt http://www.inspection.gc.ca/DAM/DAM-food-aliments/STAGING/text-texte/fish_man_standardsmethods_appendix3_1406403090196_eng.pdf
2477.1	round 1	Gitga'at First Nation	4.5	Water Quality	A silt curtain development plan must be developed.	The manner in which silt curtains are employed is dependent on numerous factors, including water depth, currents, tides, wave height, wind direction and speed, and the nature of the work conducted within the curtains. As such, a silt curtain development plan cannot be provided until these factors are established on a site-specific basis. Silt curtains will be used, where practicable, to isolate the work site from the surrounding marine environment, during dredging. Strong currents and high winds and waves may prevent placement of silt curtains, or limit their effectiveness. Fluctuating water depth due to tidal patterns may also alter the area over which silt curtains can be employed. The on-site environmental monitor will work with the dredging contractor to deploy silt curtains in the most efficient manner.
2478.1	round 1	Gitga'at First Nation	4.5	Water Quality	"The Freshwater Quality Assessment focuses on potential acidification and eutrophication effects related to air emissions from the proposed LNG facility." Why only air emissions? Many site works have the potential to impact freshwater quality. For example, water quality from the large settling ponds that are required for grubbing and clearing have the potential to stir up legacy contaminants. This should be assessed, along with other impacts such as spills and waste management. Furthermore, water management of the soils storage area is concerning given the baseline conditions (peatlands), and that contaminated marine dredgeate (with dioxins and furans) will be stored within the PDA. How will these areas be managed? How will the volume of organics be managed, including the freshwater naturally contained within these systems? What about acid rock drainage/metal leaching? Substantially more information is required.	The potential effects of soil erosion on the freshwater ecosystem are assessed under Wastewater Management in the effect "Change in Fish Abundance or Relative Abundance" in the Freshwater Fish and Fish Habitat VC, Section 4.8.5.4 of the Application. Runoff and discharges to marine water are assessed under Project Mechanisms for Change in the Physical or Chemical Composition of Marine Waters (Marine Water Quality VC, Section 4.5.15.3 of the Application). It is noted in this section that "The soils storage area will be re-vegetated, where possible and drainage patterns will be established to manage runoff to the marine environment." As noted in Mitigation 4.5.8 (Table 4.5.26, Section 4.5.15.3 of the Application), the project will be designed to maintain discharges to the marine environment within regulations and guidelines for the protection of aquatic life. Runoff from the soils storage area is therefore not expected to cause effects to the freshwater or marine ecosystem. Table 4.8-9 of Section 4.8.4 of the Application lists on-land disposal during construction, and waste management during operations, as potential project interactions. These activities include acid rock drainage/metal leaching from stored soil. The Project Description (Section 1.2.5.3) outlines management of acid generating rock to prevent low pH runoff from the soil storage area entering the freshwater ecosystem. Runoff and discharges to the freshwater environment are also assessed under Wastewater Management in Section 4.8.5.4 of the Freshwater Fish and Fish Habitat VC. As noted in Mitigation 4.8.8 (Table 4.8.8, Section 4.8.5.2), the project will be designed to maintain discharges to the freshwater environment within guidelines for the protection of aquatic life. Runoff from acid rock drainage is therefore not expected to cause effects to the freshwater ecosystem. Due to the low PCDD/F levels, marine sediment proposed for disposal in the soil storage area is not considered contaminated. This sediment has the potential to interact with the freshwater environment only through introduction of suspended sediment in surface water runoff. Suspended sediment is assessed in Section 4.8.5.4. There are regulatory requirements for the relocation of sediment to land under the Contaminated Sites Regulation, as noted in Mitigation 4.5.10, Table 4.5-26 (Marine Water Quality VC, Section 4.5.15.3). The storage of marine sediment in an engineered storage area has been designed to meet these requirements (sediment meets the most conservative criteria for PCDD/Fs; because of the saline nature of the sediment, it needs to be disposed of in an area where drainage goes to the marine environment). Preliminary design of the soils storage area is provided in the Project Description (Section 1.2.5.3).
2479.1	round 1	Gitga'at First Nation	4.5	Water Quality	The extreme flashiness of creeks and systems as a result of the extensive clearing of the site is not considered. This is especially important given that the bogs holding capacity and complexity will be removed. As such, streams and drainages will become extremely "flashy" resulting in high levels of erosion with impacts to water quality.	Potential effects of soil erosion on the freshwater ecosystem is assessed under Wastewater Management in the effect "Change in Fish Abundance or Relative Abundance" in the Freshwater Fish and Fish Habitat VC, Section 4.8.5.4 of the Application. Aurora LNG will reduce disturbance to riparian areas, to the extent possible, and will not disturb watercourses and riparian areas outside the PDA. Exclusion fencing will be installed where needed to delineate the protected areas. Runoff water will be controlled and diverted through erosion and sediment control facilities such as retention ponds to manage potential turbidity prior to testing water quality and prior to discharging into existing watercourses/marine environment. An environmental monitor will be onsite during all instream works to monitor for potential harm to fish and to evaluate erosion control measures. The soils storage area will be re-vegetated, where possible and drainage patterns will be established to manage runoff. The systems in place to mitigate sediment and erosion control will be designed to account for high flow events.
2480.1	round 1	Gitga'at First Nation	4.5.3.2	Water Quality	Water chemistry was measured for hardness nutrients, but were pollutants such as LEPH's PAHs etc. measured?	Full chemical data are provided in Appendix E of the Application (Surface Freshwater Technical Data Report). Parameters tested include total and dissolved metals nutrients, organic carbon, and physical parameters. PAHs and LEPH's were not measured as part of the freshwater assessment as there is expected to be no input of these contaminants by the Project. The future monitoring programs are anticipated to include a more detailed baseline collection program and, if shown to be relevant, these parameters may be considered during that time.
2481.1	round 1	Gitga'at First Nation	4.5.3.2	Water Quality	Does "soil characteristics" include organics? This is not clear and does not appear to be discussed.	Section 4.5.3.2 of the Application provides an overview of current conditions for freshwater systems. The pH in lakes and streams can vary due to influence from numerous factors including surficial geology, sediments and soils, rainfall, and historical pollution sources. Regions with high precipitation often have dilute waters with acidic to circum-neutral pH A detailed description of soil characteristics is available in Appendix D of the Application (Soils Acidification and Eutrophication Technical Data Report).
2482.1	round 1	Gitga'at First Nation	Table 4.5.6	Water Quality	Waste management was not included as a potential change in physical composition of surface water, and should be considered given the extensive site works planned (including the removal of natural vegetation and soil). It is likely that both flow volumes and water quality will change. Therefore, volume changes (from "flashiness" changes and reduced flows from reserve/wetland destruction) must be assessed.	Potential effects of soil erosion on the freshwater ecosystem is assessed under Wastewater Management in the effect "Change in Fish Abundance or Relative Abundance" in the Freshwater Fish and Fish Habitat assessment, Section 4.8.5.4 of the Application. Runoff and discharges to marine water are assessed under Project Mechanisms for Change in the Physical or Chemical Composition of Marine Waters (Marine Water Quality assessment, Section 4.5.15.3). It is noted in this section that "The soils storage area will be re-vegetated, where possible and drainage patterns will be established to manage runoff to the marine environment." As noted in Mitigation 4.5.8 (Table 4.5.26, Section 4.5.15.3), the project will be designed to manage discharges to the marine environment within regulations and guidelines. Runoff from the soils storage area is therefore not expected to cause effects to the freshwater or marine ecosystem. The systems to be put in place to mitigate sediment and erosion control will account for potential high flow events.
2483.1	round 1	Gitga'at First Nation	Table 4.5-15	Water Quality	Prince Rupert airport is listed as not having cumulative effects on fresh water; how is this possible due to activities or events such as de-icing, emissions, spills etc.?	The Prince Rupert airport will have its own environmental management plans in place to deal with de-icing and spills. Project related effects to freshwater are evaluated due to facility emissions of nitrogen and sulfur compounds. Airplane emissions were accounted for in the air quality model predictions by adding a background baseline to the model predictions.
2484.1	round 1	Gitga'at First Nation	4.5.13.1	Water Quality	The "detailed sediment sampling program ran from Jan 15- feb 3 2016". To be clear this is one field shift, to collect all your "detailed" data. Is this enough sampling to fully characterize sediments and to make statistically significant inferences?	A detailed sediment sampling program was carried out at the three proposed dredge footprints (Berth 1, Berth 2 and the MOF). A total of 192 samples were collected to characterize physical parameters, metals, PAHs, PCBs, and PCDD/Fs in marine sediment. This included 28 surface samples (0-0.07 m depth), 102 large interval core samples (0-1.5 m depth, divided into 0.5 m intervals), and 62 small interval core samples (0-1.0 m depth, divided into 0.2 m intervals). Sediment samples were collected over two field programs; a 5 day field program (December 15 to 19, 2014) and a 16 day field program (January 15 to February 3, 2016). Field program design was reviewed and approved by Environment and Climate Change Canada (ECCC) prior to sampling. The sampling programs also met ECCC disposal at sea criteria for number of samples required based on dredge volume. The field programs yielded a comprehensive and statistically robust dataset.
2485.1	round 1	Gitga'at First Nation	4.5.15.3	Water Quality	TSS run-off entering the marine environment. This will likely be a large amount (locally) as the project is proposing to grub and strip a large area of peatlands. Extreme sediment and erosion control methods must be employed to avoid impacts from TSS.	Potential effects of soil erosion on the freshwater ecosystem is assessed under Wastewater Management in the effect "Change in Fish Abundance or Relative Abundance" in the Freshwater Fish and Fish Habitat VC, Section 4.8.5.4. Aurora LNG will reduce disturbance to riparian areas, to the extent possible, and will not disturb watercourses and riparian areas outside the PDA. Exclusion fencing will be installed where needed to delineate the protected areas. Erosion and Sediment Control facilities will receive diverted site run-off prior to discharge into existing watercourses/marine environment. An environmental monitor will be onsite during all instream works to monitor for potential harm to fish and to evaluate erosion control measures. The soils storage area will be re-vegetated, where possible and drainage patterns will be established to manage runoff to the marine environment. The systems in place to mitigate sediment and erosion control will account for high flow events.
2486.1	round 1	Gitga'at First Nation	4.5.15.3	Water Quality	"Loss of sediment from dredge equipment is estimated at 3% of the total volume dredged" On quick calculation that is approximately 15,792 cubic meters, which is a large amount. Please assess this amount.	Loss of sediment from the dredge equipment is factored into the dredging model. Model predictions are used to assess effects to water quality in detail in Characterization of Residual Effects component of Section 4.5.13.3.
2487.1	round 1	Gitga'at First Nation	page 4.5-62	Water Quality	The operations section - "best available technology" is listed, so we expect this to apply to all aspects of the project and would like the following outlined more concisely: What kind of wastewater treatment is proposed? Is deep discharge the best available technology really? By seeing that desalination is part of the plan, is a closed loop system now out of the question?	Aurora LNG has acknowledged and committed to adhere to wastewater regulatory requirements prior to discharging to the marine environment. There are various wastewater treatment technologies available that Aurora LNG will assess prior to selecting the treatment technology for the Project. During operations water will be recirculated /recycled throughout the facility, where feasible. This includes process water and water in the cooling system. Water is lost from the closed loop system through evaporation therefore "makeup water" is required to replenish or "top up" the water supply for the process units. Makeup water is also required to dilute and flush the system water mineral concentrations that increase due to the water evaporation. It is expected that approximately 50% of the water will evaporate. The desalination plant does not exclude a closed loop system. Desalinated sea water will supply potable water, demineralized water, power plant cooling water, utility water and firewater for the facility. Included in this is the makeup water that will be required throughout operations. Please also see the "Discharges to the Marine Environment" technical memo, which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2488.1	round 1	Gitga'at First Nation	Table 4.5-27	Water Quality	4.5.2 needs to include operations, not just construction.	This comment is unclear. Table 4.5-27 shows model inputs for sediment dispersion and deposition predictions.
2489.1	round 1	Gitga'at First Nation	page 4.5-78	Water Quality	Please explain how deep outfall pipes and non recycled cooling water is considered "best available technology"?	Aurora LNG has acknowledged and committed to adhere to wastewater regulatory requirements prior to discharging to the marine environment. There are various wastewater treatment technologies available that Aurora LNG will assess prior to selecting the treatment technology for the Project. During operations, water will be recirculated /recycled throughout the facility, where feasible. This includes process water and water in the cooling system. Water is lost from the closed loop system through evaporation. Therefore, "makeup water" is required to replenish or "top up" the water supply for the process units. Makeup water is also required to dilute and flush the system for mineral concentrations that increase due to the water evaporation. It is expected that approximately 50% of the process water will evaporate. The desalination plant is not a closed loop system. The desalinated sea water will supply potable water, demineralized water, power plant cooling water, utility water and firewater for the facility. Included in this is the makeup process water that will be required throughout operations. Please also see the "Discharges to the Marine Environment" technical memo, which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.

2490.1	round 1	Gitga'at First Nation	Table 4.5-29	Water Quality	WCC is not included in the cumulative effects of water quality. Please include and reassess.	The assessment concluded that there is no potential for spatial overlap between marine water quality effects from the Aurora LNG Project and the proposed WCC LNG development. Project interactions with the marine environment were considered, to determine potential for spatial overlap. Aurora LNG and WCC LNG will, if constructed, discharge waste water to the marine environment. Wastewater discharges will be subject to permit restrictions, limiting the quality and quantity of waste, the discharge rate, and the size of the waste discharge initial dilution zone. WCC LNG may also require dredging, which will be subject to the same mitigation measures used for Aurora LNG (e.g. silt curtains), to limit sediment dispersion. Considering the wastewater regulatory restrictions, mitigation measures for dredging, and the distance of over 9 km between the two projects, no potential for spatial overlap was identified.
2491.1	round 1	Gitga'at First Nation	Figure 4.5-12	Water Quality	Cumulatively there is a lot of dredging works planned. Depending on project schedules there is huge potential for adverse effects to marine life due to WQ issues. Although as stated there is low likelihood of spatial overlap of TSS plumes, the cumulative effects to Marine life may be large. If multiple dredge programs occur simultaneously, the area of refuge for marine life will become limited. The overall suspension of contaminants becomes much more substantive and impact to local food harvest becomes dangerous. Therefore it is hard to understand the determination that the likelihood of residual cumulative effects as low.	Individual dredging programs will result in increased TSS in the surrounding water. However, without spatial overlap, simultaneous programs will not act cumulatively to further increase TSS, and associated contaminant concentrations in water. Potential cumulative effects of dredging and disposal at sea on marine fish health are assessed in Section 4.9.6.6 of the Marine Fish and Fish Habitat VC. The assessment considered the possibility that construction schedules of future proposed projects may overlap temporally with that of Aurora LNG, and the potential residual cumulative effects on marine fish health are characterized accordingly. In the event that construction schedules do overlap, a relatively larger area of the RAA would be affected by elevated TSS concentrations. However, potential cumulative effects would be limited to the Prince Rupert area, where most of the projects are proposed, and at the Brown Passage disposal at sea site. Vast areas of marine habitat within the RAA would be unaffected by elevated TSS concentrations; therefore, suitable habitats are not expected to be limited for marine species that avoid localized areas of elevated TSS.
2492.1	round 1	Gitga'at First Nation	4.5.17.2	Water Quality	Just because spatial overlap is likely minimal, does not address cumulative impact to the environment.	Individual dredging programs will result in increased TSS in the surrounding water. However, without spatial overlap, simultaneous programs will not act cumulatively to further increase TSS, and associated contaminant concentrations in water. Potential cumulative effects of dredging and disposal at sea on marine fish health are assessed in Section 4.9.6.6 of the Marine Fish and Fish Habitat VC. The assessment considered the possibility that construction schedules of future proposed projects may overlap temporally with that of Aurora LNG, and the potential residual cumulative effects on marine fish health are characterized accordingly. In the event that construction schedules do overlap, a relatively larger area of the RAA would be affected by elevated TSS concentrations. However, potential cumulative effects would be limited to the Prince Rupert area, where most of the projects are proposed, and at the Brown Passage disposal at sea site. Vast areas of marine habitat within the RAA would be unaffected by elevated TSS concentrations; therefore, suitable habitats are not expected to be limited for marine species that avoid localized areas of elevated TSS.
2493.1	round 1	Gitga'at First Nation	4.5	Water Quality	What are the impacts on water quality from the cruise ship proposed during construction?	Aurora LNG does not propose the use of a cruise ship for any project activity. A temporary floating camp is currently proposed to house early construction workers in Casey Cove until the proposed construction camp is able to accommodate the construction work force. See the "Floating Camp Review" technical memo for more details. The technical memo will be filed with the BC EAO.
2494.1	round 1	Gitga'at First Nation	4.5	Water Quality	Was a baseline groundwater survey conducted? Given the site works proposed (storing contaminated dredgate within the PDA), are there any impacts to groundwater anticipated?	A baseline groundwater survey was not conducted. Project effects to groundwater are not anticipated. The dredgate proposed for storage in the soils storage area is not considered contaminated under the BC Contaminated Sites Regulation. The maximum concentration of PCDD/F in the sediment was 2.86 picograms per gram (pg-TEQ/g). When sediments are disposed on land, they are managed as soils. The BC Contaminated Sites Regulations - Schedule 7 criterion for soil relocation to non-agricultural land for PCDD/Fs is 350 pg-TEQ/g. In addition, the dredgate storage area will be designed to capture runoff and direct it to the marine environment, rather than to groundwater sources.
2495.1	round 1	Gitga'at First Nation	4.5	Water Quality	Please provide an assessment on the potential impacts from air emissions on shoreline habitats (e.g., salt marshes), eelgrass meadows, and kelp beds.	Marine areas acidification and eutrophication is not expected to occur due to the high buffering capacity of marine waters, and as a result, this interaction was not included in the Environmental Assessment. Furthermore, no adverse effects on marine fish habitat, including salt marshes, eelgrass meadows, and kelp, due to acidification and eutrophication are anticipated.
2496.1	round 1	Gitga'at First Nation	Table 4.6-13	Vegetation and Wetland Resources	Mitigation 4.7.3 - As mentioned frequently, management plans are not mitigations, so what specific mitigations are/will be in the "Decommissioning and Abandonment Plans"? Please provide more information. Also please include evidence that Nexen considered climate change and future conditions in reclamation success of baseline ecosystems. Please also include further information on what Nexen will do to ensure the long-term viability of soils (topsoil, subsoil and organics) for use during decommissioning. Please provide evidence from past projects where organics remain viable for reclamation use. All of this information must be included in the EAC Application and not left to permitting and/or 25-30 years after disturbance.	As stated in Section 14 of the Application, each of the Environmental and Operational Management Plans will include "mitigation measures and written procedures, specifications and controls that direct Project activities", in addition to a description of "monitoring and reporting requirements". According to the Application Information Requirements, "Conceptual decommissioning and abandonment plans will be discussed in the Application, but detailed plans will be developed as part of the BC OGC LNG permitting process (Section 1.2)". Section 14.17 of the Application provides a conceptual overview of the content that the Decommissioning and Abandonment Plans will include when they are fully developed as part of the BC OGC LNG permitting process to meet the laws, regulations and standards in place during permitting. The plant species used in decommissioning and abandonment will be determined based on conditions at the time of decommissioning and abandonment. While long-term storage of soil stockpiles does affect the viability of propagules (Strohmayer 1999; AEW 2012; Rai et al. 2014), there are approaches to maintain or restore soils. One strategy for maintaining the viability of soils during stockpiling is to plant them with local native species to promote nutrient cycling and suitable soil biotic conditions, though the benefits typically occur within the top metre of stockpiled material (AEW 2012; Rai et al. 2014) Additionally, there are approaches that can help establish soil microbial communities (e.g., inoculation of tree and shrub seedlings with ectomycorriza or bacteria before they are planted on reclaimed landforms). Preliminary studies have shown positive results in the early stages of reclamation for forest species in the oil sands (Quoreshi et al. 2005; Quoreshi et al. 2008). In Alberta, best management practices call for the mixing of organic and mineral soil creates a peat-mineral mix which reduces the risk of losing organic matter due to rapid decomposition or in the event of a surface fire (AEW 2012). Aurora LNG will consider and develop reclamation alternatives in a manner that is consistent with conditions of the certificate and permitting approvals for the Project and recognized best management practices. Detailed reclamation plans will be progressed further following Project approval. References AEW (Alberta Environment and Water). 2012. 2497.1	round 1	Gitga'at First Nation	4.6	Vegetation and Wetland Resources	Based on screening comment #7, a significant effect should be concluded for "change in wetland function".	Screening comment #7 expresses concern about the accuracy of the five-year timeframe for reclamation of the site contained in the Project Description. The response to comment #7 clarifies that reclamation activities are anticipated to last for five years, but acknowledges that subsequent ecosystem recovery is a longer-term process. In response to comment # S7 here, please see Table 4.6-6 which provides the significance threshold for residual effects on wetland functions. Note that the threshold is tied to the definition of 'ecologically important wetlands,' as defined by regional guidance from Environment and Climate Change Canada (Environment Canada 2014). Some of the peatland wetland associations present in the PDA do not meet the definition of 'ecologically important wetlands' according to this regional guidance and are therefore not subject to the no-net-loss-of-wetland-functions goal of the Federal Policy on Wetland Conservation. Consequently, the significance threshold listed in Table 4.6-6 is not exceeded and Project residual effects to wetland functions are predicted to be not significant.
2498.1	round 1	Gitga'at First Nation	4.6	Vegetation and Wetland Resources	What is Nexen's plan for mitigating the huge loss of peatlands? Why are these wetlands not being compensated for?	Screening comment #7 expresses concern about the accuracy of the five-year timeframe for reclamation of the site contained in the Project Description. The response to comment #7 clarifies that reclamation activities are anticipated to last for five years, but acknowledges that subsequent ecosystem recovery is a longer-term process. In response to comment # S7 here, please see Table 4.6-6 which provides the significance threshold for residual effects on wetland functions. Note that the threshold is tied to the definition of 'ecologically important wetlands,' as defined by regional guidance from Environment and Climate Change Canada (Environment Canada 2014). Some of the peatland wetland associations present in the PDA do not meet the definition of 'ecologically important wetlands' according to this regional guidance and are therefore not subject to the no-net-loss-of-wetland-functions goal of the Federal Policy on Wetland Conservation. Consequently, the significance threshold listed in Table 4.6-6 is not exceeded and Project residual effects to wetland functions are predicted to be not significant.
2499.1	round 1	Gitga'at First Nation	4.6 Table 4.6-10	Vegetation and Wetland Resources	Mitigation 4.6.1 - "Pre- construction rare plant surveys will be conducted in the PDA, near known locations of rare plants" How is this a mitigation to avoid or reduce change in the Abundance of Plant species of Interest when it is known and assumed that all vegetation within the PDA will be removed? Gitga'at questions the reasoning behind this because confirming that rare plants exist and then clearing them away so that construction can occur is not mitigation for reducing or avoiding a plant species of interest. It's simply identifying where something is so that it can be documented and subsequently destroyed.	A pre-construction survey is required to reconfirm the full extent of each known occurrence as a precursor to plant relocation, which is the subsequent pre-construction mitigation measure. If additional plants are detected at the time of the pre-construction survey, contingency measures would be implemented such as relocation or collection of seed or propagules of those newly identified plants to reestablish populations off-site, or to augment existing off-site populations.
2500.1	round 1	Gitga'at First Nation	4.6 Table 4.6-10	Vegetation and Wetland Resources	Mitigation 4.6.3 -"The red-listed non vascular plant, Sphagnum majus and blue listed non-vascular plant, Sphagnum centrale will be translocated from the known locations within the PDA". What evidence does Aurora LNG have that this mitigation is viable? and what kind of monitoring measures is Aurora LNG prepared to put forth to monitor the success or failure of this measure? Gitga'at does not have any confidence in this mitigation measure.	The BC Conservation Data Centre's Guidelines for Translocation of Plant Species at Risk (Maslovat 2009) notes that, "in some cases, translocations may be the only viable option. For example, translocation can be a useful tool to mitigate threats to plants in development areas where no other option is feasible." Avoidance is not feasible for Sphagnum centrale and Sphagnum majus because they are located within the PDA. If the Project proceeds, the risks of attempting translocation are limited because the populations would otherwise be lost as a result of clearing within the PDA. Aurora LNG considers this a potentially-viable mitigation measure considering the successful research trials and methods of peatland restoration and moss propagation that have been developed in conjunction with the horticultural/agricultural sector and oil & gas sectors in North America and Europe. Examples of research institutes with publications that address the restoration of Sphagnum spp. include, but are not limited to the following: Peatland Ecology Research Group at the University of Laval, http://www.gret-perg.ulaval.ca/ See: Quinty, F. and L. Rochefort, 2003. Peatland Restoration Guide, second edition. Canadian Sphagnum Peat Moss Association and New Brunswick Department of Natural Resources and Energy. Québec, Québec. Peatland Restoration program at the Northern Alberta Institute of Technology http://www.nait.ca/70709.htm See: Sobze, J., M. Gauthier and R. Thomas 2012. Peatland Restoration – Harvest and Transfer of Donor Material. Technical Note. Available at: http://www.nait.ca/docs/1_Donor_Site_Harvesting_and_Moss_Transfer.pdf Aurora LNG will monitor the performance (survival, establishment, and growth) of the translocated populations during the growing season according to the Guidelines for Translocation of Plant Species at Risk (Maslovat 2009) . Translocation results will be made available to the BC Conservation Data Centre in order to increase collective knowledge of the species.
2501.1	round 1	Gitga'at First Nation	4.6 Table 4.6-10	Vegetation and Wetland Resources	Mitigation 4.6.6 - "An invasive Plant Management Plan will be implemented - The Weed Control Act and Regulations prohibit the spread of noxious weeds on highways and prohibits…" This is not "mitigation" and is required by law.	This comment cites the rationale for the mitigation measure, not the mitigation itself: The mitigation is to develop and implement an Invasive Species Management Plan.
2502.1	round 1	Gitga'at First Nation	4.6	Vegetation and Wetland Resources	In the Summary section under "Likelihood of Residual Effects For Change in Abundance of Plant Species of Interest" it is stated that "the translocation (of plant species of interest) will be successful". This is in direct relation to Sphagnum majus and Sphagnum centrale. Gitga'at disagrees with this conclusion and it should be removed. There is no evidence presented in the document that supports this statement.	The full statement in the Summary Section says, "There is a medium likelihood that residual effects to plant species of interest will occur and that the translocation will be successful. Although Sphagnum majus and Sphagnum centrale are known to be present within the PDA and disturbance cannot be avoided, their translocation to outside the PDA is expected to be successful in mitigating the effect. Potentially suitable habitat (i.e., bogs) is present within the terrestrial LAA, which will increase the likelihood of successful translocation (Maslovat 2009)."Section 4.6.2.7 defines Medium likelihood as " Medium—Adverse interactions between the Project and vegetation and wetland resources may be difficult to avoid or mitigate, and adverse residual effects are likely". So while the translocation mitigation is expected to be successful, the medium likelihood rating accounts for some uncertainty. The assumption is that if the species can be relocated to a suitable habitat (which is known to exist) then it is reasonable to assume it will be successful.
2503.1	round 1	Gitga'at First Nation	Table 4.6.11	Vegetation and Wetland Resources	Mitigation 4.6.10 - This is monitoring and not mitigation. It is stated that soils will be monitored and adaptive management will be provided if necessary. What does this mean? What adaptive management? If vegetation and soils are impacted by NO2 and SO2 atmospheric concentrations and soil acidification or soil eutrophication occur to levels that are unacceptable what actual mitigation measure outside of "monitoring" will occur?	Monitoring the predicted areas of exceedance (for acidification or eutrophication) to determine whether any adverse effects are detectable is the first step to determine whether any additional mitigation is required.The following factors are uncertain:whether potential effects will be observable and measurable,the timeframe within which effects from this mechanism could be detectable,the degree to which they could occur, andthe rate of change observed in soils and/or ecological communities. Therefore, monitoring is required before further mitigation measures are evaluated and applied. It is expected the monitoring effort will be regionally focused to encompass all of the potential airshed contributors and coordinated through the BC Ministry of Environment. In establishing that regional monitoring effort, it is assumed that the Ministry will determine the monitoring criteria and outline a suite of potential mitigation measures to address expected outcomes based on the monitoring results.Aurora LNG's framework for adaptive management is as follows: Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended).
2504.1	round 1	Gitga'at First Nation	Table 4.6.11	Vegetation and Wetland Resources	Mitigation 4.2.8 - "An Air Quality Management Plan" is cited as a mitigation measure. Management Plans are not mitigation measures but rather a Management Plan would list mitigation measures within it. Since a "Air Quality Management Plan" was not included in the Application, more information is required to assess the effectiveness of this mitigation measure. Therefore, what exactly is the mitigation measure in this case? is it the "Project Specific Program" to reduce air emissions? if so, what is the "Project Specific Program" exactly? How will it reduce Air Emissions? Those would be the mitigations measures....Please be specific about what exactly the mitigation measure is going to be.	See table 4.2-10 of the Application for specific mitigation measures that would be included in the Air Quality Management Plan. The intent of listing mitigation measure 4.2.8 in this vegetation and wetlands section is to acknowledge that mitigation measures within the Air Quality Management Plan would contribute to reducing effects (due to emissions) on vegetation.

2505.1	round 1	Gitga'at First Nation	4.6	Vegetation and Wetland Resources	Under the heading "Characterization of Residual Effects for Change in Abundance or Condition of Ecological Communities of Interest" The conclusion is made that the implementation of the mitigation measures in table 4.6-10 will reduce potential edge effects to "negligible magnitude". Please provide more information as it is not clear how this conclusion is made.	The reasoning behind the conclusion of negligible magnitude is based on first identifying the potential mechanisms that could affect ecological communities at the edges of the PDA, and then identifying a feasible mitigation measure for each potential effect-mechanism.Examples of effect mechanisms that were considered include the following: creation of additional edge by windthrow; deposition/aggradation due to erosion processes; or, changes in soil moisture levels due to stormwater flows. Examples of corresponding mitigation measures include the following: windthrow management (windfirming treatments) of remaining stands; application of erosion and sediment control measures; and maintaining pre-existing surface hydrology patterns While there may be some changes to soil moisture, soil temperature, air temperature, or light levels within communities located at the edge of the PDA, given the feasible mitigation/management measures identified in Tables 4.6-10 and 4.6-11 of the Application, any remaining changes to abiotic factors are not anticipated to result in measurable effects to ecological communities of interest due to edge effects. The characterization of residual effects is thus predicted to be negligible (see Table 4.6-5 of the Application for the definition of negligible in this context).
2506.1	round 1	Gitga'at First Nation	4.6	Vegetation and Wetland Resources	It is stated that the residual loss of old-growth forest is low in magnitude. If the old growth forest that the project will be impacting is considered in terms of the PDA (10%), Gitga'at views this as high and long term. The Characterization of Residual Effects does not consider the PDA. It gives thresholds in consideration of the entire RAA which produces a skewed conclusion of what is actually going to happen on the ground. In our view this is unacceptable. If the project is going to cut down 100% of the old growth forest within the PDA, regardless of what populations are present in the RAA or LAA, this will have a high residual effect that is long term in duration. This is of particular interest to traditional users in that the "go elsewhere to get your resources" argument is not logical or possible. If people wanted to use the resources on the PDA they will no longer be able to because it will be gone. Therefore the residual effect of the loss of this resource, within that geographical extent, is high and long term. The assessment of residual effects, in this particular case, is flawed.	The government of BC has developed the approved Great Bear Rainforest Order (GBRO), which establishes explicit retention targets for old growth forest within the landscape units that this Project intersects. The GBRO is based on a regional ecosystem management approach, which means natural resources such as old growth forests are managed on a regional scale, such as the landscape units identified in the GBRO. These landscape units are considerably larger than the PDA, or LAA. The Application aligns with the ecosystem management approach in effect within the region, and uses the retention targets contained in the GBRO to guide characterization of the magnitude of Project effects (See table 4.6-5 in the Application re: old growth magnitude criteria relative to the GBRO thresholds for the relevant landscape units.) The GBRO represents an approved Ministerial Order which allows for up to 40% loss of old growth forest from the specified landscape units which correspond to the Project's RAA. The loss of old growth forest due to the Aurora LNG Project is far below such allowable thresholds set for other (timber harvest) industries within the region. Effects on the changes in consumptive and non-consumptive land and resource use for traditional purposes are presented in Section 11.3 and 11.4 of the Application, and include assessment on vegetation gathering. Effects on First Nation harvesting-related Aboriginal interest are presented in Part C, Section 12 of the Application. Together these sections address the site-specific loss of vegetation resources for traditional use within the PDA. See also the technical memo titled, "Additional Information Regarding Methods Used to Consider Traditional Use Information in the Assessment of CEAA 5(1)(c) Factors and Aboriginal Interests" prepared by Aurora LNG in response to comments pertaining to concerns about access and availability of traditional use species. This technical memo will be filed with the BC EAO.
2507.1	round 1	Gitga'at First Nation	Table 4.6.13	Vegetation and Wetland Resources	Mitigation No. 4.6.15 - a Wetland Monitoring Program is not a mitigation; it is a Monitoring Program. What exact mitigations are Aurora LNG proposing? If the monitoring program finds that the wetland functions have not been adequately replaced or met, what actual mitigations is Aurora planning on?	Mitigation measure 4.6.15 specifically refers to monitoring the performance of restored, enhanced, or created wetlands that are established according to the Project's approved Wetland Compensation Plan. This monitoring is intended to determine whether or not the compensatory habitat is functioning as intended. In the event that restored, enhanced, or created wetland habitat is determined, through monitoring, to be not functioning as intended, then adaptive management would be applied. Aurora LNG's framework for adaptive management is as follows: Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended). Precise adaptive management measures cannot be defined ahead of time without knowing what the issue(s) regarding function is, however potential examples could include such management measures as: adjustment to wetland hydrology through grading or channel design; replanting with more-suitable plant species; controlling herbivory; or removing invasive plant species. The precise measures would depend on the stressors and/or monitoring plan results.
2508.1	round 1	Gitga'at First Nation	Table 4.6-14	Vegetation and Wetland Resources	It is unclear how Operations are not applicable to the residual effects on the change in Abundance of Plant Species of Interest and Wetland Function in the PDA, TLAA, VALAA and/or RAA . Please provide more information.	During operations, no plant species of interest or wetlands will remain in the PDA; they will have been removed during construction. During operation of the Project, no residual effects on plant species of interest or wetland functions are anticipated in the remaining study boundaries, thus the use of N/A in the residual effects summary table. Effects on wetlands due to acidification/eutrophication are addressed under changes to condition of ecological communities of interest, for which there are residual effects during the operations phase; these are characterized in Table 4.6-14 of the Application.
2509.1	round 1	Gitga'at First Nation	Section 4.6	Vegetation and Wetland Resources	"Old-growth forests are relatively undisturbed and common in the RAA; they are considered resilient because they can recover from perturbation, albeit taking over 200 years to develop" - this is not low in magnitude. The actual time it takes to re-establish vegetation populations to existing levels should be considered when evaluating residual effects.	The duration of an effect is one attribute that is used to characterize residual effects, while magnitude is another attribute. See Table 4.6-5 of the Application for definitions of each characterization. All characterizations in Table 4.6-5 are considered for each measurable parameter that contribute to each residual effect. The duration of effects on old growth forest are considered long-term, but of low magnitude according to the definitions of each term provided in Table 4.6-5.
2510.1	round 1	Gitga'at First Nation	Section 4.6.6.5	Vegetation and Wetland Resources	Under Cumulative Effects Mitigation it is stated that it is expected that future projects will be held to the same standards as past and present projects, including compensation required for ecologically important wetlands and offsetting. This is not adequate mitigation. Specific mitigations are needed with consideration for all of the other projects and development which have occurred or will possibly occur within the RAA.	Please see Table 4.6-13 of the Application for the full suite of mitigation measures intended to avoid, limit, and/or offset the loss of wetland functions for this Project. These Project-specific mitigation measures will also directly reduce potential for cumulative interactions.
2511.1	round 1	Gitga'at First Nation	Section 4.6.7.1	Vegetation and Wetland Resources	Gitga'at disagrees with the conclusion that the project residual effects to vegetation and wetland resource will not be significant based on the reasoning that plant species of interest are viable within the RAA and traditional use plants are abundant elsewhere. The "can be found elsewhere" reasoning is not acceptable. Vegetation and wetland resources within the PDA will be significantly altered because the project will destroy them.	Effects on the changes in consumptive and non-consumptive land and resource use for traditional purposes are presented in Section 11.3 and 11.4, of the Application and include assessment of vegetation gathering. Effects on First Nations harvesting-related Aboriginal interest are presented in Part C, Section 12 of the Application. Together these sections address the site-specific loss of vegetation resources for traditional use within the PDA. Please also see the technical memo titled, "Additional Information Regarding Methods Used to Consider Traditional Use Information in the Assessment of CEAA 5(1)(c) Factors and Aboriginal Interests" prepared by Aurora LNG in response to comments pertaining to concerns about access and availability of traditional use species. This technical memo will be filed with the BC EAO.
2512.1	round 1	Gitga'at First Nation	4.7	Wildlife Resources (Terrestrial)	At this time, Gitga'at considers the Marine riparian management zone associated with Delusion Bay to be too narrow to provide a sufficient buffer. The inherent richness of the estuary and edge effect are favoured habitat for many species. The conceptual layout of project components at full build-out, does not provide a depiction of a realistic concept to support terrestrial wildlife species. Species such as Western screech owl and Little brown Myotis are expected to favour these habitats . The project does not depict a concept that considers natural breaks in terrain or an effort to protect or maximize cover. Please justify why the zone is considered acceptable.	Habitats surrounding Delusion Bay were rated as having high or moderate suitability for western screech-owl and little brown myotis under existing conditions, however Delusion Bay was rated as Nil suitability for both species to support breeding activity (Section 4.7.3.2 of the Application). The assessment for change in habitat identifies that the change in area of preferred habitat (i.e., high or moderate suitability) from clearing within the PDA will result in a 17% change from existing conditions for western screech-owl and little brown myotis (Table 4.7-13) with indirect effects extending beyond the PDA boundaries (Table 4.7-14). As described in Section 4.7.5.2, the assessment of change in habitat was considered conservative because it assumed that all vegetation will be removed from within the PDA. Collectively, the riparian reserve zones, management areas, and marine riparian disturbance buffer will result in the retention of mature and old forested habitat; these areas are not predicted to continue to serve as preferred habitat for either species during operations (e.g., Figure 4.7-10 and Figure 4.7-11), but will reduce noise and light disturbance effects to adjacent habitats, including Delusion Bay. The riparian buffers also maintain connectivity between forested and wetland communities northwest of the PDA and Delusion Bay. These corridors will facilitate access to upland and intertidal habitats for species that rely on them for breeding, roosting, foraging, and staging activities.
2513.1	round 1	Gitga'at First Nation	4.7	Wildlife Resources (Terrestrial)	Gitga'at is concerned about fencing the facility, especially along the streams and Delusion Bay. There should be no restrictions or blocking of escape for terrestrial prey species such as Coastal Black tail deer. Stream crossing should be full span bridges to allow wildlife passage.	Aurora LNG is proposing to install fencing around the LNG facility and the worker camp to support security requirements and to reduce the potential for negative interaction between Project personnel and wildlife (e.g., bears, wolves). However, portions of the PDA will not be fenced (e.g., access road) to facilitate ongoing movement of wildlife, including black-tailed deer, throughout the LAA for the duration of Project operations. To the extent practicable, Aurora LNG will install crossings (e.g., at watercourses) to facilitate wildlife passage throughout the LAA while restricting access to the LNG facility.
2514.1	round 1	Gitga'at First Nation	4.7	Wildlife Resources (Terrestrial)	Mitigation 4.7.3 - As mentioned frequently, management plans are not mitigations, so what specific mitigations are/will be in the "Decommissioning and Abandonment Plans"? Please provide substantially more information. Also please include evidence that Nexen considered climate change and future conditions in reclamation success of baseline ecosystems. Please also include further information on what Nexen will do to ensure the long-term viability of soils (topsoil, subsoil and organics) for use during decommissioning. Please provide evidence from past projects where organics remain viable for reclamation use. All of this information must be included in the EAC Application and NOT left to permitting and/or 25-30 years after disturbance/ecosystem destruction.	As stated in Section 14 of the Application, each of the Environmental and Operational Management Plans will include "mitigation measures and written procedures, specifications and controls that direct Project activities", in addition to a description of "monitoring and reporting requirements". According to the Application Information Requirements, "Conceptual decommissioning and abandonment plans will be discussed in the Application, but detailed plans will be developed as part of the BC OGC LNG permitting process (Section 1.2)". Section 14.17 of the Application provides a conceptual overview of the content that the Decommissioning and Abandonment Plans will include when they are fully developed as part of the BC OGC LNG permitting process to meet the laws, regulations and standards in place during permitting. The plant species used in decommissioning and abandonment will be determined based on conditions at the time of decommissioning and abandonment. While long-term storage of soil stockpiles does affect the viability of propagules (Strohmayer 1999; AEW 2012; Rai et al. 2014), there are approaches to maintain or restore soils. One strategy for maintaining the viability of soils during stockpiling is to plant them with local native species to promote nutrient cycling and suitable soil biotic conditions, though the benefits typically occur within the top metre of stockpiled material (AEW 2012; Rai et al. 2014) Additionally, there are approaches that can help establish soil microbial communities (e.g., inoculation of tree and shrub seedlings with ectomycorriza or bacteria before they are planted on reclaimed landforms). Preliminary studies have shown positive results in the early stages of reclamation for forest species in the oil sands (Quoreshi et al. 2005; Quoreshi et al. 2008). In Alberta, best management practices call for the mixing of organic and mineral soil creates a peat-mineral mix which reduces the risk of losing organic matter due to rapid decomposition or in the event of a surface fire (AEW 2012). Aurora LNG will consider and develop reclamation alternatives in a manner that is consistent with conditions of the certificate and permitting approvals for the Project and recognized best management practices. Detailed reclamation plans will be progressed further following Project approval. References AEW (Alberta Environment and Water). 2012. 2515.1	round 1	Gitga'at First Nation	4.7.3	Wildlife Resources (Terrestrial)	More information is required on the rationale for why the focal species were selected.	The assessment for wildlife resources uses two modelling approaches to evaluate change in habitat for species known or potentially occurring within the PDA and LAA. Wildlife habitat community modelling was developed to provide an assessment of potential effects on habitat availability for 15 wildlife habitat communities within the LAA. These wildlife habitat communities provide coverage for all habitat types that occur within the LAA and are used to assess effects of change in habitat to a wider suite of wildlife species assemblages that occupy them. Methods and findings of the wildlife habitat community models are provided in Section 4.1 of Appendix J and carried forward in Section 4.7.5.2 of the Application. These sections provide a detailed description of each of the 15 communities, describes wildlife species that are expected to occur within each, and discusses potential effects to species assemblages due to construction and operation of the Project. Four terrestrial wildlife species were selected for wildlife habitat suitability modelling (i.e., marbled murrelet, western screech-owl kennicottii subspecies, little brown myotis, and western toad) based on the following suite of criteria (also described in Sections 4.7.3 of the Application and Section 4 of Appendix J): (1) likelihood of occurrence or documented use of habitats within the LAA and RAA; (2) potential interaction with Project activities; (3) conservation status; (4) ecological importance; (5) established base of information, knowledge, or data; and, (6) cultural or traditional value. The four selected species were considered to best represent the criteria listed above, given consideration of the primary habitats available within the LAA and the likelihood of occurrence based on Project and regional datasets and known habitat requirements. In addition, the four selected species were determined to be good candidates for species-specific habitat suitability models because they each require a suite of habitat features that are best assessed at the species-level (rather than at the community-level). Provincial standards advise planners to select species for suitability modelling where there is a strong understanding of the relationship between habitat characteristics and species whose life requisites (e.g., breeding, feeding) compare well with terrestrial ecosystem map units (RIC 1999). Specifically, marbled murrelet requires old to mature coniferous forests with specific tree-level characteristics for nesting (e.g., large branches, high epiphyte cover); western screech owl requires open mixedwood forest with large diameter trees for nesting and roosting; little brown myotis requires mature and old growth forests with cavities and snags for male and maternal roosting; and western toad requires shallow wetlands with fine sediments that retain open water throughout the breeding season. Collectively, the habitat requirements of the four selected species are complementary and serve to evaluate a range of habitat types within the LAA in combination with the wildlife habitat community modelling. Reference: Resource Inventory Committee (RIC). 1999. Wildlife Habitat Rating Standards, Version 2. Ministry of Environment, Lands and Parks. Victoria, BC. 98 pp.

2516.1	round 1	Gitga'at First Nation	4.7.2	Wildlife Resources (Terrestrial)	More information is required on the impacts to migratory birds.	As described in Section 4.7.1, the assessment of wildlife resources was inclusive of all species of mammals, birds, amphibians, and reptiles that rely on the terrestrial environment for all or part of their life requisites, including species defined by Article I of the Migratory Birds Convention. Section 4.7 acknowledges that habitats within the PDA and LAA provide seasonal life requisites for migratory birds, including foraging, breeding, roosting, and staging during migration. Supporting field studies were scheduled to coincide with important patterns in seasonal use for migratory birds in accordance with Resource Inventory Standards Committee Standards. Collectively, these data are used to help characterize potential Project effects to migratory birds in Sections 4.7.5, recognizing that migratory periods can increase the potential for interaction with Project activities and infrastructure. Section 5(1)(a) of CEAA 2012 also requires that environmental effects or changes to components listed in Section 5(1)(a)(iii) must be taken into account in relation to an act or thing, physical activity, or a designated project. Section 4.7.5, and Section 4.7.6 of the Application provide an assessment of effects to terrestrial wildlife, inclusive of migratory birds. Please refer to Section 11 for a summary of statutory requirements under CEAA 2012. Residual Project effects and cumulative effects are described specifically for migratory birds in Section 11.2, Table 11.2-2. A significance determination for migratory birds is provided in Section 11.9, Table 11.9-1.
2517.1	round 1	Gitga'at First Nation	4.7.3	Wildlife Resources (Terrestrial)	It is not clear where the bat assessment data/information is from given that acoustic surveys for bats was not conducted?	Incidental information on bat occurrence was collected concurrently during marbled murrelet dawn audiovisual surveys in July 2015. Recordings of bat vocalizations indicated the potential presence of little brown myotis within the PDA and LAA. To improve understanding of bat species presence and occurrence, and to support the development of the Bat Management Plan, additional information on seasonal activity patterns for bats has been prepared as a technical memo, entitled "Aurora LNG Project Bat Monitoring Program" and it will be filed with the BC EAO.
2518.1	round 1	Gitga'at First Nation	4.7.3	Wildlife Resources (Terrestrial)	The magnitude of residual effects should be species specific given the unique life-histories of species as well as status. Please provide rationale for why the magnitude used is appropriate for each species.	The magnitude of a residual effect is determined based on a measurable change from existing conditions and considers applicable legislation, management standards, or environmental and regulatory thresholds, and takes into account the viability of local or regional populations. With respect to the magnitude of residual effects (i.e., the amount of change to the Wildlife Resources [Terrestrial] VC relative to existing conditions), the definitions of the qualitative categories (i.e., negligible, low, moderate, and high) apply to all terrestrial wildlife species, including species of management concern and federally-listed species. Accordingly, the magnitude of a potential Project effect will depend on the status of a given species (and may be larger for species at risk or those with unique life histories that would increase the potential for an interaction with the Project), in which case the assessment applies the most conservative (i.e., highest) magnitude to characterize potential Project effects to wildlife, overall. Additional information on species-specific determinations for potential Project residual effects and significance determinations is provided in Section 4.7.2.8 of the Application.
2519.1	round 1	Gitga'at First Nation	4.7	Wildlife Resources (Terrestrial)	Can Nexen commit to no clearing during breeding bird season (rather than using vague language, e.g., if possible)?	Aurora LNG is committed to following a mitigation hierarchy to avoid, limit, and mitigate for potential effects to wildlife resources, including breeding birds. Accordingly, Aurora LNG will schedule vegetation clearing and site preparation to occur outside of restricted activity periods for breeding birds (as per mitigation 4.7.17) to the greatest extent feasible. If vegetation clearing is required within restricted activity periods for breeding birds, pre-clearing surveys will be completed (as per mitigation measures 4.7.18 and 4.7.19). Aurora LNG has further committed to monitoring the heron rookery if vegetation clearing for the Project overlaps with the breeding period for great blue heron. The Wildlife Management Plan and Marbled Murrelet Management Plan (specifically for marbled murrelet) will outline measures to avoid, reduce, mitigate, and monitor for breeding birds and will include direction on mitigation measures specific to breeding birds (e.g., Mitigation measures 4.5.1, 4.6.2, 4.7.1, 4.7.2, 4.7.4, 4.7.5, 4.7.6, 4.7.8, 4.7.10, 4.7.12, 4.7.14, 4.7.16, 4.7.17, 4.7.18, and 4.7.19).
2520.1	round 1	Gitga'at First Nation	4.8	Freshwater Fish and Fish Habitat	The extreme flashiness of creeks and systems as a result of the extensive clearing of the site is not considered. This is especially important given that the bogs holding capacity and complexity will be removed. As such, streams and drainages will become extremely "flashy" resulting in high levels of erosion with impacts to water quality, and causes for fish habitat loss and impacts to ecological function.	Clearing and development of the PDA will remove the majority of the existing watercourses with the exception of reaches J1-5 and J1.1. Aurora LNG acknowledges that clearing and grading of the PDA may result in higher volumes of overland flow due to removal of organic soils. Water flows within the PDA will be controlled and managed within the site stormwater management system which will be designed to handle the precipitation and surface runoff typical for this area. Stormwater flows will be diverted, as appropriate to watercourses to maintain downstream habitat. The larger, more complex, watercourse systems containing reaches J1-5, and J1.1, which will not be removed by project development, will also retain intact established riparian zones.
2521.1	round 1	Gitga'at First Nation	4.8	Freshwater Fish and Fish Habitat	In table 4.8-13 the proponent describes the area of fish habitat to be lost in the PDA to be 10,857 m². This would require an off-setting replacement at 2x which is 21,714 m² of similar fish habitat. At this time, Gitga'at is not confident that said off-setting will be successful, and avoidance is the best mitigation.	Offsetting for serious harm in the marine and freshwater environments will be considered collectively by Aurora LNG. This is because the freshwater habitats affected by the Project will affect anadromouos fish species (e.g., pink and coho salmon) that use freshwater and estuarine habitats for spawning and rearing. While efforts will be made to maximize the amount of freshwater habitat created or enhanced to offset the loss of fish habitat in watercourses within the PDA (i.e., "like-for-like" habitat replacement such as those on Digby Island presented in the Conceptual Fish Habitat Offsetting Plan [Appendix V]), the overall objective of the offset plan will be to maximize fish productivity for CRA fish species affected by the Project. Thus, where opportunities exist to create, restore, or enhance habitats used by juvenile salmon in estuarine or marine environments, particularly where options in the estuarine or marine environments have lower risks, uncertainties, or time lags than options in the freshwater environment, these projects will be included in the detailed offset plan with the objective of providing a net gain in production in the regional fishery. Through collaborative engagement with regulatory agencies (primarily DFO) and consultation with Aboriginal Groups during the Fisheries Act authorization application process, Aurora LNG fully anticipates being able to find adequate and appropriate locations, and develop suitable designs, for effective offsets.
2522.1	round 1	Gitga'at First Nation	4.8	Freshwater Fish and Fish Habitat	Further to table 4.8-13, the riparian habitat to be lost is 218,830 m², replacement at 2x would be 437,664 m². More information is required on the feasibility of this area being offsetted in an area with unique characteristics of Digby Island. In addition, to apply a minimum DFO standard, 15 m riparian zone is unacceptable. The dynamic peatland-forest ecosystem acts as a buffer to provide a moderated slow release of the ~ 3 meter annual rainfall received. It would be more appropriate to apply a minimum 30 meter riparian management zone on either side of the streams and inter-tidal zones of the Delusion Bay Estuary. Also, has modeled climate change conditions been considered in the Application? For example, with offsetting, it may be crucial to increase the foreshore buffer to adapt to future sea-level during the life of the Project.	Aurora LNG agrees that this amount of riparian offsetting would be difficult, if not impossible, to achieve. Aurora LNG takes the position that riparian habitat associated with streams that will no longer exist do not need to be included in the habitat balance accounting as this riparian habitat no longer provides "services" (e.g., shading, leaf litter) to the stream when the stream no longer exists. Only riparian habitats lost or altered adjacent to streams that remain after construction of the Project would require offsetting because it is only these streams that would receive less of the services provided by the riparian habitat and, therefore, be less able to produce fish. The gain-to-loss ratio for riparian habitats lost or altered adjacent to streams remaining after construction of the Project will be determined with DFO during permitting phase. Aurora LNG has taken a conservative approach of applying a 15 m riparian reserve zone (RRZ) on all streams (based on the Riparian Management Area Guidebook, Ministry of Forests, 1995) within the PDA,as the 15 m RRZ would only be required for the largest streams (classified as S3 streams). The most common stream class in the PDA are non-fish bearing S5 or S6 streams, which do not required a riparian reserve zone (Ministry of Forests, 1995). Discussion on the fore-shore habitat is addressed by the Marine Fish and Fish Habitat section (4.09).
2523.1	round 1	Gitga'at First Nation	4.8	Freshwater Fish and Fish Habitat	Gitga'at considers the freshwater invertebrate productivity to be essential to sustain fish health and productivity. A baseline invertebrate inventory for the streams affected in the PDA would be appropriate to provide an indicator for stream health. This should be initiated pre- construction and for reasonable increments throughout the project operations up to and including de-commissioning.	Aurora LNG acknowledges that freshwater invertebrate production is essential to fish health and productivity. However, Aurora LNG believes that it is not necessary to collect baseline invertebrate data or monitoring invertebrates in streams throughout the life of the Project. This is because Aurora LNG has committed to mitigation measures that avoid, eliminate, or reduce potential effects to CRA fish species e.g. salmon and charr, which are sensitive to changes in water quality, stream flow, and sedimentation. By doing so, Aurora LNG believes that these mitigation measures will equally protect freshwater invertebrates and their habitat. Additionally, changes in water quality that would cause a change in the abundance, distribution, or species composition of freshwater invertebrates are not anticipated. Aurora LNG will engage with appropriate regulatory agencies and Aboriginal Groups identified in Schedule B of the Section 11 Order(as amended) to develop the environmental effects monitoring plans required for freshwater and marine environments.
2524.1	round 1	Gitga'at First Nation	4.8	Freshwater Fish and Fish Habitat	p. 4.8-53, in Additional Mitigation measures: to transport salvaged fish outside the PDA is unacceptable.	Aurora LNG will transport and release fish salvaged from affected watercourses within the PDA to the nearest watercourses with similar water quality (e.g., temperature and salinity) and habitat (e.g., pools for rearing). However, transport and release of fish to watercourses outside of the PDA may be required if similar water quality and habitats are not present. The selection of potential release areas will be determined in advance of any fish salvage conducted with consideration of the water quality and habitat conditions as well as the distance and access that may affect the time required to hold fish in tanks or tubs before release. Riparian buffers (15 m minimum on both sides of the streams) will be left adjacent to all watercourses remaining within the PDA after construction and impact to the upstream watershed will be minimized, where possible. These measures will reduce the potential effect of sediment reaching the streams and the estuary, and minimize the reduction in freshwater run-off reaching the estuary; no change in any water quality parameter is expected to occur. Aurora LNG agrees that careful planning will be required in developing a detailed water management plan and erosion and sediment control measures. FEED will provide input to the Marine and Freshwater Resources Management Plan and Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of this plan.
2525.1	round 1	Gitga'at First Nation	4.8	Freshwater Fish and Fish Habitat	p. 4.8-53, the final paragraph about surface water quality changes is vague and lacks a level of description to provide assurance that fish and fish health will be protected. It is well known that clear-cut, clearing and grubbing produce a flashy hydrological response in a watershed. Gitga'at is concerned that an industrial disturbance this close to critical fish and fish habitat will cause serious and permanent damage to the fresh water and estuary environment. Settlement ponds, ditching and filter fabric systems will require careful design and engineering to mimic the natural buffering of this coastal ecosystem.	Riparian buffers (15 m minimum on both sides of the streams) will be left adjacent to all watercourses remaining within the PDA after construction and impact to the upstream watershed will be minimized, where possible. These measures will reduce the potential effect of sediment reaching the streams and the estuary, and minimize the reduction in freshwater run-off reaching the estuary; no change in any water quality parameter is expected to occur. Aurora LNG agrees that careful planning will be required in developing a detailed water management plan and erosion and sediment control measures. FEED will provide input to the Marine and Freshwater Resources Management Plan and Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of this plan.
2526.1	round 1	Gitga'at First Nation	4.8	Freshwater Fish and Fish Habitat	Table 4.8-15, Gitga'at finds this description to be inadequate for such a critical piece. Include " and excessive grease" behind leaks in the opening sentence. Remove" where possible" with respect to fueling construction vehicles. We require more information for the proponents fuel management safety systems such as: Spill response capacity must be adequate to contain/ control all volumes of hydrocarbons on site. Spill capacity must be adequate to contain/ control Spills to the ditches, ponds and silt fences for site water management systems. All machinery will be supplied with spill kits and additional spill containers will be onsite at strategic locations. All crew members will be trained and understand spill response equipment and their use. In addition, we would expect to see a detailed description of spill capacity for all Marine operations including fuel storage and adequate containment for these storage stations.	Aurora LNG acknowledges the wording suggestions and have revised Mitigation No. 4.8.10 as follows: All construction equipment onsite will be kept clean, free of leaks, excess oil, and grease. Refuelling or servicing of construction equipment will take place at least 30 m away from any watercourse or waterbody; exceptions may be made for large or immobile construction equipment in which case drip trays or bermed areas will be utilized so that any spillage will not enter the waterbody. An errata document is being compiled that captures these corrections and it will be filed with the BC EAO. The mitigation has been revised to clarify the intent of the "where possible" wording as relocation of such equipment for fueling purposes may cause more environmental disturbance. Measures related to the use of fuels and machinery on site will be included in the Marine and Freshwater Resources Management Plan. The plan will address spill containment capacity, number, type, and size of on site spill kits, and training for all personnel on site . All site personnel will review, understand, and follow all of the management plans while working on site. Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Marine and Freshwater Resources Management Plan.
2527.1	round 1	Gitga'at First Nation	4.8	Freshwater Fish and Fish Habitat	Mitigation 4.8.8 must be for all the phases, not just construction.	Aurora LNG will adhere to mitigation 4.8.8 in all project phases where there is a the potential for sediment loads to enter a watercourse.
2528.1	round 1	Gitga'at First Nation	4.9.5.1	Marine Fish and Fish Habitat	The Marine Fish and Fish Habitat VC was reviewed alongside the Marine Water Quality VC in order to understand whether effects related to exposure to TSS were addressed. Section 4.9.5.1 lists the assumptions underlying the effects assessment. To assess effects related to TSS exposure, factors including dredge volume, disposal volume, and dredge rate were used to predict concentrations and spatial extent of TSS exposure. However, assumptions around exposure duration were not explicitly stated here and need to be provided.	The amount of time TSS levels are anticipated to exceed guidelines for the protection of aquatic life associated with dredging and disposal at sea activities was included in the model as part of the sediment dispersion modeling exercises. As described in Appendix G (Technical Data Report - Aurora LNG: MOF and Terminal Dredge Modelling), elevated TSS levels are expected to persist in Casey Cove for the duration of dredging activities (dredging in Casey Cove is anticipated to run for approximately 20 hours per day for approximately 48 days), with levels returning quickly to baseline conditions upon cessation of dredging activities. At South Digby Island, elevated TSS levels are expected to persist for the duration of dredging activities (dredging is anticipated to occur for ten hours per day for approximately 13 days at Berth 1 North, 17 days at Berth 1 South, and 11 days at Berth 2), with levels returning quickly to baseline conditions upon cessation of dredging activities. As described in Appendix H (Technical Data Report - Aurora LNG: Disposal at Sea Modelling), elevated TSS levels are expected to persist at Brown Passage during and immediately following each disposal event, with levels returning to baseline conditions relatively faster in shallower waters than in deeper waters. Disposal of dredged materials from the MOF is anticipated to require 124 disposal events (once every 8 hours, for approximately 41 days); disposal of dredged materials from Berth 1 North is anticipated to require 18 disposal events (once every 16 hours, for approximately 11 days); disposal of dredged materials from Berth 1 South is anticipated to require 23 disposal events (once every 16 hours, for approximately 15 days); disposal of dredged materials from Berth 2 is anticipated to require 15 disposal events (once every 16 hours for approximately 9 days). Dredging and disposal at sea activities will be limited to the DFO least risk timing window (November 30 to February 15) and will take place over two years. The amount of time marine fish may be exposed to elevated levels of TSS during dredging and disposal at sea activities was considered in the assessment of potential changes in marine fish health (Section 4.9.5.5 of the Marine Fish and Fish Habitat VC). In addition to the duration of dredging and disposal at sea activities themselves, and associated TSS levels, other factors such as species, life stage, and the behaviour of the individual may also influence exposure duration. For example, some species (such as pelagic fish), may choose to move away from or avoid areas of elevated TSS (Kjelland et al. 2015), resulting in relatively short-duration exposure. Other species (such as demersal fish, species with lower motility, or sessile invertebrates) may remain near the dredge or disposal areas, resulting in exposure to elevated TSS for relatively longer duration (up to a maximum of approximately 2.5 months, the length of the DFO least risk timing window). Reference: Kjelland, M.E., Woodley, C.M., Swannack, T.M. and D.L. Smith. 2015. A review of the potential effects of suspended sediments on fishes: potential dredging-related physiological, behavioral, and transgenerational implications. Environment Systems and Decisions, 35(3): 334-350.
2529.1	round 1	Gitga'at First Nation	4.9.5.5	Marine Fish and Fish Habitat	The Marine Fish and Fish Habitat VC was reviewed alongside the Marine Water Quality VC in order to understand whether effects related to exposure to TSS were addressed. While estimates of exposure concentrations are stated in section 4.9.5.5, the application is less clear on exposure durations. Newcombe and Jensen (1996) provide a means for estimating severity of effects for estuarine fish (models 4 and 5) based on exposure concentration and exposure duration. These models could be used to estimate the likelihood and degree of residual effects to fish health. Further assessment is required on exposure duration. Newcombe, C. P. and J. O. Jensen. 1996. Channel suspended sediments and fisheries: a synthesis for quantitative assessment of risk and impact. North American Journal of Fisheries Management 16(4):693-727.	Duration of effect was considered in the Application. Specifically, duration is one of the metrics by which every residual effect is characterized (please see Table 4.5-5). Aurora LNG considered adopting quantitative thresholds for some of these metrics, including duration. Ultimately, however, the thresholds used were adopted because they can be applied consistently to all four potential effects and across different mechanisms within the same potential effect. In contrast, quantitative thresholds - such as the Newcombe and Jenson (1996) approach, are highly context specific. There are several reasons why the model predictions in the reference cited in the IR are not appropriate to an EA context and in particular for those in the Skeena estuary. First, Newcombe and Jensen (1996) (N&J) highlight the great variability among species, and importance of life-stages and particle size. They base their meta-analysis on studies that were (1) species-focused, (2) typically from highly controlled laboratory studies, and (3) "adequately documented". They implicitly assume information is available on several variables that are required to apply their linear models. That is, the N-J approach is of most use in data-rich, species-specific applications, where fish are exposed to steady elevations of TSS, non-stop, for a prolonged duration. In the context of an EA, where many species, life-stages and biophysical scenarios are involved, information on key variables is lacking, and (in this case) TSS plumes are highly variable over time and space, the approach is far less viable or practicable. Indeed, N-J recognize that the response of fish in wild populations exposed to episodic pulses of elevated TSS (as would be the case here) may not fit with their model predictions since, for example, wild fish are likely to actively avoid TSS plumes.

2530.1	round 1	Gitga'at First Nation	Table 4.9-2	Marine Fish and Fish Habitat	There is no reference to potential effects of “Ballast Water” on marine habitat, fish, and invertebrate species in the subtidal, tidal, and beach zones. In addition to the initial listing of species that have been reported to be introduced to the BC coast by ballast water releases, there should be a ballast water management and release monitoring approach. The Proponent needs to state whether the International Maritime Organizations (IMO’s) “International Convention for the Control of Ship’s Ballast Water and Sediments”[1] will be adhered to. As outlined in these guidelines all ships that are exchanging ballast water must: 1. Exchange water outside the Canadian EEZ (200 Nautical Miles offshore or if not possible due to storm at an absolute minimum of 50 Nautical Miles offshore), ballast water treatment and a ballast water exchange monitoring plan; 2. Carry a ballast water record book; 3. Possess a ballast water management certificate.<	As per Mitigation Measure No. 4.5.7 (Section 4.5.15.3, Table 4.5-26 of the Water Quality VC), vessels transiting to and from the Aurora LNG marine terminal will adhere to the Vessel Pollution and Dangerous Chemicals Regulations and the Ballast Water Control and Management Regulations under the Canada Shipping Act (2001). The Ballast Water Control and Management Regulations are aimed at avoiding the introduction of invasive species to local waters, and outline a number of mandatory ballast water management procedures related to ballast water management plans, ballast water exchange and treatment, reporting requirements, compliance and enforcement, and research. Therefore, no adverse effect on marine water quality as a result of ballast water discharge is expected. Subsequently, no adverse effects to marine fish and fish habitat are expected.
2531.1	round 1	Gitga'at First Nation	Table 4.9-3	Marine Fish and Fish Habitat	Under the “Potential Project Effects” column, there is no mention of one of the greatest and likely dangers for fish and fish habitat of this project, the accidental release of larger amounts of bunker oil as well as the continuous release of smaller amounts of oil and exposure to antifouling paint as part of normal operations. These effects, and their effect mechanism, measurable parameters and rationale for measurable parameters should be listed here even if they have also been listed elsewhere in the Application. The impacts of operational releases of oil and other harmful substances (e.g., mechanical fluids and antifoul paint) must be assessed.	As Gitga'at First Nation has noted, the release of bunker fuel into the marine environment would constitute an accident or malfunction. It is standard Environmental Assessment methodology to consider potential effects of accidents and malfunctions separately from other Project-related effects (i.e., effects of construction, routine operations, and decommissioning). For a discussion of the potential effects of a bunker fuel spill on marine fish and fish habitat, please see Section 9.9 of the Application. Mitigation of potential effects related to the release of "smaller amounts of oil and exposure to antifouling paint as part of normal operations" fall within the scope of best management practices. Aurora LNG is committed to ensuring that all construction equipment (including vessels) will be kept clean, free of leaks, and will have spill kits. Where possible, fueling of construction vehicles will take place at least 30 m away from any watercourse or waterbody. This mitigation measure will limit the risk of spills to the aquatic environment. Please see mitigation measure 10.8.10. Nevertheless, small releases of hazardous materials still constitute accidents or malfunctions and are considered in Section 9 of the Application.
2532.1	round 1	Gitga'at First Nation	4.9.2.5	Marine Fish and Fish Habitat	It is unclear whether the spatial boundaries are also based on oil dispersion models taking currents and wind into consideration in case of a bunker oil spill. Clarification is necessary.	Spatial boundaries for the Marine Fish and Fish Habitat VC were developed to assess potential effects resulting from Project construction, routine operations, and decommissioning, and reflect the areas within which such effects could be measurable. A bunker fuel spill is considered an unlikely event and would constitute an accident or malfunction. It is standard EA methodology to consider potential effects of accidents and malfunctions separately from other Project-related effects. For a discussion of the potential effects of bunker fuel spill on marine fish and fish habitat, please see Section 9.9 of the Application.
2533.1	round 1	Gitga'at First Nation	Table 4.9-5	Marine Fish and Fish Habitat	Within the “Magnitude” row and under the “Quantitative Measure…” column we recommend quantifying statements in the following way: For “Low”, we suggest quoting how much change from existing conditions is needed to define change.	Aurora LNG appreciates the suggestion to adopt specific thresholds for the magnitude levels, and this approach was given serious consideration during the refinement of these criteria. Ultimately, there were two main reasons why a qualitative approach was adopted: The degree of deviation from baseline conditions required to meet the different levels ('negligible', 'low', 'moderate', 'high') would likely vary depending on the specific effect and underlying mechanism. It is unlikely that adequate detail could be always obtained on each mechanism and for each potential effect to defensibly specify a % deviation from baseline conditions. In summary, Aurora LNG felt that a qualitative approach was ultimately more appropriate and defensible than having quantitative thresholds for each magnitude level.
2534.1	round 1	Gitga'at First Nation	4.9.2.8	Marine Fish and Fish Habitat	Based on the Application, “A significant adverse residual effect on marine fish and fish habitat is defined as one that threatens the long-term persistence of a marine fish population”. The determination of significance for the Marine Fish and Habitat VC was in all instances tied to “CRA fish populations” and not to just “CRA fish” as required by the Fisheries Act. We do not agree with this definition of a significant adverse residual effect and do not believe that it is based on the definition of harm to CRA Fish and Fish Habitat as defined in the Fisheries Act. Significance should be re-assessed with regards to fish and their habitat as well as ongoing productivity, not just fish populations.	The significance threshold defined in Section 4.9.2.8 of the Marine Fish and Fish Habitat assessment is different from the definition of serious harm to fish (as per the Fisheries Act), since it explicitly considers mitigation measures, which include fully offsetting serious harm to fish, as defined in the Fisheries Act (see Appendix V, Conceptual Fish Habitat Offsetting Plan). Nevertheless, the concept of serious harm to fish is a fundamental part of the measurable parameters, mitigation measures and characterization of residual effects for 'change in fish habitat' (Section 4.9.5.2) and 'change in mortality risk' (Section 4.9.5.5). Specifically, the measurable parameters (Table 4.9-3) directly inform the assessment of potential and, ultimately, residual serious harm to fish (Appendix V), which in turn guides the choice of mitigation measures. The mitigation measures (Tables 4.9-11 and 4.9-18) serve to: (a) reduce or avoid serious harm to fish and (b) counterbalance remaining serious harm to fish through offsetting (mitigation measure # 4.9.2; Appendix V). Characterization of residual effects includes the metric 'Magnitude'. The definition of the different levels for magnitude includes "change from existing conditions that is below [for low magnitude]/above [for moderate and high magnitude] environmental and/or regulatory guidelines, but does not affect [for moderate]/and has potential to adversely affect [for high] the long-term persistence of any marine fish populations" (Table 4.9-5). Compliance with the Fisheries Act is considered explicitly under "below/above...regulatory guidelines", and separately from the effect on the long-term persistence of fish populations (e.g. top of page 4.9-53).
2535.1	round 1	Gitga'at First Nation	4.9.2.8	Marine Fish and Fish Habitat	Significance of an effect should not be bounded by temporal or population level limits as is done here. A significant effect can occur over short periods of time and affect less than the whole population of a fish species. In addition, significant effects can occur for other species groups and should not be limited to “a marine fish population”. Please revise.	Aurora LNG acknowledges that defining a significance threshold for an ecological Valued Component (VC) is subjective, as it depends on what characteristics of the VC are considered of value to an individual or organization. For the Marine Fish and Fish Habitat VC, Aurora LNG took an ecological function approach, whereby an exceedance of the significance threshold (i.e., local extirpation of a population) could result in a significant effect on the function of the marine ecosystem. The definition also allowed adequate flexibility to be generalizable to all four marine fish and fish habitat potential effects. Effects manifesting over a short period of time, or on a scale that does not affect the whole population, were captured as part of the broader characterization of residual effects, based on the metrics defined in Table 4.9-5. Finally, the term 'fish' is used as per the Fisheries Act definition, which does include marine species beyond the taxonomic group of finfish. Please see page 4.9-1 (second paragraph) of the Application for this definition of 'fish'.
2536.1	round 1	Gitga'at First Nation	4.9.3.1	Marine Fish and Fish Habitat	In the listing of different modelling studies provided, there is no current and wind dispersion model for large scale and accidental bunker oil releases and for operational and likely frequent releases of bunker oil, and other mechanical fluids as well as ballast water from the tankers. Please provide such a model.	The potential effects of an accidental release of bunker fuel on marine water quality and marine fish and fish habitat are discussed in Section 9.9 of the Application. The assessments in Sections 4.5 (Water Quality VC) and 4.9 (Marine Fish and Fish Habitat VC) focus on potential effects of Project construction, routine operations and decommissioning. It is standard EA practice to consider the effects of accidents and malfunctions separately from other Project-related effects. Aurora LNG disagrees with the statement that there will be "likely frequent releases of bunker oil, and other mechanical fluids...". Vessels calling on the Aurora LNG marine terminal will comply with all relevant federal and international regulations (e.g., Vessel Pollution and Dangerous Chemical Regulations of the Canada Shipping Act, 2001) that have been established to minimize the potential for releases of hazardous materials. For a discussion on preventative measures and response measures that would be implemented in the unlikely event of an accidental spill, please see Section 9.9.2. Aurora LNG is of the opinion that undertaking current and wind modelling of large scale and or accidental bunker oil releases is not required to characterize potential Project interactions between released oil and marine fish and fish habitat. Oil trajectory modelling following an unlikely release incident would use real-time meteorological and oceanographic data to more accurately predict the movement of oil, and guide response activities at that time. The release of ballast water is regulated by Transport Canada through the Ballast Water Control and Management Regulations of the Canada Shipping Act (2001). The regulations are aimed at avoiding the introduction of invasive species to local waters, and outline mandatory management procedures for ballast water management, exchange and treatment, reporting requirements, compliance and enforcement, and research. Further discussion is provided in Table 4.5-17 and in the Water Quality VC (Section 4.5.15.3, Operations). Vessels transiting to the Aurora LNG marine terminal will comply with Transport Canada regulations, as per Mitigation 4.5.7 (Section 4.5.15.3, Table 4.5-26 of the Water Quality VC).
2537.1	round 1	Gitga'at First Nation	4.9.3.2	Marine Fish and Fish Habitat	For all of the locations the observations appear to be purely based on presence and absence without any attempt to determine densities by species or species groups. Please explain how Aurora LNG plans to measure changes in species densities or relative species composition in the intertidal and subtidal zone based on presence-absence based surveys? Please also provide a summary table for all surveyed locations for the intertidal and subtidal species composition and densities.	Detailed methods and results of Project-specific field surveys are provided in Appendix L. Estimated relative abundance of species and species groups is presented using density where appropriate (e.g., quadrat-based observations during intertidal surveys, numbers per area seined) and other metrics where more suitable (e.g., number per length of ROV transect or number per time of tangle net set). Summary tables of intertidal data are presented in Appendix 1 of Appendix L, summary tables of subtidal data are presented in Appendix 2 of Appendix L, and summary tables of marine fish data (sampled in both the intertidal and subtidal) are presented in Appendix 6 of Appendix L. The characterization of species composition and relative abundance in Appendix L was used to inform the assessment of Project-related effects that could result in changes to species composition or relative abundance. Assessment of potential change in habitat is in Section 4.9.5.2, assessment of change in behaviour is in 4.9.5.3, assessment of change in mortality risk is in Section 4.9.5.4, and assessment of change in health is in Section 4.9.5.5.
2538.1	round 1	Gitga'at First Nation	Figures 4.9-3, 4.9-4 and 4.9-5	Marine Fish and Fish Habitat	Please explain why the areas that are going to be dredged as part of the construction of marine infrastructure are by colour-coding (dark blue) characterized as “altered” and not as “lost” or as “permanently altered”.	Figures 4.9-3 to 4.9-5 show alteration and loss of marine substrate and vegetation as a result of Project construction. The area affected by dredging is captured by three colours: light pink (indicating a change from intertidal to [lower elevation] intertidal), dark pink (indicating a change from intertidal to subtidal), and blue (indicating a change from subtidal to [deeper] subtidal). These changes are classified as 'alterations' since the substrate will remain available for use by marine species (including CRA species) after dredging has been completed, but will be different in their nature. Other changes, in which the substrate is completely removed from the marine environment, are classified as "lost". The figures do not further depict between alterations that are considered temporary or permanent; this distinction is covered in the text itself. A permanent alteration is determined based on DFO's definition -- i.e., that the change is of a duration that could impair the ability of a CRA species to complete one or more life processes. Habitat changes caused by dredging (or any other mechanism), that fulfilled this definition were included in the area estimates of permanent alteration, and will be offset. The lag time during which marine communities recover to their climax state (resulting in a productivity deficit) are (and will continue to be) accounted for in estimates of offsetting requirements through an appropriate offset ratio.
2539.1	round 1	Gitga'at First Nation	Figure 4.9-7b	Marine Fish and Fish Habitat	The figure shows only one dredging location at the jetty site while Figure 4.9-3 shows another dredging location south of Tuck Island that would be exposed to higher current speeds and therefore sediment disturbed by dredging would likely be deposited at higher distances from the dredging location shown for the one dredging site close to Digby Island. Please add the second dredging site and related sedimentation patterns to Figure 4.9-7b.	The purpose of Figure 4.9-6 and Figure 4.9-7 (in the Marine Fish and Fish Habitat VC) was to demonstrate that sediment deposition associated with dredging activities is expected to occur predominantly in areas that experience natural sedimentation (as opposed to accretion). The LNG Jetty - Berth 1 North and the Pile-and-Deck MOF option were chosen as two examples to visually display this phenomenon. At the LNG Jetty – Berth 2, areas of predicted sediment deposition (displayed in Figure 10-6 of Appendix G [Technical Memorandum - Aurora LNG: MOF and Terminal Dredge Modelling]) are also expected to occur predominantly in areas that experience natural sedimentation (displayed in Figure 64a of Appendix M [Hydrodynamic Modelling of Changes in Sediment Erosion and Accretion due to Project Infrastructure]).
2540.1	round 1	Gitga'at First Nation	4.9.5.2	Marine Fish and Fish Habitat	The loss of eelgrass is not expressed in the big picture of percentage loss of eelgrass within the Prince Rupert Harbour area. The categorization of the loss of eelgrass as “moderate in magnitude” can only be made once the total historical versus current extent of eelgrass occurrence in the Prince Rupert Harbour area has been assessed. Please add an assessment of total area of historical and current eelgrass in the harbour area to this report and then base the assessment of magnitude of effect on this spatial scale.	It is standard Environmental Assessment methodology to assess and characterize project-related effects in relation to current (i.e., existing baseline) conditions. Management and restoration decisions for eelgrass, which consider a broad spatial and temporal scope, are the responsibility of regulatory agencies (such as Environment and Climate Change Canada, Fisheries and Oceans Canada, the Government of BC's Ministry of Environment and Ministry of Forest, Lands and Natural Resource Operations) and local environmental groups. Wherever possible and practicable, Aurora LNG will adopt restoration or offsetting goals to complement the objectives of these efforts. However, Aurora LNG believes that baseline conditions should be based on current -- not historical -- conditions. Please note that cumulative effects (which consider past, present and reasonably foreseeable projects) are considered in Section 4.9.6 of the Application.
2541.1	round 1	Gitga'at First Nation	4.9.5.2	Marine Fish and Fish Habitat	The characterization of dredging and marine construction as “low to moderate” is in our opinion inappropriate based on the Proponent’s own classification scheme and the Fisheries Act: The Act does not define harm as “harm to fish populations” but harm to “CRA fish” in Section 35(1) of the Fisheries Act and prohibits any work, undertaking or activity that results in serious harm to fish that are part of a CRA fishery, or to fish that support such a fishery. Serious harm to fish is defined as “the death of fish or any permanent alteration to, or destruction of, fish habitat of a spatial scale, duration, or intensity that fish can no longer rely upon such habitats for use as spawning grounds, or as nursery, rearing or food supply areas, or as a migration corridor, or any other area in order to carry out one or more of their life processes.” The Application should be revised.	Aurora LNG is of the opinion that the characterization of residual changes to marine fish habitat (under the 'change in habitat effect', Section 4.9.5.2) is fair. The magnitude of residual changes in marine fish habitat associated with dredging and marine construction activities (including infilling, pile driving, and the installation of intake and outfall pipes) is characterized as being low (i.e., measurable, but below regulatory guidelines [i.e., serious harm to fish under the Fisheries Act] and does not affect the long-term persistence of any marine fish population) to moderate (i.e., measurable, above regulatory guidelines [i.e., serious harm to fish under the Fisheries Act], but does not affect the long-term persistence of any marine fish population). The characterization of 'low magnitude' accounts for residual effects such as those associated with sediment deposition during dredging activities, which are not expected to limit or diminish the ability of CRA fishery species to complete one or more life processes; therefore, residual serious harm to fish is not anticipated. The characterization of 'moderate magnitude' accounts for residual effects such as those associated with the loss of habitat during dredging activities (e.g., eelgrass), which are expected to constitute serious harm to fish and will require offsetting. With the successful implementation of mitigation measures identified in Table 4.9-11, including the development and successful implementation of a habitat offsetting plan, residual changes in marine fish habitat from dredging and marine construction activities are not expected to threaten the long-term persistence of a marine fish population. Therefore, residual effects are considered not significant.
2542.1	round 1	Gitga'at First Nation	4.9.5.2	Marine Fish and Fish Habitat	The characterization of dredging and marine construction as “low to moderate” is in our opinion inappropriate based on the Proponent’s own classification scheme and the Fisheries Act (see comment above). Therefore, harm especially to eelgrass beds clearly falls under this classification and therefore the effects of dredging and construction should be re-classified as a significant adverse effect.	Aurora LNG is of the opinion that the characterization of residual changes to marine fish habitat (under the 'change in habitat effect', Section 4.9.5.2) is fair. The magnitude of residual changes in marine fish habitat associated with dredging and marine construction activities (including infilling, pile driving, and the installation of intake and outfall pipes) is characterized as being low (i.e., measurable, but below regulatory guidelines [i.e., serious harm to fish under the Fisheries Act] and does not affect the long-term persistence of any marine fish population) to moderate (i.e., measurable, above regulatory guidelines [i.e., serious harm to fish under the Fisheries Act], but does not affect the long-term persistence of any marine fish population). The characterization of 'low magnitude' accounts for residual effects such as those associated with sediment deposition during dredging activities, which are not expected to limit or diminish the ability of CRA fishery species to complete one or more life processes; therefore, residual serious harm to fish is not anticipated. The characterization of 'moderate magnitude' accounts for residual effects such as those associated with the loss of habitat during dredging activities (e.g., eelgrass), which are expected to constitute serious harm to fish and will require offsetting. With the successful implementation of mitigation measures identified in Table 4.9-11, including the development and successful implementation of a habitat offsetting plan, residual changes in marine fish habitat from dredging and marine construction activities are not expected to threaten the long-term persistence of a marine fish population. Therefore, residual effects are considered not significant.
2543.1	round 1	Gitga'at First Nation	4.9.5.2	Marine Fish and Fish Habitat	Where are accidental and large volume or operational and small volume oil spill effects considered under Marine Fish and Habitat? It is not sufficient to provide this information Under Accidents and Malfunctions; please also assess it here and in the context of damage to CRA fish and their habitat.	It is standard Environmental Assessment practice to consider the effects of accidents and malfunctions separately from other Project-related effects (i.e., effects of construction, routine operations, and decommissioning). Potential effects of an accidental oil release on marine fish and fish habitat are assessed in Section 9.9 of the Accidents and Malfunctions VC chapter.
2544.1	round 1	Gitga'at First Nation	4.9.5.4	Marine Fish and Fish Habitat	Eelpouts (Zoarcidae spp.) are described as “more motile…fish” . We disagree with this characterization in this context since eelpouts have the tendency to seek shelter or even burry deeper when disturbed (experience of author: Dr. Elmar Plate) and thus are unlikely to avoid mortality during dredging. Please reassess impacts.	Aurora LNG acknowledges that the mention of eelpout as a fish likely to flee the area in response to dredging was not appropriate. An errata document is being compiled that captures this correction and it will be filed with the BC EAO. The assessment of change in mortality risk described in Section 4.9.5.4 will not be affected by the removal of eelpout from the list on Page 4.9-87.
2545.1	round 1	Gitga'at First Nation	4.9.5.5	Marine Fish and Fish Habitat	Is a contingency plan for water release in place? Please state the trigger concentrations for water treatment in a table and show how the trigger concentrations are monitored for all COPCs.	Waste water discharges are subject to a range of permitting and regulatory oversight, dependent on the source and nature of the discharge. Details on Project waste discharges and associated regulations, are provided in the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2546.1	round 1	Gitga'at First Nation	Table 4.9-21	Marine Fish and Fish Habitat	This table, as does the whole “Marine Fish and Habitat” chapter, leaves out all effects of accidental and large volume oil spills and operational and small volume oil spills. Wherever else in this Application they are mentioned, please also assess them here and in the context of damage to CRA fish and their habitat.	It is standard Environmental Assessment practice to consider the effects of accidents and malfunctions separately from other Project-related effects (i.e., effects of construction, routine operations, and decommissioning). Potential effects of an accidental oil release on marine fish and fish habitat are assessed in Section 9.9 of the Accidents or Malfunctions VC chapter.

2547.1	round 1	Gitga'at First Nation	Table 4.9-22	Marine Fish and Fish Habitat	Please explain why only one of the many past projects has led to change in mortality risk and none have led to changes in health? Just like the proposed Aurora LNG Project, all past projects have led and continue to lead to changes in mortality risk and health of marine fish and fish habitat.	Aurora LNG can not speak for the assessments completed by other projects. The purpose of Table 4.9-22 in the Marine Fish and Fish Habitat VC (Section 4.9) is to identify other past, present, and reasonably foreseeable future projects and physical activities that may interact cumulatively (from a marine fish and fish habitat perspective) with the proposed Aurora LNG Project. A description of each project and physical activity that was considered in the cumulative effects assessment is included in Table 3-4 of the Assessment Methods (Section 3.0 of the Application). Table 4.9-22 identifies past projects and physical activities that have resulted in lasting effects to marine fish habitat, or that continue to adversely affect fish through changes in mortality risk, behavior, or health. For a past project or physical activity to interact cumulatively with the Aurora LNG Project itself (and receive a check mark in Table 4.9-22), the following needs to be satisfied: i) the past project continues to adversely affect marine fish and fish habitats (e.g., the project continues to result in the injury or mortality of marine fish), and ii) these adverse effects are likely to interact cumulatively with the proposed Aurora LNG Project (e.g., adverse effects of the past project or physical activity overlap on a spatial or temporal scale with the proposed Aurora LNG Project, or affect a population within the Marine Fish and Fish Habitat RAA, such that the effects are expected to interact cumulatively). Section 3.7 of the Assessment Methods Chapter provides additional details on the methods for assessing cumulative effects.
2548.1	round 1	Gitga'at First Nation	4.9.6.6	Marine Fish and Fish Habitat	In this paragraph, planned projects and their metrics of permanent ACR fish habitat alterations are listed as a start of a meaningful cumulative impact assessment. In addition to these numbers expressed in lost or permanently altered area, we need the same metrics for all existing projects in Prince Rupert Harbour to assess "real" cumulative impacts. Please provide these numbers and delineate all past and planned future loss or permanent alterations of ACR fish and fish habitat in table format and as a GIS layer on a map. As it stands, the cumulative impact assessment does not provide any overview/assessment of cumulative impact in this area. As part of this assessment, please also provide an estimate of suggested total development limits in this area to protect ecological function.	Please note that for a cumulative effects assessment, "residual" effects are considered from Aurora LNG's Project and other past, present and reasonably foreseeable projects likely to interact cumulatively. Residual effects constitute any remaining effect after the implementation of mitigations - including habitat offsetting, which is not considered in the rationale underpinning this comment. Aurora LNG is committed to fulfilling their legal obligation to develop adequate, effective offsetting to counterbalance serious harm to fish caused by the loss or permanent alteration of habitat. Further, Aurora LNG assumes that other projects will also adhere to their legal requirement to offset any serious harm to fish they cause, since failure to do so would contravene the Fisheries Act and trigger serious consequences. As such, residual effects of the Aurora LNG Project and other potentially interacting projects as a result of areas lost or permanently altered are not expected to interact cumulatively in a manner that could cause adverse effects to the productivity or sustainability of CRA species. Finally, since a consideration of the residual effect of Project should include habitat offsetting, it is not necessary, appropriate (or, indeed, possible) to map areas lost or permanently altered for all past, present or reasonably foreseeable future projects.
2549.1	round 1	Gitga'at First Nation	4.9	Marine Fish and Fish Habitat	Overall, insufficient assessment in Section 4.9. Further assessment is required on the densities and relative species composition for the marine fauna and flora as it pertains to all CRA fish and invertebrate species and their habitat in all areas that will be temporarily and permanently affected or destroyed by the Project.	Aurora LNG is of the opinion that this level of information has been presented in the Application. Detailed methods and results of Project-specific field surveys are provided in Appendix L of the Application (Marine Fish and Fish Habitat Technical Data Report). Estimated relative abundance of species and species groups is presented using density where appropriate (e.g., quadrat-based observations during intertidal surveys, numbers per area seined) and other metrics where more suitable (e.g., number per length of ROV transect or number per time of tangle net set). Summary tables of intertidal data are presented in Appendix 1 of Appendix L; summary tables of subtidal data are presented in Appendix 2 of Appendix L; and summary tables of marine fish data (sampled in both the intertidal and subtidal) are presented in Appendix 6 of Appendix L. The characterization of species composition and relative abundance in Appendix L was used to inform the assessment of Project-related effects that could result in changes to species composition or relative abundance. Potential changes to habitat are assessed in Section 4.9.5.2; potential changes in behaviour are assessed in Section 4.9.5.3; potential changes in mortality risk are assessed in Section 4.9.5.4; and potential changes in health are assessed in Section 4.9.5.5. Particular attention is given to CRA species throughout Appendix L and the effects assessment.
2550.1	round 1	Gitga'at First Nation	Appendix G, 4.1 (top panel) and Table 4-2	Marine Fish and Fish Habitat	The measured peaks of the horizontal current speeds appear to be consistently underestimated by the modeled results for all higher current speeds. Please adjust and re-calibrate the model based on empirical data. For the 16.7 m depth, the observed maximum values are more than twice the modeled values.	As discussed in Section 4.3 of Appendix G of the Application) re-calibration of the model is not considered necessary. There are a few very large speed values in the observed data, which are attributed to buoy motion. A moored buoy is often susceptible to spikes in the current data due to pitch and roll of the sensor by wave action and these are considered noise. Readings at Tuck Buoy gave a maximum current speed of up to 40.2 cms-1 at 16.7 m depth, which is unrealistic values for near the seabed. The company that collected and supplied the ADCP data (Ausenco) confirmed there were some discrepancies in data quality and the uncertainties are larger than desired for the purpose of comparison to model output. However, the data indicate that the model is performing well in this region, following the trends in the observed data. There are a number of instances at each depth where the model slightly over-predicts the currents.
2551.1	round 1	Gitga'at First Nation	Appendix G. 12.1	Marine Fish and Fish Habitat	In this paragraph it is stated that "Values exceeding 5 mg/L can extend as a narrow plume northwards to a maximum distance of 700 m, with width remaining within 300 m." Please confirm that this result was reported in Section 4.9 Fish and Fish Habitat. If missed, please add this statement to Section 4.9 and interpret its results in the light of significance of effect.	A detailed description of the spatial and temporal extent of predicted TSS sediment plumes associated with dredging activities at the MOF and the LNG Jetty is included in Appendix G (Technical Memorandum - Aurora LNG: MOF and Terminal Dredge Modelling). This information was considered in the assessment of potential effects to marine fish health associated with exposure to elevated levels of TSS (under the 'change in health' effect, Section 4.9.5.5 of the Marine Fish and Fish Habitat VC).
2552.1	round 1	Gitga'at First Nation	Appendix V, Conceptual Fish Habitat Offsetting Plan, Table 16, Table 17	Fish Habitat Offsetting Plan	The rationale that only "hard" habitats have to be offset would only apply if the "soft" habitats would not provide for ACR fish species. This is not true based on the Proponent's own baseline studies that found ACR fish species in the "hard" and the "soft" bottomed habitats especially considering that "fish" in the Fisheries Act are defined as "parts of fish, shellfish, crustaceans, marine animals and any parts of shellfish, crustaceans or marine animals, and the eggs, sperm, spawn, larvae, spat and juvenile stages of fish, shellfish, crustaceans and marine animals;". We therefore think that by applying the Fisheries Act provisions correctly to ACR" fish" rather than "whole fish populations" and including the non-fish ACR species a total minimum of 172,124 m2 of area has to be entered into the habitat offsetting account for change in marine substrate resulting from dredging, infilling , and installation of seawater system pipes. Based on the same rationale, an additional minimum of 19,883 m2 (MOF–pile-and-deck-option) or 78,675 m2 (MOF-concrete caisson option) have to be added to the offsetting account due to marine substrate loss.	The distinction between "hard" and "soft" substrates is not based on whether or not they "provide for" CRA species. Rather, the distinction is based on whether or not a change to, or removal of, such habitat has the potential to cause residual serious harm to fish - i.e., that it could impair the ability of a CRA species to complete one or more life process. As per Page 47 of the Conceptual Fish Habitat Offsetting Plan (Appendix V), "The potential for residual serious harm to fish resulting from a change in intertidal or subtidal substrates depends on the comparative value of the initial and final conditions". For this reason, the different types of changes are identified (i.e., soft to hard, hard to soft, change in height or shape of soft substrate, change in height or shape of hard substrate - Page 47; loss of hard substrate, loss of soft substrate - Page 48), and consideration is given to the potential for residual serious harm from each change. For details on this distinction, please see Pages 47 48 of the Conceptual Fish Habitat Offsetting Plan (Appendix V).
2553.1	round 1	Gitga'at First Nation	Appendix V	Fish Habitat Offsetting Plan	In this paragraph the Proponent mentions for the first time that "…offsetting is expected to be required to counterbalance the temporary loss of productivity (i.e. time lag)". It is good to see that this principle of offsetting is applied in this case but the same principle must be applied to all other cases of temporary loss of habitat for the whole project. Please add the "offsetting for temporary loss of productivity principle" to all other temporary habitat loss aspects of this Project and add the temporary loss to the offsetting account. Also the temporary loss of ecological function must be added to the offsetting account.	As described in the Conceptual Fish Habitat Offsetting Plan (Appendix V of the Application), time lags in the function of offset habitats will be reduced through offset scheduling, and accounted for in offsetting ratios (pages 53, 64) and habitat equivalency analysis (page 65). Please note that, under the Fisheries Act, habitat offsetting is required for activities that result in serious harm to fish. DFO (2013) defines serious harm to fish as: a) the death of fish; b) a permanent alteration to fish habitat of a spatial scale, duration or intensity that limits or diminishes the ability of fish to use such habitats as spawning grounds, or as nursery, rearing or food supply areas, or as a migration corridor, or any other area in order to carry out one or more of their life processes; or c) the destruction of fish habitat of a spatial scale, duration or intensity that fish can no longer rely upon such habitat for use as spawning grounds, or as nursery, rearing or food supply areas, or as a migration corridor, or any other area in order to carry out one or more of their life processes. Temporary changes to fish habitat that do not affect the the ability of fish to complete one or more life processes do not constitute serious harm to fish, and therefore, do not require habitat offsetting. Reference: Fisheries and Oceans Canada [DFO]. 2013. Fisheries Protection Policy Statement. Ecosystem Programs Policy. Ottawa, Ontario. 22 pp.
2554.1	round 1	Gitga'at First Nation	9.2	Accidents or Malfunctions	In the listing of Accidents or Malfunction scenarios, neither the accidental spill of large volumes of bunker oil due to vessel collision or sinking nor the operational spill of small amounts of oil and other mechanical fluids are mentioned. Please add both of these scenarios to this list and assess their potential risks for the environment.	A spill of marine fuel (bunker or diesel) is considered within section 9.9 (Vessel Grounding or Collision). The On-shore Hazardous Spills section (9.8) assesses the potential for spills (small or large) reaching the marine environment.
2555.1	round 1	Gitga'at First Nation	9.9.3	Accidents or Malfunctions	At the end of this chapter it is stated that "Residual effects on marine water quality from diesel or bunker fuel due to vessel grounding or collision event are predicted to be not significant." This sentence does not apply to this chapter where the residual effects for marine fish and fish habitat are supposed to be stated. Please change this sentence and re-think the categorization based on the report statement that "e.g., bunker fuel can persist in the marine environment and if left to weather, clean-up efforts can be difficult and continue over the long-term." In addition, please consider the residual effects of the Exxon Valdez deposition of oil into intertidal habitats that persisted for more than two decades.	Aurora LNG acknowledges that there are two repeated errors in Section 9.9.3 of the Application under the sub-heading Marine Fish and Fish Habitat. The final sentences of paragraphs two and four on p. 9-39 should read: 'Residual effects on marine fish and fish habitat from diesel or bunker fuel due to a vessel grounding or collision event are predicted to be not significant.' An errata document is being created that will capture these corrections and it will be filed with the BC EAO. The potential persistence of portions of unrecovered and stranded oil that may become buried in intertidal sediments is not expected to be synonymous with the persistence of effects on marine fish and fish habitat. The loss of lighter fractions of hydrocarbons through evaporation, dispersal and other weathering processes in the days and weeks after a release is expected to reduce the potential for toxic effects where pathways to exposure exist. Furthermore, pathways to exposure are expected to be limited through burial of weathered oil portions or hard crusts formed over their surface (formation of 'tar balls'). The emergency response community has benefited through experience and technological improvements in oil containment and recovery techniques in the over 27 years since the Exxon Valdez incident. Emergency response to a release of bunker fuel will focus on the containment and recovery of floating oil, and the deflection away from, and booming of, sensitive shorelines to limit the stranding of oil.
2556.1	round 1	Gitga'at First Nation	6.5.4.2	Marine Use and Navigable Waters	The Application determined that wake waves generated by LNG carriers and escort tugs are not likely to cause adverse effects on Aboriginal and commercial marine harvest. This was determined based upon a report produced for LNG Canada that predicted that wake generated by LNG carriers and escort tugs travelling at 12 knots will be less than 0.4 m high (at the source vessel), which is within the size range of naturally occurring waves in the region. They provide an example that wave height in Douglas Channel experiences a maximum height was 3.4 m with an averaged 0.14 m. The Application then screens out vessel wake in the assessment because it is expected that mariners and shoreline harvesters will be accustomed to dealing with project-related wake waves. While the magnitude vessel wake waves maybe well within the range of normal wave conditions, the predicted wave conditions are not provided for Chatham Sound. More information is required.	Environment Canada and Fisheries and Oceans Canada monitor 17 buoys that record weather data. However, none of the buoys are located in Chatham Sound. Of these buoys, two were used in Section 6.5.4.2 to represent the potential range of wave heights experienced in the Project area. The South Hecate Strait buoyis located in relatively deep water (approximately 228 m) in an exposed area with high fetch, where Hecate Strait meets Queen Charlotte Sound. The mean monthly average wave height recorded at this buoy is 1.8 m, while the historical maximum is 13.7 m. The Nanakwa Shoal buoy, in Douglas Channel, is located in relatively shallow water (approximately 22 m) in a confined area with less potential for east-west fetch. Mean monthly average wave height at this buoy is 0.14 m and the historical maximum is 3.4 m. Specific wave height information for Chatham Sound is not available through the buoy monitoring system noted above. However, the weather buoy in South Hecate Strait is relatively more exposed than Chatham Sound, while the Douglas Channel buoy is in a much more confined location. The exposure and fetch of Chatham Sound are less than the area of the South Hecate Strait buoy, yet greater than the Douglas Channel buoy location. It is therefore reasonable to assume that average wave height experienced in Chatham Sound will fall somewhere between that seen at South Hecate Strait and that seen in Douglas Channel. The assessment in Section 6.5.4.2 states that a wave height range of 0.14 m and 1.8 m is assumed to be the average natural wave height typically observed in the Project area.
2557.1	round 1	Gitga'at First Nation	6.5.4.2	Marine Use and Navigable Waters	The assessment does not consider wave frequency or timing. Increased wave frequency could increase the likelihood of shoreline and intertidal erosion, thus impacting habitat for intertidal species (i.e., harvested invertebrates and algal species). Where the timing of waves and intertidal harvesting overlap, vessel wake can have a detrimental disturbance effect on harvesting practices as harvesters must accommodate for vessel wake. In addition, there has been no vessel wave study and wake wash impact assessment conducted in the Application. A more sophisticated analysis (magnitude, frequency, timing) is required to reduce uncertainties in the assessment, and provide a more rigorous framework for comparison with both the ambient storm wave climate and the wake associated with shipping traffic.Therefore, it is premature to conclude that there will be no adverse effects on shoreline/intertidal habitats and intertidal harvesting, much less to conclude that there is no pathway for effects to occur as was done in the Application. Further assessment is required	Potential changes to marine fish habitat resulting from vessel wake generated by Project-related vessels are discussed under the 'change in habitat' effect (Section 4.9.5.2, Marine Fish and Fish Habitat), Based on the results of the assessment, wake effects resulting from vessels associated with the Project are not expected to adversely affect marine fish habitat. Therefore, wake effects were not considered further within the Marine Fish and Fish Habitat assessment. If it is conservatively assumed that intertidal harvesters working on shore are using both low tide periods in a day (this is unlikely, as the two low tides in a day are not often the same tidal height and, therefore, one is more suitable for harvesting than the other), and harvesting can be undertaken for two hours during each low tide (i.e., one hour on each side of each low), then approximately 17% (4/24 hours) of each day is available for intertidal harvesting. The potential for intertidal harvesters to interact with Project-related shipping effects is temporally restricted on a daily basis. For approximately 83% of each day, wake from Project-related shipping will not interact with intertidal harvesters Section 6.5.4.2 of the Application describes that the mean monthly average natural wave height in the area is assumed to be between 0.14 m and 1.8 m. The potential maximum wave height (immediately adjacent to the source vessel) of 0.4 m, produced by LNG carriers and escort vessels at 12 knots, is within the range of the mean monthly average wave height in the Project area. The modeled wake height of LNG carriers (and other vessel types) indicates that wake-related waves attenuate as they travel further from the source vessel (Oceanic Consulting Corporation 2014). This means that the actual wave height when it reaches the shoreline is lower than the wake height at the source vessel, and well within the natural wave height range currently experienced by shoreline harvesters. Additional large vessel traffic may alter the frequency of vessel generated wake but this is not expected to measurably change the wave activity in the area. Moreover, Project-related vessels will travel along the existing and established shipping route currently used by larger marine traffic (e.g., container ships, cargo ships, breakbulk ships, ferries) to enter and exit Prince Rupert harbour. The predicted wake-related wave height 300 m from the centreline of travel of a large, loaded LNG carrier traveling 12 knots (and that modeled for 14 knots) is similar to those predicted for ore carriers, cruise ships, and BC Ferries vessels (Oceanic Consulting Corporation 2014), all of which call at the Port of Prince Rupert. Project-related wake effects are not expected to differ from the variable wave heights and conditions already experienced by shoreline harvesters, relating to natural weather patterns and large vessel traffic. Reference: Oceanic Consulting Corporation. 2014. Kitimat Ship Wake Study. Prepared for: LNG Canada Development Inc.
2558.1	round 1	Gitga'at First Nation	6.5.2.1	Marine Use and Navigable Waters	The environmental and economic consequences of species invasions are well known in the US and Canada. However, the Application does not discuss any potential for the introduction of invasive species into the LAA and RAA. The Application does mention that the Canadian Shipping Act and the associated Ballast Water Control and Management Regulations (BWCMR) exist, but there was no formal assessment. The regulations require vessels to exchange ballast at least 50 nautical miles west of Haida Gwaii or Vancouver Island. These areas are quite far offshore so unless there is noncompliance with the regulations, this measure should reduce the likelihood of introduction of invasive species. However, the BWCMR only require a 95% exchange rate of ballast so that 100% elimination of the potential for the introduction of exotics is not required nor mentioned in the Application. In addition, the effectiveness of mid-ocean ballast exchange depends entirely on compliance and the method of ballast treatment. Pui Gwun Lo (2009) pointed out several caveats regarding the effectiveness of mid-ocean ballast exchange. Hull fouling is another means for invasive species to be introduced into the LAA and RAA. Hull fouling involves organisms such as barnacles or mussels attaching themselves to ship hulls and either encountering structures in a new port or releasing larvae into the water. Therefore, invasive species must be assessed in the Application.	Sections 6.5.2.1 and 6.5.6.4 of the Application identify the legislation and regulations pertaining to the control and management of ballast water. As per Mitigation Measure No. 4.5.7 (Section 4.5.15.3, Table 4.5-26, of the Water Quality assessment), vessels transiting to and from the Aurora LNG marine terminal will adhere to the Vessel Pollution and Dangerous Chemicals Regulations and the Ballast Water Control and Management Regulations under the Canada Shipping Act (2001). The Ballast Water Control and Management Regulations are aimed at avoiding the introduction of invasive species to local waters, and outline a number of mandatory ballast water management procedures related to ballast water management plans, ballast water exchange and treatment, reporting requirements, compliance and enforcement, and research. Project-related international shipping will be required to adhere to these regulations. The Prince Rupert Port Authority (PRPA) is a standing member of the Green Marine Program, which encourages international ship owners to implement anti-fouling measures to reduce the risk of aquatic invasive species introductions from hull-attached organisms. The PRPA also monitors the potential establishment of invasive species as part of the Plate Watch program. To date, no aquatic invasive species have been documented in the Prince Rupert harbour as part of this program. Because the above identified mandatory management procedures for preventing the introduction of aquatic invasive species are well established and effective, a separate assessment of invasive species is not warranted.
2559.1	round 1	Gitga'at First Nation	9.8.3	Accidents or Malfunctions	The Application determined that spills are not likely to cause adverse effects on Aboriginal and commercial marine harvest. Accidental discharges of fuel, oil or bilge will likely occur during the life of the project despite all regulations cited as being in place. Should there be an accidental spill of oil or fuel at an anchorage or on route, there may be adverse local effects to fish, invertebrates or marine seaweed/plants depending on the magnitude, location, and timing. To the extent that these effects might be significant will depend on many factors including the time of year, the marine receptors present, and the response measures enacted. For example, a large diesel spill during sensitive egg and larval fish life history stages may have a significant effect on that population if not contained quickly. Further assessment is required.	Aurora LNG agrees that the severity of potential effects, on marine fish and fish habitat, from a spill in the marine environment, will vary depending on various factors. This is described in Section 9.9.3 of the Application. The levels of mortality that could occur are not expected to measurably affect species at a population level, and are predicted to be not significant (as defined in the threshold for significance in the Marine Fish and Fish Habitat assessment: Section 4.9 of the Application). It is predicted that some amount of mortality may occur. However, with mitigation and relevant response measures in place, these effects should be limited to the immediate spill area but could potentially extend out to the LAA.. The extent of the spill will depend on various factors including the type and volume of material spilled, the location, weather (during and following the spill) and season, marine fish (and life stages) and habitat present; tidal influences, response time and response measures. An LNG spill would be expected to vaporize rapidly (i.e., within hours) and would not leave any residue in the marine environment. A diesel spill would be expected to spread more rapidly due to its lighter nature and evaporate and disperse/break down over the short term. A bunker fuel spill would be expected to spread more slowly and persist for a longer period of time due to its thicker consistency. The potential effects from each event may vary depending on the combination of influencing factors and will need to be evaluated and considered in the Emergency Response Plan developed for the Project.

2560.1	round 1	Gitga'at First Nation	4.9	Marine Fish and Fish Habitat	What are the impacts on fish and fish habitat from the cruise ship proposed during construction?	A cruise ship is not proposed during construction of the Project. For a discussion of the potential effects of the floating construction camp, which may be used to house construction workers in Casey Cove during the initial stages of Project construction, please refer to the "Floating Camp Review" technical memo which will be filed with the BC EAO.
2561.1	round 1	Gitga'at First Nation	4.9	Marine Fish and Fish Habitat	At this time the Marine Riparian zone appears insufficient in width, and the location of the flaring structures could impact Delusion Bay. Please justify why the zone is considered acceptable.	Section 1.2.5.1 of the Application describes the proposed flare system design. Aurora LNG considered placement options of the flare system within the PDA to reduce potential interaction with environmental valued components and to limit the amount of light dispersal (Table 1-26). As per mitigation 4.7.20, maintenance flaring events will be scheduled during daylight hours to the extent practicable to further reduce attraction by birds and bats to flare system infrastructure during nocturnal migration or foraging. Additionally, the 30 m marine riparian buffer will be maintained during all phases of the Project to retain shoreline habitats and limit noise and light dispersal, and is expected to further reduce potential for disturbance to marine species using shoreline and nearshore habitats in Delusion Bay.
2562.1	round 1	Gitga'at First Nation	4.9	Marine Fish and Fish Habitat	The Application includes a statement: "unidentified larval fish (a grouping that could possibly include eulachon, as well as other Osmerids)." Nexen should confirm identity as utilization of project area by eulachon is important information to Gitga'at.	Aurora LNG recognizes the importance of eulachon to Gitga'at First Nation. Information on eulachon in areas potentially affected by the Project was obtained from both publicly available literature and from Project-specific field studies (Appendix L, Marine Fish and Fish Habitat TDR). Project-specific field studies reported the following information on eulachon: -Thirty-six adult eulachon were captured at night by mid-water trawl in March 2015 in the channel between Digby Island and Kaien Island (n=6) and in waters off the coast of south Digby (n=30, see Section 3.4.4 of Appendix 5 of Appendix L). Trawling was not completed during any other of the six marine fish surveys; however, adult eulachon were assumed to be present in the LAA during other times of the year (e.g., during inbound spawner migration [February – March], see Table 6 of Appendix L). -Unidentified larval fish belonging to the Family Osmeridae (which may have included larval eulachon) were observed in beach seine catches completed in the LAA in August 2014, March 2015, October 2015, February 2016, and May 2016. Beach seine catches of unidentified larval fish are presented as catch per unit effort in Figure 41 (Casey Cove), Figure 43 (East Digby Island), Figure 45 (South Digby Island) and Figure 47 (Delusion Bay). It was not possible to identify individuals down to the species level in the field, as this would require DNA analysis. However, the absence of confirmation of eulachon was not used to infer absence of eulachon from the LAA. -DNA analysis of tissue samples taken from unidentified juvenile osmerids captured by beach seine and mid-water trawls in March 2015 was completed (see Section 3.4.8 of Appendix 5 of Appendix L). Tissue samples confirmed that unidentified juvenile osmerids captured by mid-water trawl were capelin, and unidentified juvenile osmerids captured by beach seine were surf smelt. DNA analysis did not identify individuals as eulachon. However, the absence of confirmation of eulachon was not used to infer absence of eulachon from the LAA. No adult eulachon were captured by beach seine at any location in the LAA during any sampling period, including February 2016, March 2015, April 2014, and May 2016. While this result does not mean that adult eulachon do not use nearshore habitats in the LAA, it does suggest that their use of these nearshore habitats - where most of the Project infrastructure will be located - is limited. Literature regarding habitat preferences supports this. Aurora LNG is of the opinion that the information collected through Project specific field studies and publicly available literature is adequate to characterize potential residual effects on eulachon. Further, Aurora LNG is confident that the proposed mitigation measures (i.e., measures 4.9.1 through 4.9.15, described in Section 4.9 of the Application) will be effective at reducing potential adverse effects on eulachon.
2563.1	round 1	Gitga'at First Nation	4.9 (page 4.9-27)	Marine Fish and Fish Habitat	Potential project interaction is missing. Project component "Waste management" and potential effect "change in habitat". Cooling tower discharge has the potential to affect fish habitat.	Installation of the deep water outfall pipe at Charles Point has the potential to affect marine fish habitat, and this is assessed under the 'change in habitat' effect (Section 4.9.5.2). Potential effects to marine fish resulting from waste discharges to the marine environment are assessed under the 'change in health' effect (Section 4.9.5.5). All effluent discharged to the marine environment from the outfall will comply with all relevant regulations and permit requirements, and will meet the BC and CCME water quality guidelines for the protection of aquatic life; therefore, effluent discharges are not expected to result in measurable changes to marine fish habitat.
2564.1	round 1	Gitga'at First Nation	4.9 (page 4.9-28)	Marine Fish and Fish Habitat	Gitga'at would like to see a follow-up study to confirm the predictions that there will be no measurable effect to marine water quality / marine resources from localized marine water acidification or eutrophication. And to confirm there will be no changes to water quality (and thus marine / estuarine vegetation from changes to TSS (especially in Delusion Bay).	Marine water acidification and eutrophication is not expected to occur due to the high buffering capacity of marine waters. Therefore, no adverse effects on marine water quality and marine fish and fish habitat are expected from acidification and eutrophication. However, it is anticipated that a selection of freshwater lakes and streams (which may include streams that flow into Delusion Bay) will be monitored to verify the prediction of no adverse effects on water quality due to acidification and eutrophication. These acidification and eutrophication monitoring programs are expected to be regionally focused and developed in consultation with MOE, Aboriginal Groups, and industry partners. Regarding TSS-driven effects on marine vegetation, all site discharges into the marine environment, including discharges into Delusion Bay (e.g., from the soils storage area), will comply with relevant regulations and permitting requirements, and therefore no adverse effects to marine vegetation in Delusion Bay are expected from these discharges. Adherence with these regulations is a legislated requirement of all proponents, including Aurora LNG, and failure to adhere to them can have serious ramifications. Aurora LNG is committed to developing and implementing a Marine Water Quality Monitoring Program, which will include monitoring turbidity and confirming the effectiveness of mitigation measures. The plan will include water quality thresholds, monitoring frequency, and specific monitoring locations. The content of the plan will be developed in accordance with industry best management practices and standards, applicable regulations, and conditions of the Environmental Assessment Certificate and relevant permits.
2565.1	round 1	Gitga'at First Nation	4.9 (Appendix M)	Marine Fish and Fish Habitat	The hydrodynamic modeling (of erosion and accretion) did not incorporate vessels at berth as a modeled scenario. This must be assessed for changes to fish habitat.	Since vessels are not expected to be berthed continuously, and do not constitute part of the Project infrastructure, they are not expected to have any prolonged, consistent or meaningful impact on sediment erosion and accretion rates. As such, Aurora LNG does not believe that incorporation of vessels into hydrodynamic modelling of Project infrastructure is necessary. Nevertheless, the potential effects of Project vessels on marine fish and fish habitat are considered throughout Section 4.9, and potential effects on marine water quality are considered in Section 4.5.
2566.1	round 1	Gitga'at First Nation	4.9 (Table 4.9-13)	Marine Fish and Fish Habitat	What is the difference between "habitat permanently altered" and "habitat lost"?	"Permanently altered" means that the habitat has changed from one type to another for a duration that could impair the ability of a species to complete one or more life process. "Habitat lost" indicates that the marine habitat is completely removed and no longer available for use by fish, such as when it is raised above the high tide level through infilling.
2567.1	round 1	Gitga'at First Nation	4.9 (Table 4.9-13)	Marine Fish and Fish Habitat	There is no characterization of the fish habitat at Brown Passage, yet there are project effects at that location. More information is required as there are known sponge reefs within the potential range of sediment deposition effects.	Please see the "Brown Passage: Characterization of Existing Conditions and Potential Effects associated with Disposal at Sea" which will be filed with the BC EAO.
2568.1	round 1	Gitga'at First Nation	4.9 (page 4.9-63)	Marine Fish and Fish Habitat	It is stated that construction activities (e.g. dredging) will occur 20 hours a day at the MOF. This is outside the window BMP from the BC OGC for noise management (near residential Dodge Cove). Clarification is required.	The construction phase noise assessment includes noise effect from dredging activities for a daily duration up to 20 hours. The BC OGC noise guideline recommends construction activity during the daytime period (7:00 to 22:00); however, the guideline does not set specific noise limits for construction activity. Noise effect from dredging activities during the nighttime period is predicted to be in compliance with the thresholds recommended by the Health Canada noise guidance. Please see the "Sleep Disturbance and Speech Interference" technical memo for a discussion on potential sleep disturbance. The technical memo assessed the potential sleep disturbance noise effect due to construction activities. The results indicate that construction noise effect at all receptors is below the noise threshold with the exception of receptor R2 (Dodge Cove). Additional mitigation measures are required during the construction phase to reduce the predicted noise effect to below the sleep disturbance threshold of 45 dBA. The additional mitigation measures are presented in the technical memo. The technical memo will be filed with the BC EAO. The "Sleep Disturbance and Speech Interference" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2569.1	round 1	Gitga'at First Nation	4.9 (Table 4.9-20)	Marine Fish and Fish Habitat	Mitigation 4.5.3 and 4.5.8 is not sufficient to ensure water quality objectives for the protection of aquatic life. It should be included that "when exceedance are discovered outside the area predicted to have exceedances then shut down of construction activities will occur until a reduction in TSS occurs (and new mitigations implemented to ensure exceedances outside the predicted area of exceedances do not occur). " Monitoring of TSS/turbidity and temperature should also be included as mitigation to water quality via regular monitoring of waste water discharge (both construction and operations, e.g. cooling tower effluent [temperature at outfall] and over burden storage area discharge [TSS / turbidity], especially during rain events])	The on-site environmental monitor will work with the dredging contractor to identify and implement site-specific mitigation measures, if water quality exceedances are detected. Waste discharges to the marine environment will be subject to effluent and receiving environment monitoring. The spatial scale, frequency, and required parameters for monitoring will be defined in waste discharge permits issued for the Project. Further details on Project waste discharges and associated regulations, are provided in the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2570.1	round 1	Gitga'at First Nation	4.9 (page 4.9-102)	Marine Fish and Fish Habitat	There is a disconnect between the daily duration of dredging activities (20hrs/day for 48 days at MOF) and the requirement for Noise Management (from the OGC 7am - 10pm). Only the noise of blasts and pile driving were modelling in the Acoustic Assessment, but realistically dredging activity will also cause noise (therefore should be modeled) and is proposed to happen outside the OGC window. Please clarify effects.	Noise effect during dredging activity is included in the assessment. The dredging activity noise emissions are summarized in Table 5-2, Section 5.1.2.1 of the Acoustic Environment Technical Data Report of the Application.
2571.1	round 1	Gitga'at First Nation	4.9	Marine Fish and Fish Habitat	What is the magnitude of change in temperature in the receiving environment (marine) at the cooling tower discharge? In order to understand potential effects this needs to be characterized (and not left to permitting).	Cooling tower blowdown water will meet CCME and BC water quality guidelines for temperature, outside of the initial dilution zone. These guidelines allow a maximum change of ±1^{0}C from ambient at any time, location, or depth and a maximum rate of change <0.5^{0}C per hour. The exact size of the mixing zone is not yet known, and will be determined through modelling in the permitting phase. Waste discharges within and outside the mixing zone, cannot be acutely toxic to fish (per the Fisheries Act)The effect of cooling tower blowdown waste discharge was assessed based on adherence to legally-binding legislation, designed to protect aquatic life (see Section 4.5.15.3). With a commitment to meet the water quality guideline of maximum change of ±1^{0}C beyond the mixing zone, the effect was characterized as not significant (low in magnitude, within the LAA, continuous, and long-term in duration). Further details on Project waste discharges and associated regulations, are provided in the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2572.1	round 1	Gitga'at First Nation	4.9	Marine Fish and Fish Habitat	Gitga'at disagrees with the characterization of residual effects to marine fish habitat given that there is no characterization of utilization of habitats by fish (to support an understanding of productivity for offsetting); that there is a significant amount of fish habitat to offset and the conceptual fish offsetting plan presented in the Application is not sufficient in detail, alternatives, or consideration of other project which may required offsetting "space" ; and that many of the suggested mitigation measures do not go the step further to include a stoppage of work if "issues"/exceedances arise or include sufficient commitment to monitoring to confirm effects predictions are correct to justify the conclusions (of residual effects to marine fish and fish habitat).	Aurora LNG has characterized the utilization of habitats by fish to support an understanding of productivity for offsetting. Extensive field studies were undertaken to characterize habitats that would be affected by the Project, and the species that use these habitats. The results of these studies, presented in Marine Fish and Fish Habitat TDR (Appendix L), guided the development of the proposed offsetting measures. Aurora LNG is committed to fulfilling their legal obligation to develop adequate, effective offsets that counter-balance residual serious harm to fish. This commitment will be accomplished by following DFO's guidance on offsetting. This guidance involves understanding habitat productivity through the concepts of species utilization of, and dependence upon, habitats, broken down by species and life stage. It also involves setting specific success criteria, that are subsequently used as benchmark indicators that the offsets have fulfilled their productivity objectives and, as such, have counterbalanced Project-driven serious harm. As stated in the Conceptual Fish Habitat Offsetting Plan (Appendix V), the offsetting philosophy and ideas presented were intended to be concepts that demonstrate Aurora LNG's approach to identifying effective offsets and concrete ideas for counterbalancing harm. They provide a transparent starting point for constructive discussions about habitat offsetting with the ultimate goal of developing widely endorsed, low-risk, effective, appropriately located and well designed offsets. Offset projects and the corresponding "space" required for those projects will be identified through field surveys and in consultation with regulatory agencies (primarily DFO) and Aboriginal Groups. Final designs, amounts, locations, success criteria and monitoring requirements will ultimately be approved by DFO in the Fisheries Act Authorization. Construction of the offsets will be monitored to ensure adherence to the proposed mitigation measures and regulatory requirements and to evaluate the effectiveness of the proposed mitigation measures. Where relevant, threshold values (e.g. CCME water quality guidelines) will be used during monitoring and exceedances will trigger construction action, such as temporary cessation of activity (stop work), or slowing of activity. Details of these adaptive measures will be included in the forthcoming Marine and Freshwater Resources Management Plan. Additionally, the final fish habitat offsetting plan, that will from part of the Request for Authorization application to DFO, will include details on offset monitoring, with specific objectives focused on assessing the effectiveness of habitat offsetting.
2573.1	round 1	Gitga'at First Nation	4.9 (Table 4.9-22)	Marine Fish and Fish Habitat	Alta Gas Propane facility is not listed in the projects interaction list for cumulative effects on Marine Fish and Fish Habitat	As outlined in section 3.7.1 of the AIR, the Project and Activities Inclusion list was finalized within three weeks of submitting the final AIR on November 23, 2015. The Environmental Evaluation for the AltaGas Ridley Island Propane Export Terminal was submitted well after this cutoff, in December 2016. On January 3, 2017, AltaGas announced it would proceed with the Project as it had received its approval under section 67 of CEAA 2012. Given the timing for these activities, the AltaGas project was not considered in the cumulative effects assessment conducted in the Application.
2574.1	round 1	Gitga'at First Nation	4.9.6.3	Marine Fish and Fish Habitat	Gitga'at does not agree with the characterization of cumulative effects to marine fish and fish habitat given that the CFHOP does not ensure that the total area of habitat destruction can be offset (the proponent cannot ensure that there is enough area in the RAA to complete the offset requirements)	Aurora LNG is committed to fulfilling their legal obligation to develop adequate, effective offsets that counterbalance residual serious harm to fish. This commitment will be accomplished by following DFO's guidance on offsetting. This guidance involves following DFO's preference for in-kind over out-of-kind offsetting and for in-situ rather than ex-situ locations. It also involves setting specific success criteria, that are subsequently used as benchmark indicators that the offsets have fulfilled thei productivity objectives and, as such, have counterbalanced Project-driven serious harm. Through collaborative engagement with DFO, and consultation associated with the Fisheries Act authorization application process, Aurora LNG fully anticipates being able to find adequate and appropriate locations, and develop suitable designs, for effective offsets. Additionally, all other proponents are legally bound to offset serious harm to fish caused by their projects. Aurora LNG assumes that other proponents will fulfill this obligation, since not doing so would violate the Fisheries Act and have severe consequences for those proponents. Consequently, Aurora LNG stands by the characterization of cumulative effects to marine fish and fish habitat.

2575.1	round 1	Gitga'at First Nation	4.9.9	Marine Fish and Fish Habitat	Follow-up monitoring is required to ensure effects to marine fish habitat are as predicted should include monitoring around the berth dredging area (and not just at Charles Point).	Aurora LNG is committed to implementing follow-up programs when there is a conclusion of potential residual adverse effect and either a low prediction confidence in that conclusion or uncertainty in a specific component of the assessment. In these cases, a follow-up program will be used to verify the accuracy of predictions. Criteria for proposed inclusion of a follow-up program are consistent with the Considerations for Developing a Follow-up Program outlined in the Operational Policy Statement Follow-up Programs under the Canadian Environmental Assessment Act (Government of Canada, 2011). Aurora LNG has committed to a number of follow-up programs specific to marine fish and fish habitat and marine water quality (see Section 15, Summary of Follow-up Programs and Compliance Reporting), including a Sediment Deposition Monitoring Program. This program will focus on monitoring sediment deposition within a localized area near Charles Point. This program has been put forward because of the potential for sediment deposition in this area to result in serious harm to fish (as defined under the Fisheries Act). As described in Section 4.9.5.2 of the Marine Fish and Fish Habitat VC, the results of hydrodynamic modeling suggest that up to 4-5 cm/year are predicted to be deposited in this area (see Figure 69 (c) of Appendix M [Hydrodynamic Modeling of Changes in Sediment Erosion and Accretion due to Project Infrastructure]), where substrates are composed primarily of a mix of cobble and boulder (see Section 5.1 and Section 2 of Appendix L, Marine Fish and Fish Habitat TDR). As a result, the deposition of sediment in this area could result in serious harm to fish, and additional offsetting would need to be discussed with DFO. However, sediment deposition in this area is only anticipated to occur if the Concrete Caisson MOF is selected for construction, and therefore the program will not proceed if the Pile-and- Deck MOF option is selected. Based on the results of sediment transport modelling (Appendix M), sediment deposition and accretion in other areas (i.e., areas away from Charles Point) are predicted to occur predominately over sediment habitats and changes are expected to be localized and gradual (see Figure 64 (c) and Figure 65 (c) of Appendix M). As such, any changes are not expected to affect the ability of marine species to complete their life processes, and serious harm to fish is not anticipated. For this reason, no monitoring is proposed for areas outside of Charles Point.
2576.1	round 1	Gitga'at First Nation	Appendix H	Marine Fish and Fish Habitat	Although Aurora LNG completed sediment transport and deposition modeling for Brown Passage (as a disposal site), there is no characterization of the habitat or fish presence and as such the characterization of effects to marine fish and fish habitat is not complete. There are multiple benthic and demersal fish species utilizing the area and there are cloud and glass sponge within the deposition zone (in previous DAS zone) (See Brown Passage Subtidal Survey, PNW LNG, Stantec, October 22, 2014) and destruction of these habitat forming species and effects to fish are not fully characterized in the Application.	Potential effects of the disposal of dredgeate on fish habitat at the Brown Passage disposal at sea site are assessed in Section 4.9.5.2 of the Marine Fish and Fish Habitat VC (see page 4.9-52). This assessment considered effects to deep-water soft sediment habitats; however, it did not consider potential effects to glass sponges (Hexactinellida), which are known to occur in this area. For a discussion and characterization of potential effects to glass sponges, Please see the technical memo titled "Brown Passage: Characterization of Existing Conditions and Potential Effects associated with Disposal at Sea"which will be filed with the BC EAO. The potential for injury or mortality of marine fish and invertebrates due to disposal of dredgeate at Brown Passage are assessed in Section 4.9.5.4 of the Marine Fish and Fish Habitat VC (see pages 4.9-87 to 4.9-88). Finally, the potential effects to marine fish health from exposure to elevated TSS concentrations during disposal at sea are assessed in Section 4.9.5.5 (see pages 4.9-103 to 4.9-104).
2577.1	round 1	Gitga'at First Nation	4.9	Marine Fish and Fish Habitat	Please provide an assessment on the potential impacts from air emissions on shoreline habitats (e.g., salt marshes), eelgrass meadows, and kelp beds.	Marine areas acidification and eutrophication is not expected to occur due to the high buffering capacity of marine waters, and as a result, this interaction was not included in the Environmental Assessment. Furthermore, no adverse effects on marine fish habitat, including salt marshes, eelgrass meadows, and kelp, due to acidification and eutrophication are anticipated.
2578.1	round 1	Gitga'at First Nation	4.9	Marine Fish and Fish Habitat	The blasting timing window and eulachon may overlap - how will Nexen ensure eulachon are not harmed or disturbed during blasting? What monitoring will Nexen commit to?	Aurora LNG recognizes that schooling adult eulachon returning to spawn in the Nass and Skeena Rivers could be migrating through the LAA during the tail end of the DFO timing window, and could therefore be in the area for a short period of time during underwater blasting. Eulachon are cited to arrive in the Nass River around early to mid-March, but a possible second run might arrive in early April (Langer et al. 1977; Noble et al. 2012). Eulachon have historically returned to the Skeena River during the first week of March, however, in the past decade, they have occasionally returned earlier, during mid to late February (Don Roberts, Kitsumkalum member, pers. comm. 2006, as cited in COSEWIC 2013). However, Aurora LNG is of the opinion that by adhering to a suite of mitigation measures during underwater blasting, the potential for residual adverse effects to marine fish, including eulachon, will be reduced. As discussed in Section 4.9.5.4 (Marine Fish and Fish Habitat VC), these mitigation measures include the following:Aurora LNG is committed to completing underwater blasting during the DFO least risk timing window (i.e., November 30 – February 15), which will avoid or reduce interactions with sensitive species and life stages such as larval eulachon. After a two to eight week incubation period, larval eulachon are flushed downstream and into the ocean, thereby entering the ocean sometime between March and May (COSEWIC 2013). Aurora LNG is committed to following guidelines for underwater blasting as outlined in Wright and Hopky (1998) and DFO (2013). Underwater blasting guidelines were published by DFO for the purpose of guiding proponents proposing works or undertakings that involve the use of confined or unconfined explosives in or near Canadian fisheries waters. The guidelines are intended to reduce harm to fish, including eulachon, and require that underwater pressure levels generated during blasting do not exceed 100 kiloPascals (kPa). Fish exposed to an overpressure in excess of 100 kPa are at risk of being injured or killed.Aurora LNG is committed to installing bubble curtains around the blast area to provide noise attenuation and reduce underwater sound levels emitted into the marine environment. Bubble curtains disrupt the shock wave generated by underwater blasting, attenuate SPLs, and can exclude fish from the work area. The use of bubble curtains will reduce the area within which fish (including eulachon) could be injured or killed during underwater blasting. Bubble curtains can reduce peak pressure levels by approximately 15 dB (Nutzel 2008, as cited in Maxon and Mikkelsen 2013). An Environmental Monitor will be onsite during underwater blasting activities to monitor for fish kills. If a fish kill is observed, blasting will be temporarily suspended and additional mitigation measures will be discussed with DFO.References: Committee on the Status of Endangered Wildlife in Canada [COSEWIC]. 2013. 2579.1	round 1	Gitga'at First Nation	4.9.2	Marine Fish and Fish Habitat	Please justify why only a 500 metre buffer around the PDA and shipping lane was assessed? This is limited for assessing underwater noise impacts.	The Marine Fish and Fish Habitat LAA includes several components, one of which is a 500 m buffer on either side of the centreline of the shipping route from LNG jetty to the Triple Island pilot boarding station. The 500 m buffer is considered appropriate for assessing potential effects associated with behavioural changes to marine fish from underwater vessel noise, based on research conducted on herring. Herring are a type-3 fish (as described in Popper et al. 2014), which means they have a swim bladder that is involved with hearing. Type-3 fish are considered the most sensitive to underwater noise (Popper et al. 2014). As described in Section 4.9.5.3 of the Marine Fish and Fish Habitat VC, herring have the ability to determine the location of a sound source within a distance of at least 400 m (Schwarz and Greer 1984). Furthermore, based on the results of a study by Misund et al. (1996), herring have been observed reorienting themselves to the path of an approaching research vessel, with the majority of individuals responding at a distance that aligns with the 400 m distance identified by Schwarz and Greer (1984). Given the results of these two studies, which focus on herring (considered to be a fish that is more sensitive to underwater noise), a 500 m buffer on either side of the shipping lane is expected to be sufficient to assess potential behavioural effects. 2580.1	round 1	Gitga'at First Nation	4.10.2.4	Marine Wildlife - Marine Mammals	The Application notes that "The term 'qualitative' was added to qualify likelihood under the measurable parameter for change in mortality risk to better reflect the style of assessment (i.e., a qualitative assessment of mortality risk was undertaken; no quantitative assessment of vessel strike likelihood was performed)." There is no explanation as to why the risk of ship strikes was not evaluated quantitatively or why a comprehensive collision risk assessment was not done.	As strike risk increases in higher density traffic areas, the likelihood of residual cumulative effects for change in mortality risk to marine mammals is considered high. In the event of an accidental vessel strike, effects on the marine mammal involved are assumed to be permanent and irreversible, and would be of heightened concern for SARA-listed species. Based on current marine mammal population sizes and trends for species known to occur in the RAA, changes in mortality risk are considered unlikely to affect population viability, and as noted in the Application, are therefore expected to be not significant. Quantitative vessel strike analysis typically has a high level of uncertainty due to significant challenges associated with predicting the level of behavioural response for specific marine mammal species and limited data available on species-specific strike rates. As a result, and as noted in the IR, a qualitative analysis was completed, with a moderate level of prediction confidence. This approach is consistent with the approach taken for the recently approved Pacific NorthWest (PNW) LNG project, that will occur in the same region of BC. The analysis conducted for Transmountain Pipeline Expansion Project provided estimates of potential vessel-whale encounter risk. This analysis did not extend to vessel-whale strike risk due to limited data available on species-specific responses (e.g., whether the animal dives or turns) to vessel approach. Aurora LNG maintains that residual effects to marine mammals from an increased potential for ship strikes have been adequately characterized and are expected to be not significant.
2581.1	round 1	Gitga'at First Nation	4.10.2.8	Marine Wildlife - Marine Mammals	It is stated that "This section describes the threshold for potential effect, beyond which a residual effect is considered significant". Although the Proponent used measurable parameters (see Table 4.10-2) to assess potential effects of the Project, no specific thresholds (e.g., km2 exposed or % population exposed to specific sound levels) are provided in this section. Instead, it is stated that "A significant adverse residual effect is defined as one that threatens the long-term persistence of a marine mammal species or local population in the RAA'. Thus, the effects assessment appears to take a more qualitative rather than a quantitative approach.	For the marine mammals assessment, a significant adverse residual effect was defined as one that threatens the long-term persistence of a marine mammal species or local population in the RAA. As outlined in Section 4.10.2.8 of the Application, the significance thresholds represent the limits of an acceptable change in a measurable parameter or state of the VC, based on applicable legislation, regulatory guidance documents or other management standards. Where thresholds are not set by legislation, guidance documents or standards (as in this case), a threshold has been developed based on scientific literature and professional judgment.
2582.1	round 1	Gitga'at First Nation	4.10.3; 4.10.5; Appendix N	Marine Wildlife - Marine Mammals	There is a lack of baseline data to characterize the seasonal distribution and relative abundance of various marine mammal species within the LAA. Although adequate data were available to determine abundance for two species (humpback whale and harbour porpoise), density estimates for other marine mammal species would contribute more to the understanding of the use by various species of the LAA and would have been pertinent in assessing potential effects of the Project on marine mammals. The data are therefore not adequate to support a quantitative impact assessment where the potential for mortality or injury is a realistic outcome of an accident or malfunction or to quantitatively assess the effects of Project activities on changes in health or behaviour.	The assessment of change in health, change in behaviour, and change in mortality risk for marine mammals relies on not only the results of the Aurora LNG marine mammal surveys and subsequent analysis and results, but baseline information that includes a literature review, the results of marine mammal surveys for other proposed projects, and information collected by the BC Cetacean Sightings Network. These sources provide information on the seasonal distribution and abundance for marine mammals present within the LAA and RAA. A quantitative vessel strike analysis typically has a high level of uncertainty due to significant challenges associated with predicting the level of behavioural response for specific marine mammal species and limited data available on species-specific strike rates. As a result a qualitative analysis for change in mortality risk was completed, with a moderate level of prediction confidence. Aurora LNG maintains that residual effects to marine mammals from an increased potential for ship strikes have been adequately characterized and are expected to be not significant.
2583.1	round 1	Gitga'at First Nation	4.10.3.2	Marine Wildlife - Marine Mammals	California sea lions (*Zalophus californianus*) should have been addressed in Table 4.10-5. Ford (2014) reported a winter haul-out for California sea lions within the RAA near Digby Island.	As noted in Appendix N of the Application, Table 7 presents the 12 marine mammal species (or ecotypes) that are considered to regularly occur in the RAA. The Application further notes that many species of marine mammal are migratory and/or wide-ranging, and the inclusion of a marine mammal in Table 4.10-5 is meant to qualitatively reflect the standard distribution of these species. Specific occurrence of a particular species within the RAA at any given time fluctuates, and is therefore uncertain. As explained in the footnotes to Table 4.10-5, other species, not included in this table, may also be infrequently sighted within the RAA. As noted in the comment, Ford (2014) identifies a California sea lion winter haulout near Digby Island. However, he recognizes that this species is predominantly observed in the Strait of Georgia and along the west coast of Vancouver Island, and is only observed near Haida Gwaii and on the central mainland coast in some years. Ford (2014) also reports that breeding occurs off southern California and Baja California, Mexico and only males are expected to migrate through BC waters in the fall and spring. As a result, it is not anticipated that California sea lions will regularly occur within the RAA.
2584.1	round 1	Gitga'at First Nation	4.10.3.2	Marine Wildlife - Marine Mammals	Although the Application references Ford (2006), the Application made no mention that Chatham Sound is recognized as an important area for northern resident killer whales.	The northern resident killer whale Important Area is included in Section 4.10.2.5 of the Application and is mapped on Figure 4.10-2.
2585.1	round 1	Gitga'at First Nation	4.10.5.1	Marine Wildlife - Marine Mammals	The statement "Pile driving was modeled in deep water sites where sound typically propagates furthest" is not necessarily true. Propagation in shallow water is highly complicated and sound may travel further under certain conditions than in deep water. In fact, Appendix P, Table 1 notes that modeling for pile driving was done for water depths <23 m, so the statement is confusing.	To clarify the intent of the statement: Out of the potential locations where Project-related pile driving activities are anticipated, acoustic modelling sites were selected based on areas of relatively deeper water. As noted, the extent of underwater noise is dependent on many factors (e.g., water temperature and depth) and all acoustic modelling included the geoacoustic properties of the sites, depth and temperature. As part of the Marine and Freshwater Resources Management Plan, developed through engagement with applicable regulatory agencies and Aboriginal Groups, field verification will be undertaken at multiple locations to confirm predicted extents of underwater noise levels over the full range of predicted values for in-water blasting and impact pile driving.
2586.1	round 1	Gitga'at First Nation	4.10.5.4	Marine Wildlife - Marine Mammals	A comprehensive collision risk assessment should have been conducted for large cetacean species in the LAA and for various types of project-related vessels. The collision risk assessment should be based on transit routes, vessel speeds, ability of vessels and marine mammals to take effective evasive action to avoid collisions, and accurate estimation of the distribution of species' relative densities. All collision risk assessments should have been presented as part of the Application and appropriately documented with uncertainties and limitations of the analyses clearly stated so that collision risk to marine mammals during all seasons is well understood. If the collision risk assessment indicates a non-zero probability of collision with any large cetacean species in the LAA, then further work would be required to determine what the likely annual incident of collisions would be and if they may detrimentally affect population viability (e.g., species listed under SARA). In addition, results of the collision risk assessment would need to be evaluated in light of adding to or modifying necessary mitigation measures. Of particular concern is the potential population level effect of mortality from ship strikes on the Northern Resident killer whale due to this population's low abundance (Williams and O'Hara 2009). It is difficult to assess the actual potential impacts of vessel collisions to marine mammals in the LAA based on the information provided in the Application, particularly due to the inadequate baseline information regarding seasonal distribution and relative abundance in the LAA, and the lack of detail regarding mitigation measures to prevent ship strikes with marine mammals.	As strike risk increases in higher density traffic areas, the likelihood of residual cumulative effects for change in mortality risk to marine mammals is considered high. In the event of an accidental vessel strike, effects on the marine mammal involved are assumed to be permanent and irreversible, and would be of heightened concern for SARA-listed species. Based on current marine mammal population sizes and trends for species known to occur in the RAA, changes in mortality risk are considered unlikely to affect population viability, and as noted in the Application, are therefore expected to be not significant. Quantitative vessel strike analysis typically has a high level of uncertainty due to significant challenges associated with predicting the level of behavioural response for specific marine mammal species and limited data available on species-specific strike rates. As a result, and as noted in the IR, a qualitative analysis was completed, with a moderate level of prediction confidence. This approach is consistent with the approach taken for the recently approved Pacific NorthWest (PNW) LNG project, that will occur in the same region of BC. The analysis conducted for Transmountain Pipeline Expansion Project provided estimates of potential vessel-whale encounter risk. This analysis did not extend to vessel-whale strike risk due to limited data available on species-specific responses (e.g., whether the animal dives or turns) to vessel approach. Aurora LNG maintains that residual effects to marine mammals from an increased potential for ship strikes have been adequately characterized and are expected to be not significant.

2587.1	round 1	Gitga'at First Nation	4.10.5.4	Marine Wildlife - Marine Mammals	Measures to be taken by a vessel to avoid a marine mammal collision have only been specified in vague terms (see Table 4.10-10), and there is not any assessment of the effectiveness of these measures on actually avoiding a collision with transiting marine mammals or an aggregation of feeding marine mammals. No analysis has been presented in the Application regarding stoppage time and stopping distance for a vessel to avoid a marine mammal collision or to determine if this is even possible given a reasonable detection range of a marine mammal from a vessel. There is also no analysis of the feasibility of making route adjustments to avoid a marine mammal.	Project-related vessels will proceed at a safe speed and respect any regionally-defined or PRPA-specific speed profiles that are applicable at the time of operations, subject to navigational safety. The intent of the educational material proposed in Table 4.10-10 is to raise awareness of potential marine mammal presence in the area. Decisions regarding the need for, and feasibility of, undertaking measures such as route or speed alterations upon sighting and approach of a marine mammal(s) rest entirely with the shipmaster and pilot after taking into account navigational and human safety. Educational materials will also detail the reporting protocols in the event of an accidental strike. The Technical Review Process of Marine Terminal Systems and Transshipment Sites (TERMPOL) process, conducted by Transport Canada, will address vessel speeds and routing, in consideration of mariner safety, environmental effects and feedback through engagement with PRPA, DFO, Aboriginal Groups, and others. Aurora LNG is willing to collaborate in regional programs planned and developed by government and in conjunction with other proponents, regarding regional management of effects of vessel strikes on marine mammals in the RAA.
2588.1	round 1	Gitga'at First Nation	4.10.5.4	Marine Wildlife - Marine Mammals	According to the Application, "….ship strikes are more likely to occur when ships are over 80 m in length and travelling at 14 kts or faster (Laist et al. 2001; Panigada et al. 2006). Potential for change in mortality risk is therefore considered greatest during transit operations (relative to other Project phases and vessel types)…". Nonetheless, the Application states that LNG carriers may travel at speeds of up to 16 kts; no vessel speed restrictions have been proposed. The Application only states that "Project-related vessels will proceed at a safe speed", but "safe speed" is not defined. To reduce the risk of ship strikes which have been assessed to be of moderate magnitude and medium likelihood during operations, LNG carriers should not travel >14 kts within the RAA.	The Technical Review Process of Marine Terminal Systems and Transshipment Sites (TERMPOL), conducted by Transport Canada, will address vessel speeds and routing, in consideration of mariner safety, environmental effects, and feedback through engagement with PRPA, DFO, Aboriginal Groups, and others. Aurora LNG is willing to collaborate in regional programs planned and developed by government and in conjunction with other proponents, regarding regional management of effects of vessel strikes on marine mammals in the RAA.
2589.1	round 1	Gitga'at First Nation	4.10.5.4	Marine Wildlife - Marine Mammals	The mitigation measures for reducing ship strike are outlined as "Aurora LNG will develop educational material that will be distributed to Project-related vessel operators, tug operators, and pilots to inform them of the species of marine mammals in the area, their conservation status, the risk of ship strikes and what mariners can do to help reduce those risks (e.g., reporting the sightings to other mariners, reducing speeds). Educational material will also detail reporting protocols in the event of an accidental strike." However, the Proponent then goes on to say that "Education does not guarantee that vessel operators will take heed of the information provided." Further information is required to gauge the adequacy of this mitigation measure. For example, the level of effort used to detect marine mammals, equipment used to enhance detection, protocols for translating sightings into mitigation action by the ship's captain, data recording, analysis, and reporting-out on the results of monitoring and the efficacy of protocols for avoiding marine mammal collisions.	Project-related vessels will proceed at a safe speed and respect any regionally-defined or PRPA-specific speed profiles that are applicable at the time of operations, subject to navigational safety. The intent of the educational material proposed in Table 4.10-10 is to raise awareness of potential marine mammal presence in the area. Decisions regarding the need for, and feasibility of, undertaking measures such as route or speed alterations upon sighting and approach of a marine mammal(s) rest entirely with the shipmaster and pilot after taking into account navigational and human safety. Educational materials will also detail the reporting protocols in the event of an accidental strike. The Technical Review Process of Marine Terminal Systems and Transshipment Sites (TERMPOL) process, conducted by Transport Canada, will address vessel speeds and routing, in consideration of mariner safety, environmental effects and feedback through engagement with PRPA, DFO, Aboriginal Groups, and other interested stakeholders. Aurora LNG is willing to collaborate in regional programs planned and developed by government and in conjunction with other proponents, regarding regional management of effects of vessel strikes on marine mammals in the RAA.
2590.1	round 1	Gitga'at First Nation	4.10.9	Marine Wildlife - Marine Mammals	The Proponent must implement a follow-up program to monitor underwater noise effects on marine mammals as a result of increased shipping as the magnitude of the residual effects are deemed to be moderate and the likelihood is deemed to be high. In addition, follow-up monitoring for harbour porpoise should occur, as the Application found a Significant effect on the change in behaviour of harbour porpoise. Monitoring would help discern what the actual changes in behaviour are and to what extent they are Significant.	Aurora LNG will engage with the appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Marine and Freshwater Resources Management Plan. This plan will describe best management practices and mitigation measures that will be implemented during construction and operation of the LNG facility to avoid or reduce potential adverse effects of Project activities on marine mammals. The plan will include details on the following: Prior to the start of marine construction, acoustic modelling of in-water blasting will be done to verify assumptions and predictions made in this assessment and refine mitigation measures, as necessary.Field verification will be undertaken at multiple locations to confirm predicted extents of underwater noise levels over the full range of predicted values for in-water blasting and impact pile driving.A marine mammal monitoring program will be developed and implemented to enforce an exclusion zone during in-water impact pile driving and around the in-water blasting area.Aurora LNG is willing to collaborate in regional programs planned and developed by government and in conjunction with other proponents, regarding regional management of effects of underwater noise and vessel strikes on marine mammals in the RAA.
2591.1	round 1	Gitga'at First Nation	9.9	Accidents or Malfunctions	For Accidents or Malfunctions, Significant Impacts are expected for On-shore Spills, Vessel Grounding or Collision (only bunker oil, not LNG or diesel), and LNG Spills at Loading Zone. For the Significant impacts, residual effects were deemed to be of moderate magnitude with a medium likelihood, but reversible. It is confusing why LNG Spills at the Loading Zone are assessed to be Significant whereas LNG releases from a Vessel Grounding or Collision are not deemed to have Significant impacts. If residual effects from an LNG spill are assessed to be potentially Significant at the loading zone, they should also be of moderate magnitude, likelihood and consequence, and thus Significant during a Vessel Grounding or Collision.	Aurora LNG acknowledges this discrepancy and agrees that the two accidental LNG release events assessed, whether at the loading facility or along the shipping route, may both result in significant effects to marine mammals if the release results in acute effects (e.g., mortality) on marine mammal species at risk, either from direct exposure or injury from a pressure explosion. We also suggest that the likelihood of a residual effect to marine mammals following the release of LNG under either scenario is more accurately characterized as 'low likelihood' and of 'moderate consequence'. An errata document is being created that will capture these corrections and it will be filed with the BC EAO.
2592.1	round 1	Gitga'at First Nation	Appendix N: 3.1.3.1	Marine Wildlife - Marine Mammals	The Appendix notes that "There have been a few rare sightings of California sea lions (*Zalophus californianus*), and northern elephant seals (*Mirounga angustirostris*) (Ford 2014). This statement is not supported by the reference. According to Ford (2014), northern elephant seals are not considered rare in northern BC; there is not enough information for this claim for the RAA. In fact, Ford (2014) report a winter haul-out for California sea lions within the RAA near Digby Island. Thus, the statement is incorrect and this species should have been included in the Application in Table 4.10-5 under 4.10.3.2. Northern elephant seals must be assessed in the Application as well.	As noted in Appendix N of the Application, Table 7 presents the 12 marine mammal species (or ecotypes) that are considered to regularly occur in the RAA. The Application further notes that many species of marine mammal are migratory and/or wide-ranging, and the inclusion of a marine mammal in Table 4.10-5 is meant to qualitatively reflect the standard distribution of these species. Specific occurrence of a particular species within the RAA at any given time fluctuates, and is therefore uncertain. As explained in the footnotes to Table 4.10-5, other species, not included in this table, may also be infrequently sighted within the RAA. As noted in the IR, Ford (2014) identifies a California sea lion winter haulout near Digby Island. However, he recognizes that this species is predominantly observed in the Strait of Georgia and along the west coast of Vancouver Island, and is only observed near Haida Gwaii and on the central mainland coast in some years. Ford (2014) also reports that breeding occurs off southern California and Baja California, Mexico and only males are expected to migrate through BC waters in the fall and spring. As a result, it is not anticipated that California sea lions will occur regularly within the RAA. Ford (2014) does not show elephant seal sightings within the RAA and reports they may occur along the northern BC coast. Sightings of elephant seals are typically of individual animals. Although it is possible they may be observed within the RAA, it is anticipated sightings would be infrequent.
2593.1	round 1	Gitga'at First Nation	Appendix N: 3.1.3.1	Marine Wildlife - Marine Mammals	Northern fur seals (Callorhinus ursinus) are not mentioned in the Application but it is possible that they could occur in the RAA so they must be assessed.	Many species of marine mammal are migratory and/or wide-ranging, and the inclusion of a marine mammal in Table 4.10-5 (of the Application) is meant to qualitatively reflect the standard distribution of these species. Specific occurrence of a particular species within the RAA at any given time fluctuates, and is therefore uncertain. Other species, not included in Table 4.10-5 , may also be infrequently sighted within the RAA. Northern fur seals are more typically observed over the continental shelf (Ford 2014) than within the RAA. As a result, the potential for Project interactions with fur seals is anticipated to be very low.
2594.1	round 1	Gitga'at First Nation	Appendix N: 4.4.1	Marine Wildlife - Marine Mammals	It is reported that "Humpback whale sighting numbers were the lowest in the spring and early-summer survey periods." No attempt is made to explain why the survey found lower numbers of humpbacks during the summer than the rest of the year. It is noted that PNW also found lower numbers during summer. However, these findings are in contrast to Ford (2014) that humpbacks are most numerous from April through November. Additionally, according to Appendix O, the number of detection days in 2014 with humpback whale calls peaked from mid-July to late October.	Ford (2014) reports that humpback whales are observed year-round in BC waters, and as noted in the IR, are most abundant in BC waters from April to November. Substantial changes in humpback whale distribution and abundance within the feeding season and inter-annually are also noted (Ford 2014). The Aurora marine mammal surveys covered the RAA (Chatham Sound) and as a result, only provide information on marine mammal presence within the RAA. As the data collected are not reflective of humpback whale abundance "in BC waters", humpback whale sighting information does not contradict Ford (2014). Ford et al. 2010 reported that winter sightings of humpback whales, observed during surveys conducted by DFO, were noted to occur particularly in Chatham Sound and off northern Haida Gwaii. As noted in Appendix O, acoustic data were collected between July and October/November 2014, not during the winter months. It should also be noted that an absence of marine mammal calls does not reflect an absence of the species. Ford, J.K.B., Abernethy, R.M., Phillips, A.V., Calambokidis, J., Ellis, G.M., and Nichol, L.M. 2010. Distribution and relative abundance of cetaceans in western Canadian waters from ship surveys, 2002-2008. Can. Tech. Rep. Fish. Aquat. Sci. 2913: v + 51 p.
2595.1	round 1	Gitga'at First Nation	Appendix O: 1.2	Marine Wildlife - Marine Mammals	No explanation is provided as to why acoustic monitoring was not done year-round – monitoring only took place during July to October/November 2014.	While the data collected during the acoustic monitoring program (Appendix O) was analyzed for marine mammal vocalizations, detection of marine mammals was not the primary objective of this program. The primary objective of the acoustic monitoring program was to document the baseline noise conditions near the proposed Project site so as to provide a statistical noise distribution of the pre-Project development conditions. The timing and duration of the program were therefore developed primarily in consideration of the desire to characterize the existing ambient sound levels and existing vessel traffic, both of which are adequately captured in the selected 3.5 month period that spans periods of lower and higher expected vessel traffic in the region.
2596.1	round 1	Gitga'at First Nation	Appendix O: 3.3	Marine Wildlife - Marine Mammals	The acoustic data were not analyzed for minke whale or Steller sea lion vocalizations, but no explanation is given as to why. Also, no explanation is provided why the acoustic monitoring was not done year-round – monitoring only took place during July to October/November 2014. Please provide explanations.	While the data collected during the acoustic monitoring program (Appendix O) was analyzed for marine mammal vocalizations, detection of marine mammals was not the primary objective of this program. The primary objective of the acoustic monitoring program was to document the baseline noise conditions near the proposed Project site so as to provide a statistical noise distribution of the pre-Project development conditions. The timing and duration of the program were therefore developed primarily in consideration of the desire to characterize the existing ambient sound levels and existing vessel traffic, both of which are adequately captured in the selected 3.5 month period that spans periods of lower and higher expected vessel traffic in the region.
2597.1	round 1	Gitga'at First Nation	4.10	Marine Wildlife - Marine Mammals	A specific exclusion zone was not provided for pile driving.	Aurora LNG will engage with the appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Marine and Freshwater Resources Management Plan. This plan will describe BMPs and mitigation measures that will be implemented during construction and operation of the LNG facility to avoid or reduce potential adverse effects of Project activities on marine mammals. The plan will include details on the following: Prior to the start of marine construction, acoustic modelling of in-water blasting will be done to verify assumptions and predictions made in this assessment and refine mitigation measures, as necessary.Field verification will be undertaken at multiple locations to confirm predicted extents of underwater noise levels over the full range of predicted values for in-water blasting and impact pile driving.A marine mammal monitoring program will be developed and implemented to enforce an exclusion zone during in-water impact pile driving and around the in-water blasting area.Aurora LNG is willing to collaborate in regional programs planned and developed by government and in conjunction with other proponents, regarding regional management of effects of underwater noise and vessel strikes on marine mammals in the RAA.
2598.1	round 1	Gitga'at First Nation	4.10	Marine Wildlife - Marine Mammals	Acoustic modelling for blasting must be completed prior to blasting commences, with field noise verification taking place to modify mitigation measrues as necessary, and an interim conservative exclusion zone must be used for pile driving activities during the field noise verification program.	Aurora LNG will engage with the appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Marine and Freshwater Resources Management Plan. This plan will describe BMPs and mitigation measures that will be implemented during construction and operation of the LNG facility to avoid or reduce potential adverse effects of Project activities on marine mammals. The plan will include details on the following: Prior to the start of marine construction, acoustic modelling of in-water blasting will be done to verify assumptions and predictions made in this assessment and refine mitigation measures, as necessary.Field verification will be undertaken at multiple locations to confirm predicted extents of underwater noise levels over the full range of predicted values for in-water blasting and impact pile driving.A marine mammal monitoring program will be developed and implemented to enforce an exclusion zone during in-water impact pile driving and around the in-water blasting area.Aurora LNG is willing to collaborate in regional programs planned and developed by government and in conjunction with other proponents, regarding regional management of effects of underwater noise and vessel strikes on marine mammals in the RAA.
2599.1	round 1	Gitga'at First Nation	4.10	Marine Wildlife - Marine Mammals	NMFS 2016 should be reviewed and the proponent should justify why their assessment is still appropriate with the new guidelines. Or conduct new assessment with use of the guidelines. [NMFS (National Marine Fisheries Service). 2016. Technical Guidance for Assessing the Effects of Anthropogenic Sound on Marine Mammal Hearing: Underwater Acoustic Thresholds for Onset of Permanent and Temporary Threshold Shifts. U.S. Dept. of Commer., NOAA. 178 pp.]	As discussed on p.4.10-33/34 of the Application, the 2016 NOAA peak SPL and SEL24h thresholds (which are only applicable to assessment of auditory injury) were not available at the time of modelling. The Application therefore focuses on the three approaches that were considered in the acoustic modelling and assessment of injury. The methods used by Southall et al. (2007) and Wood et al. (2012) differ somewhat from the new NOAA guidance (NMFS 2016) in terms of how the peak SPL and SEL24h metrics are weighted for different marine mammal hearing groups, and are thus not directly comparable. Further details on the different thresholds, including discussion of 2016 NOAA guidance, is presented in the Aurora LNG Acoustic Study: Modelling of Underwater Sounds from Pile Driving, Rock Socket Drilling, and LNG Carrier Berthing and Transiting (Appendix P of the Application). An assessment applying the 2016 NOAA peak SPL and SEL24h thresholds (which are only applicable to assessment of auditory injury) is not anticipated to alter the conclusions presented in the Application. 2600.1	round 1	Gitga'at First Nation	4.10	Marine Wildlife - Marine Mammals	There was little information on how chronic exposure to disturbance may affect survival, reproduction, and habitat use of marine mammals. Please provide further assessments for each species.	For the purposes of the Application, 'change in health' focused on potential physical injury resulting from underwater noise or in-water blasting. Increased levels of stress, which may in turn cause physiological responses such as diminished reproductive effort, avoidance behaviour, and effects on foraging patterns and foraging success, were considered in the assessment of change in behaviour in marine mammals (see Section 4.10.5.3). The assessment of cumulative effects, including change in behaviour as a result of acoustic disturbance, can be found in Section 4.10.6 of the Application. A significant adverse residual effect is defined as one that threatens the long-term persistence of a marine mammal species or local population in the RAA. As a result, Aurora LNG maintains that the assessment of potential residual effects on marine mammals is complete.

2601.1	round 1	Gitga'at First Nation	4.10.6.6	Marine Wildlife - Marine Mammals	Using Nexen's definition, why isn't a significant effect for all marine mammals concluded (because a high magnitude effect is predicted)?	As defined in the Application, a significant adverse residual effect is defined as one that threatens the long-term persistence of a marine mammal species or local population in the RAA. A high magnitude characterization of a residual effect is defined as "A measurable change from existing conditions, that is above environmental and/or regulatory guidelines, and has potential to affect the long-term persistence of any marine mammal population in the assessment area." A high magnitude residual effect on marine mammals was concluded for change in behaviour as a result of construction activities. Residual effects of change in behaviour resulting from impact pile driving of multiple simultaneous piles are expected to be of high magnitude, as the thresholds considered predicted a broad range of values depending on the location and species of interest. Residual effects from this activity will extend into the LAA as multiple irregular events over the medium-term. While effects on marine mammals are expected to be reversible following completion of marine construction, and potentially between activities, it is noted that return to pre-Project conditions may be delayed by a few months to a few years. This result would be particularly true for any marine mammal species that abandons the area of behavioural disturbance during the marine construction period. This effect will occur in a disturbed area of active human development and will combine with other marine construction activities for an overall residual effect of change in behaviour on marine mammals during the construction phase. Results from marine mammal surveys conducted for the Aurora LNG Project (see the Marine Mammals TDR, Appendix N) and for the PNW LNG project (Stantec 2016) suggest that most species of marine mammal in the RAA show fairly broad distributions, and/or seasonal higher density areas in more than one location. For example, humpback whales were observed throughout the RAA, with seasonal (fall/winter) areas of higher relative abundance predicted both in the coastal waters around Kinahan Islands (primarily on the southern side) and between Triple and Melville Islands (Stantec 2016). During impact pile driving, sound levels above the species-specific behavioural disturbance threshold were predicted to overlap with a portion of the higher density area for humpback whales around Kinahan Islands, but not to extend around the southwestern side. This suggests that suitable alternative habitat for humpback whales will continue to exist in this area as well as around Triple Islands during Project construction. During operations, underwater noise above behavioural disruption thresholds will overlap both of these higher predicted relative density areas; however, this effect will be transient (i.e., <1-2 hrs per 24-hr period) during Project-related LNG carrier transit. In contrast to predicted 'hot spots' for humpback whales, highest density areas for harbour porpoises were consistently observed in the waters south of Digby Island, in Porpoise Channel, around Ridley Island, Lelu Island and the northeast coast of Stephens Island. This porpoise high use area shows a large degree of overlap with sound levels above the species-specific behavioural disturbance threshold during marine construction activities. Based on the distribution and habitat use of marine mammals in the RAA and understood species-specific behavioural responses to underwater noise, this residual effect is not anticipated to threaten the long-term persistence of most marine mammal species or local populations in the assessment area. The likelihood of change in behaviour for marine mammals, including species listed on Schedule 1 of SARA, is considered high for the Project's construction and operations phases but the residual effect is predicted to be not significant for all species except harbour porpoise. Given demonstrated avoidance responses by harbour porpoise during previous pile driving studies, the residual effect of change in behaviour may threaten the long-term persistence of this local population of harbour porpoise in this area and is therefore considered to be significant.
2602.1	round 1	Gitga'at First Nation	4.11.3, Appendix Q	Marine Wildlife - Marine Birds	The Application, including the assessment of potential environmental effects on marine birds and the Marine Bird Technical Data Report (Appendix Q) does not provide a level of detail on marine bird population trends, threats, and Aboriginal reliance on the species group that is required to support the environmental assessment of a development project of this nature in the North Coast of British Columbia. Further assessments are required.	To support the assessment of effects to marine birds, the current status of marine birds potentially occurring within the LAA and RAA was considered. The status of species of management concern was described in Table 2 of Appendix Q and Table 4.11-7 of the Application, and represents species that have shown either declining populations or trends in recovery but are currently not considered secure. Marine birds not listed in these tables are considered not at risk (i.e., have stable or increasing populations). A summary of traditional use of marine birds is provided in Section 4.11.3.2.
2603.1	round 1	Gitga'at First Nation	4.11.3, Appendix Q	Marine Wildlife - Marine Birds	The technical data report only provides a high-level overview of the marine bird ecology in the RAA and is deficient in the following areas: • The Proponent followed standardized protocols for the collection of marine bird data, but only report on species occurrence data. • The report authors make inferences between these data and species abundance and richness, without the support of statistical analysis and/or population models on relative abundance and/or densities. • The technical data report does not present information on the population status (e.g., stable, increasing, decreasing) of marine birds that occur in the LAA and RAA. • Specific data and information of the seasonal abundance (density or total number) of marine birds in the LAA and RAA is not provided. • An indication of habitat quality (either in a sense within the LAA/RAA or compared to other regions that are used to fulfill those same life-history requirements) for various life functions or marine bird species in the LAA and RAA is not provided.	Appendix Q of the Application provided a summary of the seasonal presence, abundance, richness, and distribution of marine birds from stationary shoreline count and vessel-based survey data completed for the Project. These were placed into context with presence, abundance, and richness information provided for other projects within the RAA. Please refer to Tables 1-2, and 1-3 for a detailed summary of the total number of marine birds observed during Project field studies. The technical data report specifically characterizes abundance (i.e., the total number of individuals observed), relative frequency of species detection (i.e., the percentage of total observations), and species richness (i.e., the number of species observed). For vessel-based surveys, the average number of species and individual birds per transect is also reported with a measure of error (i.e., standard deviation) to facilitate seasonal comparison of marine bird presence within the RAA. Characterization of residual effects to marine birds can be reasonably determined through the existing evaluation of Project specific and regional data in combination with information available in scientific literature and professional judgement and experience. To support the assessment of effects to marine birds, the current status of marine birds potentially occurring within the LAA and RAA was considered. The status of species of management concern was described in Table 2 of Appendix Q and Table 4.11-7 of the Application, and represents species that have shown either declining populations or trends in recovery but are currently not considered secure. Marine birds not listed in these tables are considered not at risk (i.e., have stable or increasing populations). Aurora LNG was limited in drawing comparisons in marine bird habitat associations and their relative importance, with other regional datasets due to the methods used (in those other datasets) to collect or present those data (i.e., site specific habitat information was not collected or not presented). However, information on seasonal abundance, richness, and distribution of marine birds is still considered in combination with life history information on species and species groups, to provide context or the relative importance of marine habitats within the LAA for breeding, foraging, roosting, and staging activities compared to those available in the region.
2604.1	round 1	Gitga'at First Nation	4.11.2.4	Marine Wildlife - Marine Birds	The evaluation of potential effects is based primarily on a qualitative assessment. For the assessment of the change in marine bird habitat, the Proponent states that this was based on a quantitative measure, but this measure only documents the areal extent of the marine habitat that will be lost or altered by the construction of the project facilities. This effect does not account for the value that this habitat provides for the various life requisites of marine birds.	Section 4.11.5.2 of the Application provides a combined quantitative and qualitative discussion of the direct change in habitat for marine birds as a result of Project activities and infrastructure as well as indirect change resulting from sensory disturbance. A description of the habitats, the species (or species groups) expected to be affected by change in those habitats, and their value to support foraging, staging, roosting, or breeding activities is described in 'Project Mechanisms for Change in Habitat' therein. A more detailed discussion of species presence and use of habitats within the PDA and LAA is found in Appendix Q and summarized in Section 4.11.3.
2605.1	round 1	Gitga'at First Nation	4.11.5.2	Marine Wildlife - Marine Birds	While the Proponent has quantified the amount of habitat impacted, the Application makes weak inferences regarding the importance of this habitat to marine birds. Habitat associations are not specifically addressed in the Project-specific field surveys.	Marine habitat associations for individual species, or species groups, are described in detail in Appendix Q. Species observed to be associated with nearshore marine habitats within the LAA during Project field studies are described in Sections 4.1.3 and 4.2.3 of Appendix Q. Section 4.2.3 of Appendix Q provides additional information on species observations and associations on farshore marine habitats. Tables 2-1 and Table 3-1 of Appendix Q provide a break down of detection for individual species, across habitat types sampled during Project field studies. Species' habitat associations were used in Section 4.11.5.2 to characterize effects of change in habitat from construction and operation of marine infrastructure (e.g., foraging and roosting opportunities).
2606.1	round 1	Gitga'at First Nation	4.11.5.2	Marine Wildlife - Marine Birds	The Proponent stated that results from the Project-specific field surveys showed that marine bird abundance was highest at the mouth of Delusion Bay, which is directly adjacent to the project development area (footprint), but it has not characterized the importance of the habitat in Delusion Bay for marine birds. The Proponent also makes inferences that the results of the field studies are consistent with existing regional data, with specific regard to marine bird abundance, and not habitat associations. While sources are identified in the literature review section of the Marine Bird Technical Data Report (Table 1 in Appendix Q), the specific references that describe known marine bird abundance in the area are not cited.	Section 4.1.3 of the Application provides a description of the findings, indicating that bird abundance and richness was generally similar across points (with exceptions to stations reporting higher numbers of individuals and species described therein). Table 2-1 of Appendix Q of the Application provides a summary of individual species reported at each shoreline stationary count. Compared to other locations, counts completed in Delusion Bay (i.e., MBDI09 and MBDI10) recorded fewer individual birds and species but nonetheless indicate that habitats at those locations support use by shorebirds, ducks, grebes, loons, gulls, corvids, and eagles (for example). Aurora LNG was limited in drawing comparisons in marine bird habitat associations with other regional datasets due to the methods in which some of those regional records were collected and presented in publicly-available reports (i.e., not all include site-specific information to draw habitat associations). However, information on seasonal abundance, richness, and distribution is still valuable in combination with life history information on species and species groups, to provide context on the importance of marine habitats within the LAA relative to those available in the region. Table 1-1 of Appendix Q of the Application provided a detailed summary of historical marine bird occurrence records within the RAA by species and dataset. Citations for each data source were provided as footnotes to the table and correspond to citations provided in Section 6 of Appendix Q (Literature Review).
2607.1	round 1	Gitga'at First Nation	4.11.5.2	Marine Wildlife - Marine Birds	On page 4.11-27, it is stated that "Given that most marine birds present in the LAA and RAA have secure populations (no reference provided) and have access to other suitable marine habitats, marine birds are expected to demonstrate a moderate degree of resilience to change in habitat availability as a result of the Project." In making this determination, the Proponent has not provided evidence that "most marine bird populations" are secure, nor has it provided information to describe suitable marine bird habitats in the region.	Section 4.11.3 and Appendix Q of the Application outline the methods and findings for characterizing existing conditions for marine birds. Both parts of the Application considered whether marine birds had secure populations by providing a review of their conservation status. Species of management concern include species known to, or with potential to, occur within the RAA that are considered of interest from a conservation perspective (i.e., federal or provincial species or subspecies at risk). Information on species of management concern, including occurrence records, species accounts, management plans, or other guidance documents, was compiled from the BC CDC (BC CDC 2017) and the Species at Risk Public Registry (Environment Canada 2016) and are referenced in the Application. The remaining marine bird species are considered to have secure federal or provincial conservation status (i.e., are designated Not at Risk or on the BC Yellow List). Marine habitat associations for individual species, or species groups, are described in detail in Appendix Q of the Application. Species observed to be associated with nearshore marine habitats within the LAA during Project field studies are described i Sections 4.1.3 and 4.2.3 of Appendix Q. Section 4.2.3 of Appendix Q provides additional information on species observations and associations on farshore marine habitats. Tables 2-1 and Table 3-1 of Appendix Q provide a break down of detections for individual species, across habitat types sampled during Project field studies. Information on species presence, richness, abundance, and distribution was used to inform the assessment and characterization of potential Project effects. Accessed: March 2017. Government of Canada (GOC). 2017. Species at Risk Registry. Available at: https://www.registrelep-sararegistry.gc.ca/default.asp?lang=En&n=24F7211B-1. Accessed: March 2017.
2608.1	round 1	Gitga'at First Nation	4.11.5.2	Marine Wildlife - Marine Birds	The Proponent states that the primary mitigation for the loss and alteration of marine bird habitats is the Conceptual Fish Habitat Offsetting Plan that is aimed to offset the loss of marine fish and habitat. As its name implies, this plan is conceptual and will need approval by Fisheries and Oceans Canada. There is an obvious lack of information in this plan regarding marine birds. The Application has not provided details such as how and when marine birds would utilize new habitats, how the types and amounts of habitat lost compare to the new habitat that will be created, and time lag between building of new habitat features and becoming functional habitat.	The conceptual fish habitat offsetting plan provides information on the types and quantities of habitats expected to be destroyed or altered that would ultimately lead to serious harm to fish (Section 9, Appendix V of the Application). The type, quantity, and location of habitat affected is explicitly considered in the design of habitat offsetting along with the ecological roles of those habitats, within that specific environmental context. Offsets will be designed in keeping with DFO's guidelines by selecting in-kind offsets over out-of-kind offsets where appropriate (see Section 10.4 and 10.5 of Appendix V; DFO 2013). In-kind offsets are intended to replace the same quantity and quality of habitat that is being destroyed or altered as a result of the Project. In turn, in-kind offsets will provide replacement habitat for fish communities as a mechanism to counterbalance serious harm to fisheries affected by the Project. Because in-kind offsets will be developed to replace the quantity, quality, and function of fish habitat removed or altered by the Project, they are expected to provide similar compensatory marine bird habitat (inclusive of habitat types and the marine prey species they support). Once built, the effectiveness of the offsets will be monitored to confirm they are performing as designed. Reference: Fisheries and Oceans Canada (DFO). 2013. Fisheries Productivity Investment Policy: A Proponent's Guide to Offsetting. Available at: http://www.dfo-mpo.gc.ca/pnw-ppe/offsetting-guidecompensation/index-eng.html. Accessed: March 2017.
2609.1	round 1	Gitga'at First Nation	4.11.5.2	Marine Wildlife - Marine Birds	The Proponent makes the over simplistic assumption that marine birds will use this new habitat without providing any evidence to support this case. In this regard, no discussion was provided to quantify the abundance of marine birds in the habitat that will be lost or the expected timeframe (e.g., short-term or long-term) for both creating this habitat and ensuring that it becomes a functional habitat for marine birds.	Marine bird shoreline stationary counts were located in areas of the LAA adjacent to proposed Project infrastructure (e.g., the MOF, marine terminal, trestle and berths) to characterize seasonal abundance, richness, habitat associations. A detailed summary was provided in Appendix Q of the Application. The conceptual fish habitat offsetting plan provides information on the types and quantities of marine habitats expected to be destroyed or altered as a result of Project activities and infrastructure (Section 9, Appendix V of the Application). The type, quantity, and location of habitat affected is explicitly considered in the design of habitat offsetting along with the ecological roles of those habitats, within that specific environmental context. Offsets will be designed in keeping with DFO's guidelines by selecting in-kind offsets over out-of-kind offsets where appropriate (see Section 10.4 and 10.5 of Appendix V; DFO 2013). In-kind offsets are intended to replace the same quantity and quality of habitat that is being destroyed or altered as a result of the Project. In turn, in-kind offsets will provide replacement habitat for fish communities as a mechanism to counterbalance serious harm to fisheries affected by the Project. Because in-kind offsets will be developed to replace the quantity, quality, and function of fish habitat removed or altered by the Project, they are expected to provide similar compensatory marine bird habitat (inclusive of habitat types and the marine prey species they support). Once built, the effectiveness of the offsets will be monitored to confirm they are performing as designed.
2610.1	round 1	Gitga'at First Nation	4.11.5.3	Marine Wildlife - Marine Birds	The Proponent has stated it will increase employee awareness regarding the potential for mortality and/or injury to marine birds caused by lit infrastructure and that some staff will be provided information on how to handle and release birds that are grounded. These measures are typically more challenging to implement unless standards are in place and key staff (e.g., environmental monitors) are specifically trained to take on the responsibility for dealing with birds that are found on site. It is also challenging to ensure that all project staff are reporting occurrences of marine birds.	Aurora LNG is committed to monitoring potential effects of the Project on bird and bat mortality, and promoting an environment of awareness and compliance among Project personnel. To facilitate compliance with Project mitigation measures, educational materials provided to employees and contractors will include information on procedures for documenting and reporting bird injury or mortality, and handling and release of stranded birds. The on-site Environmental Monitor or Monitors will be responsible for providing access to educational materials, training and advising staff, maintaining an accurate record of injury and mortality events, and communicating this record to applicable regulatory authorities at a prescribed interval. Complete details will be outlined in the Wildlife Management Plan.
2611.1	round 1	Gitga'at First Nation	4.11.5.4	Marine Wildlife - Marine Birds	The Proponent provided an overly simplified conclusion that marine birds observed near the marine terminal and MOF have been observed to use shoreline or nearshore habitats throughout the LAA and are expected to move to other similarly suitable habitats present in the LAA or RAA during Project construction. The Proponent provides no details as to why or when marine birds are using habitats throughout the LAA and RAA - please provide evidence on this inference. Also, there can be an energetic cost associated with marine bird avoidance of Project activities, or displacement from preferred habitats, but the Proponent has not provide a measurement or details on these energetic costs in the effects assessment.	A discussion of marine bird abundance, richness, and seasonal distribution, and use (e.g., foraging, staging, roosting) is found in several locations in the Application, including Appendix Q, Section 4.11.3, and Section 4.11.5.2. The determination that marine birds observed using habitats near the marine terminal and MOF have been observed to use shoreline and nearshore habitats throughout the LAA and are expected to move to similarly suitable habitats is supported by Project and regional data, literature, and professional judgement from prior experience. These materials provide information on the overall distribution and use of habitats within the LAA. Section 4.11.5.4 provides reference to supporting information in Appendix Q. The energetic cost associated with marine bird avoidance or displacement due to Project activities was assessed in Section 4.11.5.4. As indicated therein with reference to supporting literature, behavioural responses are known to be species-specific. Although flushing distances have been measured for some species under specific conditions (e.g., marbled murrelet response to high-speed recreational vessel traffic), the energetic expenditures associated with those movements are not widely available, nor are they easily placed into appropriate context with the nature of Project-specific disturbance effects. In absence of detailed information, a qualitative approach was used to evaluate change in behaviour (including the energetic cost of avoidance or displacement). See Sections 4.11.5.1 and 4.11.5.4 for further details.

2612.1	round 1	Gitga'at First Nation	9 and 4.11	Marine Wildlife - Marine Birds	The Proponent has concluded that the accidental releases of hydrocarbons into the marine environment would have Significant residual and cumulative effects on marine birds, but these conclusions are limited to one sentence in the application. The Proponent has not made the connection between these types of accidents and the chronic effect of oiling that is a common occurrence and threat in coastal waters. In addition, O'Hara and Morgan (2006) concluded that the density of ship traffic (i.e., ship movements per year through an area) can be used as a predictor of mortality risk to marine birds, and therefore; an increase in ship traffic can be expected to elevate the risks of operational spills. This can have cumulative impacts on marine bird populations, and as such, must be assessed further. [O'Hara, P.D. and K.H. Morgan. 2006. Do low rates of oiled carcass recovery in beached bird surveys indicate low rates of ship-source oil spills? Marine Ornithology 34:133-140.]	Section 9.0 Accidents or Malfunctions assesses potential residual effects on marine birds as a result of small-scale and large-scale on-shore hazardous spills, vessel grounding or collision, and releases from LNG carriers (while loading). A description of potential effects of hydrocarbon releases was provided in Sections 9.8, 9.9, and 9.10. As noted in these sections, the potential for exposure and the extent of residual effects for small and large-scale spills depends on the volume and location of the spill, the toxicity of the hazardous substance, the speed of response and containment, in combination with the seasonal presence, abundance, and distribution of different marine bird species. Depending on the nature of the interaction (considering the factors described above), exposure to hazardous materials, including hydrocarbons, could result in acute or chronic effects. The mechanisms for exposure and resulting acute or chronic effects to marine birds are described in each subsection, as applicable. Accidental releases were considered to be have a significant effect to marine birds if a spill were to result in acute mortality or long-term chronic exposure to the extent caused population level effects. Aurora LNG has committed to several preventative measures designed to limit chronic hydrocarbon releases and are not expected to contribute to existing cumulative effects of chronic oiling. See Sections 9.8, 9.9, and 9.10 for details. Project accidents or malfunctions that are considered most likely to result from the Project in combination with other Projects and physical activities within the RAA were associated with vessel-to-vessel collisions. The likelihood of such an event was considered highly unlikely, however, in consideration of mitigation and response measures (see Section 9.11). Although chronic spills can contribute to hydrocarbon inputs into marine environments, they typically stem from small, regularly occurring illegal discharges that go unreported. O'Hara and Morgan (2006) acknowledge there are limitations in drawing conclusions on the extent of oil-induced mortality in western Canada due to geographic and weather factors that potentially bias results. The authors recognize that a much lower proportion and density of birds recovered from beached bird surveys showed evidence of oil contamination relative to studies in eastern Canada and elsewhere globally (Burger 2002, O'Hara and Morgan 2006). Earlier summaries of beach bird surveys found oil birds were predominantly recorded on Vancouver Island, with no detection on the north or central BC coast (Burger 2002). However, recognizing that acute and chronic oil spills poses a threat to marine birds, Aurora LNG has committed to reporting releases or discharges of substances not authorized under the Environmental Management Act, as established by the Spill Reporting Regulation (BC 2008) as part of the preventative and response measures outlined in Section 9. Aurora LNG has also committed to mortality monitoring and reporting (mitigation 4.7.14). The Wildlife Management Plan will provide details on procedures for identifying, recording, and reporting on injury or mortality related to Project activities; where possible, Project personnel will be required to describe the cause of mortality (including oil exposure, where possible]). Reference: Burger, A.E. 2002. Beached Bird Surveys in British Columbia, 1986-1997. Prepared for: the Nestucca Trust Fund. 48 pp. Government of British Columbia (BC). 2008. Environmental Management Act. Spill Reporting Regulation. Available at: http://www.bclaws.ca/Recon/document/ID/freeside/46_263_90. Accessed: March 2017. O'Hara, P.D. and K.H. Morgan. 2006. Do low rates of oiled carcass recovery in beached bird surveys indicate low rates of ship-source oil spills? Marine Ornithology 34:133-140
2613.1	round 1	Gitga'at First Nation	4.11	Marine Wildlife - Marine Birds	While the Application acknowledged the four Important Bird Areas in the region, the Proponent failed to address their importance in the effects assessment; impacts to these must be assessed.	Appendix Q of the Application provides a discussion of the important bird areas located in proximity to the Project and notes that these areas provide important habitat used by congregating marine bird species, and have also documented high concentrations of individual species and colonial nesting sites. Three IBAs are in close proximity to the Project, only one (BC124) overlaps with the LAA, on the west side of Digby Island. Please refer to Section 2 of Appendix Q for further details. The locations of the important bird areas, and the species they support (including seasonal presence and abundance) were considered, alongside data from Project field studies and regional datasets to characterize potential mechanisms for interaction between Project activities or infrastructure and marine birds. They were also identified as an administrative boundary in Section 4.11 of the Application. Accordingly, the assessment of residual effects of change in habitat, change in mortality, and change of movement on marine birds considered the value of these regional habitats in the potential for residual Project effects described in Section 4.11.5 and their contribution to cumulative effects in Section 4.11.6.
2614.1	round 1	Gitga'at First Nation	4.11	Marine Wildlife - Marine Birds	The Proponent has not provided detailed information on marine bird movements, habitat associations, and the delineation of key habitats in the LAA. The Proponent concluded that marine infrastructure (including the marine terminal, MOF, and pioneer facility) were not expected to limit access to key breeding, foraging, staging, or roosting habitats for marine birds, but the locations of these areas were not clearly described in the Application. Please provide more information.	A discussion of marine bird abundance, richness, and seasonal distribution, and use (e.g., foraging, staging, roosting) is found in several locations in the Application, including Appendix Q, Section 4.11.3, and Section 4.11.5.2. Sections 4.1.3 and 4.2.3 of Appendix Q provides additional information on species observations and associations with nearshore and farshore marine habitats observed during Project field studies. Tables 2-1 and Table 3-1 of Appendix Q provide a break down of detections fo individual species, across habitat types sampled during Project field studies; these habitat delineations are also illustrated in Figures 3 to 6 of Appendix Q. Additional key marine bird habitats (e.g., parks, important bird areas, colonial nesting sites) are depicted in Figure 1 of Appendix Q and Figure 4.11-1 of the Application. Information on species presence, richness, abundance, and distribution was used to inform the assessment and characterization of potential Project effects in Section 4.11. As noted in Section 4.11.2, the assessment of change in behaviour considers potential changes in marine bird movement due to the introduction of physical or perceived barriers to habitats and resources. The determination that marine birds observed using habitats near proposed Project marine infrastructure are expected to move to similarly suitable habitats is supported by Project and regional data showing observed to use shoreline and nearshore habitats throughout the LAA in combination with literature and professional judgement from prior experience. Please refer to Section 4.11.5.4 for more details.
2615.1	round 1	Gitga'at First Nation	4.11	Marine Wildlife - Marine Birds	At this time the Marine Riparian zone appears insufficient in width, and the location of the flaring structures could impact Delusion Bay. Please justify why the zone is considered acceptable.	Section 1.2.5.1 of the Application describes the proposed flare system design. Aurora LNG considered placement options of the flare system within the PDA to reduce potential interaction with environmental valued components and to limit the amount of light dispersal (Table 1-26). As per mitigation 4.7.20, maintenance flaring events will be scheduled during daylight hours to the extent practicable to further reduce attraction by birds and bats to flare system infrastructure during nocturnal migration or foraging. Additionally, the 30 m marine riparian buffer will be maintained during all phases of the Project to retain shoreline habitats and limit noise and light dispersal, and is expected to further reduce potential for disturbance to marine species using shoreline and nearshore habitats in Delusion Bay.
2616.1	round 1	Gitga'at First Nation	5.1	Economic Conditions	The northwest coast has always been a thriving region based on natural resource abundance (not just diversified economy).	Aurora LNG acknowledges this comment.
2617.1	round 1	Gitga'at First Nation	5.1	Economic Conditions	Economic effects of the Project are expected to affect the reserve community of Hartley Bay who depend directly on services in Prince Rupert.	Aurora LNG acknowledges this comment.
2618.1	round 1	Gitga'at First Nation	5.2.1	Economic Conditions	The introduction implies positive economic benefits of the Project and does not introduce potential negative effects; e.g., the Project could increase the costs of infrastructure and services for the surrounding reserve communities such as Hartley Bay.	The assessment of change in activities for commercial businesses affected by Project spending (Section 5.2.5.2) addresses labour costs, which could affect costs of infrastructure and services to reserve communities. As noted in Section 5.2.1, potential effects on cost of living is addressed in Section 13.
2619.1	round 1	Gitga'at First Nation	5.2.2.2	Economic Conditions	Table 5.2-1 lists labour drawdown and that potential effect of 'change in activities for commercial businesses affected by Project spending' was added. In addition, change in activities can potentially draw resources away from Aboriginal communities such as Hartley Bay and thereby impacting local economies (e.g., eco-tourism, and fishing lodges).	Aurora LNG agrees that labour drawdown could affect commercial businesses, such as eco-tourism and fishing lodges. Mitigation 5.2.4 (paying market wage rates) is expected to help mitigate this.
2620.1	round 1	Gitga'at First Nation	5.2.2.4	Economic Conditions	What about the measureable parameter of impacts on local community economics (e.g., eco-tourism, conservation, commercial fishing, etc.)?	Data on the economic value of commercial fishing is provided in sections 5.2-45 to 5.2-47 of the Application. Effects on eco-tourism and conservation is broadly considered in the assessment of effects on commercial businesses affected by Project spending. Effects on marine tourism is also addressed in Section 6.5 – Marine Use and Navigable Waters.
2621.1	round 1	Gitga'at First Nation	5.2.2.4	Economic Conditions	The increase in land value in Prince Rupert and regionally (in Terrace) from the Project and cumulatively with other Projects, can prohibit local Aboriginal communities from generating their own economies as a Nation. With the exception of a few direct contracts and individual jobs, First Nations outside the Project area may not be in any position to develop businesses if land, services and goods are inflated.	Potential adverse effects related to upward pressure on wages are addressed in Section 5.2.5.2 – Assessment of Change in Activities for Commercial Businesses Affected by Project Spending, particularly on pages 5.2-70 and 5.2-71. Section 13.5.4 addressed potential for Project interactions with the cost of living in the LAA.
2622.1	round 1	Gitga'at First Nation	5.2.2.5	Economic Conditions	Hartley Bay must be included in the LAA of all components (not just marine) as Gitga'at has a direct reliance on Prince Rupert, and because the Project may draw workers away from economic ventures in Hartley Bay (e.g., eco-tourism, local construction, and commercial fishing), among other things.	The spatial boundaries used in the assessment were defined in the final approved AIR.
2623.1	round 1	Gitga'at First Nation	5.2.3.2 and 5.2.3.3	Economic Conditions	All sub-sections and tables in this section must include all Tsimshian reserve communities, including Hartley Bay. For example for the subsection 'Education and Training', the number of individuals with apprenticeships, trade certificate, or diploma when compared to the LAA and RAA populations would likely be lower if all Tsimshian reserve communities were considered. The Aboriginal trades and education may be based on non-Tsimshian Aboriginal people. Using accurate data from all Tsimshian communities is important; however, because these are missing, the Proponents support for education and training among all Tsimshian communities may not be equal.	Aboriginal communities for which baseline information in Section 5.2 is provided include those located within the LAA and the RAA, as described in Table 5.2-3. While it is understood that the communities identified in the LAA and RAA are part of the Tsimshian cultural group, the general criteria for inclusion within the LAA is potential to experience direct Project effects (generally due to proximity to the Project). General criteria for inclusion within the RAA is potential to experience cumulative effects.
2624.1	round 1	Gitga'at First Nation	5.2.3.2	Economic Conditions	It is not clear in Figure 5.2-4 what the breakdown of the Aboriginal population is for the LAA and RAA, and what the Tsimshian population is compared to other non-Tsimshian Aboriginal groups. And further, what the breakdown of population is for each Tsimshian Nation.	A breakdown of the Aboriginal population of the LAA and RAA is provided in Table 5.2-7. Disaggregated information is provided for the LAA population while an aggregate of the RAA (inclusive of Aboriginal and non-Aboriginal populations) is provided. Figure 5.2-4 is based on labour force data for the LAA and RAA, as employed by occupation, from information provided in Table 5.2-16. Information provided in Table 5.2-16 is not disaggregated by Aboriginal group or by LAA community.
2625.1	round 1	Gitga'at First Nation	5.2.3.2	Economic Conditions	Throughout the sub-sections, it is not clear who is included in "Aboriginal"; it would be helpful to have a breakdown of Aboriginal groups.	Aboriginal Groups with reserves in the RAA are identified in Table 5.2-8.
2626.1	round 1	Gitga'at First Nation	5.2.3.2	Economic Conditions	Table 5.2-24 is incomplete - what about commercial fishing, fish processing, and tourism, all of which are important industries for Gitga'at.	Tables 5.2-23 and 5.2-24 include a sample of employers in the LAA and RAA, and are not intended as comprehensive lists. Several fish processing and tourism operators are identified in Table 5.2-23.
2627.1	round 1	Gitga'at First Nation	5.2.5.1	Economic Conditions	For Project Mechanisms for Change in Labour Supply and Demand, Construction - the statement that "the unemployment rate in the LAA will decline" may not be accurate because the LAA may not contain enough trained individuals for the required construction jobs.	Aurora LNG assumes that some otherwise unemployed individuals in the LAA will take up Project construction positions, and thereby drive the unemployment rate down. While the precise number of individuals with construction related skills that may be unemployed at the start of Project construction is unknown, this has been estimated by multiplying the LAA labour force with occupations in trades, transport, equipment operations and related occupations (a total of 1,280 persons) with the unemployment rate (approximately 10.3% as of July 2016 for North Coast end Nechako Economic Regions). Based on this estimate, approximately 130 persons within the LAA with construction related occupations are currently unemployed, and potentially able to take up Project employment.
2628.1	round 1	Gitga'at First Nation	5.2.5.1	Economic Conditions	Table 5.2-34, Mitigation 5.2.1 , Mitigation Mechanism - what about capacity support to ensure Tsimshian people are trained prior to job and procurement opportunities are needed. There has to be direct engagement with communities and support to build an effective workforce, including direct and indirect jobs, and development of job retention skills.	In Mitigation 5.2.5, Aurora LNG proposes to "Identify potential shortages of workers with specific skill requirements, and work with training and education facilities, Aboriginal Groups, and local communities to increase opportunities for Aboriginal and local community members to obtain training required for Project participation."
2629.1	round 1	Gitga'at First Nation	5.2.5.1	Economic Conditions	Table 5.2-34, Mitigation 5.2.1, Expected Success/Risks and Uncertainty - what is meant by "within reason"? Also, there is risk and uncertainty that if jobs are given to groups that Aboriginal communities are not involved with (e.g., Union groups) then Aboriginal workers may not have employment opportunities. Therefore, the Proponent must work directly with Aboriginal communities.	Aurora LNG will contract the construction of the Project to one or more prime contractors, who will in turn work with numerous sub-contractors. While Aurora LNG will set out policies and requirements with respect to local hiring and local content, it will ultimately be the contractors and sub-contractors responsibility to hire most of the construction workforce. Aurora LNG will work directly with Aboriginal Groups to facilitate Project employment opportunities.
2630.1	round 1	Gitga'at First Nation	5.2.5.1	Economic Conditions	Table 5.2-34 and Table 5.2-37, Mitigation 5.2.2, Mitigation - providing information is not enough but rather providing support is needed.	Mitigation 5.2.2. aims to support the role that employment agencies and economic development organizations have in planning and preparing for large construction projects. Aurora LNG will undertake considerable planning and preparation for the Project including human resources planning . In Mitigation 5.2.5, Aurora LNG proposes to "Identify potential shortages of workers with specific skill requirements, and work with training and education facilities, Aboriginal Groups, and local communities to increase opportunities for Aboriginal and local community members to obtain training required for Project participation."
2631.1	round 1	Gitga'at First Nation	5.2.5.1	Economic Conditions	Table 5.2-34 and Table 5.2-37, Mitigation 5.2.2, Rationale - what about commitments from the Proponent?	Mitigation 5.2.2. aims to support the role that employment agencies and economic development organizations have in planning and preparing for large construction projects. Aurora LNG will undertake considerable planning and preparation for the Project including human resources planning. In Mitigation 5.2.5, Aurora LNG proposes to "Identify potential shortages of workers with specific skill requirements, and work with training and education facilities, Aboriginal Groups, and local communities to increase opportunities for Aboriginal and local community members to obtain training required for Project participation."
2632.1	round 1	Gitga'at First Nation	5.2.5.1	Economic Conditions	Table 5.2-34 and Table 5.2-37, Mitigation 5.2.2, Expected Success/Risks and Uncertainty - success will depend on the Proponent continually providing support for education and training, and to ensure that impacts to current economies (such as commercial fishing and eco-tourism) are negligible.	Support for education and training is provided in Mitigation 5.2.5: Identify potential shortages of workers with specific skill requirements, and work with training and education facilities, Aboriginal Groups, and local communities to increase opportunities for Aboriginal and local community members to obtain training required for Project participation. Mitigation 5.2.2 does not address effects on commercial fishing and ecotourism, rather it helps planners plan for change in demand for construction labour.
2633.1	round 1	Gitga'at First Nation	5.2.5.1	Economic Conditions	Table 5.2-34, Mitigation 5.2.3, Mitigation - what about mitigations for older workers with experience but not with Grade 12?	Older workers with applicable skills/experience but without Grade 12 will not be excluded from consideration. The objective of Mitigation 5.2.3 is to help prevent younger people from leaving school prematurely to take employment.
2634.1	round 1	Gitga'at First Nation	5.2.5.1	Economic Conditions	Table 5.2-34 and Table 5.2-37, Mitigation 5.2.5, Mitigation - who is responsible for costs associated with this mitigation?	Specific details with respect to this mitigation, such as how Aurora LNG will work with relevant organizations to increase opportunities for Aboriginal and local community members to receive appropriate training, will be developed as part of Aurora LNG's human resources planning. Aurora LNG will have overall accountability for this mitigation.
2635.1	round 1	Gitga'at First Nation	5.2.5.1	Economic Conditions	Table 5.2-34 and Table 5.2-37, Mitigation 5.2.5, Rationale - what best management practices?	Under the "Rationale for Selection" column "best management practice" refers to measures that Aurora LNG feel are appropriate for achieving identified outcomes. With respect to Mitigation 5.2.5 the identified outcome is to enhance the capacity of the local workforce.
2636.1	round 1	Gitga'at First Nation	5.2.5.1	Economic Conditions	Table 5.2-34 and Table 5.2-37, Mitigation 5.2.5, Expected Success/Risks and Uncertainty - more information is needed on how this conclusion on success can be made. Also, the success will depend on the commitment from the Proponent on providing support to train Tsimshian people.	The predicted success, that there will be a moderate to high likelihood that the mitigation will be effective, assumes that there will be interest and willingness on the part of community members to engage in the appropriate training to be qualified for consideration for a project position. While Aurora LNG does not guarantee that persons who undergo training will be able to secure a position, because of the large size of the Project, and demand for qualified workers, the odds of an appropriately trained individual securing employment are high. Aurora LNG will work with training and education facilities to develop and help fund training programs to support Project needs. The details of this support and the training will be developed as the Project moves into detailed planning.
2637.1	round 1	Gitga'at First Nation	5.2.5.1	Economic Conditions	Indirect and Induced Employment - What about other indirect opportunities created as a result of a strain on existing facilities (e.g., nurses, social workers)? The Proponent must not limit indirect jobs from the industry only; they must consider indirect jobs as a result of the impacts on limited resources that currently exist.	Aurora LNG is uncertain about what the commenter is requesting.

2638.1	round 1	Gitga'at First Nation	5.2.5.1	Economic Conditions	Construction Summary - the statement that "Project demand for 5,000 workers at peak construction will largely have beneficial effects within the LAA and RAA through direct, indirect and induced employment" may be extrapolated if the local and regional working population is untrained and if the Proponent does not effectively promote and support employment and training within the LAA and RAA.	Aurora LNG will seek to maximize local hiring during construction and operations, as stated in the Application. Mitigation 5.2.5 indicates Aurora LNG will work with training and education facilities, Aboriginal Groups, and local communities to increase opportunities for Aboriginal and local community members to obtain training required for Project participation.
2639.1	round 1	Gitga'at First Nation	5.2.5.1	Economic Conditions	Construction Summary - it appears that the statement "Adverse effects will be minimized through the housing of workers in a closed-access camp as indirect and induced employment created in the LAA from the spending of FIFO workers will be reduced" contradicts earlier statements that workers in camps can contribute to the local economy.	It is stated under "Project-Mechanisms for Change in Labour Supply and Demand" that spending by direct and indirect workers will result in induced employment. However, this was intended to mean spending by direct and indirect workers that reside in the LAA, not FIFO workers.
2640.1	round 1	Gitga'at First Nation	5.2.5.1	Economic Conditions	Operations, Direct Employment - local hiring during operations must be maximized and this includes a commitment from the Proponent to support training and education of Tsimshian people prior to the operation phase.	Aurora LNG will seek to maximize local hiring during operations, as stated in the Application. Mitigation 5.2.5 indicates Aurora LNG will work with training and education facilities, Aboriginal Groups, and local communities to increase opportunities for Aboriginal and local community members to obtain training required for Project participation.
2641.1	round 1	Gitga'at First Nation	5.2.5.3	Economic Conditions	Table 5.2-40, Mitigation 6.4.1 - what about engagement with affected holders within the RAA due to the cumulative impacts from all projects?	Aurora LNG has identified numerous mitigation measures for addressing potential adverse effects on resource-based and subsistence economies in Table 5.2-40. Aurora LNG maintains that with application of these measures, the Project contribution to cumulative effects on resource-based primary and subsistence economies will be low. However, ongoing engagement by Aurora LNG with Aboriginal Groups could also include discussion of cumulative effects.
2642.1	round 1	Gitga'at First Nation	5.2.5.3	Economic Conditions	Table 5.2-40, Mitigation 6.5.1, Mitigation - what about non-routine and emergency medical travel for Gitga'at people from Hartley Bay?	Mitigation 6.5.1 refers to the use by the Project's LNG carriers of the Coast Guard Marine Communication and Traffic System (MCTS) to provide notice of planned arrival time at Triple Island. It does not address medical-related travel.
2643.1	round 1	Gitga'at First Nation	5.2.5.3	Economic Conditions	Table 5.2-40, Mitigation 6.5.1, Expected Success/Risks and Uncertainty - the risk and uncertainty is not entirely associated with the mitigation being mandatory or not. As people become more economically independent, boating will become more popular which will limit the moorage space in Prince Rupert required for service delivery and medical to communities such as Hartley Bay.	Aurora LNG seeks clarification on how the concern identified in this comment relates to Mitigation 6.5.1. Mitigation 6.5.1 specifies that: "Project-related marine traffic, including LNG carriers, will use the Coast Guard Marine Communication and Traffic System (MCTS) to provide notice of planned arrival time at Triple Island. Aurora LNG will encourage Aboriginal Groups and stakeholders to use the system to plan their routing and scheduling."
2644.1	round 1	Gitga'at First Nation	5.2.5.3	Economic Conditions	Table 5.2-40, Mitigation 6.5.2, Mitigation - the Marine Activities Plan must be developed specifically to meet the needs of marine-based communities such as Hartley Bay that rely on Prince Rupert for food and freight delivery, and medical.	The objective of the Marine Activities Plan is to identify and develop various tools to communicate the Project's marine-related activities with other marine users and to be able to develop and document potential mitigation measures to address potential adverse effects. Aurora LNG will engage with regulators and Aboriginal communities during the development of this plan.
2645.1	round 1	Gitga'at First Nation	5.2.5.3	Economic Conditions	It is not clear what species were considered for Commercial Fishing? On p. 5.2-83 it appears that salmon and shrimp are the only species. If this is the case, all commercial species important to Gitga'at and residents within the region should be assessed.	Section 6.5: Marine Use and Navigable Waters assesses potential effects on marine fisheries. See Tables 6.5-8, 6.5-10, and 6.5-11 for full details. The commercial, recreational, and Aboriginal fisheries considered in the assessment include the following: Salmon (all species)Groundfish (rockfish, lingcod, halibut, etc.)Small pelagics (herring, etc.)Invertebrate (crab, prawn, urchin, geoduck, etc.)
2646.1	round 1	Gitga'at First Nation	5.2.5.3	Economic Conditions	"The Project is predicted to have a low economic effect on subsistence economic activities…" but even "low" effect can have a large effect on Aboriginal communities as economics transcends cultural and social aspects of Tsimshian peoples lives.	Aurora LNG acknowledges that Gitga'at First Nation are concerned that the predicted low economic effect on subsistence economic activities may be disproportionately felt by Aboriginal communities. However, Aurora LNG maintains that through the application of the proposed mitigation measures, Project adverse effects will not be significant.
2647.1	round 1	Gitga'at First Nation	5.2.6.3	Economic Conditions	The statement "In the cumulative effects scenario the implementation of mitigation measures and government sponsored training initiatives will reduce the likelihood of adverse residual effects on labour supply and demand" puts too much reliance on government sponsored training rather than Proponent sponsored training. Please clarify how much reliance will be on government sponsored training.	This statement acknowledges that government-sponsored training initiatives, such as those discussed in Section 5.2.6.3 will play a role in addressing cumulative effects on labour supply and demand, as will the initiatives proposed by Aurora LNG and other project proponents. There is no special reliance placed on the role of government-sponsored training. Aurora LNG intends to work with with training and education facilities, Aboriginal Groups, and local communities to increase opportunities for Aboriginal and local community members to obtain training required for Project participation.
2648.1	round 1	Gitga'at First Nation	5.2.6.3	Economic Conditions	Will Aurora LNG dictate to successful bidders where to purchase materials and supplies?	Aurora LNG will not require that its contractors use particular suppliers. However, it will require that work packages be developed that consider the capacity and capabilities of local and regional businesses, to enable local firms to compete for Project contracts.
2649.1	round 1	Gitga'at First Nation	5.2.7.1	Economic Conditions	The mitigations measures in the entire Section 5 can only be effective if the Proponent commits to supporting Tsimshian communities in obtaining sufficient training and education for employment and procurement opportunities.	In Mitigation 5.2.5, Aurora LNG proposes to "Identify potential shortages of workers with specific skill requirements, and work with training and education facilities, Aboriginal Groups, and local communities to increase opportunities for Aboriginal and local community members to obtain training required for Project participation."
2650.1	round 1	Gitga'at First Nation	5.2.7.2	Economic Conditions	The summary conclusions made in this section are vague with minimal solutions and commitments. The Proponent must commit to supporting Tsimshian communities in obtaining sufficient training and education required for Project employment and procurement opportunities.	The intent of Section 5.2.7.2 is to provide a determination of significance for potential cumulative effects on economic conditions. Mitigation #5.2.5 indicates that Aurora LNG will identify potential shortages of workers with specific skill requirements, and work with training and education facilities, Aboriginal Groups, and local communities to increase opportunities for Aboriginal and local community members to obtain training required for Project participation.
2651.1	round 1	Gitga'at First Nation	5.3.1	Economic Conditions	Table 5.3-1 - due to comments above for each potential effect, we do not agree with the Proponents conclusions at this time.	Aurora LNG acknowledges this comment and refers Gitga'at First Nation to the responses provided to the comments above.
2652.1	round 1	Gitga'at First Nation	1.4.1	Proposed Project Overview	The information presented in the application summary and in the project benefits section in the application (e.g., s.1.4.1) suggests that Project will have very substantial economic benefits. To the reader lacking a skill set in major project economics – which may include many final government decision-makers and stakeholders – the take-away message is that this Project is very good for the economy. However, the assessment conducted for and presented in the application is one of gross benefits, not net benefits, and can reasonably be expected to be a large if not huge exaggeration of the Project's actual incremental benefits. The proponent used the method of economic impact analysis (using input-output analysis and associated techniques) to estimate the Project's benefits, consistent with BC EAO requirements at present, but these methods are widely known to be incapable of estimating actual net benefits of development. Economic impact analysis ignores opportunity costs and treats all expenditures as benefits, and ignores many other costs of projects that can readily be examined in financial terms such as incremental financial burdens on government (e.g., Vining, A. R. and A. E. Boardman (2007). The Choice of Formal Policy Analysis Methods in Canada. In: Policy Analysis in Canada: The State of the Art. L. Dobuzinskis, M. Howlett and D. Laycock. Toronto, University of Toronto Press: 48-85; Barclay, J. (2009). Predicting the Costs and Benefits of Mega-Sporting Events: Misjudgement of Olympic Proportions? Economic Affairs 29(2): 62-66.). As a consequence, project expenditures are treated as benefits when they are real costs to the economy, and employment benefits, GDP stimulus, and impacts on government revenues are exaggerated. Just as wildlife biologists strive in EA to estimate a project's residual (i.e., net) adverse effects by examining how the project's adverse effects will be reduced by mitigation, so to should proponents be required to estimate net economic benefits. Please provide an analysis of the net economic benefits of the project. Also, it appears that due to the tiered approach to consultation, inequitable access to economic benefits from this Project has resulted. Gitga'at requests further discussion with Nexen to reconcile these differences.	As identified in Section 1.4 of the AIR, economic impacts of the Project are estimated based partly on the results of an input-output modeling exercise (using the Statistics Canada Interprovincial Input-Output Model). Input-output modelling is a well-established method for estimating economic impacts of incremental expenditures (i.e. economic shocks). However, a discussion of the theoretical basis of this approach is beyond the scope of the Application. Aurora agrees that Section 1.4 presents benefits (actually, economic impacts) on a "gross" basis, which is how input-output modelling works. However, Aurora LNG disagrees with the statement that "As a consequence, project expenditures are treated as benefits when they are real costs to the economy, and employment benefits, GDP stimulus, and impacts on government revenues are exaggerated." Aurora LNG acknowledges the potential for adverse economic social and economic effects. These are addressed in detail in Section 5.2 - Economic Effects, Section 6.2 – Visual Quality, Section 6.3 Infrastructure and Services, Section 6.4 Marine Use and Navigable Waters, and Section 6.5 – Community Health. Within these sections of the Application, Aurora LNG has identified numerous mitigation measures designed to address and manage the identified adverse socio-economic effects. Beyond such mitigation measures, the Project will result in increased local/regional, provincial, and federal government revenues (see Section 1.4.5 of the Application). How these governments choose to spend such revenue will be their own prerogative. However, because this revenue was generated by economic activity based primarily on financial inflows into British Columbia, the increase in government revenue is incremental and thus beneficial to residents of local communities in British Columbia, and Canada. Aurora LNG disagrees with the statement that "employment benefits, GDP stimulus, and impacts on government revenues are exaggerated." First, these estimates were derived using the SCIPIOM model based on best estimates of the extent of Project expenditure within Canada. The SCIPIOM model is based on the input-output structure of the entire Canadian economy, based on Statistics Canada data. Within this structure, goods and services are only modeled if there is an economic basis for doing so. In other words, if a good or services cannot be procured within Canada, the model will "leak" it to outside of Canada. Second, Aurora LNG considered whether and to what extent that equipment, goods, and services needed for various project phases were available in Canada, and applied reasonable assumptions with respect to domestic procurement. For example, out of a total capital cost of nearly $28 billion it is estimated that approximately 30% ($8.3 billion) will occur in Canada. Finally, the estimates provided from the analysis would be theoretically "exaggerated" if the Canadian economy were running at 100% capacity, with no potential for expansion, and in a condition of full employment. However, this was not the condition as of November 2016 when the Application was filed (in November 2016 the unemployment rate for British Columbia and Canada were 5.8% and 6.9%). It was therefore, reasonably assumed that the Canadian economy could absorb the $8.3 billion in incremental capital expenditure over the six year construction period (by comparison, British Columbia's 2015 GDP was nearly $250 billion and Canada's 2015 GDP was nearly $2 trillion). Aurora LNG understands that there are limitations to the input-output modelling technique, and that the estimates provided by this approach are indicative rather than precise. It is also acknowledged that at the current early stage of Project planning, expenditure information used in the analysis are preliminary, as noted in Application Section 1.4.2. However, Aurora LNG maintains that the jobs, economic stimulus, and additional government revenue provided by the Project will substantially benefit communities within the north coast, as well as British Columbia overall. Sources: Unemployment rates in Canada: http://economicdashboard.alberta.ca/Unemployment#interprovincial
2653.1	round 1	Gitga'at First Nation	1.4.4.1 and 1.4.3.2	Proposed Project Overview	The proponent provides estimates of proportions of employment that will flow to locals, residents of BC, residents of elsewhere in Canada, and foreigners (e.g., s.1.4.3.2 (p1-55), s.1.4.4.1 (p1-58)). However, no rationale or explanation for how such estimates were generated which is important because the geographic distribution of employment on the Project plays a key role in understanding Project Benefits as well as adverse effects on multiple VCs (e.g., Economic Effects VC, Services and Infrastructure VC, etc.). Please explain how estimates of proportions of employment flowing to locals, residents of BC, etc. were generated, including any assumptions that were made in generating these estimates.	Aurora LNG's predicted break-down of operating labour by BC residents (estimated at 64% of operating labour), other Canadian residents (16%), and imported labour (20%), is based on consideration of the skills needed to operate an LNG plant, overall understanding of the labour market, and anticipated potential to "train-up" workers for operational positions. Operating and maintaining an LNG plant requires highly trained and experienced personnel. Aurora LNG anticipates that a substantial proportion of its operating workforce will consists of BC residents, whose skills will be developed through technical training programs and hands-on experience at overseas LNG plants. Nevertheless, because of the limited LNG operating expertise available in Canada, Aurora LNG anticipates that a proportion of its workforce will be hired from outside Canada. This proportion should decline over time, as more "homegrown" LNG expertise is developed.
2654.1	round 1	Gitga'at First Nation	1.4.4.2	Proposed Project Overview	It would seem logical that if a project is going to be assessed for the effects that it will cause – both positive and negative – that a common boundary, or scope, is identified. But this is not the case when you compare how Project benefits are estimated and Project adverse effects are assessed. By using economic impact analysis (specifically the technique of input-output analysis), the scope of Project benefits is extended throughout and even beyond the Canadian economy. Most Project jobs will flow to people outside the region: as stated in s.1.4.4.2 (p1-64), the proponent estimates that 81% (18,600 PY) of total operations employment of the Project (22,900 PY) "will be associated with natural gas exploration, production, and transportation in Canada and the other 19% will be associated with facility operation". So the proponent counts jobs in north-east BC or wherever gas wells are developed as job benefits of the Project, yet impacts on wildlife, water, communities, and other things in north-east BC (or elsewhere) are ignored. This is a lopsided analysis that favours the Project. If the Project can reasonably be expected to stimulate new natural gas development then these other jobs might be incremental (but this case hasn't been made), but then so to should the EA examine environmental impacts of expanded gas development there. Please revise the benefits section to report on only the benefits solely attributable to the proposed Aurora LNG facility and shipping, i.e., benefits matched with the scope of the Project as defined in s.1.2 (p1-3), or otherwise please provide the analysis to indicate that the Project will stimulate incremental upstream natural gas development to justify inclusion of economic benefits associated with upstream development in the tally of Project benefits and then revise the EA to include all of the environmental and other impacts associated with this additional upstream development.	The scope of Section 1.4 (Project Benefits) is based on the requirements specified in Section 1.4 of the AIR. The AIR specifies that the employment estimates are to include: "the number of people that are expected to be hired locally, provincially, nationally, or internationally" and "generated indirect and induced employment by project phase." Natural gas will be purchased during the operations phase, and for this reason the economic impact assessment includes the effects of this expenditure. Tables 1-15, 1-16, and 1-17 distinguish indirect and induced employment effects between those associated with the facility, and those associated with the gas supply. The spatial scoping boundaries for assessing effects on environmental, socio-economic, and heritage VCs are identified in tables 3-3 and 3-4 of the AIR.
2655.1	round 1	Gitga'at First Nation	1.4.4.4	Proposed Project Overview	The proponent notes in s.1.4.4.4 (p1-66) that there is high unemployment in the region and that the Project provides the opportunity for the unemployed to enter (or re-enter) the workforce. The proponent notes that the Project will help develop individuals' skill sets that could then be used in other employment elsewhere. Later, in Table 5.2-34 (s.5.2.5.1 (p5.2-60)), the proponent proposes mitigation measure 5.2.5 entailing working with training authorities in the region and other labour stakeholder groups to address skill gaps amongst Aboriginal and other locals. This is constructive towards maximizing local benefits and minimizing leakage of benefits out of the region, but skill gaps is but one challenge impeding local take-up of employment with the Project; other challenges include mobility, conflicts with traditional lifestyles, racism and lack of cultural awareness among non-Aboriginals, and health conditions (some of these things are noted later in s.6.6.5.3 (p6.6-68)). Regardless, in the benefits section of the application which showcases the Project's purported benefits, the proponent doesn't seem to recognize the wider variety of challenges to gaining employment that many people in the study area face which diminish the local employment benefits of the project. Please edit the benefits section to be transparent with respect to the variety of challenges that people face with gaining major project employment, and please revise the associated analyses of potential local employment benefits accordingly.	The scope of the benefits section, as defined by Section 1.4 of the AIR, does not include an assessment of employment challenges, as requested by the commenter. As noted in the comment, these topics are addressed elsewhere in the Application. Aurora LNG has proposed a number of mitigation measures that are expected to help facilitate local employment and help address potential employment challenges, including: Mitigation 5.2.1 - Inform local residents and Aboriginal Groups of job and procurement opportunities during all Project phases. Develop work packages that consider the capacity and capabilities of local and regional businesses Mitigation 5.2.2 - Provide information to employment agencies and economic development organizations to help them plan for increased demand for construction labour. Mitigation 5.2.3 - Require that all of workers (not inclusive of summer students) 19 years and younger complete grade 12 or have an appropriate equivalency in order to prevent young people from leaving school prematurely. Mitigation 5.2.5 - Identify potential shortages of workers with specific skill requirements, and work with training and education facilities, Aboriginal Groups, and local communities to increase opportunities for Aboriginal and local community members to obtain training required for Project participation. Mitigation 6.3.3 - Require all staff and contractors to undertake worker orientation, including communication of expected behaviours when transiting to/from local communities (a worker code of conduct) and cross-cultural awareness to help build awareness and respect of local concerns and customs to reinforce the importance of respectful conduct when in communities. Mitigation 6.3.4 - A Community Engagement Plan will be developed and implemented to facilitate ongoing and meaningful community engagement, including monitoring, recording, and addressing community complaints and concerns. Mitigation 6.3.11 - Engage with local communities and Aboriginal Groups to address community concerns associated with the Project.
2656.1	round 1	Gitga'at First Nation	1.4.4 and 5.2.5.1	Proposed Project Overview	The estimates of local employment provided in s.5.2.5.1 (e.g., p5.2-62) highlight the small number of Project jobs that may flow to existing locals, and how the vast majority of employment benefits will flow to non-locals working on a fly-in/fly-out basis or in-migrants with the necessary skills. Gitga'at, decision-makers and other local stakeholders need to know the small number of jobs that are estimated to flow to locals, especially given that most of the rest of the employment can be expected to occur anyway because Canada has a well-functioning economy with low unemployment. Please revise the benefits section of the application to indicate such important findings or direct the reader to material elsewhere in the application (such as s.5.2.5.1) highlighting the limitations of local economic benefits so that readers of the benefits section have a complete understanding and can put the benefits information into context.	The majority of construction jobs will, by necessity, go to workers from outside the region because labour requirements during construction far exceeds the predicted available construction workforce. This is explained in Section 5.2.5.1 under the heading "Construction/Direct Employment" under "Characterization of Residual Effects for Change in Labour Supply and Demand" on page 5.2-61. The number of direct construction jobs estimated in Table 5.2-35 should not be regarded as a cap on local hiring potential, but rather an estimate based in consideration of the estimated labour force involved in construction-related occupation. Aurora LNG is proposing a number of mitigation measures aimed at facilitating local employment.

2657.1	round 1	Gitga'at First Nation	5.2.2.5	Economic Conditions	The boundary of the LAA is too restrictive in that the proponent doesn't seem to recognize the tight economic linkages between communities in the region. Hartley Bay, for example, is tightly linked to economic activities in the Prince Rupert area by way of: (1) employment, i.e., Gitga'at people may move to Prince Rupert for work, or live in both locales, or send earnings back to family in Hartley Bay; and (2) costs of goods and services, e.g., housing construction and economic development in Hartley Bay are affected by competition for construction labour which is shaped largely by economic development in Prince Rupert, Terrace, and Kitimat. It is therefore not enough to include communities like Hartley Bay in the RAA; such communities should be in the LAA so that the EA fully covers the direct economic effects of the Project. Please revise the LAA to include communities like Hartley Bay that are strongly linked to conditions in Prince Rupert, and please revise the assessment accordingly.	Aurora LNG's understanding of Gitga'at First Nation's comment requesting the inclusion of Hartley Bay in the LAA to be: Members who either move to Prince Rupert for work, live in both Prince Rupert and Hartley Bay, as well as those members who work in Prince Rupert and send money to family members in Hartley Bay could experience adverse residual effects of the ProjectMembers living in Hartley Bay who draw upon goods and services in Prince Rupert, Terrace and Kitimat could experience adverse effects related to changes in the cost of goods and services due to the Project Regarding the assessment of Economic Conditions (Section 5.3) and Infrastructure and Services (Section 6.3), communities included in the LAA are those where it is reasonably expected that direct interactions with the Project could occur, potentially resulting in adverse effects that could be predicted/estimated. It is recognized that Hartley Bay, as well as other communities within the region (e.g., Terrace and Aboriginal communities in the Terrace area) have economic and social ties to Prince Rupert. However, Aurora LNG maintains that there is much less potential for the Project to directly affect socio-economic conditions in Hartley Bay, compared to communities within the LAA. Aurora LNG recognizes that there could be indirect effects on Gitga'at members living in Hartley Bay – such as those identified above – but maintains that it is difficult to distinguish such phenomena from those resulting from other socio-economic changes occurring in the region (e.g. adverse effects are difficult to predict/estimate), and are therefore adequately addressed in cumulative effects assessments. For these reasons, Hartley Bay was not included within the LAAs for the socio-economic VCs noted above, but included in the RAA. As delineated and applied, the LAA and RAA for Sections 5.2, 6.3, and 6.6 also align with those used in similar applications within northwest BC. Specific to residual effects, it is important to note that effects assessed at the LAA level could also be realized by residents outside the LAA who may work within, draw upon, or visit the LAA. For example, Gitga'at members living in Hartley Bay who draw upon hotels, motels and health care services (among other considerations) from Prince Rupert could realize adverse effects associated with the Project as characterized at the LAA level. This rationale holds for other individuals, not just members of Gitga'at First Nation, within the RAA (and further) who may draw upon infrastructure and services within Prince Rupert. Due to potential direct Project interactions with Gitga'at First Nation harvesting locations, Hartley Bay is included in the LAA for the residual effect assessments 'change in resource-based primary industries and subsistence economies' (Section 5.2). With respect to cumulative effects, as assessed in Sections 5.2 and 6.3, cumulative residual effects are predicted to extend to the RAA (which includes Hartley Bay). This includes changes in economic conditions and infrastructure and services. Characterizations provided at the RAA level account for indirect effects noted by Gitga'at First Nation and would apply to members living in Hartley Bay. In summary, as per the methodology outlined in the AIR, Hartley Bay has not been added to the LAA as the community is outside of the spatial extent to which Project-related activities are anticipated to result in a direct, predictable and measurable adverse change in the referenced socio-economic VCs. The concerns identified in relation to Gitga'at First Nation members who live, work, draw upon services or visit communities within the LAA are already assessed within the socio-economic VCs as characterized at the LAA level. Aurora LNG believes that the concerns identified by Gitga'at First Nation in relation to the economic, employment and infrastructure and service linkages between Hartley Bay and Prince Rupert are therefore also assessed at the LAA level in aggregate-population form. Characterizations provided at the RAA level for Project and cumulative effects apply to members of Gitga'at First Nation members residing in Hartley Bay and cover concerns related to indirect socio-economic and cumulative effects from the Project. As part of its engagement with Gitga'at First Nation during development of the Social Management Plan, Aurora LNG will discuss specific socio-economic concerns and issues that may affect Gitga'at First Nation members, including residents of Hartley Bay.
2658.1	round 1	Gitga'at First Nation	5.2.2.5	Economic Conditions	However, the proponent notes that they examine significance of project direct effects, as well as cumulative effects, for the RAA, which does include a larger set of communities than the LAA. The question then begs: if significance of project direct effects is determined for the RAA, mustn't effects assessment and existing conditions therefore be conducted for the RAA? And then what is the point of the LAA? Please explain how Project direct effects are properly examined when different spatial boundaries are used for different steps in the process.	The use of LAA and RAA are conventions to help define the scope of the assessment. Generally, more economic effects are anticipated within the LAA because it includes communities that are closer to the Project. However, through the process of the assessment it was determined that both Project and cumulative effects are predicted to occur within the RAA, as indicated in tables 5.2-41 and 5.2-43.
2659.1	round 1	Gitga'at First Nation	5.2.2.7	Economic Conditions	On p5.2.11 (s.5.2.2.7) the proponent provides definitions of low, medium, and high likelihood. Each definition relies on the terms 'unlikely', 'likely', and 'highly likely' in the likelihood definitions, but what do these terms mean to the proponent? It is good practice to define expressions of probability in quantitative terms, such as the IPCC does in its climate change science communications (see Intergovernmental Panel on Climate Change (2010). Guidance Note for Lead Authors of the IPCC Fifth Assessment Report on Consistent Treatment of Uncertainties. Intergovernmental Panel on Climate Change. 4pp + Annexes. http://www.ipcc.ch/pdf/supporting-material/uncertainty-guidance-note.pdf), so that it is clear to all how the terms are being used and to ensure consistency among users of the terms. Please define what is meant by the terms unlikely, likely, and highly likely.	A qualitative approach is used to describe the likelihood of residual Project effects on community health based on professional judgement and experience of the assessor. A definitive or quantitative approach to defining these terms (i.e., 0-15% chance of occurrence) is not practical. In general, the term 'unlikely' in this instance means that adverse effects between the Project and community health are not predicted to occur. The term 'likely' in this instance means adverse effects between the Project and community health are probable as it may be difficult to avoid or mitigate residual effects. The term 'highly likely' in this instance means adverse effects will occur as residual effects cannot be practically avoided or mitigated.
2660.1	round 1	Gitga'at First Nation	5.2.2.8	Economic Conditions	This threshold is problematic for three reasons. One, as written, effects are significant simply if they are distinguishable from current conditions. What does it mean for effects to be 'distinguishable'? Does this simply mean measurable, or must the effects be not just measurable but more substantial to some degree? The threshold is therefore too ambiguously defined leaving the door open for a wide range of interpretation. Further, a literal interpretation of the threshold is that there simply needs to be a residual effect on this VC for there to be a significant residual effect on this VC – virtually guaranteed! Second, the threshold has no clear connection to stakeholder values, including Gitga'at's. What, specifically, do stakeholders care about with respect to changes to economic conditions? The threshold should be tied to specific economic conditions that stakeholders/Gitga'at care about so to allow for an analysis that hones in on what matters to people. Significance is fundamentally grounded in acceptability, and the threshold should therefore make this connection. Third, the threshold is redundant in that the latter part of the definition refers to mitigation when the assessor at this point (of determining significance) should've already separated out residual effects from non-residual effects. Please clarify what would make a residual effect significant to stakeholders and revise the subsequent analysis accordingly.	Absent any well established quantitative thresholds for determining a significant economic effect (or most other socio-economic effects) the determination of significance is based on a assessment of whether there is a material and adverse change in the condition of the valued component,with incorporation of mitigation and management measures. "Distinguishable" in the context of the economic significance threshold definition, means distinct from current conditions or trends. In other words, the condition can be reasonably attributed to the Aurora LNG project rather than due to other economic factors, such as seasonal variations or structural changes affecting the economy (including such factors as in-migration, out-migration, closure and opening of other businesses and projects). The significance definition allows us to first characterize effects post mitigation, and based on this characterization determine if the significance threshold has been passed. If it is evident that there will be material un-mitigated residual adverse economic effects attributable to the Project then it may be considered significant. However, this conclusion will need to be made with appropriate consideration of the local economic context. For example, businesses may be both positively affected (through increased commercial activity) and adversely affected (through higher labour costs) by the presence of the Project.
2661.1	round 1	Gitga'at First Nation	5.2.2.8	Economic Conditions	In Table 5.2-5 (s.5.2.2.8 (p5.2-12)) the definitions of moderate and high magnitude effects use the term risk, which is the scale of an impact in consideration of its probability. As such, the definitions introduce probability, when probability is discussed elsewhere in the likelihood (ss.5.2.2.7, 5.2.5.1, 5.2.5.2, and 5.2.5.3) and confidence (s.5.2.8) sections. Please explain how the assessor examines uncertainty in the effects characterization, likelihood categorization, and confidence parts of the assessment, and how each segment of this examination of uncertainty is used to build the broader argument.	The intent of the word "risk" in Table 5.2-5 is in regards to the consequences and probability of an adverse effect occurring. Serious risk indicates that there is a high probability of an adverse consequence. Likelihood refers to the likelihood of the residual economic effects occurring based on the criteria definitions in Section 5.2.2.7. The likelihood determinations are based on Aurora LNG's understanding of current and anticipated economic conditions, and anticipated residual effects in consideration of mitigation measures. The prediction confidence section (Section 5.2.8) recognizes that there may be uncertainties in the residual effects characterization because of uncertainties in future economic conditions.
2662.1	round 1	Gitga'at First Nation	5.2.2.8	Economic Conditions	It is important that ambiguous terms are clearly defined to ensure everyone has a common understanding of what is being referred to, and so the use of terms like "serious risk", "unlikely", and "likely" in Table 5.2-5 (s.5.2.2.8 (p5.2-12)) should be defined. Please define what is meant by "serious", "unlikely", and "likely". It may help to refer to quantitative thresholds such as that used by the IPCC when discussion climate change (see Intergovernmental Panel on Climate Change (2010). Guidance Note for Lead Authors of the IPCC Fifth Assessment Report on Consistent Treatment of Uncertainties. Intergovernmental Panel on Climate Change. 4pp + Annexes. http://www.ipcc.ch/pdf/supporting-material/uncertainty-guidance-note.pdf).	A qualitative approach is used to describe the likelihood of residual Project effects on community health based on professional judgement and experience of the assessor. A definitive or quantitative approach to defining these terms (i.e., 0-15% chance of occurrence) is not practical. In general, the term 'unlikely' in this instance means that adverse effects between the Project and community health are not predicted to occur. The term 'likely' in this instance means adverse effects between the Project and community health are probable as it may be difficult to avoid or mitigate residual effects. The term 'highly likely' in this instance means adverse effects will occur as residual effects cannot be practically avoided or mitigated.
2663.1	round 1	Gitga'at First Nation	5.2.2.8 and 5.2.5.3	Economic Conditions	The concept of reversibility does not make sense for effects on some primary resource users. In s.5.2.5.3 (p5.2-83), the proponent concludes that impacts on commercial trappers will be reversible upon Project closure. This qualification of the impacts of the Project seems meaningless given that traplines are typically held by individuals, and the duration of the Project – several decades from construction through decommissioning – could effectively eliminate trapping for many trappers' active years. Please justify the qualification of impacts on trappers as reversible and if appropriate revise your definition and/or your use of the concept of reversibility for this VC.	Reversibility is defined in regards to the entire Project life-cycle. In other words, at the end of the Project's economic life, it will be decommissioned and the area restored to a natural condition. The duration of effects are characterized in the "Duration" criteria.
2664.1	round 1	Gitga'at First Nation	5.2.3.2	Economic Conditions	On p. 5.2-15, a population decline of -87.3% in Hartley Bay is listed, however, this is based on incorrect information. Aurora LNG should not knowingly conduct assessments in an EA with incorrect information. Aurora LNG must consult Gitga'at in estimating an accurate number and revise the effects assessment accordingly. This comment applies to all areas in the Application where the census data is referenced.	Statistics Canada reported the population of Kulkayu 4 (Hartley Bay) as 157 in 2006 but in 2011 reported the population as 20. This decrease seems unlikely and is identified as 'likely incorrect' in Table 6.3-5 (and should have been noted). The change in population does not affect the effects assessment or the conclusions of the assessment. Rather, changes in population would be characterized as being greater in magnitude (i.e., a greater percent change) assuming a population of 20. An errata document is being created that will capture these corrections and it will be filed with the BC EAO.
2665.1	round 1	Gitga'at First Nation	5.2.3.2 and 5.2.5.3	Economic Conditions	Baselines are the 'no-project' scenario from which project direct, as well as cumulative effects of other projects and activities, get measured. As such, it's very important to have a good sense of VC conditions. However, the baselines developed in the Project's EA application frequently provide insufficient context from which to characterize effects and determine their significance. For example, in s.5.2.3.2, very little understanding is demonstrated for the decline in commercial fishing in the area. On p5.2-48, the value of the shrimp fishery is noted to have declined over the last decade, "primarily due to a decline in the catch volume". No doubt, economic value of the catch will decline when catch volume declines, as value is a product of catch volume and price. So according to the proponent, price didn't have much to do with a drop in value, but why then has catch volume declined? Might it be the increase in marine shipping and industrialization in the area that the proponent has noted to have occurred, or other things? The baseline information provided for commercial fishing, as well as other dimensions of the Economic Conditions VC, requires greater depth of analysis to provide the adequate context to know if further adverse effects on commercial fishing by the Project will lead to significant impacts or not. This lack of context bears out in the effects assessment on commercial fishing (s.5.2.5.3 (p5.2-84)) where the proponent concludes that the Project will cause only "low" impacts that will be "reversible" upon Project closure – sometimes all it takes is a straw to break the camel's back, and sometimes the camel's back may already be broken. Please revise the baseline to demonstrate a deeper understanding of the factors affecting the decline in commercial fishing in the area, and revise effects assessment and significance determinations accordingly.	A comprehensive examination of all factors underpinning past and current economic conditions within the LAA is beyond the scope of the assessment. Rather, the Application seeks to describe baseline economic conditions and then predict potential effects based on anticipated interactions of the Project. However, a comparison of historical shipping data with salmon catch shows no correlation between shipping volume and salmon catch success (see the "Effects of Lost Fishing Time" technical memo which will be filed with the BC EAO).
2666.1	round 1	Gitga'at First Nation	5.2.4	Economic Conditions	It was good to read in s.12 of the application that impacts on traditional harvesters depend not just on real impacts to the environment (such as measurable pollution) but also perceived impacts on the environment (such as perceived changes in environmental quality), but then in Table 5.2-32 (s.5.2.4 (p5.2-54)) the proponent did not identify LNG production as a source of real and/or perceived environmental impact on change in resource-based primary and subsistence economies. Please explain why neither real nor perceived impacts of LNG production on subsistence harvesters was examined in s.5.2 of the application.	Table 5.2-32 broadly identifies whether various Project activities interact with the economic effects considered in Section 5.2. LNG production per se was not identified as an interaction, though the effects related to the employment of individuals in LNG production was identified. Perceived effects are addressed in Section 12 – Aboriginal Consultation.
2667.1	round 1	Gitga'at First Nation	5.2.5.1	Economic Conditions	As with employment benefit numbers presented in s.1.4 of the application, the proponent does not explain in s.5.2.5.1 (p5.2-56) how it estimated the proportions of employment that will flow to locals, residents of BC, residents of elsewhere in Canada, and foreigners. No rationale or explanation is provided explaining how such estimates were generated, and this is important because the geographic distribution of employment on the Project plays a key role in understanding Project Benefits as well as adverse effects on multiple VCs (e.g., Economic Effects VC, Services and Infrastructure VC, etc.). Please explain the method used and any assumptions adopted to estimate how many jobs in each phase will flow to locals, non-locals, including in-migrants and FIFO workers.	Aurora LNG's predicted break-down of operating labour by BC residents (estimated at 64% of operating labour), other Canadian residents (16%), and imported labour (20%), is based on consideration of the skills needed to operate an LNG plant, overall understanding of the labour market, and anticipated potential to "train-up" workers for operational positions. Operating and maintaining an LNG plant requires highly trained and experienced personnel. Aurora LNG anticipates that a substantial proportion of its operating workforce will consists of BC residents, whose skills will be developed through technical training programs and hands-on experience at overseas LNG plants. Nevertheless, because of the limited LNG operating expertise available in Canada, Aurora LNG anticipates that a proportion of its workforce will be hired from outside Canada. This proportion should decline over time, as more "homegrown" LNG expertise is developed.
2668.1	round 1	Gitga'at First Nation	5.2.5.1	Economic Conditions	The proponent seems to assume that if other major projects planned to mitigate adverse effects in certain ways and the Aurora LNG project implements the same mitigation measures that mitigation will be effective. For example, the CEA assumed that other LNG proponents in the region implement similar mitigations as proposed by Aurora LNG and that all of these actions will be effective: "Noted in their applications for an environmental assessment certificate, proponents of the Pacific NorthWest LNG Project and the LNG Canada Export Terminal propose similar mitigation measures to address adverse residual effects related to employment as those proposed in Table 5.2-34 Based on these considerations, mitigation measures proposed by Aurora LNG and other project proponents are therefore predicted to manage to an acceptable level cumulative adverse effects on labour supply and demand within the RAA (p5.2-91)." Similar statements are made in the mitigation sections of other VCs, yet neither of the two other LNG projects mentioned have yet to be implemented, and thus there presumably is no data from these other projects' mitigation programs to support the notion that the planned mitigation measures will be effective. Please provide further evidence to indicate why decision-makers and stakeholders should have confidence that mitigation measures used by other projects and planned for Aurora LNG will be effective.	The statement "acceptable level" is based on the assumption that other project proponents, as well as Aurora LNG will, in good faith and based on regulatory requirements and certificate conditions, implement proposed mitigation measures and work with local communities to address adverse socio-economic effects. The commenter is correct in pointing out that no LNG projects have been constructed along the North Coast in BC, so the actual effectiveness of mitigation measures has yet to be determined. Aurora LNG predicts that there is a low likelihood of the cumulative effects scenario occurring (i.e. multiple LNG projects being built concurrently – see Section 5.2.8 – Prediction Confidence). However, if the cumulative effects scenario does occur then the cumulative effect on labour and economy during construction is predicted to be of high magnitude.
2669.1	round 1	Gitga'at First Nation	5.2.5.3	Economic Conditions	In s.5.2.5.3 (p5.2-85) the proponent predicts that the Project will not affect seaweed and shellfish harvesting because the area affected "represents a small proportion of such areas available within the region". This logic is faulty because natural resources are unequally distributed across space, and ease of physical but also political access (i.e., traditional governance structures) to natural resources is also not uniform across space.	The quoted excerpt in the comment is about one aspect of the factors considered to determine that shoreline harvesting sites will not incur significant adverse effects from Project-related shipping traffic (see Section 6.5.4.2 of the Application). Shipping traffic will not disrupt fish and fish habitat or shoreline harvesters because wake waves from LNG carriers or support vessels will be well within the size range of naturally occurring waves (the mean monthly average of naturally occurring waves is 0.14 to 1.8 m in height). Wakes waves at the source-vessel (e.g., LNG carrier or escort tug) are predicted to be up to 0.4 m in height when travelling at 12 knots. Wake waves attenuate as they travel outward, reducing in size until they reach a shoreline. By the time the wake waves reach potential shorelines harvesters (providing an LNG carrier travels past a site during a low tide period when active harvesters are present), the waves will be even smaller (than the predicted 0.4 m height at the source vessel) and well within the size range of naturally-occurring waves (Oceanic Consulting Corporation 2014). In consideration of the relatively small size of wake waves compared to those naturally occurring in the region, seaweed and shellfish harvesters are not expected to be displaced by Project-related vessel traffic regardless of how harvesting sites are distributed within the area.

2670.1	round 1	Gitga'at First Nation	5.2.6.5	Economic Conditions	The CEA of Project effects on resource-based primary and subsistence harvesting concluded that the CEs of the Project and other project's large vessel shipping would have low to moderate adverse effects throughout the RAA continuously for medium- to long-term duration, that would (eventually) be reversible (Table 5.2-43, p5.2-97). This conclusion is based upon the prediction that if all projects considered in the CEA go ahead there will be a fourfold increase in large vessel shipping (s.6.5.6) and the conclusion – based upon a comparison of historical shipping and salmon catch that was supposedly presented in s.6.5.6.4 of the application, and a 2007 study that found the economic contribution of ocean transport increased while that of the seafood industry remained the same over the 2002 to 2005 period (s.5.2.6.5 (p5.2-95)) – that shipping traffic has little effect on commercial fish harvesting. The proponent suggests a variety of other factors may affect fishing. Please clarify where the comparison of shipping and salmon catches is provided in the application as nothing on the topic was found in our review of s.6.5.6.4. Please indicate why Gitga'at, decision-makers, and other stakeholders should put faith in the conclusion that a fourfold increase in large vessel shipping would have only a moderate impact (defined as a "measureable change but unlikely to pose a serious risk to the VC or to represent a management challenge" (Table 5.2-5 on p5.2-12)) on commercial fishing given that the sole empirical data that the CEA on this VsC appears to rest upon is a comparison of shipping with salmon catch that is not seemingly actually provided in the application and a 2007 study that only provided a very coarse examination of trends in shipping and seafood industry economic activity over a very short time period.	Aurora LNG is developing an errata document that will correct the erroneous reference to Section 6.5.6.4. The errata document will be filed with the BC EAO. The assessment of Marine Use and Navigable Waters suggests that shipping traffic at the Port of Prince Rupert may increase up to four-fold if all past, present, and reasonably foreseeable projects are built. However, because most fisheries do not overlap with the main shipping route or use gear or practices that preclude interactions with shipping traffic, residual effects on marine fisheries, and subsequently resource-based primary and subsistence economies, will be minimized. In consideration of the existing economic and marine conditions in Prince Rupert, the potential Project effects, and the extensive mitigation measures proposed by Aurora LNG (e.g., Tables 5.2-40 and 6.5-14), the potential cumulative effects on marine use and navigable waters and economic conditions were each predicted to be not significant. The Prince Rupert Port Authority (PRPA), Marine Communication and Traffic Services (MCTS)—a branch of the Canadian Coast Guard, Transport Canada (TC), and Royal Canadian Mounted Police (RCMP) will help manage shipping traffic using proven protocols and safety systems to minimize the potential effects on commercial, recreational, and Aboriginal (CRA) fishers and other mariners. As a comparison, the Port of Prince Rupert is predicted to operate at approximately 80% of the large, commercial shipping traffic volume that is currently experienced at Port Metro Vancouver. The information on shipping traffic and salmon catch is provided in the "Effects of Lost Fishing Time" technical memo which will be filed with the BC EAO. Consequently, Aurora LNG is confident in the assessment and conclusion that, with the proposed mitigation, the potential Project effects on marine fisheries and on resource-based primary and subsistence economies will not be significant.
2671.1	round 1	Gitga'at First Nation	5.2.7.1	Economic Conditions	In s.5.2.7.1 (p5.2-98) the proponent concludes that the Project may cause some residual effects that are "distinguishable from current conditions and trends" but that these effects will be managed by planned mitigation and therefore are not significant. It is confusing to follow the logic that led the proponent to this conclusion. In effect, the proponent's logic is the following, based upon how they structured their analysis: (1) the effect is significant if it can be measured and mitigation doesn't address it, i.e., if there are measurable residual effects ('significance threshold' – see s.5.2.2.8 (p5.2-11)); (2) there are ways the Project might affect the VC ('project mechanisms' – see s.5.2.4 (p5.2-43)); (3) there are residual effects, and some residual effects are moderately to highly likely because mitigation might not totally work ('summary of residual effects' – s.5.2.5.4 (p5.2-87)); (4) but the residual effects are not significant because mitigation will work ('significance of effects' – s.5.2.7.1 (p5.2-98)). The same 'logic' is followed for the CEA on this VC. Please explain how you conclude both that there will be residual effects (i.e., mitigation won't be totally effective, and thus by your significance threshold's definition there are significant effects) yet your significance determination concludes that mitigation will totally address adverse effects. In other words, please reconcile the statement on p5.2-98 that there will be adverse residual effects but that these are predicted to be not significant.	Absent any well established quantitative thresholds for determining a significant economic effect (or most other socio-economic effects) the determination of significance is based on a assessment of whether there is a material and adverse change in the condition of the valued component,with incorporation of mitigation and management measures. "Distinguishable" in the context of the economic significance threshold definition, means distinct from current conditions or trends. In other words, the condition can be reasonably attributed to the Aurora LNG project rather than due to other economic factors, such as seasonal variations or structural changes affecting the economy (including such factors as in-migration, out-migration, closure and opening of other businesses and projects). The significance definition allows us to first characterize effects post mitigation, and based on this characterization determine if the significance threshold has been passed. If it is evident that there will be material un-mitigated residual adverse economic effects attributable to the Project then it may be considered significant. However, this conclusion will need to be made with appropriate consideration of the local economic context. For example, businesses may be both positively affected (through increased commercial activity) and adversely affected (through higher labour costs) by the presence of the Project. The application does not state that mitigation measures will "totally" address adverse effects, as indicated by the commenter. Rather, it is stated in Section 5.2.7.1 that adverse effects are expected to be managed by identified Project mitigation measures, as well as identified government programs, policies, and plans. Applicable government government programs, policies, and plans are identified in Section 5.2.2.1, and through the combination of these plans as well as Project specific mitigation measures, residual adverse effects on economic conditions will be not significant.
2672.1	round 1	Gitga'at First Nation	6.2.2.8	Visual Quality	Gitga'at has concerns regarding the threshold for significance. 1) Why use the Partial Retention VQC as the threshold as opposed to Retention or Modification VQCs? No justification is provided. 2) Why is the presence of VQ planning objectives among local authorities a criterion for significance? Would this not imply that the visual quality VC could have just been scoped out of the EA altogether if no planning objectives were present? Furthermore, it assumes that if no planning objectives were present, then visual quality is of no concern to any other groups who had input into the plans, which is almost certainly not the case. It also assumes that there are no groups external to the local planning process that are concerned about visual quality, which is not true given the Gitga'at's interests in the area. As such, we request that this criterion be omitted from the assessment.	The significance threshold used in the assessment of effects on visual quality incorporates a number of elements. These are: - The post-development EVC exceeds Partial Retention. - The average existing EVC was either Preservation, Retention or Partial Retention - The viewpoints from which the change is viewed are of moderate to high importance - Visual quality is documented as an important planning objective for government authorities in the LAA. These thresholds incorporate both quantitative and qualitative elements. The first two elements relate to existing visual condition (EVC) in the post-development and baseline conditions. EVC is a measure of the degree of visual disturbance that is present. This element indicates that if the project is causing the EVC to exceed partial retention (i.e. over 7% disturbance) in an area for which disturbance is less than 7% then this could result in a significant effect. A higher threshold for potential significant effect was not used because then even with substantial project-induced change to visual quality the effect would not be significant. The third element relates to importance. While there is a degree of subjectivity in quantifying "importance", the criteria considered include the number, type, and intensity of receptors that may be affected, including residences, scenic highways, tourist locations, and recreational areas. The fourth element, planning context, recognizes that the assessment of visual quality should not be based on measurable criteria only, but should incorporate the extent to which government agencies (local, regional, provincial) seek to protect visual quality as a policy objective. This element allows for the possibility that significance determination can be made even in situations where change in visual quality based on measured elements (e.g. EVC) does not warrant it. Conversely, if protection of visual quality in an area is not considered an important policy objective by relevant government and regulatory authorities then this is also relevant when making a significance determination.
2673.1	round 1	Gitga'at First Nation	6.2.5	Visual Quality	The justifications to exclude the shipping route from the assessment are not convincing. First, while the Project's LNG vessels will not add a "new visual element" to the viewscape, they are expected to triple the current shipping traffic through the PRPA, which is significant (if it is not considered significant, it should be explained why that is the case). Second, the Pacific Northwest LNG EA concluded that the effects of the project were not significant on the basis that there were no planning objectives specific to visual quality in any local development plans. As indicated in the previous comment, Gitga'at does not agree that this is an appropriate criteria to evaluate significance. Additionally, the Pacific Northwest LNG EA indicated that along with the terminal, the LNG vessels created a residual effect that triggered a cumulative effects assessment. No comparable CEA would be possible if shipping is scoped out of the assessment. Given the large increase in shipping traffic the Project will bring, a cumulative effects assessment including shipping is warranted. Gitga'at continues to request that an assessment of shipping on visual quality be included.	As discussed in Section 6.2.2.4 of the Application, the effects from shipping were not carried forward in the visual quality assessment because Project shipping will not result in a new visual element within the LAA (because the Prince Rupert Port is already regularly visited by large marine traffic), and based on the EAC Application results for the PNW LNG project (which is proposing to use similar sized ships, shipping frequency, and shipping route as for Aurora LNG) it was concluded that Project shipping will not introduce new visual elements or be visibly prominent from most viewpoints along the proposed shipping route.
2674.1	round 1	Gitga'at First Nation	6.2.3\6.2.5	Visual Quality	There seems to be a disconnect with respect to the assessment methodology and the determination of significance. The assessment goes to great lengths to describe the current and post-development EVC for each VSU affected by the project, but the final determination of significance is based only on the average change in EVC over the entire LAA. It is clear from table 6.2-14 that each of the three VSUs located on Digby Island will undergo significant changes to EVC, yet that is not considered at all in the significance determination. Given that the bulk of the analysis in the assessment is specific to the VSUs, the potential changes to EVC in those VSUs should be included as a criteria in the determination of significance.	The assessment considers the change to visual quality within the LAA, not change specifically from the assessed viewpoints. The four viewpoints that were analysed show potential effects from a number of different locations, including several locations located close to the facility. These viewpoints could be expected to be affected more than those located further away within the LAA. The assessment weighted the potential effects on the assessed viewpoints, but also considered the likely change to visual quality within the LAA overall. This balance is evident in Table 6.2-14 of the Application, which presents change in EVC both to individual visual sensitivity units, as well as to the overall view from each viewpoint.
2675.1	round 1	Gitga'at First Nation	6.2.5.2	Visual Quality	Table 6.2-14 indicates that the % Alteration for the Project Condition for the overall view of VP01 is 1.9%, but the EVC is listed as Retention, when it should be Partial Retention. The same goes for VLI 292 for VP02. Additionally, the Existing Condition EVC for VLI 280 should be Partial Retention.	In Section 6.2.5.2, Table 6.2-14, Page 6.2-39, the EVC of the Overall View for VP01 in the Project Condition should be changed to "Partial Retention" from "Retention." In the same table the EVC for VP02, VLI 292 should be changed to "Partial Retention" to "Retention." As well, the EVC for VPO2, VLI 280 should be changed to "Partial Retention" from "Retention." An errata document is being created that will capture this correction and it will be filed with the BC EAO.
2676.1	round 1	Gitga'at First Nation	6.2.3.2	Visual Quality	No information is presented on night time viewers of the landscape and/or night sky in order to establish context on any assessment of lighting effects. Are there any beaches or camp sites where the views of the night sky could be affected? Additional information is needed to assess the lighting effects.	It is acknowledged in Section 6.2.10 of the Application that the Project will contribute to skyglow in the Prince Rupert area. Depending on atmospheric conditions, the sky glow created by a combination of Prince Rupert, nearby industrial facilities, as well as the Project may be discernable from a considerable distance. However, the magnitude of sky glow generated from the Prince Rupert area at receptor locations located more than a few km away is likely limited by the relatively small size of the lit urban and industrial areas. Through the use of shielded and directional lighting fixtures (mitigations 4.7.9 and 6.2.1) the Project's contributions to sky glow will be minimized. Other lighting effects (glare and light spill) are more relevant to receptor locations within a direct line of sight to Project lighting. As discussed in Section 6.2.5.2 of the Application, the only residential receptors within a direct line of site of the Project are in Prince Rupert. There is a possibility that the Project will be visible from one campground - the Prince Rupert R.V. Campground, though topographical and/or vegetation screening are expected to limit the line of view towards the Project from this location. If the Project is visible from this location, it is anticipated that the change in visual quality will be similar to that for VP03 (Prince Rupert Residences), in that the Project will result in a small incremental change in a view already heavily modified by industrial development along the Prince Rupert waterfront.
2677.1	round 1	Gitga'at First Nation	6.2.3.2	Visual Quality	The selection of viewpoints did not include any considerations for use as light receptors. Of the four viewpoints selected, only VP03 was suitable as a light receptor, as it was the only one that people would actually visit at night. Additional receptors for the light assessment could have been identified that were appropriate for use in an assessment of lighting effects and were safe to access at night. We request that at least one additional view point as a light receptor be considered.	Other viewpoints were considered in the assessment of lighting effects, including potential receptor locations in Port Edward. However, because Port Edward does not have a direct view towards the Project, lighting effects were not assessed. Similarly, most streets in Prince Rupert run SW to NE, with most homes and commercial buildings oriented SE to NW (i.e. either looking back towards Mount Hays or looking across the harbour towards the Tsimshian Peninsula). Because the Project is located SE of Prince Rupert, and because of topographical shielding, it will not be visible to the majority of Prince Rupert residences. For this reason, VP03 was selected for assessing lighting effects, because it is the closest residential area within a direct line of site of the Project, and thus has the highest potential to experience adverse effects.
2678.1	round 1	Gitga'at First Nation	6.2.5.1	Visual Quality	The justification for the qualitative assessment of ambient light is based on the distance of VP03 from the Project, but no mention is made of the effect of sky glow, which could very well be apparent at that distance, especially under more rural conditions. A discussion of sky glow in the context of nighttime use of the surrounding landscape should be included in the justification of a qualitative assessment.	It is acknowledged in Section 6.2.10 of the Application that the Project will contribute to skyglow in the Prince Rupert area. Depending on atmospheric conditions, the sky glow created by a combination of Prince Rupert, nearby industrial facilities, as well as the Project may be discernable from a considerable distance. However, the magnitude of sky glow generated from the Prince Rupert area at receptor locations located more than a few km away is likely limited by the relatively small size of the lit urban and industrial areas. Through the use of shielded and directional lighting fixtures (mitigations 4.7.9 and 6.2.1) the Project's contributions to sky glow will be minimized. Other lighting effects (glare and light spill) are more relevant to receptor locations within a direct line of sight to Project lighting. As discussed in Section 6.2.5.2 of the Application, the only residential receptors within a direct line of site of the Project are in Prince Rupert. There is a possibility that the Project will be visible from one campground - the Prince Rupert R.V. Campground, though topographical and/or vegetation screening are expected to limit the line of view towards the Project from this location. If the Project is visible from this location, it is anticipated that the change in visual quality will be similar to that for VP03 (Prince Rupert Residences), in that the Project will result in a small incremental change in a view already heavily modified by industrial development along the Prince Rupert waterfront.
2679.1	round 1	Gitga'at First Nation	6.2.7.1	Visual Quality	It is not described anywhere how the average post-development EVC of the LAA was calculated, nor how that relates to Table 6.2-14, despite both items being critical to the assessment. Please include an explicit methodology regarding the calculation of average post-development EVC over the LAA.	The average post development EVC change resulting from the Project considered the change in views from assessed viewpoints, as well as potential visibility of the Project based on the viewshed analysis. The viewshed analysis shows that the Project will not be visible from most areas within the LAA (see Figure 6.2-5), and thus will not contribute to a change in visual quality for most of the LAA. Those areas where the Project is visible is represented by the four assessed viewpoints. Of the four viewpoints assessed, only VP02 (Mt. Hays) is expected to have an overall change in EVC that exceeds partial retention, and is attributable to the Project. For these reasons, it is concluded that the average post development EVC change in the LAA resulting from the Project will not exceed 7% (i.e. partial retention).
2680.1	round 1	Gitga'at First Nation	6.3.2.5	Infrastructure and Services	The boundary of the LAA is too restrictive in that the proponent doesn't seem to recognize the tight linkages between communities in the region. The quality of life in Hartley Bay, for example, is tightly linked to the services and infrastructure provided in the Prince Rupert area by way of for example: (1) health care, i.e., Gitga'at people travel to Prince Rupert and rely upon health care services there; and (2) housing, as many Gitga'at people live in Prince Rupert and are affected by costs of housing, and when Gitga'at people move back to Hartley Bay challenges arise in Hartley Bay given the insufficient volume of housing and the state of repair of many houses in the community. It is therefore not enough to include communities like Hartley Bay in the RAA; such communities should be in the LAA so that the EA fully covers the direct effects of the Project. Please revise the assessment to recognize the spatial extent of direct effects of major projects in the Prince Rupert area. It is also not simply enough to conduct assessments on an aggregated population.	Aurora LNG's understanding of Gitga'at First Nation's comment requesting the inclusion of Hartley Bay in the LAA to be: That member's quality of life could be adversely affected due to changes in infrastructure and services (e.g., accommodations [inclusive of hotels and motels] and health care) in Prince Rupert due to the ProjectOut-migration of members from Prince Rupert to Hartley Bay due to changes in the affordability and/or availability of housing in Prince Rupert could increase demand for housing in Hartley Bay (of which limited capacity exists to absorb increased demand).Socio-economic changes within Prince Rupert could affect the health and wellbeing of Gitga'at First Nation members due to tight linkages between Hartley Bay and Prince Rupert. Regarding the assessment of the following economic and social VCs: Sections 5.2 Economic Conditions, 6.3 Infrastructure and Services and 6.6 Community Health, communities included in the LAA are those where it is reasonably expected that direct interactions with the Project could occur, potentially resulting in adverse effects that could be predicted/estimated. It is recognized that Hartley Bay, as well as other communities within the region (e.g., Terrace and Aboriginal communities in the Terrace area) have economic and social ties to Prince Rupert. However, Aurora LNG maintains that there is much less potential for the Project to directly affect socio-economic conditions in Hartley Bay, compared to communities within the LAA. Aurora LNG recognizes that there could be indirect effects on Gitga'at members living in Hartley Bay – such as those identified above – but maintains that it is difficult to distinguish such phenomena from those resulting from other socio-economic changes occurring in the region (e.g. adverse effects are difficult to predict/estimate), and are therefore adequately addressed in cumulative effects assessments. For these reasons, Hartley Bay was not included within the LAAs for the socio-economic VCs noted above, but included in the RAA. As delineated and applied, the LAA and RAA for Sections 5.2, 6.3, and 6.6 also align with those used in similar applications within northwest BC. Specific to residual effects, it is important to note that effects assessed at the LAA level could also be realized by residents outside the LAA who may work within, draw upon, or visit the LAA. For example, Gitga'at members living in Hartley Bay who draw upon hotels, motels and health care services (among other considerations) from Prince Rupert could realize adverse effects associated with the Project as characterized at the LAA level. This rationale holds for other individuals, not just members of Gitga'at First Nation, within the RAA (and further) who may draw upon infrastructure and services within Prince Rupert. Due to potential direct Project interactions with Gitga'at First Nation harvesting locations, Hartley Bay is included in the LAA for the residual effect assessments 'change in resource-based primary industries and subsistence economies' (Section 5.2) and 'change in harvested foods' (Section 6.6). With respect to cumulative effects, as assessed in Sections 5.2, 6.3, and 6.6, cumulative residual effects are predicted to extend to the RAA (which includes Hartley Bay). This includes changes in economic conditions, infrastructure and services, and community health. Characterizations provided at the RAA level account for indirect effects noted by Gitga'at First Nation and would apply to members living in Hartley Bay. In summary, as per the methodology outlined in the AIR, Hartley Bay has not been added to the LAA as the community is outside of the spatial extent to which Project-related activities are anticipated to result in a direct, predictable and measurable adverse change in the referenced socio-economic VCs. The concerns identified in relation to Gitga'at First Nation members who live, work, draw upon services or visit communities within the LAA are already assessed within the socio-economic VCs as characterized at the LAA level. Aurora LNG believes that the concerns identified by Gitga'at First Nation in relation to the economic, employment and infrastructure and service linkages between Hartley Bay and Prince Rupert are therefore also assessed at the LAA level in aggregate-population form. Characterizations provided at the RAA level for Project and cumulative effects apply to members of Gitga'at First Nation members residing in Hartley Bay and cover concerns related to indirect socio-economic and cumulative effects from the Project. As part of its engagement with Gitga'at First Nation during development of the Social Management Plan, Aurora LNG will discuss specific socio-economic concerns and issues that may affect Gitga'at First Nation members, including residents of Hartley Bay.

2681.1	round 1	Gitga'at First Nation	6.3.2.7	Infrastructure and Services	On p6.3-11 (s.6.3.2.7) the proponent provides definitions of low, medium, and high likelihood. Each definition relies on the terms 'unlikely', 'likely', and 'highly likely' in the likelihood definitions, but what do these terms mean to the proponent? It is good practice to define expressions of probability in quantitative terms, such as the IPCC does in its climate change science communications (see Intergovernmental Panel on Climate Change (2010). Guidance Note for Lead Authors of the IPCC Fifth Assessment Report on Consistent Treatment of Uncertainties. Intergovernmental Panel on Climate Change. 4pp + Annexes. http://www.ipcc.ch/pdf/supporting-material/uncertainty-guidance-note.pdf), so that it is clear to all how the terms are being used and to ensure consistency among users of the terms. Please define what is meant by the terms unlikely, likely, and highly likely.	A qualitative approach is used to describe the likelihood of residual Project effects on infrastructure and services based on professional judgement and experience of the assessor. A definitive or quantitative approach to defining these terms (i.e., 0-15% chance of occurrence) is not practical. In general, the term 'unlikely' in this instance means that adverse effects between the Project and infrastructure and services are not predicted to occur. The term 'likely' in this instance means adverse effects between the Project and infrastructure and services are probable as it may be difficult to avoid or mitigate residual effects. The term 'highly likely' in this instance means adverse effects will occur as residual effects cannot be practically avoided or mitigated.
2682.1	round 1	Gitga'at First Nation	6.3.2.8	Infrastructure and Services	The significance threshold for this VC is defined as following: "A significant adverse residual effect on infrastructure and services would be an exceedance of available capacity, or a substantial decrease in the quality of a service provided, on a persistent and ongoing basis, which cannot be mitigated with current or anticipated programs, policies, or other mitigation measures (s.6.3.2.8 (p6.3-11))." This threshold is useful in that it provides a means by which Project impacts might be measured against: the notion that there are limits to the capacity of services and infrastructure, and that a minimum level of quality is necessary. However, the proponent doesn't define what a "substantial decrease" in quality means, nor how one might observe or infer that available capacity has been exceeded. These ambiguities weaken the proponent's, and everyone else's, ability to judge whether quality and capacity are acceptable or not. Please define the term 'substantial decrease' and explain how this is measured.	"Substantial" refers to a high magnitude measurable change from baseline conditions while available capacity is determined through baseline measures of service demand vs. planned and/or established operating thresholds or targets (see Section 6.3.3.2). Where thresholds or targets are not set by guidelines, management standards or regulations, a qualitative threshold was developed to present the limits of an acceptable change based on professional judgement and experience of the assessor. A definitive or quantitative approach to defining the term 'substantial decrease' (i.e., 0-15% decrease) is not practical for determining significance for infrastructure and services.
2683.1	round 1	Gitga'at First Nation	6.3.2.8	Infrastructure and Services	Furthermore, there is a logical error in the threshold: there could be a substantial decrease in quality of services and infrastructure but still be adequate quality (or the decrease could bring quality below what is acceptable, or the starting point for the decrease might already be below what is acceptable). The threshold must specify and communicate the minimum quality level that needs to be upheld. Along these lines, the proponent notes that acceptable change is guided by applicable legislation, regulatory guidance, other management standards, scientific literature, and/or professional judgment, but makes no reference to what Gitga'at and other stakeholders in the affected area think or feel. Please revise the threshold to specify the minimum quality necessary, and please incorporate stakeholder perspective on these minimum acceptable conditions. Please then revise your analysis accordingly.	"Substantial" refers to a high magnitude measurable change from baseline conditions while available capacity is determined through baseline measures of service demand vs. planned and/or established operating thresholds or targets (see Section 6.3.3.2). Where thresholds or targets are not set by guidelines, management standards or regulations, a qualitative threshold was developed to present the limits of an acceptable change based on professional judgement and experience of the assessor. A definitive or quantitative approach to defining the term 'substantial decrease' (i.e., 0-15% decrease) is not practical for determining significance for infrastructure and services. Regarding stakeholder perspectives, the influence of consultation (Section 6.3.2.2 of the Application) and traditional knowledge and traditional use incorporation (Section 6.3.2.3 of the Application) has been considered in the assessment and taken into consideration when determining the significance of predicted residual effects.
2684.1	round 1	Gitga'at First Nation	6.3.3.2	Infrastructure and Services	Gitga'at acknowledges the note/* on the "population segment" of Hartley Bay in 2011 is "likely incorrect"; however, Aurora LNG should not knowingly conduct assessments in an EA with incorrect information. Aurora LNG must consult Gitga'at in estimating an accurate number and revise the effects assessment accordingly.	As identified in Table 6.3-5, Statistics Canada reported the population of Kulkayu 4 (Hartley Bay) as 157 in 2006 but in 2011 reported the population as 20. This decrease seems unlikely and is identified as 'likely incorrect'. The change in population does not affect the effects assessment or conclusions of the assessment; rather, the changes in population would be characterized as being greater in magnitude (i.e., a greater percent change) assuming a population of 20.
2685.1	round 1	Gitga'at First Nation	6.3.3.2	Infrastructure and Services	It is clear with omissions throughout the Application that Aurora LNG does not have a good understanding on Gitga'at specific socio-economic conditions. For example, on p 6.3-63, the ferry running twice a week from Prince Rupert to Hartley Bay is not mentioned. The Application must be revised, which is important given that the route is through the area where air emission effects are predicted.	Aurora LNG acknowledges that the ferry running twice a week from Prince Rupert to Hartley Bay is not mentioned in Section 6.3.3.2. However, as Project workers will be transported from the Prince Rupert area to Digby Island via a Project-dedicated ferry, increased demand on the Prince Rupert to Hartley Bay ferry service is not expected. See Section 6.5 (Marine Use and Navigable Waters) for the assessment of change in marine navigation which applies to operation of this ferry service.See Section 4.2 (Air Quality) for a detailed discussion on predicted Project Air emissions.
2686.1	round 1	Gitga'at First Nation	6.3.5.1	Infrastructure and Services	In s.6.3.5.1 (p6.3-52), the proponent explains that their method is conservative for several reasons including that "[m]mitigation measures based on best practices and generally accepted forecasting address worst-case scenarios and are considered more than adequate for reducing an effect to acceptable levels." It is unclear if this is meant to communicate that there will not be any residual effects; we note that the proponent concludes (see Table 6.3-27 on p6.3-83) that there will be residual effects from the Project on the Services and Infrastructure VC. Please clarify the meaning of the quoted statement, and place the statement in the context of the broader method being used to assess residual effects.	A conservative approach (plausible worst-case scenario) was used to reduce the potential for underestimating the significance of an effect and err on the side of overstating an effect. The statement noted above, indicates that mitigation measures, using the conservative approach, are suitable for addressing worst-case scenarios and are more than adequate for reducing adverse effects. This statement is not meant to conclude that there are not residual effects.
2687.1	round 1	Gitga'at First Nation	6.3.5.2	Infrastructure and Services	In s.6.3.5.2 (p6.3-53; also elsewhere in the application), the proponent notes that they will build a camp for construction workers, and that this camp will be "closed-access, meaning that Project employees will be encouraged to remain onsite… Failure to adhere to the camp policies will result in worker termination." The wording of the two sentences raises the question about what exactly will be the policy towards staying in camp. Please clarify the policy that construction workers will be subject to with respect to leaving the work camp.	A closed-camp policy will be implemented that will expect employees to remain onsite. However, Aurora LNG cannot force workers to remain onsite. Those that do choose to leave the site will be in breach of the policy and face employment disciplinary actions potentially including termination. Additional details on camp-related accommodation policies will be provided in the Worker Lodging Plan (mitigation 6.3.10).
2688.1	round 1	Gitga'at First Nation	6.3.5.2	Infrastructure and Services	In Table 6.3-21 (p6.3-55), the proponent proposes a number of mitigation measures to address Project effects on services and infrastructure. The proponent writes that they expect the first mitigation – development of a social management plan – to be highly successful because of a new provincial government directive for LNG proponents to develop such plans and then monitor and report on results. The plan is not provided in the application but is promised following Project approval. Given that development of such plans to manage impacts of LNG development is a new measure with little testing in BC, and given that we are not able to see this plan at the present time, please indicate why Gitga'at, decision-makers and other stakeholders should have confidence in this mitigation measure.	Noted in Section 14.12 of the Application, the Social Management Plan (SMP) will follow guidance provided by the Ministry of Community Sport and Cultural Development (MCSCD 2014) and will be informed through SMP-specific engagement with various regulators, Aboriginal Groups, and other stakeholders. The description of the SMP provided in Section 14.12 provides a commitment from Aurora LNG and a framework from which further development of the SMP will occur. This level of detail is consistent with that of other applications and the AIR.
2689.1	round 1	Gitga'at First Nation	6.3.5.2	Infrastructure and Services	The second mitigation measure proposed in Table 6.3-21 (p6.3-55) is for alcohol and drug testing (this same mitigation measure is also presented in Table 6.3-26 (p6.3-79)). The proponent concludes that the measure will be highly successful because of the commonality of such policies in the oil and gas sector, and that the measure has low risk and uncertainty "because of well-established corporate policies". This measure, like the first and eighth in the table, highlights two broader problems with many mitigation plans proposed by the proponent which are (1) lack of distinction between implementation success and effectiveness at addressing adverse effects, and (2) a lack of, or insufficient, evidence that the measure will be effective. Please provide evidence as to whether such policies actually work, despite their commonality.	The alcohol and drug policy (mitigation 6.3.2) has a high likelihood of establishing a common and thorough understanding of Aurora LNG's standards related to drugs and alcohol at the workplace and will reduce the potential personal risks and risks posed to nearby communities (see 'mitigation mechanism' under mitigation 6.3.2). Aurora LNG recognizes that the success of mitigating potential drug and alcohol-related effects on local residents will depend on the level of engagement and standards communicated to the workforce when they are not working. To reduce potential effects on nearby communities from workers while off-shift, Aurora LNG will require all staff and contractors to undertake a worker orientation (mitigation 6.3.3) that will include communication of expected behaviour when transiting to/from local communities (a worker code of conduct) and cross-cultural awareness to help build awareness and respect of local concerns and customs to reinforce the importance of respectful conduct when in communities (the expected success of this mitigation is moderate).
2690.1	round 1	Gitga'at First Nation	6.3.5.2	Infrastructure and Services	Mitigation 6.3.5 (construction camp) - does this include the cruise ship camp that is also proposed? It is not clear in the Application if the effects of this camp (both socio-economic and environmental) have been assessed. If so, please provide where they are assessed. If not, please revise the Application to include the assessment.	Please see the "Floating Camp Review" technical memo which will be filed with the BC EAO.
2691.1	round 1	Gitga'at First Nation	Table 6.3-22	Infrastructure and Services	Mitigation 6.3.11 "engage with local communities and Aboriginal Groups to address community concerns associated with the Project", lists for expected success "this is a standard mitigation that has a moderate to high likelihood of success" - please provide effectiveness evidence to support this claim.	Regarding mitigation 6.3.11, this is a standard mitigation used in the oil and gas sector and as such has a moderate to high likelihood of success. Communication and engagement is known to be valuable in managing the relationships between Aurora LNG, Aboriginal Groups, communities, and stakeholders. This mitigation measure has a moderate degree of risk and uncertainty which relate to the willingness of residents and stakeholders to participate in the proposed engagement activities.
2692.1	round 1	Gitga'at First Nation	Table 6.3-26	Infrastructure and Services	Mitigation 6.3.16 "heliport for medivac transfers will be constructed. In the event of injury requiring evacuation of workers via air ambulance, Aurora LNG will coordinate with local and provincial health providers for evacuation to appropriate medical facilities" - will Aurora LNG have their own "air ambulance"? Also, what impacts to the accessibility of the heliport at the local and provincial health providers is expected?	As outlined in Section 1.2.5 of the Application, a heliport is proposed to enable emergency evacuation of injured personnel to appropriate medical facilities. It is not anticipated that Aurora LNG will own their own air ambulance. To limit the potential that Project-related patient transfers could affect services to resident populations, as noted in Mitigation 6.3.16, "...Aurora LNG will coordinate with local and provincial health providers for evacuation to appropriate medical facilities". This coordination would include all involved parties, not limited to Northern Health, Patient Transfer Network (PTN), and BC Ambulance Services (BCAS). In addition, the Health and Medical Services Plan (mitigation 6.3.13) will outline patient transfer and escalation procedures (as recommended by Northern Health in its best management guide).
2693.1	round 1	Gitga'at First Nation	6.3.5.2	Infrastructure and Services	The 7th measure proposed in in Table 6.3-21 (p6.3-55) exhibits another problem with some mitigation measures, that of contradictions that seem to arise due to the proponent's discussions of both 'expected success' (i.e., which seems to mean the level of expected success in the face of uncertainty) and 'risk and uncertainty' for each mitigation measure. The measure entails informing local governments about Project-induced population change. The proponent concludes that as an established strategy "[t]here is a high degree of likelihood that the mitigation will be effective" yet "[t]here is moderate risk and uncertainty" that it won't work due to reliance on the local authority to do something with the information that the proponent provides. Please reconcile the statements on expected success and risk and uncertainty for measure 6.3.7 so that we have a clearer idea if, and why, the measure will be effective, and what the uncertainties and associated risks are if the measure fails.	The high degree of likelihood was determined as this measure is expected to be effective at mitigating adverse effects. However, there is uncertainty associated with this mitigation as it is up to the local authority to make the necessary changes or improvements which are not within the control of Aurora LNG. In addition to this mitigation measure, it is expected that the social management plan (Mitigation 6.3.1)will include an adaptive management framework. Aurora LNG's framework for adaptive management is as follows: management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended). This could help address unanticipated effects on community infrastructure and services.
2694.1	round 1	Gitga'at First Nation	6.3.5.2	Infrastructure and Services	As with employment numbers presented in ss. 1 and 5.2 of the application, it is unclear how the proponent estimated the proportion and number of workers would in-migrate or work on a FIFO basis in s.6.3.5.2 (p6.3-60). Please explain the method used and any assumptions adopted to estimate how many jobs in each phase will flow to locals, non-locals, including in-migrants and FIFO workers.	Aurora LNG's predicted break-down of FIFO labour is based on consideration of the skills needed to construct, operate and maintain the LNG plant, overall understanding of the labour market, and anticipated potential to "train-up" workers for operational positions. Construction of various Project components as well as operation and maintenance of the LNG plant will require a highly trained and experienced workforce. Aurora LNG anticipates that a substantial proportion of its operating workforce will consists of BC residents, whose skills will be developed through technical training programs and hands-on experience at other construction sites and overseas LNG plants. Nevertheless, because of the limited LNG construction, operation and maintenance expertise available in Canada, Aurora LNG anticipates that a proportion of its workforce will be hired from outside Canada. This proportion should decline over time, as more "homegrown" LNG expertise is developed.
2695.1	round 1	Gitga'at First Nation	6.3.5.2	Infrastructure and Services	In s.6.3.5.2 (p6.3-63) the proponent points out that in-migrating workers and their families (i.e., who move to the Prince Rupert area) will contribute to the local tax base. This is a good point and helps address a gap in the benefits section of the application pertaining to the lack of information provided there on the net economic benefits of the project. As pointed out on p6.3-63, incremental burdens on services and infrastructure will be offset to some extent by incremental tax revenue. But the larger question arises as to what exactly are the estimated net effects on services and infrastructure. Please revise your assessment to provide a financial accounting of net effects on different levels of government by comparing tax revenues associated with the Project and tax burdens associated with the Project.	The level of detail provided in the Application is sufficient for an Environmental Assessment, which is considered a planning document. As such, a cost-benefit analysis comparing Project-residual effects on community, transportation, and health care infrastructure and services against estimated government revenues is not required or a requirement of the Application Information Requirements. However, with respect to the City of Prince Rupert, as noted and referenced throughout Section 6.3.3.2, cost estimates have been derived by the City regarding capital expenditures required to sustain current operations as well as capital expenditures required to support the LNG industry in northwestern BC (see the report City of Prince Rupert Preparing for Growth - KPMG Report). Reference KPMG .2015. City of Prince Rupert Preparing for Growth –KPMG Report. Available at: http://www.princerupert.ca/sites/default/files/Planning/MajorProjects/City%20of%20Prince%20Rupert%20-%20Preparing%20for%20Growth%20-%20KPMG%20-%20Jan%2022%2C%202015.pdf. Accessed: January 2016.
2696.1	round 1	Gitga'at First Nation	6.3.5.3	Infrastructure and Services	In the section on 'project mechanisms' in s.6.3.5.3 (p6.3-64) the proponent notes several ways in which the Project might affect accommodations, but this discussion omits one important pathway of effect: that during construction, despite the construction of a work camp to house construction workers, there may be pressure from Project staff or contractors on available accommodation in Prince Rupert. My understanding is that Kitimat experienced housing shortages and rent escalation in recent years despite the use of work camps (including a cruise ship to house workers). This pathway is explored in subsequent pages but it seems important to make clear in the 'project mechanisms' section that Project construction will put pressure on accommodation infrastructure. Please justify the omission of pressure on accommodations during construction or revise material accordingly to reflect the scope of the effects assessment.	The "Project mechanisms" acknowledges that Project-related demographic changes have the potential to affect the demand for accommodations throughout the life of the Project, including during construction. Adverse effects on accommodations during construction is not noted in the Project mechanisms; however, it is not omitted from the assessment of residual effects. Project mechanisms provide a general overview of key potential effects.
2697.1	round 1	Gitga'at First Nation	6.3.5.3	Infrastructure and Services	In s.6.3.5.3 (p6.3-67) the proponent notes that despite construction of a camp to house construction and (later) operations FIFO workers there will be pressure on accommodation infrastructure in the LAA communities (most notably Prince Rupert). This conclusion makes sense. However, it seems odd that the proponent only refers to hotels, motels, and possible future 'open lodge' worker accommodations as places where Project workers as well as indirect and induced employees will live prior to the construction of the Digby Island worker camp and new housing in Prince Rupert. Why are rental homes, rental suites, rental apartments, etc. excluded and assumed to not be used during the Project's early years? In the albeit limited discussion of rental housing stock in s.6.3.3.2 (p6.3-38) the proponent noted that rental prices have been rising since 2008 and rental vacancy was only 3.8% in 2015, suggestive of a tight rental housing market translating very possibly to many vulnerable households. Please explain why rental accommodations are omitted from consideration in the effects assessment.	During construction, an estimated 95% of the peak workforce is anticipated to be comprised of fly-in/fly-out (FIFO) workers, 3% current residents of the LAA/RAA and 2% in-migrating workers (100 workers). To clarify, short-term, early Project demand for housing from FIFO site-preparation workers will likely be accommodated by a floating camp, local hotels and motels or 'open lodge' worker accommodations because the amount of housing required will vary and the length of time that the accommodations will be required will be short term (i.e., limited to the duration of shifts). Once the construction camp is set up, FIFO site preparation workers will be lodged at the on-site camp. In the longer term, in-migrating workers (this considers workers [direct, indirect and induced] in-migrating during construction and operations) will increase demand for renter-occupied and owner-occupied accommodations. To reduce adverse Project effects on accommodations, Aurora LNG will implement a Worker Lodging Plan (see Section 14 Summary of Proposed Environmental and Operational Management Plans). The details of the Worker Lodging Plan will be developed prior to commencement of the Project phase to which it applies, consistent with any requirements outlined in EAC conditions.
2698.1	round 1	Gitga'at First Nation	6.3.5.3	Infrastructure and Services	The assessment on accommodation infrastructure seems divorced from what I would think is the most important housing issue in the study area – housing challenges experienced by vulnerable people. To its credit, the baseline material on housing explored core housing need, seniors housing issues, and other related topics, and thus recognized that there are vulnerable households in the area, and the proponent noted the connections between low income, costs of housing, and health in s.6.6.3.2 (pp 6.6-22 and 6.6-26). Yet the effects assessment of the Services and Infrastructure VC completely omits any discussion of how the Project may affect vulnerable households. Please explain the omission of discussion in this VC of potential Project effects on vulnerable households, and please estimate how the Project will affect housing for such households.	Section 13.5.4.5 of the Application acknowledges that vulnerable groups in Prince Rupert, such as low income households, will be affected by the increase in cost of living more severely than those that can participate in the economic benefits of the Project through high paying job opportunities. This section also notes that there will be indirect economic changes that cannot be managed directly through the proposed Project mitigation, especially during the construction phase. Aurora LNG will engage with local communities and Aboriginal Groups to address community concerns associated with the Project (mitigation 6.3-15). Aurora LNG will also develop and implement a community grievance process for addressing issues related to the Project (mitigation 6.4-8).
2699.1	round 1	Gitga'at First Nation	6.3.5.4	Infrastructure and Services	In s.6.3.5.4 (p6.3-76) the proponent predicts that, "with mitigation, the Project will result in low to high magnitude", continuous, reversible residual effects on transportation infrastructure in a low to moderate resiliency context. On the next page (p6.3-77) the proponent then says that adverse effects "can largely be avoided, and there is a low likelihood of residual adverse effects". This is very confusing because the two statements seem to contradict one another. Please clarify your conclusion of the Project's effects on transportation infrastructure.	The likelihood describes the probability of an adverse residual effect (in this case predicted to be low to high in magnitude) occurring on infrastructure and services and is determined based on an understanding of the potential effect and the mitigation available to reduce or avoid the predicted effect. A low likelihood was selected because, based on Project design (i.e., demand on transportation infrastructure and services), the expected success of proposed mitigation measures, the information obtained during consultation and engagement with service providers, and professional judgment of the assessor, adverse effects can be largely avoided or mitigated and it is therefore unlikely for residual effects (low to high in magnitude) to occur.
2700.1	round 1	Gitga'at First Nation	6.3.5.5	Infrastructure and Services	Mitigation measure 6.3.13 in presented in Table 6.3-26 (p6.3-79) indicates that the proponent will develop a Health and Medical Services Plan to reduce pressure of Project-related population growth on local health care. The proponent notes that they expect the success of the measure to be high, with low risk and uncertainty. However, as with other management plans that the proponent says in the application that it will create, we have no way of evaluating the plans nor knowing without seeing what is in them how effective they might be. Just as will other mitigation measures it is incumbent upon the proponent to demonstrate that they have a mitigation plan that can reasonably be expected to work. Please provide all management plans prior to requesting an EA application so that decision-makers and stakeholders can evaluate the plans.	The Health and Medical Services Plan (HMSP) will be developed with reference to Northern Health's "Health and Medical Services Plan Best Management Guide for Industrial Camps" (March 2015). The HMSP will complement the Social Management Plan (mitigation 6.3.1) by outlining health and medical policies, services and protocols to be implemented at the worker accommodation camp. The HMSP is an internal shared document between Aurora LNG and Northern Health. Development of the Social Management Plan, which includes consideration of health care infrastructure and services (the subject matter mitigated through the HMSP), will be informed through engagement with appropriate regulators, Schedule B Aboriginal Groups and other interested stakeholders.

2701.1	round 1	Gitga'at First Nation	6.3.5.6 and 6.3.6.3	Infrastructure and Services	In Table 6.3-27 (s6.3.5.6 (p6.3-83)) the proponent presents a summary of predicted residual adverse effects on services and infrastructure. The effects predicted include those of high magnitude, some are continuous and of long duration, some are within low resilience contexts, and some are given a high likelihood of occurring. Yet, in the CEA section for this VC (s.6.3.6.3 (p6.3-89)) the proponent notes that because other major project developers propose similar mitigation measures as that proposed for Aurora LNG, cumulative adverse effects are expected to be "managed to an acceptable level". This statement in the CEA section would seem to contradict the conclusions presented in Table 6.3-27. On p6.3-90 the proponent then seems to make a contradiction again by writing that the CEs of all development including the Project "are expected to be high in magnitude, extend throughout the RAA, will occur continuously over the long-term and occur within a socio-economic context that has low to moderate resiliency to change." The back-and-forth nature of the material occurs elsewhere in the application and makes the material challenging to understand because it is hard to reconcile the seemingly contradictory statements. This does everyone a disservice. Please explain why the effects of multiple major projects will be 'managed to an acceptable level' when it is stated that other projects will use mitigation measures similar or even identical to Aurora LNG and at the same time it is concluded that the Aurora LNG project will cause numerous adverse residual effects (i.e., despite planned mitigation).	The statement "acceptable level" is based on the assumption that other proponents, as well as Aurora LNG will, in good faith and based on regulatory requirements and certificate conditions, implement mitigation measures and work with local communities to address adverse socio-economic effects. The comment correctly notes that no LNG projects have been constructed along the North Coast in BC, so the actual effectiveness of proposed mitigation measures has yet to be determined. Aurora LNG predicts that there is a low likelihood of the cumulative effects scenario occurring (i.e. multiple LNG projects being built concurrently – see Section 5.2.8 – Prediction Confidence). However, if the scenario does occur, then the cumulative effect on labour and economy during construction is predicted to be of high magnitude.
2702.1	round 1	Gitga'at First Nation	6.3.6.4	Infrastructure and Services	The discussion in the second paragraph on p6.3-91 (in s.6.3.6.4) explains that the proponent predicts that CEs on housing of all of the major project development in the area "is not expected to affect the availability of housing over the long term" and that "[o]ver time, housing markets are expected to adjust in increased demand and correction of the housing market will mitigate potential adverse effects", but then in the last two paragraphs on the same page the proponent concludes that impacts on housing will occur over the long-term. Please clarify what the conclusion is with respect to the timeframe of impacts on housing.	Cumulative demand for accommodations will temporarily exceed available supply until the housing market can adjust to changes in market pressure. Over the longer term, the housing market is expected to return to a supply/demand balance; however, net effects (i.e., increased demand from baseline conditions) related to population change (i.e., increased population) will persist.
2703.1	round 1	Gitga'at First Nation	6.3.6.4	Infrastructure and Services	As noted on p10 of the CEA Agency's most recent guidance on characterization of residual adverse effects, reversibility is about recovery of effects "within a reasonable timescale" (CEA Agency, 2015. *Determining Whether a Designated Project is Likely to Cause Significant Adverse Environmental Effects under the Canadian Environmental Assessment Act, 2012* . 11pp.). The timeframe of the CEs of the Project and other major projects on housing is on the order of one or more decades, a duration of which can have lasting and potentially permanent impacts on persons subject to housing challenges, and yet the proponent says explicitly (e.g., last two paragraphs of p6.3-91) and implicitly elsewhere that the impacts on housing are reversible. Please justify the conclusion that impacts on housing are reversible and whether this is a reasonable qualification in light of the nature of impacts of housing challenges on vulnerable households.	See table 6.3-4 for the definition of reversibility used in the assessment of infrastructure and services. The definition of reversibility from the referenced guide, updated July 2016, is as follows: "A reversible environmental effects is one where the VC is expected to recover from the environmental effects caused by the Project. This would correspond to a return to baseline conditions or other target (e.g., a population management objective, remediation target), through mitigation or natural recovery within a reasonable timescale. Reversibility is influenced by the resilience of the VC to imposed stresses and the degree of existing stress on that VC". With reference to the cited guidance from the CEA Agency, residual effects on accommodations are anticipated to be reversible (to anticipated management objectives [in this case understood to be reflective of historical trends]) following decommissioning (as the Project will have effects on accommodations during decommissioning). This characterization is made in recognition that effects will commence with construction and perpetuate, albeit of differing magnitude and for differing accommodations, until the completion of the last phase of the Project (decommissioning). While this characterization is (as noted in the comment) decades in duration, as characterized in Section 6.3.5.4, the housing market in the LAA and RAA is considered responsive to market pressures and over the long term will adjust for increased demand. It is therefore not likely that high-demand, limited supply housing conditions would perpetuate within the LAA and RAA for decades without an adjustment in supply. In other words, it is unlikely that effects would not reverse (in this case return to a level that is consistent with management objectives) within a reasonable timescale.
2704.1	round 1	Gitga'at First Nation	6.3.7.1	Infrastructure and Services	The proponent concludes that the Project itself won't cause a significant effect on health care given that the additional pressure that it (especially the in-migrating population associated with the Project) will not be persistent (s.6.3.7.1 (p6.3-97)), despite health care in the LAA already failing to meet demands of the existing population (s.6.3.3.2 (p6.3-18+)). Yet, the proponent concludes that with other major project development occurring, effects on health care (and housing) will be significant because it will be "ongoing", i.e., persistent (p6.3-97). Given that there will not realistically be a future to which the only change from present is that the Project proceeds, i.e., other development will also occur thus other pressures on top of the Project on services and infrastructure will also occur, the Project will necessarily contribute to causing significant effects on the VC. Please explain how one can find a conclusion of non-significance for Project effects on the services and infrastructure yet find a conclusion of significance for CEs on the VC when the Project would only occur alongside these other sources of CEs, i.e., when the only future that is realistic is one in which both the Project and other major projects contribute to CEs on this VC. The Project's contribution relative to other projects' contributions to CEs is a separate issue.	The assessment for Project effects and cumulative effects as included in the Application, follow the requirements of both the British Columbia Environmental Assessment Act (BCEAA) and the Canadian Environmental Assessment Act 2012 (CEAA 2012). The Project effects were assessed utilizing baseline data, which incorporates known existing effects associated with other, already established projects within the LAA, and where applicable, RAA. The assessment of Project residual effects aligns with the aforementioned guidance to determine the extent to which the Project could potentially affect health care infrastructure and services. This distinction is important (from that of cumulative effects) as it informs the development of Project-specific mitigation measures. That is, it would be unreasonable to expect any one proponent to mitigate all adverse effects on health care infrastructure and services. To this end, taking into consideration the Project's peak construction and operations workforce, the composition of these workforces comprised of fly-in/fly-out workers (95% during construction and 20% during operations), Project design (i.e., a closed-access camp) and proposed mitigation (e.g., an on-site medical facility), it is reasonable to conclude that Project-specific adverse effects on health care infrastructure and services are predicted to be moderate to high and short-term to long-term (depending on Project phase; see Table 6.3-27) but will not be significant (see Section 6.3.2.8 for the significance threshold for infrastructure and services and Section 6.3.7.1 for the determination of significance of Project residual effects). With reference to the reviewer's statement that "the only future that is realistic is one in which both the Project and other major projects contribute to CEs on this VC". If the reviewer is of the position that there are likely multiple projects that will be established within the RAA in the long term, then the Significance of Residual Cumulative Effects presented in Section 6.3.7.2 remains relevant. As stated in Section 6.3.7.2 and within the reviewer's comment, the difference of significance determination between Project residual effects and residual cumulative effects was principally driven by the potential for multiple projects (cumulative) to increase demand by way of an increase in population (estimated to be a 40% increase over baseline projections) within the RAA. Increased demand associated with this population increase is estimated to result in significant adverse effects (see Section 6.3.2.8 for the significance threshold for infrastructure and services and Section 6.3.7.2 for the determination of significance of residual cumulative effects).
2705.1	round 1	Gitga'at First Nation	6.5.2.6	Marine Use and Navigable Waters	The definition of moderate magnitude effects in Table 6.5-5 (s.6.5.2.6 (p6.5-12)) uses the terms 'lower activity level' and 'moderate areas of navigable waters'. The definitions of low and high magnitude effects also rely on ambiguous qualifiers that are open to interpretation. Please explain what these terms mean so that Gitga'at, decision-makers and other stakeholders are able to evaluate conclusions reached in the effects assessment. It might help to specify quantitative categories using units such as km2, or proportions of the LAA or RAA.	Residual effects are described using multiple characterizations (e.g., magnitude, geographical extent, frequency, etc.) with either quantitative (e.g., an area, distance, or count) or qualitative (e.g., low, medium, high) measures for each characterization. Wherever possible and reasonable, quantitative measures are preferred to promote understanding of the potential effects. However, where quantitative federal or provincial standards/thresholds, or industry guidelines are lacking, qualitative descriptions must be used to describe potential effects. The characterizations, descriptions, and definitions used for Marine Use and Navigable Waters are provided in Table 6.5-5. The intent of Table 6.5-5 is to provide a conceptual overview of the characterizations and how they are used to inform and illustrate the effects assessment. Additional context and supporting detail is provided in the accompanying text discussions.
2706.1	round 1	Gitga'at First Nation	6.5.2.8	Marine Use and Navigable Waters	The significance threshold for this VC is defined as "one where the Project-activities are not compatible with established marine use plans or policies, or where the Project will create a change or disruption that widely restricts or degrades present marine uses to a point where the activities cannot continue at current levels and for which this change cannot be mitigated (s.6.5.2.8 (p6.5-14)). This threshold is arbitrary in that it is not clear how it is connected to Gitga'at values. While marine use plans and policies may embody Gitga'at values, it is presumptuous to assume that current levels of use are acceptable to Gitga'at. Significance is fundamentally about Gitga'at values, and so significance thresholds must be connected in some way to Gitga'at values, whether known or judged. Elsewhere in the application the proponent seems to recognize that the baseline for primary resource-based activities may be compromised – p1-51 (s.1.3.2) with regards to steady growth in industrial and other use of the region, and p6.6-41 (s.6.6.3.2) with regards to industrial development and traditional harvesting – but the significance threshold and significance determinations don't reflect this important context. Please justify the presumption made in the threshold that current levels of marine use and activities are acceptable to Gitga'at, and as necessary please revise the threshold and subsequent effects assessment and significance determination accordingly.	A determination of significant residual Project effects for Marine Use and Navigable Waters is one where the proposed Project activities are not compatible with established marine use plans or policies, or where the Project will create a change or disruption that widely restricts or degrades present marine uses to a point where the activities cannot continue at current levels and for which this change cannot be mitigated (see Section 6.5.2.8). Key elements of this threshold are explained further:"Not compatible" indicates that the Project completely eliminates the option to practice a marine activity."change or disruption that widely restricts or degrades present marine use" indicates that the potential Project effect has a large geographical extent or severely reduces the ability to practice a marine activity relative to the existing conditions."Cannot continue at current levels and for which this cannot be mitigated" indicates that the current marine practices cannot continue even with mitigation. The assessment used extensive data, including: literature, government reports, other Environmental Assessment Applications from similar projects in the region, and Traditional Use and Knowledge studies. Issues specific to Aboriginal Groups were assessed in Part C of the Application. Data were obtained from Fisheries and Oceans Canada (DFO), the Pacific Pilotage Authority (PPA), the British Columbia Marine Conservation Analysis (BCMCA) online database (see Section 6.5.3 for more information on the information sources, and the "Effects of Lost Fishing Time" technical memo for further assessment of marine fisheries). The assessment made conservative assumptions to improve prediction confidence. A discussion of the assumptions made and prediction confidence are provided in Sections 6.5.5.1 and 6.5.8, respectively. Overall, Aurora LNG is confident in their understanding of the baseline conditions, the assumptions made, and the conclusion of no significant adverse effects on Marine Use and Navigable Waters.
2707.1	round 1	Gitga'at First Nation	6.5.3	Marine Use and Navigable Waters	The baseline information provided in s.6.5.3 provides a description of activities and players and designations but provides no context from which to understand future impacts; no information is provided on the adequacy of current marine uses and navigation conditions to stakeholders nor the factors that have contributed to current conditions. For example, the baseline does not relay historical and recent factors contributing to a decline in commercial fishing nor sentiments (i.e., value statements that are critical to understanding the significance of these changes) towards this decline among seafood industry stakeholders. Similarly, the historical, political, and economic factors shaping Aboriginals' harvesting and other marine activities is not explored, and no information is provided on Aboriginals' contentedness with current harvesting levels and conditions. This context is critical to interpretation of the Project's effects, as well as to the interpretation of the effects of other major project development. It is not enough to know what activities occur; quality effects assessment requires a grounding in the acceptability of VC conditions and knowledge of why VC conditions are the way they are. This gap in the baseline has erroneously resulted in the proponent concluding that the context for Project effects on these VsCs is 'high resiliency', as seen in Table 6.5-16 (s.6.5.5.4 (p6.5-63)) where the summary of predicted residual effects of the Project are presented. The proponent posits that the context for Project effects is high resiliency "on account of the experience of the [Prince Rupert Port Authority] and involvement of other agencies such as [Transport Canada, Canadian Coast Guard, and the Pacific Pilotage Authority]", the long shipping history in the area, and the size of available fishing space in the area (p6.5-62). No consideration seems to be given to the possibility that political, regulatory, economic, oceanographic, or other factors might create a very vulnerable context for further impacts on marine use in the area, and that the context might accordingly be 'low resiliency'. Please provide additional baseline material exploring the acceptability of current conditions for marine users, the broad array of factors that shape marine use conditions, and revise effects assessment accordingly.	The assessment used extensive data, including: literature, government reports, other Environmental Assessment Applications from similar projects in the region, and Traditional Use and Knowledge studies to understand the current marine use conditions in the Regional and Local Assessment Areas (RAA and LAA). Data were also obtained from Fisheries and Oceans Canada (DFO), the Pacific Pilotage Authority (PPA), the British Columbia Marine Conservation Analysis (BCMCA) online database (see Section 6.5.3 for more information on the information sources). This information was more than sufficient to carry out the assessment as outlined in the Application Information Requirements (AIR). For example, as outlined in the AIR (Section 6.5), potential effects on marine navigation were to be assessed using an understanding of the physical characteristics of the channel (Table 6-7). Consequently, measurements of the marine infrastructure and their effect on channel dimensions were discussed. Similarly, potential effects on marine fisheries were to be assessed using an understanding of fishing locations (and their overlap with the shipping route), gear used, and shipping traffic volume (Table 6-7). This information was provided in the assessment. While additional information on the historical, political, and economic factors contributing to Aboriginal and other seafood stakeholder 'contentedness' would provide added context for the assessment, it is not required to assess the parameters described in the AIR. Resilience refers to the ability to accommodate a disturbance without adverse effects (Table 6.5-16). Marine use and navigable waters was assessed as 'high resilience' because it has many traits that make it able to withstand change (e.g., additional shipping traffic or construction of new marine infrastructure) without manifestation of significant adverse residual effects. For example, the Port of Prince Rupert has been in use since 1914 and was established as a federal port with a governing body (e.g., the Prince Rupert Port Authority [PRPA]) since 1997 (Section 6.5.3.2). The PRPA has extensive traffic management and safety systems in place to promote safe navigation in the port. In addition to the approximately 20 years of experience the port has managing vessel traffic, they are supported by the Marine Traffic Communications Services (MCTS), Pacific Pilotage Authority (PPA), Transport Canada (TC), and the Royal Canadian Mounted Police (RCMP) who also have extensive experience and expertise. These government and non-government agencies will promote and enhance navigational safety in the Port of Prince Rupert. Given the long history of use (e.g., by commercial shipping traffic, commercial, recreational, and Aboriginal (CRA) fishers and other shipping traffic), established international and national safe-navigation protocols (e.g., the Collision Regulations and those implemented by the PRPA, and the use and continual improvement of navigational technology), and the mitigation measures proposed by Aurora LNG (see Table 6.5-14), the marine use and navigable waters VC was assigned a status of 'high resilience' with respect to potential Project effects.
2708.1	round 1	Gitga'at First Nation	6.5.2.7	Marine Use and Navigable Waters	On p6.5-14 (s.6.5.2.7) the proponent provides definitions of low, medium, and high likelihood. Each definition relies on the terms 'unlikely', 'likely', and 'highly likely' in the likelihood definitions, but what do these terms mean to the proponent? It is good practice to define expressions of probability in quantitative terms, such as the IPCC does in its climate change science communications (see Intergovernmental Panel on Climate Change (2010). Guidance Note for Lead Authors of the IPCC Fifth Assessment Report on Consistent Treatment of Uncertainties. Intergovernmental Panel on Climate Change. 4pp + Annexes. http://www.ipcc.ch/pdf/supporting-material/uncertainty-guidance-note.pdf), so that it is clear to all how the terms are being used and to ensure consistency among users of the terms. Please define what is meant by the terms unlikely, likely, and highly likely.	For the assessment of marine use and navigable water there is no empirical basis for assigning quantitative probabilities. Therefore, a qualitative approach is used to describe the likelihood of residual Project effects on marine use and navigable waters based on professional judgement and experience of the assessor. In general, the term 'unlikely' in this instance means that adverse effects between the Project and marine use and navigable waters are not predicted to occur. The term 'likely' in this instance means adverse effects between the Project and marine use and navigable waters are probable as it may be difficult to avoid or mitigate residual effects. The term 'highly likely' in this instance means adverse effects will occur as residual effects cannot be practically avoided or mitigated.
2709.1	round 1	Gitga'at First Nation	6.5.5.2	Marine Use and Navigable Waters	Mitigation measure 4.11.2 presented in Table 6.5-13 (s.6.5.5.2 (p6.5-51)) is that Project vessels including LNG carriers will not exceed a speed of 16 knots. However, the proponent writes that "[t]his mitigation will *promote* safe operating speeds" (italics added), "[t]his mitigation is in*support* " of collision regulations (italics added), and that "this mitigation *can* be enforced" by the Prince Rupert Port Authority. The proponent expects a "[h]igh likelihood of success". The various language used suggests that Project vessel speeds will not necessarily be 16 knots or less, and thus calls into question how effective the mitigation measure will actually be. This issue of implementation success vs. effectiveness is one common to many mitigation measures presented in the application. Please clarify whether the port authority does enforce speeds and provide evidence pertaining to the success of such enforcement at controlling the speeds of vessels in the port authority's jurisdictional boundaries.	The Prince Rupert Port Authority (PRPA) will be responsible for enforcing vessel speed limits within the PRPA-boundaries (see Figure 6.5-4 to see the boundary). For additional information, see the "Port Information Guide" for the Port of Prince Rupert. Available at: http://www.rupertport.com/port-information-guide.pdf. Port pilots will also play an important role in maintaining safe passage of LNG vessels. For additional discussion on the effectiveness of the proposed mitigation measures, see the "Effects of Lost Fishing Time" technical memo which will be filed with the BC EAO.
2710.1	round 1	Gitga'at First Nation	6.5.5.2	Marine Use and Navigable Waters	As with other VCs, mitigation of Project effects on this VC relies in part on management plans that are yet to be developed by the proponent. For example, a Marine Activities Plan will be developed to facilitate communication between the proponent and other marine users during construction (Table 6.5-14 in s.6.5.5.3 (p6.5-57)). The proponent writes that "[t]his mitigation will provide a strong marine safety and awareness platform for the region." While the proponent acknowledges "medium" risk and uncertainty due to the need to get input and participation in the plan by multiple stakeholders, the broader issue is that these management plans cannot be taken to be effective until we are able to see the plans and evaluate them. Please provide the Marine Activities Plan so that decision-makers and stakeholders can review and evaluate this mitigation measure's potential effectiveness.	As with other environmental management plans, the marine activities plan is not part of the EAC Application, but will be prepared prior to commencement of construction if the Aurora LNG project is certified. This way, the plan will benefit from the more detailed planning and design information, as well as from ongoing engagement with regulators, Aboriginal Groups, and stakeholders.
2711.1	round 1	Gitga'at First Nation	6.5.5.3	Marine Use and Navigable Waters	Other mitigation measures proposed in Table 6.5-14 (s.6.5.5.3 (p6.5-57) also lack evidence of the measures' effectiveness. For example, mitigation measure 6.5.5 proposes workshops with mariners to promote safe navigation, and apparently past workshops enjoyed good participation rates from local mariners, but the question begs: did the workshops translate into safer or otherwise improved use of marine space? Please provide evidence as to why the proposed mitigation measures in Table 6.5-14 will be effective.	Aurora LNG cannot provide evidence for mitigation effectiveness because they have yet to be implemented, and no current project has implemented the same set of measures similar to what is proposed in Table 6.5-14. As described in Section 6.5.3.3, Aurora LNG will develop a Marine Activities Plan (Mitigation 6.5.2) to describe how the Project's marine activities will be managed to avoid or reduce effects on current marine users and other stakeholders. Aurora LNG will engage with regulatory agencies, Aboriginal Groups, marine users, and other interested stakeholders in the development of this plan. It's expected that the safe-shipping workshops, TERMPOL study, and participation on the Prince Rupert Port Authorities' Marine Construction and Coordination Committee could lead to recommendations regarding such issues as ship design/operation, terminal design, navigational routes, risks and accident avoidance, and pollution prevention. Additional information on the nature of the Marine Activities Plan will be shared as the plan is developed.
2712.1	round 1	Gitga'at First Nation	6.5.6.2	Marine Use and Navigable Waters	On p6.5-66 (s.6.5.6.2), and again on p6.5-69, the proponent states that Project will contribute approximately 8% to the total large vessel traffic predicted for the region as a whole, but on p6.5-67 (s.6.5.6.3) the proponent states that the Project will contribute approximately 12.5% to the predicted increase in traffic going into Prince Rupert. Please reconcile these two numbers so it is clearer what the contribution of the Project will be on future large vessel traffic.	The difference in contribution (i.e., the percentages presented) is a result of dividing the Project total shipping volume by a different denominator--first for the regional traffic (which includes traffic going to Kitimat, for example), and second, only for traffic bound for Prince Rupert (see Section 6.5.6 for further explanation).
2713.1	round 1	Gitga'at First Nation	6.5.6.3	Marine Use and Navigable Waters	The proponent presents information on shipping traffic in the ports of Vancouver, Nanaimo, and Victoria on p6.5-67 (s.6.5.6.3). The proponent argues that despite higher shipping levels in Vancouver, the Port of Vancouver "still functions safely while offering sustainable [commercial, recreational, and Aboriginal] fishing and marine recreation and tourism opportunities." This assertion that all is well in Vancouver is not backed up by any evidence. Please provide evidence to support your assertion that the relatively high marine traffic volumes in the Port of Vancouver are acceptable to marine users there including harvesters and recreational users.	See the "Effects of Lost Fishing Time" technical memo which will be filed with the BC EAO.

2714.1	round 1	Gitga'at First Nation	6.5.9	Marine Use and Navigable Waters	On p6.5-73 (s.6.5.8) the proponent indicates that it is only moderately confident in its predictions of the Project's effects on marine fisheries and other marine uses, yet the proponent feels that no follow-up monitoring of the Project's effects on marine fisheries and other uses is necessary (s6.5.9 (p6.5-74)). The proponent does indicate that it will develop a Marine Activities Management Plan as part of its mitigation program, but from what is written in s.6.5.9 it would appear that no monitoring or remediation in the event that effects are more than predicted in the EA are planned as part of the Plan. It would seem responsible to monitor actual effects in any situation where there is not high confidence in EA predictions, and such monitoring would serve the precautionary orientation of EA. Prediction accuracy, lack of follow-up monitoring, and lack of translation of what is learned in monitoring of EA predictions is a widely-noted problem in EA (e.g., Bjorkland, R. (2013). Monitoring: The missing piece: A critique of NEPA monitoring. Environmental Impact Assessment Review 43: 129-134.; BC Auditor General (2011). An Audit of the Environmental Assessment Office's Oversight of Certified Projects. Victoria, BC, Office of the Auditor General of British Columbia. 25pp.; Briggs, S. and M. D. Hudson (2013). Determination of significance in Ecological Impact Assessment: Past change, current practice and future improvements. Environmental Impact Assessment Review 38(0): 16-25.}. Please justify further why no follow-up monitoring is proposed or needed.	As described in Section 6.5.3.3 of the Application, Aurora LNG will develop a Marine Activities Plan (Mitigation 6.5.2) to outline how the Project's marine activities will be managed to avoid or reduce effects on current marine users and other stakeholders. Aurora LNG proposes to develop this plan in consultation with regulatory agencies, Aboriginal Groups, marine users, and other interested stakeholders. In general, follow-up is indicated when there is a low level of confidence in the residual effects prediction and/or sufficiency of key mitigation measures; that is not the case with this VC. The Marine Activities Plan will incorporate and adaptive management framework. Aurora LNG's framework for adaptive management is as follows: the marine activities plan, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plan will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the plan will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended). Similarly, the safe-shipping workshops, TERMPOL study, and participation on the Prince Rupert Port Authorities' Marine Construction and Coordination Committee could lead to recommendations for the Marine Activities Plan regarding such issues as ship design/operation, terminal design, navigational routes, risks and accident avoidance, and pollution prevention). Additional information on the nature of the Marine Activities Plan will be shared as the plan is developed.
2715.1	round 1	Gitga'at First Nation	6.5.4.2	Marine Use and Navigable Waters	The Application determined that wake waves generated by LNG carriers and escort tugs are not likely to cause adverse effects on Aboriginal and commercial marine harvest. This was determined based upon a report produced for LNG Canada that predicted that wake generated by LNG carriers and escort tugs travelling at 12 knots will be less than 0.4 m high (at the source vessel), which is within the size range of naturally occurring waves in the region. They provide an example that wave height in Douglas Channel experiences a maximum height was 3.4 m with an averaged 0.14 m. The Application then screens out vessel wake in the assessment because it is expected that mariners and shoreline harvesters will be accustomed to dealing with project-related wake waves.While the magnitude vessel wake waves maybe well within the range of normal wave conditions, the predicted wave conditions are not provided for Chatham Sound. More information is required.	Environment Canada and Fisheries and Oceans Canada monitor 17 buoys that record weather data. However, none of the buoys are located in Chatham Sound. Of these buoys, two were used in Section 6.5.4.2 to represent the potential range of wave heights experienced in the Project area. The South Hecate Strait buoy is located in relatively deep water (approximately 228 m) in an exposed area with high fetch, where Hecate Strait meets Queen Charlotte Sound. The mean monthly average wave height recorded at this buoy is 1.8 m, while the historical maximum is 13.7 m. The Nanakwa Shoal buoy, in Douglas Channel, is located in relatively shallow water (approximately 22 m) in a confined area with less potential for east-west fetch. Mean monthly average wave height at this buoy is 0.14 m and the historical maximum is 3.4 m. Specific wave height information for Chatham Sound is not available through the buoy monitoring system noted above. However, the weather buoy in South Hecate Strait is relatively more exposed than Chatham Sound, while the Douglas Channel buoy is in a much more confined location. The exposure and fetch of Chatham Sound are less than the area of the South Hecate Strait buoy, yet greater than the Douglas Channel buoy location. It is therefore reasonable to assume that average wave height experienced in Chatham Sound will fall somewhere between that seen at South Hecate Strait and that seen in Douglas Channel. The assessment in Section 6.5.4.2 states that a wave height range of 0.14 m and 1.8 m is assumed to be the average natural wave height typically observed in the Project area.
2716.1	round 1	Gitga'at First Nation	6.5.4.2	Marine Use and Navigable Waters	The assessment does not consider wave frequency or timing. Increased wave frequency could increase the likelihood of shoreline and intertidal erosion, thus impacting habitat for intertidal species (i.e., harvested invertebrates and algal species). Where the timing of waves and intertidal harvesting overlap, vessel wake can have a detrimental disturbance effect on harvesting practices as harvesters must accommodate for vessel wake. In addition, there has been no vessel wave study and wake wash impact assessment conducted in the Application. A more sophisticated analysis (magnitude, frequency, timing) is required to reduce uncertainties in the assessment, and provide a more rigorous framework for comparison with both the ambient storm wave climate and the wake associated with shipping traffic.Therefore, it is premature to conclude that there will be no adverse effects on shoreline/intertidal habitats and intertidal harvesting, much less to conclude that there is no pathway for effects to occur as was done in the Application. Further assessment is required.	Potential changes to marine fish habitat resulting from vessel wake generated by Project-related vessels are discussed under the 'change in habitat' effect (Section 4.9.5.2, Marine Fish and Fish Habitat). Based on the results of the assessment, wake effects resulting from vessels associated with the Project are not expected to adversely affect marine fish habitat. Therefore, wake effects were not considered further within the Marine Fish and Fish Habitat assessment. If it is conservatively assumed that intertidal harvesters working on shore are using both low tide periods in a day (this is unlikely, as the two low tides in a day are not often the same tidal height and, therefore, one is more suitable for harvesting than the other), and harvesting can be undertaken for two hours during each low tide (i.e., one hour on each side of each low), then approximately 17% (4/24 hours) of each day is available for intertidal harvesting. The potential for intertidal harvesters to interact with Project-related shipping effects is temporally restricted on a daily basis. For approximately 83% of each day, wake from Project-related shipping will not interact with intertidal harvesters Section 6.5.4.2 of the Application describes that the mean monthly average natural wave height in the area is assumed to be between 0.14 m and 1.8 m. The potential maximum wave height (immediately adjacent to the source vessel) of 0.4 m, produced by LNG carriers and escort vessels at 12 knots, is within the range of the mean monthly average wave height in the Project area. The modeled wake height of LNG carriers (and other vessel types) indicates that wake-related waves attenuate as they travel further from the source vessel (Oceanic Consulting Corporation 2014). This means that the actual wave height when it reaches the shoreline is lower than the wake height at the source vessel, and well within the natural wave height range currently experienced by shoreline harvesters. Additional large vessel traffic may alter the frequency of vessel generated wake but this is not expected to measurably change the wave activity in the area. Moreover, Project-related vessels will travel along the existing and established shipping route currently used by larger marine traffic (e.g., container ships, cargo ships, breakbulk ships, ferries) to enter and exit Prince Rupert harbour. The predicted wake-related wave height 300 m from the centreline of travel of a large, loaded LNG carrier traveling 12 knots (and that modeled for 14 knots) is similar to those predicted for ore carriers, cruise ships, and BC Ferries vessels (Oceanic Consulting Corporation 2014), all of which call at the Port of Prince Rupert. Project-related wake effects are not expected to differ from the variable wave heights and conditions already experienced by shoreline harvesters, relating to natural weather patterns and large vessel traffic. Reference: Oceanic Consulting Corporation. 2014. Kitimat Ship Wake Study. Prepared for: LNG Canada Development Inc.
2717.1	round 1	Gitga'at First Nation	6.5.5.3	Marine Use and Navigable Waters	The Application determined that increased vessel traffic is not likely to cause adverse project-related effects or cumulative effects on Aboriginal and commercial marine harvest activities. The Application assumed that a commercial or Aboriginal seine or gillnet fisher that has to retrieve gear due to a passing LNG carrier might lose up to 30 minutes of fishing time (and associated catch) if the gear is retrieved and no fish are retained. A worst-case, unmitigated, and unlikely scenario is that a fisher might lose a total of one hour of fishing time per day because of interacting with both LNG carrier transits. Overall, the Application predicted that is unlikely that fishers will have to stop fishing for any of the daily LNG carrier movements with the proper implementation of the proposed mitigation measures. As mentioned in other comments, more information (including evidence of effectiveness) is required for listed mitigations. Also, the assessment failed to acknowledge that specific fisheries (i.e., salmon) are only open during limited periods of time, measured in hours. Therefore, the loss of one hour of fishing effort can have a significant effect on harvest, sustenance, and economic gain. Mitigation measures should include scheduled vessel sailings outside of these time-sensitive fishery periods to not impact Aboriginal or commercial fisheries. This mitigation measure has been applied in other ports.Therefore, it is inappropriate to conclude that there will be no adverse effects on Aboriginal and commercial marine harvest until appropriate mitigation measures have been proposed to reduce the effect.	See the "Effects of Lost Fishing Time" technical memo which will be filed with the BC EAO.
2718.1	round 1	Gitga'at First Nation	6.5.5.3	Marine Use and Navigable Waters	The Application failed to adequately assess the interactions between vessel activity and Aboriginal harvest activities in two instances. First, the Application did not consider that Aboriginal fishing occurs throughout the LAA and RAA, even though it previously was stated in the sections that Aboriginal fishing occurs throughout the area and in the Gitga'at's Traditional Use and Occupancy Study. As such there is a spatial overlap between most fisheries. Second, the act of moving traps and long lines to accommodate vessel traffic is an interaction. Regardless if shipping traffic could safely pass over the buoy, the vessel traffic must be considered by the fisher. As such there is an interaction in the harvest of Pacific Herring, prawn, shrimp, and Dungeness Crab. Fishers may have to relocate to less productive locations due to navigating around vessel traffic.Therefore, it is premature to conclude that there will be no adverse effects on Aboriginal and commercial marine harvest until spatial overlap and fisheries types are adequately considered and assessed. Also, visual quality impacts were not assessed (see visual comments).	The Application conservatively assumes that Aboriginal harvesting areas occur, at a minimum, where commercial fishing does. The Application also understands that the same gear types and techniques are used interchangeably between commercial and Aboriginal harvesting. In these ways, the assessment was conservative in determining the geographical extent and nature of Aboriginal fisheries. However, issues specific to Aboriginal Groups are assessed in Part C of the Application. Aurora LNG maintains that as a result of the location of the fishing areas or gears or techniques used, and in consideration of the proposed mitigation measures, that Project-related shipping will not cause significant adverse effects to fisheries for Pacific herring, prawn, shrimp, and Dungeness crab. Nonetheless, Aurora LNG is open to receiving additional information regarding Aboriginal harvesting locations or techniques. Please see Section 6.2 for the effects assessment of Visual Quality.
2719.1	round 1	Gitga'at First Nation	6.5.2.1	Marine Use and Navigable Waters	The environmental and economic consequences of species invasions are well known in the US and Canada. However, the Application does not discuss any potential for the introduction of invasive species into the LAA and RAA. The Application does mention that the Canadian Shipping Act and the associated Ballast Water Control and Management Regulations (BWCMR) exist, but there was no formal assessment. The regulations require vessels to exchange ballast at least 50 nautical miles west of Haida Gwaii or Vancouver Island. These areas are quite far offshore so unless there is noncompliance with the regulations, this measure should reduce the likelihood of introduction of invasive species. However, the BWCMR only require a 95% exchange rate of ballast so that 100% elimination of the potential for the introduction of exotics is not required nor mentioned in the Application. In addition, the effectiveness of mid-ocean ballast exchange depends entirely on compliance and the method of ballast treatment. Pui Gwun Lo (2009) pointed out several caveats regarding the effectiveness of mid-ocean ballast exchange. Hull fouling is another means for invasive species to be introduced into the LAA and RAA. Hull fouling involves organisms such as barnacles or mussels attaching themselves to ship hulls and either encountering structures in a new port or releasing larvae into the water. Therefore, invasive species must be assessed in the Application.	Sections 6.5.2.1 and 6.5.6.4 of the Application identify the legislation and regulations pertaining to the control and management of ballast water. As per Mitigation Measure No. 4.5.7 (Section 4.5.15.3, Table 4.5-26, of the Water Quality assessment), vessels transiting to and from the Aurora LNG marine terminal will adhere to the Vessel Pollution and Dangerous Chemicals Regulations and the Ballast Water Control and Management Regulations under the Canada Shipping Act (2001). The Ballast Water Control and Management Regulations are aimed at avoiding the introduction of invasive species to local waters, and outline a number of mandatory ballast water management procedures related to ballast water management plans, ballast water exchange and treatment, reporting requirements, compliance and enforcement, and research. Project-related international shipping will be required to adhere to these regulations. The Prince Rupert Port Authority (PRPA) is a standing member of the Green Marine Program, which encourages international ship owners to implement anti-fouling measures to reduce the risk of aquatic invasive species introductions from hull-attached organisms. The PRPA also monitors the potential establishment of invasive species as part of the Plate Watch program. To date, no aquatic invasive species have been documented in the Prince Rupert harbour as part of this program. Because the above identified mandatory management procedures for preventing the introduction of aquatic invasive species are well established and effective, a separate assessment of invasive species is not warranted.
2720.1	round 1	Gitga'at First Nation	6.6.2.3	Community Health	Gitga'at's Traditional Use and Occupancy Study is not listed for "Sources of Project specific information provided by Aboriginal Groups".	Reference to Gitga'at's Traditional use and Occupancy Study should be listed under Section 6.6.2.3 of the Application. This document is referenced in Section Section 6.6.3.2 with respect to Gitga'at First Nation harvested foods. The following should be included in the bullet list of traditional knowledge/traditional use studies: Draft Preliminary Report: Gitga'at First Nation Traditional Use and Occupancy Study for the Aurora LNG Project, Prince Rupert Harbour Region (Inglis Consulting. 2016) The following reference should also be added to Section 6.6.11: Inglis Consulting. 2016. Draft Preliminary Report: Gitga'at First Nation Traditional Use and Occupancy Study for the Aurora LNG Project, Prince Rupert Harbour Region. Prepared for Gitga'at First Nation. Prepared for Aurora LNG Project. An errata document is being created that will capture these corrections and it will be filed with the BC EAO.
2721.1	round 1	Gitga'at First Nation	6.6.2.5	Community Health	For "change in community health and wellness", Hartley Bay must be assessed and included within the LAA. There are unique impacts to Hartley Bay, e.g., accessibility in Prince Rupert, specifically over-crowding of moorage space for emergencies and unavailability and increasing costs of hotels to accommodate patients seeking medical care.	Aurora LNG's understanding of Gitga'at First Nation's comments requesting the inclusion of Hartley Bay in the LAA to be: That member's quality of life could be adversely affected due to changes in infrastructure and services (e.g., accommodations [inclusive of hotels and motels] and health care) in Prince Rupert due to the ProjectSocio-economic changes within Prince Rupert could affect the health and wellbeing of Gitga'at First Nation members due to tight linkages between Hartley Bay and Prince Rupert. Regarding the assessment of the following social VCs: 6.3 Infrastructure and Services and 6.6 Community Health, communities included in the LAA are those where it is reasonably expected that direct interactions with the Project could occur, potentially resulting in adverse effects that could be predicted/estimated. It is recognized that Hartley Bay, as well as other communities within the region (e.g., Terrace and Aboriginal communities in the Terrace area) have economic and social ties to Prince Rupert. However, Aurora LNG maintains that there is much less potential for the Project to directly affect socio-economic conditions in Hartley Bay, compared to communities within the LAA. Aurora LNG recognizes that there could be indirect effects on Gitga'at members living in Hartley Bay – such as those identified above – but maintains that it is difficult to distinguish such phenomena from those resulting from other socio-economic changes occurring in the region (e.g. adverse effects are difficult to predict/estimate), and are therefore adequately addressed in cumulative effects assessments. For these reasons, Hartley Bay was not included within the LAAs for the socio-economic VCs noted above, but included in the RAA. As delineated and applied, the LAA and RAA for Sections 6.3, and 6.6 also align with those used in similar applications within northwest BC. Specific to residual effects, it is important to note that effects assessed at the LAA level could also be realized by residents outside the LAA who may work within, draw upon, or visit the LAA. For example, Gitga'at members living in Hartley Bay who draw upon hotels, motels and health care services (among other considerations) from Prince Rupert could realize adverse effects associated with the Project as characterized at the LAA level. This rationale holds for other individuals, not just members of Gitga'at First Nation, within the RAA (and further) who may draw upon infrastructure and services within Prince Rupert. Due to potential direct Project interactions with Gitga'at First Nation harvesting locations, Hartley Bay is included in the LAA for the residual effect assessments 'change in harvested foods' (Section 6.6). With respect to cumulative effects, as assessed in Sections 6.3, and 6.6, cumulative residual effects are predicted to extend to the RAA (which includes Hartley Bay). This includes changes in infrastructure and services and community health. Characterizations provided at the RAA level account for indirect effects noted by Gitga'at First Nation and would apply to members living in Hartley Bay. In summary, as per the methodology outlined in the AIR, Hartley Bay has not been added to the LAA as the community is outside of the spatial extent to which Project-related activities are anticipated to result in a direct, predictable and measurable adverse change in the referenced socio-economic VCs. The concerns identified in relation to Gitga'at First Nation members who live, work, draw upon services or visit communities within the LAA are already assessed within the socio-economic VCs as characterized at the LAA level. Aurora LNG believes that the concerns identified by Gitga'at First Nation in relation to the economic, employment and infrastructure and service linkages between Hartley Bay and Prince Rupert are therefore also assessed at the LAA level in aggregate-population form. Characterizations provided at the RAA level for Project and cumulative effects apply to members of Gitga'at First Nation members residing in Hartley Bay and cover concerns related to indirect socio-economic and cumulative effects from the Project. As part of its engagement with Gitga'at First Nation during development of the Social Management Plan, Aurora LNG will discuss specific socio-economic concerns and issues that may affect Gitga'at First Nation members, including residents of Hartley Bay.
2722.1	round 1	Gitga'at First Nation	6.6	Community Health	How many unionized jobs verses non-unionized jobs will there be? And what is the wage disparity between unionized jobs and non-unionzed? Many Tsimshian workers are not union members, so what will Aurora LNG do to ensure that Tsimshian workers have equal opportunities.	The level of detail requested by this comment is out of the scope of an Environmental Assessment. The potential roles required for the Project are listed in Section 1.4.4 (Employment) of the Application. Aurora LNG anticipates that a percentage of jobs will be filled by unionized workers. Aurora LNG is an equal opportunity employer and will consider all qualified applications appropriately.
2723.1	round 1	Gitga'at First Nation	6.6.3.2	Community Health	Composite Socio-Economic Index Rankings - It is important to consider that 60% of youth in care are Aboriginal despite that Aboriginal youth only make up 9% of the total child and youth population in British Columbia. Please assess this.	Aurora LNG understands that Aboriginal People are more vulnerable to changes in community health and wellness due to disparity in baseline conditions. As noted in the comment, BC Stats' composite socio-economic index provides just a few of many measures that validate this understanding, such as youth in care. Recognizing that vulnerable populations, such as Aboriginal People, are more likely to realize disproportionate effects, as noted in Section 6.6.5.2, qualified characterizations are provided to account for this difference (where appropriate).
2724.1	round 1	Gitga'at First Nation	6.6.5.3	Community Health	Health Status - discussion should be separated based on Project phases because employment opportunities are greatly different among the phases, i.e., construction jobs vs. operation jobs vs. decommissioning jobs.	The Project residual effects on health status are predicted to be similar for each of the Project phases. However, the magnitude of the residual effects are predicted to differ for each phase of the Project. For example, residual adverse effects on income and social status, social support networks, social environments, and personal health practices and coping skills could lead to adverse effects on health status. These adverse effects may occur during any phase of the proposed Project. However, adverse effects on health status are predicted to be greater in magnitude during construction when there is predicted to be a rapid increase in the LAA's population As per Table 6.6-22, the magnitude is predicted to be moderate to high during construction, low to moderate during operation, and moderate to high during decommissioning and abandonment.
2725.1	round 1	Gitga'at First Nation	6.6.5.3	Community Health	Health Status - negative effects on employed individuals can also occur, and employment can exacerbate impacts if substance abuse already exists and effective and adequate services are not in place. Please assess this.	As discussed in Section 6.6.5.3 of the Application, adverse health effects may occur, on employed individuals, through increased levels of stress and anxiety from employment-related stressors (e.g., deadlines, workloads, new responsibilities). This could contribute to drug and alcohol misuse and unhealthy lifestyle choices. Increased levels of individual and household income could also increase accessibility to drugs and alcohol and unhealthy lifestyle choices. To reduce the potential magnitude of adverse effects on health status an employee assistance program (mitigation 6.6.1) will be available to workers directly employed by the Project.

2726.1	round 1	Gitga'at First Nation	6.6.5.3	Community Health	Health Status - further discussion on vulnerable populations is required, including single parents and elderly populations.	The assessment of change in community health and wellness recognizes that vulnerable populations could be disproportionately affected by adverse Project effects. For the purpose of this assessment, vulnerable populations include: children and youth, women, seniors, Aboriginal persons, individuals and households on fixed incomes, individuals and households classified as low-income earners (as by Statistics Canada Statistics Canada [2015]), marginally-housed individuals (includes individuals or households in core housing need as defined by CMHC [2014]; similar to at-risk homelessness as defined by the Canadian Observatory on Homelessness [2012]), and individuals classified as homeless (includes individuals whom are absolutely homeless [unsheltered], individuals staying in overnight shelters [emergency sheltered] and individuals whose accommodation is temporary or lacks security of tenure [provisionally accommodated] [Canadian Observatory on Homelessness 2012]).
2727.1	round 1	Gitga'at First Nation	6.6.5.3	Community Health	Income Inequality - other social factors can increase inequality regardless of wages, e.g., availability of daycare and high cost of living, and these need to be assessed and considered in the EA. These need to be assessed in the Application.	Aurora LNG recognizes that numerous social factors could influence income inequality regardless of wages. Some of these social factors (e.g., age, sex, Aboriginal identity, living conditions) have been captured in the disaggregated consideration of effects on vulnerable populations (see Section 6.6.5.2 for a definition of vulnerable populations). However, Aurora LNG acknowledges that not all possible social factors affecting income inequality are assessed in the Application. To assess all possible variations of social factors affecting income inequality would be impractical. Aurora LNG is confident that a sufficiently conservative approach has been taken to the development of proposed mitigation measures (that mitigation measures are more than adequate to mitigate predicted Project effects) and as such any potential mis-characterization due to technical limitations (i.e., assessing all variations of all possible social factors influencing income inequality) would be accounted for through the mitigation. With respect to cost of living, this topic is discussed through case study analysis in Section 13.5.4 of the Application.
2728.1	round 1	Gitga'at First Nation	6.6.5.3	Community Health	Social Environments - social demographic changes can lead to the marginalization of First Nation people and impact workplace performance and reduce opportunities to participate in relevant cultural activities like feasts and clan gatherings.	Noted in Section 12.5.9 of the Application, Aurora LNG understands the Gitga'at First Nation concerns related to the participation of Gitga'at First Nation members in Project-related employment opportunities, which may cause members to be less available to participate in cultural activities or culturally relevant employment. These potential effects are considered in the Community Health assessment (see Section 6.6 of the Application). Prince Rupert, where over two-thirds of Gitga'at First Nation members reside, is included in the Community Health LAA. Although Hartley Bay is not included in the Community Health LAA, the potential effect mechanisms assessed in the Community Health assessment would apply to any Hartley Bay residents who choose to pursue Project-related employment opportunities. It is acknowledged in the Community Health assessment that a change in population, employment, and income could affect social determinants of health. For example, depending on a person's pre-employment situation, Project employment could increase or decrease the amount of time a person has to spend with family and community members or engaged in community events. To reduce the potential magnitude of adverse Project effects on social support networks, an employee assistance program will be made available to workers directly employed by the Project (mitigation 6.6.1). Aurora LNG will also implement its Indigenous Peoples policy (see Section 12.5.9.6 (subsection 'Mitigation Measures') which recognizes the importance of cultural practices, and fostering opportunities for Indigenous Peoples and communities to participate in economic and social benefits of Aurora LNG's projects.
2729.1	round 1	Gitga'at First Nation	6.6.5.3	Community Health	Personal Health Practices and Coping Skills - inadequate support systems can lead to poor work habits and job retention. Please assess this.	Aurora LNG employees will be provided with access to an employee assistance program (mitigation 6.6.1) to reduce the risk of poor work habits, job stressors, and job retention concerns. The program will promote holistic worker health from a physical, mental, cultural and social perspective. However, success of this mitigation measure depends on the extent to which Aurora LNG employees take advantage of the program. To reduce this risk and encourage Project employees to take advantage of the programs, awareness materials and messaging will be provided to the workforce as part of general communications.
2730.1	round 1	Gitga'at First Nation	6.6.5.3	Community Health	Mitigation for Change in Community Health and Wellness - what about communities that will be impacted by an outward migration due to the Project?	Aurora LNG acknowledges that circumstances evaluated throughout Section 6 of the Application could result in the out-migration of particular sub-populations (e.g., pressures on vulnerable populations) from some areas; however, the effects of outward migration were not explicitly assessed.
2731.1	round 1	Gitga'at First Nation	6.6.5.3	Community Health	Table 6.6-18, Mitigation 6.6.1 - Employee assistance programs are not always culturally relevant. These programs must be offered in-person (rather than over the phone) and must be culturally relevant. The Proponent should support Aboriginal communities own support systems and services. What about support for family members? Will Aurora LNG provide relevant discretionary cultural days? Also how will Aurora LNG ensure that this mitigation measure is "effective over the medium to long term"?	Aurora LNG employees will be provided with access to an employee assistance program (mitigation 6.6.1). At this point Aurora LNG cannot commit to the structure or delivery of the program as it will be administered through a third party with included programs and details established during contractual negotiations. As with most employee assistance programs, family members of employees will also have access to the program.
2732.1	round 1	Gitga'at First Nation	6.6.5.3	Community Health	Table 6.6-18, Mitigation 6.6.2 - More support is needed for health prevention and promotion. On reserves this is through the First Nation Health Authority and the Federal Environmental Health Officer - how are these organizations being engaged/consulted by Aurora LNG?	The infection control policy (mitigation 6.6.2) will be included in the Health and Medical Service Plan (HMSP; mitigation 6.3.13) and will outline infectious disease control procedures not limited to prevention measures and outbreak response. The development of the policy will be informed through Northern Health's Infection Control Plan Best Management Guide for Industrial Camps. The HMSP describes on-site health and medical facilities, procedures to follow regarding medical escalations and detail health and wellness programs available to workers. The HMSP will be based on Northern Health's Health and Medical Services Best Management Plan Guide. Development of the HMSP will take into consideration information obtained during engagement with relevant stakeholders (e.g., the First Nation Health Authority), Working Group members (e.g., Northern Health) and Aboriginal Groups.
2733.1	round 1	Gitga'at First Nation	6.6.5.3	Community Health	Table 6.6-18, Mitigation 4.4.2 - how is 10 p.m. considered "daytime hours"? Notices should be distributed through Canada Post so that families and individuals are aware to protect their children and pets. This comment is applicable to all VCs where this mitigation is listed.	The definition of daytime hours (7 am to 10 pm), utilized in the Aurora LNG Application, is based on the BC OGC noise guideline. This daytime definition is consistent with the daytime period definition by both Health Canada and the World Health Organization noise guidance. As per mitigation 4.4.1, high disturbance noise activities will be scheduled to occur during daytime hours. In response to concerns received, Aurora LNG will endeavor to schedule high disturbance activities to occur before 8 pm, where possible. Regular construction activities will be scheduled over a 24 hour period as required to complete specific tasks or meet schedules. Aurora LNG will be developing a Noise Management Plan that will include a description of requirements for notifying local residents of high disturbance noise activities, and outlining how noise complaints will be addressed. Aurora LNG will engage with appropriate regulatory agencies, the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended), and other key stakeholders regarding the development of this plan.
2734.1	round 1	Gitga'at First Nation	6.6.5.3	Community Health	Table 6.6-18, Mitigation 4.4.9 - how will residents be notified?	A Noise Management Plan (mitigation 4.7.2) will be developed and implemented and will describe the procedures, to be implemented during normal operations of the LNG facility, to avoid causing excessive noise on human and wildlife receptors and to adhere to any noise conditions of the EAC and the LNG Facility Permit. The plan is expected to describe the requirements for notification of local residents regarding scheduled construction works, and a process outlining how noise complaints will be addressed.
2735.1	round 1	Gitga'at First Nation	6.6.5.3	Community Health	Table 6.6-18, Mitigation 5.2.1 - more information and clarity is needed on this mitigation. From our experience with other major project developments, Proponents must have control or a mandate to instruct the successful general contractors on job and training opportunities, especially for unionized worksites. How will the contractor advertise jobs? There must be a commitment to support either an employment agency or have all jobs listed through existing employment sites like Hecate Strait. In addition, daily job availability must be faxed and emailed to each Band Office. The Proponent and general contractors must not only use their websites as Aboriginal workers will be excluded.	Aurora LNG acknowledges the mitigation recommendations, including the request for additional details regarding Mitigation 5.2.1, suggested by Gitga'at First Nation. Aurora LNG will continue to engage with Aboriginal Groups on such measures as Project design and employment needs are more defined..
2736.1	round 1	Gitga'at First Nation	6.6.5.3	Community Health	Table 6.6-18, Mitigation 5.2.2 - information must be provided to Bands as well.	Aurora LNG acknowledges the mitigation recommendation of providing information to Band Offices as suggested by Gitga'at First Nation.Aurora LNG is currently reviewing specific feedback on proposed mitigation measures received from Aboriginal Groups and any revised or new mitigation measures proposed will be included as part of an updated Table 16-1 and 16-2 to be submitted to the BC EAO on Day 90.
2737.1	round 1	Gitga'at First Nation	6.6.5.3	Community Health	Table 6.6-18, Mitigation 5.2.3 - older workers may be excluded if they do not have Grade 12 so worker experience and worker experience must be considered as equal to Grade 12.	Mitigation measures 5.2.3 is proposed as follows: "Require that all of workers (not inclusive of summer students) 19 years and younger complete grade 12 or have an appropriate equivalency in order to prevent young people from leaving school prematurely." As proposed, caveats have been made for older workers that may not have completed grade 12 ".... or have an appropriate equivalency...". While Aurora LNG cannot commit to what 'appropriate equivalency' may constitute at this time (as this will be determined on a case-by-case basis with consideration of employment tasks, roles and responsibilities), Aurora LNG will take into consideration that 'equivalency' can also be demonstrated/informed through the review of worker experience.
2738.1	round 1	Gitga'at First Nation	6.6.5.3	Community Health	Table 6.6-18, Mitigation 5.2.4 - in cases where Aboriginal workers are not part of a union, Aboriginal workers must be given equal opportunity for jobs.	Aurora LNG is an equal opportunity employer and will consider all qualified persons for Project-related employment. With respect to unionized work, Aurora LNG and its contractors must adhere to established contractual agreements with any union(s).
2739.1	round 1	Gitga'at First Nation	6.6.5.3	Community Health	Table 6.6-18, Mitigation 5.2-5 - Proponent must support Gitga'at in obtaining adequate training and equal opportunities, including providing support for required services such as daycare and travel.	Aurora LNG acknowledges the mitigation recommendation suggested by Gitga'at First Nation. Aurora LNG will continue to engage with Aboriginal Groups regarding such measures as the Project design and employment programs become more defined.
2740.1	round 1	Gitga'at First Nation	6.6.5.3	Community Health	Table 6.6-18, Mitigation 6.3.2 - the Proponent must also support community based treatment centres in the region, and increase existing services capacity. Also the Proponent should offer support incentives such as percentage of wages for workers through a health and wellness program or otherwise the problem will continue as workers may fear losing their jobs.	Aurora LNG acknowledges the mitigation recommendations suggested by Gitga'at First Nation. Aurora LNG will continue to engage with Aboriginal Groups regarding such measures as the Project design and employment programs become more defined.
2741.1	round 1	Gitga'at First Nation	6.6.5.3	Community Health	Table 6.6-18, Mitigation 6.3.3 - the Proponent should provide community engagement sessions prior to worker orientations so prospective workers are aware of the job and workplace requirements.	Aurora LNG acknowledges the mitigation recommendation suggested by Gitga'at First Nation. Aurora LNG will continue to engage with Aboriginal Groups regarding such measures as the Project design and employment programs become more defined. As per Mitigation 5.2.1, Aurora LNG will inform local residents and Aboriginal Groups of job and procurement opportunities during all Project phases and develop work packages that consider the capacity and capabilities of local and regional businesses.
2742.1	round 1	Gitga'at First Nation	6.6.5.3	Community Health	Table 6.6-18, Mitigation 6.3-4 - in addition, successes, challenges and gaps should be communicated so each community can address any issues within their jurisdiction. Also, the Proponent should have adequate outreach support workers to promote this within each community.	Aurora LNG acknowledges the mitigation recommendations suggested by Gitga'at First Nation. Aurora LNG will continue to engage with Aboriginal Groups regarding such measures as the Project design and employment programs become more defined.
2743.1	round 1	Gitga'at First Nation	6.6.5.3	Community Health	Table 6.6-18, Mitigation 6.3.10 - this Plan must also include the need for local foods within camp as to meet the dietary requirements of Tsimshian people.	Aurora LNG acknowledges the mitigation recommendations suggested by Gitga'at First Nation. Aurora LNG will continue to engage with Aboriginal Groups regarding such measures during the development of relevant management plans.
2744.1	round 1	Gitga'at First Nation	6.6.5.3	Community Health	Table 6.6-18, Mitigation 6.3-13 - the First Nations Health Authority, the Northwest Inter-Nation Family and Community Services, and the Friendship Centre (the Friendship Centre provides services to off-reserve members) must also be involved.	The Health and Medical Services Plan (HMSP; mitigation 6.3.13) will be developed with reference to Northern Health's "Health and Medical Services Plan Best Management Guide for Industrial Camps" (March 2015). The HMSP will complement the Social Management Plan (mitigation 6.3.1) by outlining health and medical policies, services and protocols to be implemented at the worker accommodation camp. The HMSP is an internal shared document between Aurora LNG and Northern Health. Development of the Social Management Plan, which includes consideration of health care infrastructure and services (the subject matter mitigated through the HMSP), will be informed through engagement with interested stakeholders (including the groups outlined in the comment), Working Group members and Aboriginal Groups.
2745.1	round 1	Gitga'at First Nation	6.6.5.3	Community Health	Communicable Diseases and STIs - support and involvement must be extended to local health prevention services providers, the Northwest Inter-Nation and Community Services and the Friendship Centre.	To reduce averse Project effects on communicable disease and STIs, Aurora LNG will implement an infection control policy (mitigation 6.6.2). The policy will be included in the Health and Medical Service Plan (HMSP; mitigation 6.3.13) and will outline infectious disease control procedures not limited to prevention measures and outbreak response. The development of the policy will be informed through Northern Health's Infection Control Plan Best Management Guide for Industrial Camps. The HMSP will describe on-site health and medical facilities, procedures to follow regarding medical escalations and detail health and wellness programs available to workers. The HMSP will be based on Northern Health's Health and Medical Services Best Management Plan Guide. Development of the HMSP will take into consideration information obtained during engagement with relevant stakeholders, Working Group members (e.g., Northern Health) and Aboriginal Groups.
2746.1	round 1	Gitga'at First Nation	6.6.5.3	Community Health	Communicable Diseases and STIs - overcrowding is already a reality so how will this be addressed?	Section 6.6.5.3 acknowledges that within the LAA, population change associated with the Project could have an adverse effect on the availability and affordability of accommodations which could displace vulnerable populations and increase the number of persons living in inadequate housing conditions (e.g., overcrowded). Adverse Project effects on accommodations will be mitigated through the use of onsite camp facilities to lodge the Project's workforce as well as measures to address Project effects on housing identified in Table 6.3-22 of the Application. The infection control policy (mitigation 6.6.2) that will be included in the Health and Medical Service Plan (HMSP; mitigation 6.3.13) will outline infectious disease control procedures not limited to prevention measures and outbreak response at the accommodation camp. The development of the policy and HMSP will be informed through Northern Health's best management guides.
2747.1	round 1	Gitga'at First Nation	6.6.5.3	Community Health	Income and Social Status - the Proponent must commit to training and employment opportunities. The Proponent must support social housing so that unemployed residents have the means to afford an appropriate standard of living.	Aurora LNG will inform local residents and Aboriginal Groups of job and procurement opportunities during all Project phases (Mitigation 5.2.1) and will provide information to employment agencies and economic development organizations to help then plan for increased demand for construction labour (Mitigation 5.2.2). The provision of social or non-market housing is the responsibility of local, regional and provincial governments and Project-specific mitigation measures have not been proposed. As noted in Section 5.2, Aurora LNG will contribute to the local tax base; government income that could be used to support such initiatives.
2748.1	round 1	Gitga'at First Nation	6.6.5.3	Community Health	Social Support Networks - If workers are absent from important cultural events, this can have a severe impact on cultural and family obligations and overall traditional social systems. In addition to the adverse effects listed, this could also lead to depression and suicide, including once the Project is complete, and cultural ways are lost. Further assessment is required.	Noted in Section 12.5.9 of the Application, Aurora LNG understands the Gitga'at First Nation concerns related to the participation of Gitga'at First Nation members in Project-related employment opportunities, which may cause members to be less available to participate in cultural activities or culturally relevant employment. These potential effects are considered in the Community Health assessment (see Section 6.6 of the Application). Prince Rupert, where over two-thirds of Gitga'at First Nation members reside, is included in the Community Health LAA. Although Hartley Bay is not included in the Community Health LAA, the potential effect mechanisms assessed in the Community Health assessment would apply to any Hartley Bay residents who choose to pursue Project-related employment opportunities. It is acknowledged in the Community Health assessment that a change in population, employment, and income could affect social determinants of health, in-turn affecting health status (including mental health). For example, depending on a person's pre-employment situation, Project employment could increase or decrease the amount of time a person has to spend with family and community members or engaged in community events and/or result in changes in personal health practices and coping skills. These changes could affect stress and anxiety and mental health. To reduce the potential magnitude of adverse Project effects on social support networks, an employee assistance program will be made available to workers directly employed by the Project (mitigation 6.6.1). Aurora LNG will also implement its Indigenous Peoples policy (see Section 12.5.9.6 (subsection 'Mitigation Measures') which recognizes the importance of cultural practices, and fostering opportunities for Indigenous Peoples and communities to participate in economic and social benefits of Aurora LNG's projects.
2749.1	round 1	Gitga'at First Nation	6.6.5.3	Community Health	Social Support Networks - employee assistance programs must be culturally appropriate and relevant. Please describe how Aurora LNG will ensure this.	Aurora LNG employees will be provided with access to an employee assistance program (mitigation 6.6.1). At this point Aurora LNG cannot commit to the structure or delivery of the program as it will be administered through a third party with included programs and details established during contractual negotiations. As with most employee assistance programs, family members of employees will also have access to the program.
2750.1	round 1	Gitga'at First Nation	6.6.5.3	Community Health	Presence of Workers - families adjusting to new community or readjusting through employment changes due to the Project phases, can cause stressors to the family and on children in new schools. Please assess this.	Potential effects to family dynamics is provided in the assessment of "social support networks". For example, it is noted that prolonged absences could strain family relationships and contribute to feelings of isolation. Under this scenario, adverse effects on family dynamics could adversely affect rates of domestic violence, juvenile and youth crime, and alcohol and drug use. To reduce the potential magnitude of adverse Project effects on social support networks, an employee assistance program (mitigation 6.6.1) will be made available to workers directly employed by the Project.

2751.1	round 1	Gitga'at First Nation	6.6.5.3	Community Health	Crime - it is incorrect to assume that "…the degree of interaction between the Project workforce and community residents will be limited" - not all workers will be in camp, all workers have to travel to and from camp, etc. Please revise and re-assess.	The closed-access camp will limit worker interactions with local communities. For the 95% of workers anticipated to be employed on a fly-in/fly-out basis during construction and 20% during operations this conclusion applies (Aurora LNG anticipates that a logistics policy requiring workers to be returned to their home communities following the completion of their work shifts will be implemented). To reduce adverse effects related to the activities of current residents (3% at peak construction, 12% peak during operations) employed with the Project and in-migrating workers (2% at peak construction and 68% during peak operations) to the LAA/RAA Aurora LNG will implement a worker code of conduct including a worker orientation (mitigation 6.3.3) and a Community Engagement Plan (mitigation 6.3.4). Mitigation 6.3.3 is predicted to reduce adverse effects of in-migrating and non-local workers on LAA communities by clearly communicating expected behaviours of all workers when they are transiting to/from the Project, on Digby Island, and visiting nearby communities while Mitigation 6.3.4 will provide a mechanism from which community grievances can be addressed. Workers found to be willfully violating the code will be subject to disciplinary measures, potentially including termination. It is therefore expected that the degree of interaction between the Project workforce and community residents will be intentionally limited and will reduce the likelihood of criminal activities associated with the Project workforce from occurring.
2752.1	round 1	Gitga'at First Nation	6.6.5.3	Community Health	Crime - due to the adverse effects listed such as potential for domestic violence and youth and juvenile crime, more capacity for support services is required, including mental health services, school counseling services, and family support services. Please describe what and how Aurora LNG plans on addressing these.	The Project will monitor changes in crime incidents within the LAA as part of the Social Management Plan (mitigation 6.3.1), and will take additional measures, if necessary, to address crime activities attributable to the Project workforce.
2753.1	round 1	Gitga'at First Nation	6.6.5.3	Community Health	Personal Health Practices and Coping Skills - eliminating traditional diets may lead to diabetes in Aboriginal populations. What will Aurora LNG do to prevent this.	Effects to Gitga'at First Nation's harvesting-related Aboriginal interests is discussed in Section 12.5.9.5 of the Application. In summary, the Project is predicted to interfere with Gitga'at First Nation's ability to harvest resources within the PDA. However, Aurora LNG believes that the resources harvested by Gitga'at First Nation members within or adjacent to the PDA (i.e., clams, mussels, and cockles) are widely available elsewhere in the region (including other areas near Prince Rupert) and closer to Hartley Bay. As such, diets are not expected to measurably changes from current conditions. Aurora LNG is committed to continued consultation with Gitga'at First Nation to understand and further reduce any potential adverse Project effects on Gitga'at First Nation's harvesting-related activities.
2754.1	round 1	Gitga'at First Nation	6.6.5.3	Community Health	Personal Health Practices and Coping Skills - it states "Individuals successful in securing employment with the Project will have access to employee assistance programs (Aurora LNG will also encourage its contractors to make available similar programs)…", instead of "encourage", it should be "required".	The term "encourage" was chosen as at this time it is premature to establish such contractual conditions.
2755.1	round 1	Gitga'at First Nation	6.6.2.5	Community Health	As with other VCs, the LAA (see Table 6.6-3 on p6.6-7 in s.6.6.2.5) is too restrictive as it does not capture the full spatial area in which important Project effects may occur. Small communities excluded from the LAA used for assessing changes to community health and wellness, such as Hartley Bay, are strongly linked to Prince Rupert and the other major communities in the region by virtue of impacts on employment (e.g., Gitga'at members from Hartley Bay may take up employment on the Project with consequent effects on their families in Prince Rupert and/or Hartley Bay), population exchange and connection between the communities (i.e., families spread between communities), and the reliance of people in the smaller communities on services provided only in the larger communities. As the proponent notes in the application (s.6.6.5.5), some social determinants of health are expected to be affected by the influx of people associated with the Project (and other future development). Such impacts will extend to Hartley Bay and other nearby communities outside of the proponent's LAA by virtue of the tight linkages between the communities. Please revise the LAA to include communities like Hartley Bay that are strongly linked to conditions in Prince Rupert, and please revise the assessment accordingly. It is also not simply enough to conduct assessments on an aggregated population.	Aurora LNG's understanding of Gitga'at First Nation's comments requesting the inclusion of Hartley Bay in the LAA to be: Members who either move to Prince Rupert for work, live in both Prince Rupert and Hartley Bay, as well as those members who work in Prince Rupert and send money to family members in Hartley Bay could experience adverse residual effects of the ProjectMembers living in Hartley Bay who draw upon goods and services in Prince Rupert, Terrace and Kitimat could experience adverse effects related to changes in the cost of goods and services due to the ProjectThat member's quality of life could be adversely affected due to changes in infrastructure and services (e.g., accommodations [inclusive of hotels and motels] and health care) in Prince Rupert due to the ProjectOut-migration of members from Prince Rupert to Hartley Bay due to changes in the affordability and/or availability of housing in Prince Rupert could increase demand for housing in Hartley Bay (of which limited capacity exists to absorb increased demand).Socio-economic changes within Prince Rupert could affect the health and wellbeing of Gitga'at First Nation members due to tight linkages between Hartley Bay and Prince Rupert. Regarding the assessment of the following economic and social VCs: Sections 5.2 Economic Conditions, 6.3 Infrastructure and Services and 6.6 Community Health, communities included in the LAA are those where it is reasonably expected that direct interactions with the Project could occur, potentially resulting in adverse effects that could be predicted/estimated. It is recognized that Hartley Bay, as well as other communities within the region (e.g., Terrace and Aboriginal communities in the Terrace area) have economic and social ties to Prince Rupert. However, Aurora LNG maintains that there is much less potential for the Project to directly affect socio-economic conditions in Hartley Bay, compared to communities within the LAA. Aurora LNG recognizes that there could be indirect effects on Gitga'at members living in Hartley Bay – such as those identified above – but maintains that it is difficult to distinguish such phenomena from those resulting from other socio-economic changes occurring in the region (e.g. adverse effects are difficult to predict/estimate), and are therefore adequately addressed in cumulative effects assessments. For these reasons, Hartley Bay was not included within the LAAs for the socio-economic VCs noted above, but included in the RAA. As delineated and applied, the LAA and RAA for Sections 5.2, 6.3, and 6.6 also align with those used in similar applications within northwest BC. Specific to residual effects, it is important to note that effects assessed at the LAA level could also be realized by residents outside the LAA who may work within, draw upon, or visit the LAA. For example, Gitga'at members living in Hartley Bay who draw upon hotels, motels and health care services (among other considerations) from Prince Rupert could realize adverse effects associated with the Project as characterized at the LAA level. This rationale holds for other individuals, not just members of Gitga'at First Nation, within the RAA (and further) who may draw upon infrastructure and services within Prince Rupert. Due to potential direct Project interactions with Gitga'at First Nation harvesting locations, Hartley Bay is included in the LAA for the residual effect assessments 'change in resource-based primary industries and subsistence economies' (Section 5.2) and 'change in harvested foods' (Section 6.6). With respect to cumulative effects, as assessed in Sections 5.2, 6.3, and 6.6, cumulative residual effects are predicted to extend to the RAA (which includes Hartley Bay). This includes changes in economic conditions, infrastructure and services, and community health. Characterizations provided at the RAA level account for indirect effects noted by Gitga'at First Nation and would apply to members living in Hartley Bay. In summary, as per the methodology outlined in the AIR, Hartley Bay has not been added to the LAA as the community is outside of the spatial extent to which Project-related activities are anticipated to result in a direct, predictable and measurable adverse change in the referenced socio-economic VCs. The concerns identified in relation to Gitga'at First Nation members who live, work, draw upon services or visit communities within the LAA are already assessed within the socio-economic VCs as characterized at the LAA level. Aurora LNG believes that the concerns identified by Gitga'at First Nation in relation to the economic, employment and infrastructure and service linkages between Hartley Bay and Prince Rupert are therefore also assessed at the LAA level in aggregate-population form. Characterizations provided at the RAA level for Project and cumulative effects apply to members of Gitga'at First Nation members residing in Hartley Bay and cover concerns related to indirect socio-economic and cumulative effects from the Project. As part of its engagement with Gitga'at First Nation during development of the Social Management Plan, Aurora LNG will discuss specific socio-economic concerns and issues that may affect Gitga'at First Nation members, including residents of Hartley Bay.
2756.1	round 1	Gitga'at First Nation	6.6.2.5	Community Health	The following references provided on p6.3-10 (s.6.6.2.5) are not listed in the bibliography: Health Canada (2014), Canadian Institute of Health Research (2013), Veerman et al. (2007), and Kemm (2003). Please revise the bibliography accordingly and provide stakeholders with an amendment.	The Canadian Institute of Health is not directly referenced; the referenced publication is associated with Statistics Canada 2013a. This reference is included in Section 6.6.11. The following references should have been included in Section 6.6.11: Health Canada. 2004. Canadian Handbook on Health Impact Assessment: Volume 2: Approaches and Decision-Making: Health Canada. Kemm, J. 2003. Perspectives on Health Impact Assessment. Bulletin of the World Health Organization(81 (6)), 387. Veerman, J. L., Mackenbach, J. P., & Barendregt, J. J. 2007. Validity of Predictions in health Impact Assessment. Journal of Epidemiology and Community Health, 2015(61 (4)), 362-366. doi: 10.1136/jech.2006.047840 An errata document is being created that will capture these corrections and it will be filed with the BC EAO.
2757.1	round 1	Gitga'at First Nation	6.6.2.6	Community Health	In Table 6.6-5 (s.6.6.2.6 (p6.6-11)), the definitions of moderate and high magnitude differ with respect to effects on regional population health but not with respect to harvesting and country food consumption. Please clarify the difference(s) between these two magnitude categories.	Differing magnitude definitions are provided in Table 6.6-5 for regional population health (see bullet 'a'), volume of harvested foods (see bullet 'b), and country food consumption (see bullet 'c') for low, moderate and high magnitude characterizations.
2758.1	round 1	Gitga'at First Nation	6.6.2.6	Community Health	For the effect characteristic reversibility, the definition of reversible reads that "[t]he effect is likely to be reversed after activity completion and reclamation" (Table 6.6-5, p6.6-12 (s.6.6.2.6)). The proponent concluded that effects of the Project on harvested foods would be reversible upon Project decommissioning (p6.6-102 (s.6.6.5.4)). The same conclusion of reversibility is repeated in the CEA section of the application (p6.6-110 (s.6.6.6.4)). While the proponent's use of the term reversible in the assessment is consistent with their definition, the question begs of whether the proponent's conceptualization of reversibility is appropriate in the context of traditional harvesting. As noted on p10 of the CEA Agency's most recent guidance on characterization of residual adverse effects, reversibility is about recovery of effects "within a reasonable timescale" (CEA Agency, 2015.*Determining Whether a Designated Project is Likely to Cause Significant Adverse Environmental Effects under the Canadian Environmental Assessment Act, 2012*. 11pp.). While best left to traditional harvesters and their communities to decide, it would seem that several decades of loss of harvesting space (given the Project's proposed duration, and potential lag effects due to possible perceptions of environmental degradation following decommissioning) might be a very damaging loss, especially considering some people's lifespans. Please justify your conception of 'reversibility' in the traditional harvesting context, and whether it is meaningful and respectful to qualify the loss of harvesting opportunities for several decades as 'reversible'.	Project residual effects as well as the Project's contribution to cumulative adverse effects and cumulative effects with the Project are characterized in error. Effects should be characterized as irreversible as Section 6.6 draws on conclusions from Section 4 and 6.4 and 6.5 and conservatively applies a worse-case characterization of all effects (in this case some effects from Section 4 are identified as irreversible). For all other measures, this conservative approach was observed. This change in characterization does not change the other conclusions related to change in harvested foods. An errata document is being created that will capture these corrections and it will be filed with the BC EAO.
2759.1	round 1	Gitga'at First Nation	6.6.2.7	Community Health	On p6.6-13 (s.6.6.2.7) the proponent provides definitions of low, medium, and high likelihood. Each definition relies on the terms 'unlikely', 'likely', and 'highly likely' in the likelihood definitions, but what do these terms mean to the proponent? It is good practice to define expressions of probability in quantitative terms, such as the IPCC does in its climate change science communications (see Intergovernmental Panel on Climate Change (2010). Guidance Note for Lead Authors of the IPCC Fifth Assessment Report on Consistent Treatment of Uncertainties. Intergovernmental Panel on Climate Change. 4pp + Annexes. http://www.ipcc.ch/pdf/supporting-material/uncertainty-guidance-note.pdf), so that it is clear to all how the terms are being used and to ensure consistency among users of the terms. Please define what is meant by the terms unlikely, likely, and highly likely.	A qualitative approach is used to describe the likelihood of residual Project effects on community health based on professional judgement and experience of the assessor. A definitive or quantitative approach to defining these terms (i.e., 0-15% chance of occurrence) is not practical. In general, the term 'unlikely' in this instance means that adverse effects between the Project and community health are not predicted to occur. The term 'likely' in this instance means adverse effects between the Project and community health are probable as it may be difficult to avoid or mitigate residual effects. The term 'highly likely' in this instance means adverse effects will occur as residual effects cannot be practically avoided or mitigated.
2760.1	round 1	Gitga'at First Nation	6.6.2.8	Community Health	The significance threshold for the community health and wellness VsC is defined as "highly distinguishable from current conditions and trends and cannot be managed or mitigated through adjustments to programs, policies, plans, or other mitigation (p6.6-13 (s.6.6.2.8))." There are several problems with this threshold. First, what is meant by highly distinguishable? This term should be defined as different people may interpret these words differently. Second, this threshold presumes that all that matters is a quantity of change in the condition of the VsC, yet significance is not simply about change but about change in reference to stakeholders' views of what conditions are and are not acceptable. For example, substantial change doesn't matter if conditions are still acceptable to stakeholders. This threshold embodies a presumption that current conditions are acceptable to stakeholders, when they may not be. Significance is fundamentally about acceptability of impacts to stakeholders, and thus significance must be tied to stakeholder values. Third, the threshold's reference to mitigation is redundant, as significance is judged only on residual effects. Please clarify usage of the term 'distinguishable', please revise the threshold to incorporate stakeholder perspective on what constitutes acceptable conditions, and please revise your effects assessment accordingly.	In the absence of any well-established quantitative thresholds for determining a significant effect, the threshold presented in Section 6.6.2.8 is an "expression of condition" approach. "Distinguishable" in the context of the community health significance threshold definition, means distinct from current conditions or trends. In other words, the condition can be reasonably attributed to the Aurora LNG project rather than due to other socio-economic factors, such as variations or structural changes affecting the economy (including such factors as general in-migration, out-migration, closure and opening of other businesses and projects). It is difficult to apply a numerical threshold, that would be reasonably accepted. For some, no amount of adverse change is acceptable, regardless of whether the community health as a whole may benefit. Therefore, we are using a definition that allows us to first characterize effects post mitigation, and based on this characterization determine if the significance threshold has been passed. If it is evident that there will be material un-mitigated residual adverse Project effects on community health, then it may be considered significant. However, this conclusion will need to be made with appropriate consideration of the local context. For example, residents may be both positively affected (through changes in employment and income) and adversely affected (through population change or adverse changes in personal health practices and coping skills) by the Project.
2761.1	round 1	Gitga'at First Nation	6.6.2.8	Community Health	The significance threshold for the harvested foods VsC is defined as "a persistent and substantial decline in availability and/or perceived quality of harvested foods (p6.6-13 (s.6.6.2.8))." This threshold has the same problems mentioned in the previous comment, namely clarity of key terms in the definition, and the lack of reference to what conditions are and are not acceptable to stakeholders. Please clarify usage of the terms 'distinguishable', 'persistent', and 'substantial', please revise the threshold to incorporate stakeholder perspective on what constitutes acceptable conditions, and please revise your effects assessment accordingly.	"Distinguishable" means that the adverse effect is measurable, predictable, and attributable to one or more project or cumulative interactions (i.e., it is not within the boundaries of normal variation of the measurable parameter under baseline conditions). "Persistent" refers to effects that exist for a long period of time; in this instance, beyond Project activities. "SubstantialTefers to a high magnitude measurable change from baseline conditions.
2762.1	round 1	Gitga'at First Nation	6.6.2.8, 6.6.5.3, 6.6.5.5, and 6.6.7.1	Community Health	The significance threshold for the community health and wellness VsC is defined as "highly distinguishable from current conditions and trends and cannot be managed or mitigated through adjustments to programs, policies, plans, or other mitigation (p6.6-13 (s.6.6.2.8))." As such, by the proponent's definition, effects on this VC are significant if they vary substantially from current conditions and are not addressed through mitigation, i.e., are residual. This is a strange definition for significance since significance is typically assessed on residual effects, i.e., it's a given that the effects cannot be managed through mitigation because mitigation has already been accounted for. Regardless, on p6.6-73 (s.6.6.5.3) the proponent concluded that there was a high likelihood that the Project would cause residual effects (and again indicated in Table 6.6-22 "Summary of Project Residual Effects on Community Health" on p6.6-103 (s.6.6.5.5)), yet then on p6.6-113 (s.6.6.7.1) with respect to significance the proponent concluded that "[w]while changes in community health and wellness are anticipated to be distinguishable from current conditions and trends, adverse effects are expected to be managed through the application of mitigation measures (p6.6-113)." So the proponent not just establishes a definition of significance that is non-sensical by way of retaining reference to mitigation when significance is to be determined on residual effects but then goes back and forth in the course of effects assessment and significance determination saying that there will be residual effects but then there won't be residual effects. The proponent seems to be saying that planned mitigation will reduce residual effects to acceptable levels, but this remains problematic given how they characterized residual effects: in Table 6.6-22 (p6.6-103 (s.6.6.5.5)) the worst Project direct effects are characterized as high magnitude, continuous frequency, long-term duration, irreversible, a context that is low to moderate resiliency, and high likelihood. Therefore the conclusion that these effects aren't significant doesn't fit the antecedents. Please revise the significance threshold, effects assessment, and significance determination to ensure that significance is assessed on residual effects only and to provide consistency and clarity through the application. Please clarify if there are residual effects of the Project or not, and if the residual effects are significant or not. Please justify the conclusion of non-significant impacts given how residual effects were characterized.	In the absence of any well established quantitative thresholds for determining a significant Project effect on community health and wellness (or most other socio-economic effects) Aurora LNG is using an "expression of condition" approach to define the threshold. "Distinguishable" in the context of the community health significance threshold definition, means distinct from current conditions or trends. In other words, the condition can be reasonably attributed to the Aurora LNG project rather than due to other socio-economic factors, such as seasonal variations or structural changes affecting the LAA or RAA (including such factors as general in-migration, out-migration, closure and opening of other businesses and projects). It is difficult to apply a numerical threshold, that would be reasonably accepted. For some, no amount of adverse change is acceptable, regardless of whether the LAA or RAA as a whole may benefit. Therefore, Aurora LNG is using a definition that first allows for the characterization of Project effects post mitigation, and based on this characterization determine if the significance threshold has been passed. If it is evident that there will be material un-mitigated residual adverse effects attributable to the Project then it may be considered significant. In the case of change in community health and wellness and change in harvested foods this was not determined to be the case.

2763.1	round 1	Gitga'at First Nation	6.6.3.2, 6.6.5.4, and 6.6.6.4	Community Health	Baselines are the 'no-project' scenario from which project direct, as well as cumulative effects of other projects and activities, get measured. As such, it's very important to have a good sense of VC conditions. However, the baselines developed in the Project's EA application frequently provide insufficient context from which to characterize effects and determine their significance. In the Community Health chapter, the baseline on harvested foods – which is mostly focused on Aboriginal traditional harvesting – provides little sense of the actual context for further impacts of major project development. The baseline outlines what foods are gathered but doesn't explore the history of colonization and industrialization on Aboriginal harvesting and most importantly the acceptability of current conditions of harvesting to Aboriginal groups in the area. This is not simply an academic issue but is critical for interpreting Project effects. In the effects assessment, the proponent concluded that Project effects on harvesting would occur within a "resilient socio-economic context because alternative areas of hunting, trapping, fishing and gathering exist within the LAA and RAA where the harvesting of country foods can occur and therefore localized changes in use can be accommodated (p6.6-102 (s.6.6.5.4))." This then led the proponent to conclude in s.6.6.7.1 (p6.6-114) that the Project would not cause significant adverse effects on harvesting. A parallel conclusion is made in the CEA section of the application (p6.6-110 in s.6.6.6.4, and p6.6-115 in s.6.6.7.2). The proponent defines a resilient socio-economic context as one that has "[h]igh capacity for the VC to recover from a perturbation, with consideration of the existing level of disturbance" (Table 6.6-5 on p6.6-12 (s.6.6.2.6)). While the baseline hints at the issue of existing conditions that are unsatisfactory to First Nations in the area (e.g., impacts on Kitselas traditional harvests due to "degradation of access, abundance and quality of resources" are noted on p6.6-40 (s.6.6.3.2), and harvesting challenges for Gitga'at are noted on p6.6-41 (s.6.6.3.2)), First Nations for the most part do not view current harvesting conditions as acceptable but instead as already heavily compromised. From this perspective, any further impacts on traditional harvesting are significant. Further, the notion that harvesters can simply shift their activities to other harvesting grounds ignores the fact of unequal distribution of resources across the region and the limitations imposed by traditional governance boundaries, and also assumes that alternative sites are felt to be of adequate environmental quality. The proponent seems to recognize the possibility that shifting to other locations may carry problems, but this notion isn't noted until the CEA portion of the application (p6.6-109 in s.6.6.6.4). Even then, in the CEA where major Projects affecting a larger portion of the study area are examined, the proponent still concludes that harvesters can just shift harvesting locations. The proponent seems to conclude that the larger RAA means that harvesters have an even larger space from which to shift their activities, thus repeating the issues of unequal distribution of resources, political boundaries, and available of suitable alternative sites raised above further. Please revise the baseline for the harvested foods VsC to reflect a deeper understanding of context and please revise the effects assessment and cumulative effects assessment accordingly.	Additional details regarding harvesting, including past, present and future use, is provided in Part C of the Application, and particularly Section 12.2.9 for Gitga'at First Nation. This includes a discussion on changes to harvested species, changes to harvesting location and access routes, and changes in the harvesting experience. A conservative approach was used in the assessment of harvested foods and therefore, reasonable worst case assumptions (i.e., potential to harvest throughout the PDA at any time) have been made upon which to base a prediction of the significance of environmental effects. Additional baseline detail is therefore not predicted to change the effects assessment and cumulative effects assessment.
2764.1	round 1	Gitga'at First Nation	6.6.5.2	Community Health	On p6.6-47 (s.6.6.5.2) the proponent indicates that 27% of the site preparation workforce will be hired from within the LAA. How did the proponent estimate this? Please explain how this parameter, as well as other estimates of where proportions of the workforce come from, were estimated.	Aurora LNG's predicted break-down of labour by LAA residents, RAA residents, BC residents, other Canadian residents, and imported labour, is based on consideration of the skills needed during site preparation, overall understanding of the labour market, and anticipated potential to "train-up" workers for related positions. Aurora LNG anticipates that a substantial proportion of its workforce will consists of BC residents, whose skills will be already developed through technical training programs and hands-on experience at other construction sites. Nevertheless, because of the limited available labour force within the LAA, Aurora LNG anticipates that a proportion of its workforce will be hired from outside the LAA. This proportion should decline over time, as more LAA residents seek to increase skills relevant to site preparation.
2765.1	round 1	Gitga'at First Nation	6.6.5.3 and 6.6.5.4	Community Health	In s.6.6.8 (p6.6-115) the proponent notes that its prediction confidence is predicated on several things including expected effectiveness of proposed mitigation measures, and professional judgment from prior experience and understanding of proven mitigation measures. Yet little empirical evidence is provided in the mitigation section (s.6.6.5.4) about the effectiveness of proposed mitigation measures. For example, the proponent indicates that it will develop a Health and Medical Services Plan and provides some information on what will be in the plan (e.g., p6.6-65 (s6.6.5.3)). However, insufficient evidence is provided to understand how effective the measures will be once implemented. What evidence is there that such plans have been effective for other proponents who have developed similar plans? Please provide empirical data or other evidence to support the effectiveness of management plans.	The Health and Medical Services Plan will be based on Northern Health's Health and Medical Services Best Management Plan Guide. The Health and Medical Services Plan has not yet been developed. Aurora LNG will consult with regulators and Aboriginal Groups on the development of the Plan.
2766.1	round 1	Gitga'at First Nation	6.6.5.4	Community Health	The proponent provides a number of ideas on how it will mitigate Project effects on community health, including traditional harvesting, but there may yet be more that could be done and that would be effective and appreciated by stakeholders. Aurora LNG must commit to working with Gitga'at in developing and implementing mitigation measures.	Aurora LNG requested and received specific feedback on proposed mitigation measures from Aboriginal Groups during Technical Workshops #4 and #5. Aurora LNG is currently reviewing feedback received to date on mitigation measures and any revised or new mitigation measures proposed will be included as part of an updated Table 16-1 and 16-2 to be submitted to the BC EAO on Day 90.
2767.1	round 1	Gitga'at First Nation	6.6.6.3	Community Health	The proponent notes on p6.6-108 (s.6.6.6.3) that Aurora LNG will implement the same mitigation measures as proposed by two other major projects in the region (Pacific Northwest LNG and LNG Canada) and that because all three projects will use the same mitigation measures the CEs of development "are therefore expected to [be managed] to an acceptable level". The proponent seems to assume that if other major projects planned to mitigate adverse effects in certain ways and the Aurora LNG project implements the same mitigation measures that mitigation will be effective. Similar statements are made in the mitigation sections of other VCs, yet neither of the two other LNG projects mentioned have yet to be implemented, and thus there presumably is no data from these other projects' mitigation programs to support the notion that the planned mitigation measures will be effective. Please provide further evidence to indicate why Gitga'at, decision-makers and other stakeholders should have confidence that mitigation measures used by other projects and planned for Aurora LNG will be effective.	Mitigation described in Tables 6.6-18 and 6.6-21 of the Application are predicted to reduce the Project's contribution to cumulative effects on change in community health. Other proposed projects will likely be subject to similar mitigation expectations through the environmental assessment and permitting process which would be expected to reduce each project's potential contribution to cumulative effects. Aurora LNG has committed to participating in provincial and/or regional led initiatives to further reduce cumulative adverse effects on community health.
2768.1	round 1	Gitga'at First Nation	6.6.5.3	Community Health	Workplace incidents may affect the health and well-being of affected workers and their families. Community-wide effects may occur because of demand on local treatment centres (local health care providers and ambulatory care facilities), which are not listed. Assessment on these is required.	Section 6.3.5.5 of the Application assesses change in health care infrastructure and services related to population change (direct, indirect and induced workers and their families) as well as demand from the Project (e.g., from workplace incidents).
2769.1	round 1	Gitga'at First Nation	6.6.5.3	Community Health	Both beneficial and adverse impacts on health and wellbeing can arise from Project activities, depending on employment status and level of involvement in personal/family and local community activities. Mitigation includes an employee assistance program but it is not clear how this would enhance/reduce effects. The Application simply states that it will "promote holistic worker health from a physical, mental, cultural and social perspective". Please provide more information on the employee assistance program, including evidence of effectiveness.	Aurora LNG employees will be provided with access to an employee assistance program (mitigation 6.6.1) that will promote holistic worker health from a physical, mental, cultural and social perspective. Aurora LNG will encourage its subcontractors to make available similar programs. This mitigation measure was selected as it aligns with industry best practice regarding health and safety programs and is currently offered by Nexen (a Joint Venture Partner of Aurora LNG). There is predicted to be a moderate likelihood of success as this mitigation measure depends on the Aurora LNG employees taking advantage of the program and the subcontractors making available similar programs (as well as the extent to which subcontracted workers take advantage of applicable plans, where available). Since there is uncertainty as to the extent by which the workforce that will take advantage of the program and the degree to which subcontractors make available similar plans, there is a moderate degree of uncertainty associated with this mitigation measure. To reduce this risk, awareness materials and messaging will be provided to the workforce as part of communications and worker engagement processes built into the HMSP.
2770.1	round 1	Gitga'at First Nation	6.6	Community Health	Details on how mitigation measures collectively changed the effect characterization and how that in turn resulted in a determination of not significant remains unclear for all parameters assessed. Please provide more information. A decision matrix or narrative around how the decisions were made with respect to characterizing effects post-mitigation and how the overall conclusions were made should be developed. For example, what combination of characteristics (magnitude, geographic extent, frequency, duration, reversibility and resiliency) results in a significant outcome versus a not significant outcome?	The assessment of Project residual effects completed in Section 6.6 of the Application align with methods described in Section 3.5 (which align with methods established in the AIR [see AIR section 3.6]). In accordance with these methods, the assessment characterizes Project residual effects following the implementation of mitigation measures; a characterization of potential Project effects without the application of mitigation measures is not completed. Effects characterized in Sections 6.6.5.3 and 6.6.5.4 are predicted effects post-mitigation. Effect characterizations take into consideration effect mechanisms (identified in Table 6.6-2 and expanded upon in Sections 6.6.5.3 and 6.6.5.4) and interactions between potential effects (i.e., change in community health and wellness and change in harvested foods) and Project components and physical activities (see table 6.6-17). Project residual effects are characterized using criteria identified in Table 6.6-5 with significance measured against thresholds presented in Section 6.6.2.8. A specific combination of these characterizations does not necessarily result in a significant effect as additional criteria are described in the significance thresholds. For example, despite characterization (e.g., magnitude, duration, extent...), effects on community health and wellness may "be managed or mitigated through adjustments to programs, policies, plans or other mitigation" and therefore may not be considered significant.
2771.1	round 1	Gitga'at First Nation	6.6	Community Health	Mitigation measures make seek to improve potential impacts; however, impacts specifically to vulnerable populations is missing. Please conduct assessments on all parameters evaluated on vulnerable populations.	The assessment of change in community health and wellness considers measurable parameters and effect mechanisms identified in Table 6.6-2 with the assessment completed at the LAA level (i.e., for the total population). However, as noted in Section 6.6.5.2, the assessment of change in community health and wellness recognizes that Project-related adverse effects could disproportionally affect vulnerable populations. As such, residual effect characterizations provided for the LAA level are further qualified, where appropriate, for vulnerable populations. These qualified characterizations are provided in the following subsections of 6.6.5.3 (Characterization of Residual Effects for Change in Community Health and Wellness): 'Communicable Diseases and STIs', 'Income and Social Status', 'Personal Health Practices and Coping Skills'. Characterizations are summarized in Table 6.6-22. As a result of this approach, all measurable parameters identified in Table 6.6-2 are considered in the assessment of change in community health and wellness for vulnerable populations.
2772.1	round 1	Gitga'at First Nation	6.6	Community Health	Communicable diseases and STIs - mitigation includes encouraging workers to remain on-site; how will Nexen do this? And please provide evidence of effectiveness.	As stated in Section 6.6.5.3 subsection (Mitigation for Change in Community Health and Wellness), the construction camp will be a closed-access camp, meaning that Project employees will be expected to remain onsite for the duration of their work shifts (see Section 1.2 Proposed Project Description). Failure to adhere to the camp policies will result in employee disciplinary actions potentially including termination. Consequently, it is anticipated that this camp policy will be effective at reducing or eliminating adverse Project effects, such as communicable diseases and STIs, on community health and wellness associated with FIFO workers interacting and being present in LAA and RAA communities. In addition, Aurora LNG will implement an infection control policy (Mitigation 6.6.2) that will outline infectious disease control procedures not limited to prevention measures and outbreak response. This is in addition to WorkSafeBC encouraged hygiene policies and mandatory reporting of the outbreak or occurrence of illness (above the incident level that is normally expected) at the camp per the Industrial Camps Regulation under the Public Health Act. The infection control plan will be developed in accordance with Northern Health's best management guide on this topic and included in the Health and Medical Services Plan (also developed in accordance with Northern Health best management guidance). Stated in Table 6.6-18 under the column 'Expected Success/ Risk and Uncertainty', there is a moderate to high likelihood of success. Success of the mitigation depends on the extent to which the workforce adheres to hygiene policies. There is uncertainty as to the percentage of the workforce that will strictly adhere to workplace hygiene policies outlined in the plan. To reduce risk, awareness materials and messaging will be provided to the workforce as part of communication and worker engagement processes built into the HMSP.
2773.1	round 1	Gitga'at First Nation	6.6	Community Health	Higher income for workers may improve healthy behaviors and overall health status. However, income can also increase the accessibility of drugs and alcohol, and higher rates of stress and anxiety may be experienced by workers due to employment demands. An alcohol and drug policy and employee assistance program is proposed as mitigation. Please provide evidence of effectiveness.	Table 6.6-18 of the Application provides both 'rationale for selection' and 'expected success/risk and uncertainty' regarding the proposed mitigation measures. Alcohol and Drug Policy The alcohol and drug policy (mitigation 6.3.2), was selected as it is a best management practice within the oil and gas sector to address issues relate to the abuse of alcohol and drugs and other impacts posed to communities located withing proximity of construction camps. Given the high occurrence of corporate drug and alcohol policies in the oil and gas sector, and focus of communicating pre-placement testing and awareness, the mitigation has a high likelihood in successfully mitigating effects posed to the health and safety of the construction workforce. However, the success of mitigating potential drug and alcohol-related effects on local residents will depend on the level of engagement and standards communicated to the workforce when they are not working. Employee Assistance Program Aurora LNG employees will be provided with access to an employee assistance program (mitigation 6.6.1) that will promote holistic worker health from a physical, mental, cultural and social perspective. Aurora LNG will encourage its subcontractors to make available similar programs. This mitigation measure was selected as it aligns with industry best practice regarding health and safety programs and is currently offered by Nexen (a Joint Venture Partner of Aurora LNG). There is a moderate likelihood of success as this mitigation measure depends on the Aurora LNG employees taking advantage of the program and the extent to which subcontractors make available similar programs (as well as the extent to which subcontracted workers take advantage of applicable plans, where available). Since there is uncertainty as to the extent the workforce will take advantage of the program and the degree to which subcontractors make available similar plans, there is a moderate degree of uncertainty associated with this mitigation measure. To reduce this risk, awareness materials and messaging will be provided to the workforce as part of communications and worker engagement processes built into the HMSP.
2774.1	round 1	Gitga'at First Nation	6.6	Community Health	For perceived decrease in the quality of harvested foods, the proponent proposes mitigation via communication and reporting of grievances. It is unclear the effectiveness of this mitigation so please provide further evidence.	Table 6.6-21 provides both 'rationale for selection' and 'expected success/risk and uncertainty' regarding the proposed mitigation measures. With respect to the referenced mitigation measures, Aurora LNG proposes to continue to engage with local communities and Aboriginal Groups to address community concerns associated with the Project (mitigation 6.3.11) and to develop and implement a community grievance process for addressing issues related to the Project (mitigation 6.4.8). These mitigation measures were selected as they are considered industry best practice. Regarding mitigation 6.3.11, this is a standard mitigation used in the oil and gas sector and as such has a moderate to high likelihood of success. Communication and engagement is known to be valuable in managing the relationships between Aurora LNG, Aboriginal Groups, communities, and stakeholders. With respect to perceived decreases in the quality of harvested foods, communication of Project activities and monitoring results are expected to help inform concerned stakeholders of Project activities and physical works that could have interactions with harvested foods and measures taken by Aurora LNG to manage the potential adverse effects. This mitigation measure has a moderate degree of risk and uncertainty which relates to the willingness of residents and stakeholders to participate in the engagement activities. Regarding mitigation 6.4.8, this is a standard mitigation used in the oil and gas sector and is considered to have a moderate likelihood of success. While some issues brought forward to Aurora LNG will be easily resolvable, others may not be resolvable. In the case of perceived decreases in the quality of harvested foods, grievances brought forward by concerned stakeholders will be reviewed by Aurora LNG with appropriate responses provided. As with mitigation 6.3.11, risk and uncertainty are moderate as the effectiveness of the mitigation measure is in part dependent on the degree to which residents and stakeholders are willing to participate and the degree to which issues are able to be resolved.

2775.1	round 1	Gitga'at First Nation	6.6	Community Health	Harvested Foods - for the cumulative effects assessment, it is acknowledged that construction and operation of future projects could further impact access to, and availability of harvested foods; however, the effect of changes to harvested foods was considered not significant. To assess this conclusion, more information is needed, specifically on vulnerable populations and the actual level of resiliency to the loss of harvest areas.	The assessment of cumulative residual effects on harvested foods provided in Section 6.6.6.4 of the Application is completed at the RAA level (i.e., the total population). Additional qualification of cumulative residual effect characterizations for vulnerable groups was not completed. As stated in Section 6.6.5.2, differing characterizations are provided for the assessment of change in community health and wellness for vulnerable groups; this does not extend to the assessment of change in harvested foods. Information provided in Section 6.6.3.2 subsection 'Harvested Foods', as supported through referenced baseline information and effect characterizations provided in valued components included in Section 4 (Environmental Effects) and Section 6 (Social Effects) of the Application, is sufficient to support the assessment of the Project's contribution to cumulative effects and cumulative residual effects with the Project. Concluded in Section 6.6.6.4, as informed through the above mentioned assessments of valued components, because of the large size of the RAA, and the availability and abundance of terrestrial and marine country food species available for harvesting, cumulative effects occur within a socio-economic context that is resilient to change; however, as noted in Section 6.6, regardless of the potential availability of alternative harvesting locations it is recognized that alternative locations may not be favorable and that harvesters could experience additional adverse effects related to the relocation of harvesting activities (e.g., increased costs, increased time spent travelling to harvesting locations, poorer quality yields).
2776.1	round 1	Gitga'at First Nation	6.6	Community Health	Harvested Foods, states ""while harvested food gathering in the PDA will no longer be possible this represents only a small fraction of areas available for Local Assessment Area (LAA) community members to sustainably harvest terrestrial country foods", without elaboration on important factors such as: • What is the 'small fraction' affected? • Are there disproportionate impacts on certain groups? For example, does that area account for 100% of the harvest foods collected for a specific group or community? • What assistance is available for those who are unable to make use of alternate harvest areas?	The assessment of change in harvested foods relies, in part, on effect assessment completed in Section 6.4 (Land and Resource Use) and 6.5 (Marine Use and Harvested Areas). Section 6.4 and 6.5 provide quantitative and qualitative descriptions of areas removed for potential harvest within associated LAAs and RAAs. These sections also provide a summary of harvested foods taken from the LAA and RAA. Information on the intensity of harvesting locations within the LAA and RAA in comparison to other locations within traditional territories on a Nation-by-Nation basis is not provided in Section 6.4 or 6.5 of the Application. Mitigation measures proposed in Section 6.4 are predicted to reduce Project residual effects on consumptive non-tenured land use (e.g., hunting, fresh-water fishing, vegetation gathering and marine plant harvesting) while mitigation measures proposed in Section 6.5 reduce Project residual effects, among others, on marine fisheries. See section 6.4 and 6.5 of the Application for additional information on the proposed mitigation measures.
2777.1	round 1	Gitga'at First Nation	6.6	Community Health	A total of 105 mitigation measures are listed to reduce or eliminate the effects of the Project on harvested foods. It appears that these measures were not developed directly to address harvested foods, but were taken from other sections of the Application and evaluated for their applicability and relevance to impacts on harvested foods. Aurora LNG must commit to working with Gitga'at in developing and implementing mitigation measures.	The comment correctly identifies that mitigation measures presented in Table 6.6-21 were applied from other sections of the Application and evaluated for their applicability and relevance to effects on harvested foods. This approach is valid as it recognizes that the combination of mitigation measures proposed in Sections 4.2 (Air Quality), 4.3 (Greenhouse Gases), 4.4 (Acoustic Environment), 4.5 (Water Quality), 4.6 (Vegetation and Wetland Resources), 4.7 (Wildlife Resources), 4.8 (Freshwater Fish and Fish Habitat) and 4.11 (Marine Birds) are predicted to manage adverse Project effects related to changes in the abundance of harvested foods within the LAA which could affect harvesting. Mitigation measures from Section 6.2 (Visual Quality), 6.3 (Infrastructure and Services), 6.4 (Land and Resource Use) and 6.5 (Marine Use and Navigable Waters) are predicted to manage adverse Project effects related to social-based effects (e..g, changes in the visual landscape, access and use of lands and waters) on harvesting within the LAA. Aurora LNG will continue to engage with Aboriginal Groups on development of the mitigation measures which will form part of the proposed environmental management plans.
2778.1	round 1	Gitga'at First Nation	6.6	Community Health	Harvested Foods, there is a lack of differentiation between the study population at large and vulnerable groups. Although such groups have been identified (e.g., "Dodge Cove and Crippen Cove residents and vulnerable populations"), additional detail around how they may be differentially impacted, and how mitigation measures affect them differently (positively or negatively) should be added to verify that the determination of significance is valid.	The assessment of change in harvested foods is completed at the LAA level (i.e., the total population). Additional qualification of adverse Project effect characterizations for vulnerable groups was not completed. As stated in Section 6.6.5.2, differing characterizations are provided for the assessment of change in community health and wellness for vulnerable groups; this does not extend to the assessment of change in harvested foods.
2779.1	round 1	Gitga'at First Nation	7.2.2.4	Heritage	Increased human presence should be considered during construction, operations and closure as a potential adverse effect on archaeological sites. Sites such as coastal shell middens are particularly sensitive to increase human presence and it is known that there currently are and will likely to continue to be exposed archaeological materials in the LSA.	Potential Project interactions with archaeological and heritage resources are only anticipated to occur during activities that result in tree removal or ground disturbance (including dredging) during the construction phase. The operation and decommissioning phases are not anticipated to result in additional tree removal or ground disturbance (including dredging) outside of the area affected during the construction phase, and therefore do not have potential to cause a measurable interaction with archaeological and heritage resources. Access to archaeological sites within the LAA/RAA by members of the public is not anticipated to increase during the construction and operation phases, as there will be on-site security services and restricted access to the PDA. Access to archaeological sites by project personnel is not anticipated (see mitigation 6.4.4). Therefore, tree removal or ground disturbance related to increased human presence are not anticipated and human presence is unlikely to cause a measurable interaction with archaeological and heritage resources.
2780.1	round 1	Gitga'at First Nation	7.2.2.5	Heritage	The RAA should be larger than the LAA. As there is no regional setting provided it is not possible to assess the significance of the sites that will be impacted (How rare are the site types that are being impacted? Is the density of sites in the project area normal for this region?).	The regional setting for archaeology and heritage is addressed in the permitted AIA report (Appendix W). The AIA was completed in accordance with regulatory guidelines and considers appropriate regional data to assess the significance of, and potential effects to, sites situated in the LAA/RAA.Within the Application process, the AIR describes the LAA and RAA as being the Project Development Area and this is consistent with what is included in the Application, Section 7.2.2.5.
2781.1	round 1	Gitga'at First Nation	7.2.2.5	Heritage	The RAA should be larger than the LAA.The LAA and RAA are limited to ground disturbance from construction but do not consider disturbance to archaeological sites as a result of increased human presence on the island. Both the LAA and RAA should be increased in size to take this into consideration.	The regional setting for archaeology and heritage is addressed in the permitted AIA report (Appendix W). The AIA was completed in accordance with regulatory guidelines and considers appropriate regional data to assess the significance of, and potential effects to, sites situated in the LAA/RAA.Within the Application process, the AIR describes the LAA and RAA as being the Project Development Area and this is consistent with what is included in the Application, Section 7.2.2.5. The LAA and RAA are used to assess effects during all project phases; however, only construction activities are predicted to have an effect on this VC because vegetation clearing and ground disturbance with the potential to impact archaeological and heritage resources will be completed during the construction phase. Access to archaeological sites within the LAA/RAA by members of the public is not anticipated to increase during the construction and operation phases, as there will be on-site security services and restricted access to the PDA. Access to archaeological sites by project personnel is not anticipated (see mitigation 6.4.4). Therefore, tree removal or ground disturbance related to increased human presence are not anticipated and human presence is unlikely to cause a measurable interaction with archaeological and heritage resources. For these reasons, no change to the Application is considered warranted.
2782.1	round 1	Gitga'at First Nation	7.2.2.6	Heritage	The assessment assumes that archaeological sites will only be impacted during the construction phase. This needs to be revised to account for increased human presence that will also occur during operations and closure that may result in impacts to sites. Additionally, buried deposits such as shell midden sites may be disturbed during closure and reclamation.	Potential Project interactions with archaeological and heritage resources are only anticipated to occur during activities that result in tree removal or ground disturbance (including dredging) during the construction phase. The operation and decommissioning phases are not anticipated to result in additional tree removal or ground disturbance (including dredging) outside of the area affected during the construction phase, and therefore do not have potential to cause a measurable interaction with archaeological and heritage resources. Access to archaeological sites within the LAA/RAA by members of the public is not anticipated to increase during the construction and operation phases, as there will be on-site security services and restricted access to the PDA. Access to archaeological sites by project personnel is not anticipated (see mitigation 6.4.4). Therefore, tree removal or ground disturbance related to increased human presence are not anticipated and human presence is unlikely to cause a measurable interaction with archaeological and heritage resources.
2783.1	round 1	Gitga'at First Nation	7.2.3.2	Heritage	Gitga'at is concerned with the lack of testing on Spire Island where two rock overhangs were identified and visually examined but not tested. High potential areas like these must be tested or more information provided on the rationale for not testing.	Two rock overhangs were identified on Spire Island during the AIA. Visual examination of the areas did not identify any archaeological materials or remains. However, given the potentially sensitive nature of these features as potential burial places, intrusive subsurface inspection was not conducted. As per the AIA report (Appendix W), avoidance is recommended. If avoidance is not feasible, additional archaeological study would be undertaken prior to construction.
2784.1	round 1	Gitga'at First Nation	7.2.9	Heritage	With the large number of sites in very close proximity to the Project, on going monitoring to ensure the sites are not impacted is required. We would like to see monitoring during construction and yearly monitoring of the sites during operations, and monitoring during closure and reclamation activity.	Potential Project interactions with archaeological and heritage resources are only anticipated to occur during activities that result in tree removal or ground disturbance (including dredging) during the construction phase. The operation and decommissioning phases are not anticipated to result in additional tree removal or ground disturbance (including dredging) outside of the area affected during the construction phase, and therefore do not have potential to cause a measurable interaction with archaeological and heritage resources. Access to archaeological sites within the LAA/RAA by members of the public is not anticipated to increase during the construction and operation phases, as there will be on-site security services and restricted access to the PDA. Access to archaeological sites by project personnel is not anticipated (see mitigation 6.4.4). Therefore, monitoring of the sites after initial construction (tree removal and ground disturbance) may not be required however Aurora LNG will review the requirement for monitoring on a site by site basis in discussion with the appropriate regulatory authorities. Aurora LNG welcomes further discussions with Gitga'at First Nation regarding heritage and archaeological resources.
2785.1	round 1	Gitga'at First Nation	7.2.3.2	Heritage	Fossil sites have been attributed to Digby Island, however the report states that there is no potential for fossil finds. It is not clear from the Paleontology report if a qualified professional paleontologist conducted this assessment. Please state the qualifications of the person who did the study.	Edits were made to Sections 7.2.1, 7.2.2.1, 7.2.2.8, 7.2.3.1, 7.2.3.2, 7.2.3.3, 7.2.8, and 7.2.9 in response to comments from the Heritage Branch during the screening of theapplication in December 2016 which address this comment. To clarify, a high-level review of paleontology has been conducted for the Project. The review was conducted by a professional Palaeontologist with a PhD who is a member of the British Columbia Paleontological Alliance. A paleontological assessment will be conducted prior to construction and will include review of relevant information and databases. The assessment and reporting will be conducted under a permit issued by the province. If any fossils are identified, they will be managed in consultation with the Heritage Branch. The Archaeological and Heritage Resources Management Plan will include measures to manage any unexpected fossil finds during project activities. The plan will meet Heritage Branch standards regarding management of fossil sites. The management plan will be prepared prior to construction. An edit was made to Table 7-7 during screening to reflect that the Heritage Branch will be consulted during its preparation.
2786.1	round 1	Gitga'at First Nation	7.2.4	Heritage	Gitga'at disagrees with the assessment of potential project interactions with archaeological sites. This section needs to include potential impacts from increased human presence throughout the project lifecycle, and impacts to buried deposits during construction, decommissioning and closure.	Potential Project interactions with archaeological and heritage resources are only anticipated to occur during activities that result in tree removal or ground disturbance (including dredging) during the construction phase. The operation and decommissioning phases are not anticipated to result in additional tree removal or ground disturbance (including dredging) outside of the area affected during the construction phase, and therefore do not have potential to cause a measurable interaction with archaeological and heritage resources. Access to archaeological sites within the LAA/RAA by members of the public is not anticipated to increase during the construction and operation phases, as there will be on-site security services and restricted access to the PDA. Access to archaeological sites by project personnel is not anticipated (see mitigation 6.4.4). Therefore, tree removal or ground disturbance related to increased human presence are not anticipated and human presence is unlikely to cause a measurable interaction with archaeological and heritage resources.
2787.1	round 1	Gitga'at First Nation	7.2.5.1	Heritage	Gitga'at disagrees with the assumption that the effects of the Project on Heritage resources are well understood based on the work done in the LAA and RAA. The LAA and RAA are too small to understand the affects of the Project and Heritage resources and need to be expanded.	The regional setting for archaeology and heritage is addressed in the permitted AIA report (Appendix W). The AIA was completed in accordance with regulatory guidelines and considers appropriate regional data to assess the significance of, and potential effects to, sites situated in the LAA/RAA.Within the Application process, the AIR describes the LAA and RAA as being the Project Development Area and this is consistent with what is included in the Application, Section 7.2.2.5. The LAA and RAA are used to assess effects during all project phases; however, only construction activities are predicted to have an effect on this VC because vegetation clearing and ground disturbance with the potential to impact archaeological and heritage resources will be completed during the construction phase. Access to archaeological sites within the LAA/RAA by members of the public is not anticipated to increase during the construction and operation phases, as there will be on-site security services and restricted access to the PDA. Access to archaeological sites by project personnel is not anticipated (see mitigation 6.4.4). Therefore, tree removal or ground disturbance related to increased human presence are not anticipated and human presence is unlikely to cause a measurable interaction with archaeological and heritage resources. For these reasons, no change to the Application is considered warranted.
2788.1	round 1	Gitga'at First Nation	7.2.5.2	Heritage	Gitga'at disagrees with the assessment of residual effects. The assessment has not considered the significance of the sites regionally. The project area has a very high density of archaeological and historic sites and is evidence of the high use and significance of the area over a long period of time. There a few places on the coast that have such a high density of sites in such a small area and location. It is also an excellent area for public interpretation to occur. The loss of these sites would have a significant residual impact on the population of archaeological and heritage sites in the larger region.	The regional setting for archaeology and heritage is addressed in the permitted AIA report (Appendix W). The AIA was completed in accordance with regulatory guidelines and considers appropriate regional data to assess the significance of, and potential effects to, sites situated in the LAA/RAA. Aurora LNG acknowledges the concern of Gitga'at First Nation regarding the archaeological and heritage sites in the PDA. Aurora LNG is confident that the correct approach to mitigating the loss of information about or alteration to site contents or contexts resulting from construction of the Project has been employed. Avoidance is recognized as being the preferred option, and the majority of the archaeological sites with high significance within the PDA are situated within the proposed buffer (Figure 7-1 and Figure 7-2). If avoidance is not feasible, a program of systematic data recovery and/or archaeological monitoring will take place under a Section 12 alteration permit issued for HCA protected sites. Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Archaeological and Heritage Resources Management Plan. The success of the measures that are ultimately determined through this engagement is predicted to be high. Therefore, with the implementation of mitigation measures 7.1.1 to 7.1.3, residual effects are assessed to be not significant.
2789.1	round 1	Gitga'at First Nation	7.2.5.3	Heritage	The assessment of residual effects needs to be revised to reflect the significance of the very high density of archaeological and heritage sites in this location and how the loss of this resource will carry forward in to the future and result in the loss a significant resource. Mitigation through data recovery and monitoring of the sites will not be enough to offset losing an area like this that has this time depth of occupation, density and diversity of sites.	Aurora LNG acknowledges the concern of Gitga'at First Nation. Avoidance of archaeological and heritage sites is the preferred method of mitigation. If avoidance is not feasible, a program of systematic data recovery and/or archaeological monitoring will take place under a Section 12 alteration permit issued by the Archaeology Branch for HCA protected sites. For non-protected heritage resources, mitigation is determined in consultation with the Heritage Branch and potentially affected Aboriginal Groups, as applicable, and typically follows established best practices. Therefore, with the implementation of mitigation measures 7.1.1 to 7.1.3, residual effects are assessed to be not significant.Aurora LNG will engage the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Archaeological and Heritage Resources Management Plan.
2790.1	round 1	Gitga'at First Nation	7.2.6	Heritage	A cumulative effects assessment is necessary for this project as the logic that the mitigation will offset the residual effects is flawed. The current mitigation plan does not offset the significant loss the collective archaeological and heritage resources in this area.	Aurora LNG is confident that the correct approach to mitigating the loss of information about or alteration to site contents or contexts resulting from construction of the Project has been employed. Avoidance is recognized as being the preferred option, and the majority of the archaeological sites with high significance within the PDA are situated within the proposed buffer (Figure 7-1 and Figure 7-2). If avoidance is not feasible, a program of systematic data recovery and/or archaeological monitoring will take place under a Section 12 alteration permit issued for HCA protected sites. Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Archaeological and Heritage Resources Management Plan. The success of the measures that are ultimately determined through this engagement is predicted to be high. Therefore, with the implementation of mitigation measures 7.1.1 to 7.1.3, residual effects are assessed to be not significant. In accordance with the AIR, an assessment of cumulative effects on archaeological and heritage resources was not undertaken as the following two conditions were not met: 1) proposed Project is assessed as having residual effects on the VC and 2) residual effects could act cumulatively with residual effects of other past, present, or reasonably foreseeable future physical activities. Further assessment of cumulative effects on archaeological and heritage resources is not warranted because the Project effects on archaeological and heritage resources will be mitigated prior to alteration. As a result, there are no predicted residual effects to archaeological and heritage resources. Consequently, the Project is not expected to interact cumulatively with potential residual effects from other projects or activities.
2791.1	round 1	Gitga'at First Nation	7.2	Heritage	Gitga'at recommends to protect old growth areas in the PDA and access to them.	Access will not be permitted in the PDA during the construction and operation phases of the project. Aurora LNG welcomes further discussion with Gitga'at First Nation regarding the management of any old growth areas in the buffered portion of PDA that will not be felled during construction.
2792.1	round 1	Gitga'at First Nation	7.2	Heritage	Nexen must commit that all workers must be educated on chance finds.	The Archaeological and Heritage Resources Management Plan will include a chance finds procedure which would include training for relevant project staff and/or contractors. All personnel working on the Project will receive an orientation and be required to receive all applicable training as per the environmental management plans.

2793.1	round 1	Gitga'at First Nation	8	Human Health	According to the human health assessment, emissions during the operations phase will exceed those associated with construction of the Project. For that reason, the construction phase of the Project was not assessed in the human health assessment. However, the air quality assessment indicates that construction emissions will exceed operations emissions for certain air contaminants (e.g., PM2.5 and PM10 emissions; see Table 4.2-11 and Table 4.2-12). Therefore, the health risks associated with construction of the Project should be quantitatively assessed.	The potential health risk associated with the construction phase was not assessed in the Application because the amount of PM10 and PM2.5 produced was similar between the construction and Project-alone phase. For example, the Air Quality TDR (Appendix A of the Application), Table 13 (page 21) provides the average annual emissions of PM10 and PM2.5 during the construction phase and Project-alone phase. - Construction PM10 emissions = 21.5 tonnes/year. - Construction PM2.5 emissions = 20.9 tonnes/year. - Project operations PM10 emissions = 19.2 tonnes/year. - Project operations PM2.5 emissions = 18.4 tonnes/year. Based on the results of the Human Health assessment (Chapter 8 of the Application), Table 8.2-9 (page 8-34), the potential change in health risk from particulate matter in the operations phase is negligible. In locations such as Dodge Cove (i.e., Receptor ID: D-337D, D-372F and D-385) and the worker camp within the Project PDA (i.e., Receptor ID: IF-1764, IF-1825, and IF-385), the concentration ratio increases marginally from 0.00 to 0.04 above the Base Case which means that levels of PM increases about 0% to 4% of the applicable air quality objective. There are negligible changes in the health risk to people from particulate matter in the communities that are closest to the proposed Project. People in communities more distal from the proposed Project (e.g., Prince Rupert, Port Edward, Metlakatla Village) would experience even lower exposures. Given this information, it is logical to conclude that the assessment of particulate matter in the operations phase (i.e. Application Case) would provide sufficient information to conclude a similar degree of health risk in the construction phase. For other types of potential construction emissions such as volatile organic compounds, refer to the "Volatile Organic Compound and Human Health Assessment" technical memo which will be filed with the BC EAO. The "Volatile Organic Compounds and Human Health Assessment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2794.1	round 1	Gitga'at First Nation	8.3.1	Human Health	Other applications in BC that included a marine traffic component were required to assess the health effects of diesel particulates. Rationale should be provided why diesel emissions were excluded from the Application. If such rationale cannot be provided, diesel emissions should be included in both the air quality and human health assessment.	The potential health risk associated with the construction phase was not assessed in the Application because the amount of PM10 and PM2.5 produced was similar between the construction and project-alone phase. For example, the Air Quality TDR (Appendix A of the Application), Table 13 (page 21) provides the average annual emissions of PM10 and PM2.5 during the construction phase and project-alone phase. - Construction PM10 emissions = 21.5 tonnes/year. - Construction PM2.5 emissions = 20.9 tonnes/year. - Project operations PM10 emissions = 19.2 tonnes/year. - Project operations PM2.5 emissions = 18.4 tonnes/year. Based on the results of the Human Health assessment (Chapter 8 of the Application), Table 8.2-9 (page 8-34), the potential change in health risk from particulate matter in the operations phase is negligible. In locations such as Dodge Cove (i.e., Receptor ID: D-337D, D-372F and D-385) and the worker camp within the Project PDA (i.e., Receptor ID: IF-1764, IF-1825, and IF-385), the concentration ratio increases marginally from 0.00 to 0.04 above the Base Case which means that levels of PM increases about 0% to 4% of the applicable air quality objective. There are negligible changes in the health risk to people from particulate matter in the communities that are closest to the proposed Project. People in communities more distal from the proposed Project (e.g., Prince Rupert, Port Edward, Metlakatla Village) would experience even lower exposures. Given this information, it is logical to conclude that the assessment of particulate matter in the operations phase (i.e. Application Case) would provide sufficient information to conclude a similar degree of health risk in the construction phase.
2795.1	round 1	Gitga'at First Nation	8.2.2.8	Human Health	The relevance of the significance threshold should be further described. For example, according to Table 8.2-5, *"if the baseline HQ for food or water ingestion is greater than 0.2, the significance threshold is reached when the Project or cumulative case HQ is greater than baseline HQ + 0.2 "*. No information is provided for why the "HQ + 0.2" benchmark constitutes a significance threshold (i.e., the metric seems somewhat arbitrary). Additional information should be provided as to why this benchmark is considered significant.	The application of adding 0.2 to the baseline CR/HQ was made following comments from the Ministry of Health. The Ministry of Health has commented in working group meetings that the project's contribution to health risk should not exceed 20% (i.e., a CR or HQ of 0.2) of the applicable regulatory guideline.
2796.1	round 1	Gitga'at First Nation	8.2.2	Human Health	The Application only focused on a select number of COPC (e.g., CACs like CO, PM, SO2 and NO2). No rationale is provided for excluding trace air contaminants like PAHs, VOCs or metals. Other (similar) applications in BC have included a detailed characterization of health risks associated with TACs. Information should be provided why only CACs were considered.	The Application focused on criteria air contaminants that could be produced in sufficient amounts so as to reasonably pose a risk to human health. The scope of the assessment was determined in collaboration with federal and provincial regulators and other stakeholders. Polycyclic aromatic hydrocarbons, volatile organic compounds and metals were not included in the Application Information Requirements under Section 8 for the assessment of human health. Volatile organic compounds in LNG are predominantly methane, ethane, propane and other short chained hydrocarbons which are not toxic when inhaled. There is no pathway for the project to contribute metals in the air. The assessment of metals in air are typical of mine projects, which produce mineralized dust. A rationale for excluding a chemical substance is only provided for substances that were identified in the Application Information Requirements, which defines the scope of the Application.
2797.1	round 1	Gitga'at First Nation	8.2.4	Human Health	Boiling water will neither change the pH nor metal concentrations of water. There is an assumption that the residents use a point of source filtration device rather than boiling the water.	The Application does not state that boiling water will change the pH or metal concentrations in the water, noting that the predicted change in water pH (less than 0.3 pH units in the Dodge Cove water reservoir) does not result in a health concern as described in Section 8.2.4 of the Application (Human Health VC - 8.2.4 Project Interactions with Human Health). The boil water advisory is intended to protect residents from water-borne diseases caused by Escherichia coli (E.coli) and fecal coliforms that could be present in untreated or unboiled water. The Project does not affect fecal coliform levels in the Dodge Cove drinking water reservoir. The Application also states that "some Dodge Cove residents apply a point-of-use personal water filtration system for surface waters collected from Digby Island". This statement only indicates that some residents choose to apply a water filtration device as a personal preference.
2798.1	round 1	Gitga'at First Nation	8.2.5.3	Human Health	COPC were selected by comparing measured sediment concentrations against sediment quality guidelines that are intended for the protection of aquatic life. This pathway is not immediately relevant to human health. As a result, it is unclear if the human health includes all COPCs relevant or applicable to the Project. Other screening criteria should be considered for the identification of COPC and the subsequent characterization of multiple exposure pathways.	Aurora LNG stands by the methods used to screen chemicals of potential concern to apply to marine traditional foods. As noted in Section 8.2.2.5.4 of the Application, there are no sediment quality guidelines for the protection of human health from any provincial, federal or international regulatory agency. Other screening criteria (e.g., screening against soil quality guidelines for the protection of human health) would encounter similar issues where guidelines are not entirely applicable. The screening was conducted in a manner that consistent with the assessments of other projects that involved dredging (e.g., Pacific Northwest LNG, Prince Rupert Gas Transmission Pipeline, LNG Canada (in Kitimat)). Aurora LNG acknowledges that during the AIR development in 2014, the Ministry of Health (MOH) indicated that the use of CCME sediment quality guidelines as a screening tool for food pathways is not appropriate. A request was made at that time for MOH to suggest alternative screening methods because the proponent recognized that no environmental guidelines would be entirely applicable. Ministry of Health declined to provide alternative screening methods that would be acceptable. Aurora LNG had considered applying the following methods as screening tools: - Canadian Food Inspection Agency tissue residue limits for dioxins and furans. - BC Contaminated Sites Regulations Soil Quality Guidelines for the Protection of Human Health (residential land). However, if these screening methods were applied, copper, dioxins and furans would be screened out of the assessment because the concentration of dioxins and furans were below the CFIA tissue residue limit, and the concentrations of copper, dioxins and furans in the sediment are below the BC CSR soil quality guidelines defining them as contaminants. Therefore, in order to be consistent with the methods used in other LNG projects that propose dredging, the CCME sediment quality guidelines were applied.
2799.1	round 1	Gitga'at First Nation	8.2.5.3	Human Health	Consumption rates used for the exposure assessment are lower than those estimated by the Gitga'at. Gitga'at must be consulted on this.	Refer to the document "Supplemental Information for Traditional Marine Foods", which will be submitted to the EAO. The "Supplemental Information for Traditional Marine Foods" technical memo was presented to the Working Group in draft for a pre-read on April 18, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2800.1	round 1	Gitga'at First Nation	8.2.5.3	Human Health	PAH that were below the detection limits were not included in the assessment. Please update the Application by including these.	Polycyclic aromatic hydrocarbons (PAH) are a broad class of chemicals. Among these, nine individual PAH compounds are considered carcinogenic. When any one of these PAHs were above the applicable screening guideline, all nine PAHs were included in the assessment of human health. This is the standard protocol when addressing the health risk associated with chemicals that have a similar mode of action with respect to human health. For carcinogenic PAHs that were below the detection limit, the assessment assumed that the concentration of PAHs in the food was equal to the detection limit, which is the most conservative approach.
2801.1	round 1	Gitga'at First Nation	8.2.5.3	Human Health	Arsenic concentrations were not speciated and were not considered in the assessment although exposure pathways for arsenic are identical to those presented for copper, which was assessed. The rationale for excluding arsenic from further analysis is inconsistent with retaining copper as a COPC (i.e., COPC selection criteria should be consistent). Please assess arsenic risk.	Arsenic in seafood such as fish, crustaceans and molluscs is predominantly in the form of arsenobetaine, an organometallic which is largely considered non-toxic and harmless to humans when consumed. This rationale was provided in the Human Health Technical Data Report (Appendix R, Section 4.1.2.1 - Rationale for Excluding Arsenic from Marine Harvested Foods). In contrast, there is no supporting body of research that indicates different levels of toxicity associated with inorganic and organic forms of copper. Therefore, all forms of copper were assumed to have the equivalent level of toxic potential. Please refer to the following literature sources regarding the relative toxicity of arsenobetaine in seafood and marine life in general: https://www.iupac.org/publications/pac/pdf/2010/pdf/8202x0373.pdf http://ceqg-rcqe.ccme.ca/download/en/230
2802.1	round 1	Gitga'at First Nation	8.2.5.3	Human Health	No analytical results for the crab tissue or the crab hepatopancreas are provided. No details regarding the crab tissues are provided. Analysis should conducted on crab muscle, total crab (including hepatopancreas) and hepatopancreas in order to adequately assess exposure. Please provide these results and assess impacts.	Please see the "Supplemental Information for Traditional Marine Foods" technical memo which includes responses to this comment. This technical will be filed with the BC EAO. The "Supplemental Information for Traditional Marine Foods" technical memo was presented to the Working Group in draft for a pre-read on April 18, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2803.1	round 1	Gitga'at First Nation	8.2.5.3	Human Health	The results of the analysis of 5 clam samples are provided and the mean concentrations of copper from the 5 samples are used in the assessment. Given the small sample size risk for the maximum concentrations should also be calculated.	Health Canada's "Supplemental Guidance on Human Health Risk Assessment for Country Foods" recommends that for simple risk assessments, a minimum of 5 to 10 tissue samples be taken for each species and tissue of interest. Clam samples were composite samples (i.e., multiple individual clams were used to generate a single tissue sample) Each composite sample was composed of 8-10 clams, totaling a range of 40-50 clams. The maximum concentrations are provided in the laboratory results.
2804.1	round 1	Gitga'at First Nation	8.2	Human Health	Rather than calculating health risk through a multi-pathway assessment, individual pathways were assessed. Please reassess using multi-pathways. Worked examples of specific calculations of exposure in the HHRA are needed.	The guidance framework provided by Health Canada for risk assessments only considers multi-pathway assessments if people are exposed to the same chemical from different exposure pathways (e.g., inhalation, ingestion, dermal pathway). The assessment of human health for the Project does not apply the same chemicals. The inhalation pathway considers sulphur dioxide, nitrogen dioxide and particulate matter. The ingestion pathway for marine food considers dioxins, furans, polycyclic aromatic hydrocarbons and copper.
2805.1	round 1	Gitga'at First Nation	8.2	Human Health	Dermal exposure to sediments during clamming was not assessed. Please update the Application with this assessment	The concentrations of chemicals in the sediment do not constitute levels that could pose a significant risk to people from dermal exposure. The maximum concentration of dioxins measured in surface sediments in the area was 2.86 picograms per gram (i.e., 2.86 trillionths of a gram). Concentrations of dioxin in sediment may be compared to soil quality guidelines because sediment is essentially soil material in water. The BC Contaminated Sites Regulations guideline for dioxins in soils for the protection of human health is 350 pg/g (for residential soil). http://www.bclaws.ca/EPLibraries/bclaws_new/document/ID/freeside/375_96_07 This means that if the equivalent amount of dioxins were found in the soil of a residential area, there would be no significant risk since the levels would be 100-times below what is considered contaminated. Dermal exposure to sediment while clamming is intermittent and short-term. In comparison, dermal exposure to residential soil is considered a potential long-term exposure. If the exposure to dioxin in soils (at a concentration of 2.86 pg/g) does not constitute a significant risk, intermittent exposure to sediments at this concentration would also not be a significant risk. Sediment core samples have demonstrated that the highest levels of dioxins are in the surface layers. Therefore, any dredging to a depth of 15 meters would only serve to further reduce dioxin concentrations in the localized sediment.
2806.1	round 1	Gitga'at First Nation	8.2	Human Health	Were health impacts assessed for crew and terminal operators if a "rapid transition phase" (or "cold explosion") event were to occur (cryogenic and asphyxiation could occur)?	The accidents and malfunctions section of the Application (Section 9) describes the scenarios that could result in a release of LNG into the marine environment resulting in rapid phase transition, and the overall implications to each VC including health.
2807.1	round 1	Gitga'at First Nation	8.2	Human Health	How can the impacts to human health be 'reversible'?	The characterization of "reversible" and "irreversible" health effects refers to the nature of the effect. For example, if exposure to a substance (e.g., sulphur dioxide or nitrogen dioxide) results in a respiratory response, that effect is reversible because after the exposure has stopped, a person is expected to recover from the effects. An irreversible effect would be permanent, and the effect would not recover after the exposure has stopped. This refers to cancerous effects where genetic damage resulting from an exposure has occurred. An example would be cigarette smoking where the cancer risk is cumulative over an individual's lifetime.
2808.1	round 1	Gitga'at First Nation	8.2	Human Health	Why wasn't change to human health from changes in marine food quality assessed cumulatively with other Projects?	A cumulative effects assessment considers other future projects that have the potential to overlap temporally and spatially with the effects of the Aurora LNG Project. In this case, a cumulative effects assessment would be conducted if there were activities from other projects that would occur at the same time as dredging, and/or in the same location. No other future projects were identified which would result in overlapping marine activities in the Aurora LNG dredge footprint that could affect marine foods.

2809.1	round 1	Gitga'at First Nation	8.2	Human Health	What during and post-dredging monitoring will take place?	Aurora LNG will consider the need for post-dredge monitoring related to human health prior to the start of construction. Given that chemicals of potential concern (e.g., dioxins) will not increase in the sediment during or after Project dredging, monitoring is not currently proposed.
2810.1	round 1	Gitga'at First Nation	8.2	Human Health	Who will be track health effects (e.g., changes in asthma, diabetes, cancer)?	Aurora LNG proposes to monitor Project-related effects on health care infrastructure and Services through the Social Management Plan (see mitigation 6.3.1 and Section 14.12). Monitoring and reporting of Project-related changes in health status beyond that required by WorkSafeBC is not proposed. On-going monitoring of changes in health status is completed at the federal and provincial level. Federally, Health Canada, Statistics Canada and the Canadian Institute for Health Information monitor and report on various measures of health status. Provincially, BC Stats, the Provincial Health Services Authority, Local Health Authorities (e.g., Northern Health) and the Aboriginal Health Authority monitor and report on various measures of health status.
2811.1	round 1	Gitga'at First Nation	8.2	Human Health	Why wasn't health impacts from Project related noise, vibration and light not assessed in this section?	The effects of noise and vibration was assessed in the Acoustic Environment valued component Application (Section 4.4 of the Application), which applies the same metrics for noise applicable to human health (i.e., percent highly annoyed; or %HA. The assessment concluded that there would be no significant changes in the %HA. The conclusion would be the same when applied to human health, because such an assessment would apply the %HA metric in the same manner. Potential effects from light are described in the Visual Quality assessment (Section 6.2 of the Application). This section already describes the potential lighting effects to nearby receptors/residences.
2812.1	round 1	Gitga'at First Nation	9	Accidents or Malfunctions	According to the Society of International Gas Tanker and Terminal Operators Ltd. (SIGTTO) "Site Selection and Design for LNG Ports and Jetties" (SIGTTO, 1997), LNG safety is reliant (among others) on the siting of LNG terminals away from civilians and that berths must be far from transit routes to prevent collision (and ignition); the Aurora LNG Project is not compliant with either of these standards. This is concerning to Gitga'at, especially considering the climatic and oceanographic conditions of the north coast. [SIGTTO, 1997: available at http://reallnghearings.org/wp-content/uploads/2015/05/sigtto-standards.pdf]	As stated in Section 9.8.2. of the Application, 'the Project will comply with Canadian Standards Association Z276-15 code, as per the LNG Facility Regulation' which includes 'prescribed setbacks from occupied areas to protect the public based on modelled heat transfer from a Project-induced fire and dispersion of an unignited vapor cloud.' Control zones, described in Section 6.5.2.5 of the Application, on p. 6.5-7, and shown in Figure 6.5-2, are 500 m diameter zones surrounding the berths of the marine terminal that other marine traffic will be required to avoid as a precaution for safety and security. Section 9.9 of the Application considers a credible worst case scenario involving a vessel-to-vessel collision.
2813.1	round 1	Gitga'at First Nation	9	Accidents or Malfunctions	Given the worst-case scenario of an LNG release, and subsequent LNG drift, the impacts can be devastating. Please assess this scenario, including health and socio-economic impacts - consider who, what and where evacuations would result. Also consider worst-case weather and navigation conditions, e.g., high winds.	The release of LNG is already considered in three scenarios within the Application: Section 9.6 On-shore Fires or Explosions; Section 9.8 On-shore Hazardous Spills; and Section 9.9 Vessel Grounding or Collision. Within each of these sections, the relevant VCs which may experience an adverse effect have been assessed.
2814.1	round 1	Gitga'at First Nation	9	Accidents or Malfunctions	The Application states that the LNG industry has an exceptional safety record - please provide evidence to support this statement, including the metrics used to evaluate and conclude such statement. It is known that the LNG carrier shipping industry often uses a total loss of a vessel as their metric which can provide skewed inferences.	Comment noted. Natural gas is a clean burning fuel when compared to other fossil fuels. Reference to the exceptional LNG industry safety record is reflected by the GIIGNL 2012 report on the safety of commercial LNG shipping. Stringent safety and environmental regulations in Canada will only serve to improve this record further.
2815.1	round 1	Gitga'at First Nation	9.1	Accidents or Malfunctions	The response plans must address First Nations capacity to respond to emergencies. Communication plans need to involve First Nations communities and be agreed on between the company and First Nations (also local small communities such as dodge cove). These should include evacuation plans, who to notify, and how.	As stated in Section 12.6 of the Application, 'Aurora LNG looks forward to continuing to consult with Aboriginal Groups about safety and emergency response strategies'. Such discussions will help Aurora LNG to identify meaningful ways in which Aboriginal Groups such as the Gitga'at First Nation may be integrated into Project-related response planning and preparedness.
2816.1	round 1	Gitga'at First Nation	9.1	Accidents or Malfunctions	The HSE plan does not address cumulative environmental impact but does it address cumulative health and safety concerns? Impact to human health and such?	The Nexen Corporate HSE Management System referred to in the comment is designed to assess the safety risk to people and the effects to the environment of a single scenario occurring. The probability of any particular accident and malfunction scenario occurring is extremely low (e.g., aircraft impacting the facility) to low e.g., vehicle accidents), while the types of safety risks are different for each scenario (e.g., fire, exposure to LNG, explosions, vehicle collision) and they are not cumulative with each subsequent accident and malfunction event. The project specific Emergency Response Plan described in section 14.16 will describe the procedures to be implemented to response to all incidents and emergencies associated with the Project. The plan will identify protection of emergency response staff, workers, the public, property and the environment as priorities in an emergency.
2817.1	round 1	Gitga'at First Nation	table 9.3-1	Accidents or Malfunctions	Facility impacts from air craft - what are the impacts of the facility to aircraft? Such as changing micro-climate, potential re-routing of air craft etc.	Section 9.7 of the Application discusses the potential effects of a facility malfunction including potential effects on infrastructure and services such as civil aviation. Also see the "Potential Effects on Aviation as a result of Accidents or Malfunctions" technical memo to address the issues raised by this comment. This technical memo will be filed with the BC EAO.
2818.1	round 1	Gitga'at First Nation	table 9.3-1	Accidents or Malfunctions	Vessels grounding or collision would certainly affect vegetation and wetland resources. Salt marshes, seaweed and kelp beds and harvest, intertidal vegetation, and wildlife would be impacted. The socio-economic impacts have been proven to be enormous to local economies when disasters like a collision and spill occur, not to mention impacts to visual quality from spills, wreckage and damage. Table 9.3.1 does not appear well thought out, justified or inclusive of all the potential impacts.	Potential effects of vessel grounding or collision on salt marshes, seaweed and kelp beds, intertidal vegetation are included within the assessment of Marine Fish and Fish Habitat (p. 9-38). The interactions in 9.3-1 are considered based on the measurable parameters, potential effects and characterization of residual effects as described for each VC in their respective sections in Part B. There are other interactions that may occur as a result of these accident or malfunction scenarios however based on the characterization of residual effects criteria, they are not expected to be of concern. Section 9.3 on page 9-5 describes how these determinations where made.
2819.1	round 1	Gitga'at First Nation	9.4.1 conclusion	Accidents or Malfunctions	" there are no interactions between motor vehicle collisions within the PDA with any VC's" what about fuel delivery? Service trucks? Crew busses? Heavy equipment?	The potential interactions between a motor vehicle collision involving a fuel delivery truck or other large vehicle and VCs could arise if the collision resulted in an on-shore spill. Potential interactions between an on-shore spill and VCs are described in the Application, Section 9.6.
2820.1	round 1	Gitga'at First Nation	9.6.2	Accidents or Malfunctions	Aurora will perform fire and explosion analysis as per company requirements - What does this look like in comparison to provincial and or federal guidelines (if any)? how will this be monitored and recorded? Please provide more information.	The LNG Plant will be designed and built according to the CSA standard for LNG facilities (including completion of a Quantitative Risk Assessment) as well as the fire code standards.
2821.1	round 1	Gitga'at First Nation	9.7.1	Accidents or Malfunctions	"….Full emergency shutdown of a maximum of one production train with associated flaring." What does this mean? Is this worst-case? For example, why only one train?	The probability of an emergency shutdown of one train is low but more likely than an emergency shutdown of all four trains. Potential effects of an emergency shutdown of one train are therefore assessed for Wildlife Resources (Terrestrial), Marine Birds, Infrastructure and Services (see Table 9.3 1). Potential effects of a four train shutdown are assessed for Air Quality, GHGs , and Human Health VCs, as a result of "worst case" air emission and dispersion modelling assumptions.
2822.1	round 1	Gitga'at First Nation	9	Accidents or Malfunctions	What exclusions or shutdowns to vessels or vehicle traffic will occur? Either by order of Nexen, the Port Authority or transport Canada.	As noted in Section 6.5.2.5 of the Application, Aurora LNG has proposed a control zone of 500 m radius surrounding each marine terminal berth which is expected to define the ignition-free areas and areas that will be used to dock the LNG vessels. Other marine traffic will be required to avoid these zones as a matter of safety and security while the LNG carrier is loading. The final size of the control zones is subject to change based on the results of a detailed risk assessment to be undertaken as part of facility design (see Figure 6.5-2). Aurora LNG will be participating in a TERMPOL process and will abide by the recommendations resulting from this process related to safe shipping practices. The recommendations will serve as the basis for additional mitigation measures and may lead to the refinement of the proposed control zone.
2823.1	round 1	Gitga'at First Nation	9.7.3	Accidents or Malfunctions	"Flaring activities could temporarily interfere with civil aviation." As the project is in close proximity to the airport, this seems risky. Please provide more information on how Nexen plans on managing this risk.	Please see the "Potential Effects on Aviation as a result of Accidents or Malfunctions" technical memo which will be filed with the BC EAO.
2824.1	round 1	Gitga'at First Nation	9.7.3	Accidents or Malfunctions	"concentrations of sulphur dioxide, nitrogen dioxide and particulate matter would be less than applicable health based ambient air quality objectives" - does this consider if a second LNG facility such as PNW is operating? What will Nexen do in the event of an exceedance? does this result in an immediate shut down?	Dispersion modelling was used to predict air quality concentrations relative to a four-train shutdown. resulting in flaring of the full LNG plant inventory (see Section 7.2.2 of Appendix A of the Application). Model predictions were found to be below applicable ambient air quality objectives. If emergency flaring is required as a result of a full scale shutdown, Aurora LNG will activate the EMP and inform applicable jurisdictions. Air quality will be monitored relative to applicable thresholds established during permitting. If ambient air quality concentrations exceed applicable objectives as a result of a four-train shutdown, Aurora LNG will use the ERP to inform the public. The assessment of multiple LNG facility malfunctions is not within the scope of the AIR and is therefore not included in the assessment.
2825.1	round 1	Gitga'at First Nation	9.7.4	Accidents or Malfunctions	"…and accidents and malfunctions scenario involving an LNG plant malfunction, will result in no significant effect to the VC's (i.e. air quality, GHG's, wildlife resources (terrestrial), Marine birds, infrastructure and services, and human health)" - what about a major flaring event, large leak or catastrophic failure? Although the table is listed for residual effects, there would be significant acute effects.	Flaring as a result of an all train shutdown is assessed in Section 9.7. Onshore hazardous spills are assessed in Section 9.8. Potential effects of ignited leaks (i.e., natural gas, flammable liquids and vapours) are assessed in Section 9.6.
2826.1	round 1	Gitga'at First Nation	9.8.2	Accidents or Malfunctions	"Drainage systems will be in place to collect contaminated water and process effluents" - this material must be avoided in the first place but if it occurs it must be treated and mitigated.	Aurora LNG acknowledges and agrees with the comment; this is why spills are considered to be accidents or malfunctions, as opposed to part of normal operations. Contaminated water will be handled as hazardous material and be treated as disposed of in accordance with legislation.
2827.1	round 1	Gitga'at First Nation	9.9.1	Accidents or Malfunctions	"Released marine fuel is expected to spread quickly …..Diesel quickly degrades within one to two months through naturally occurring processes." IN the event of a grounding and spill of bunker and/or diesel, large impacts to local economies, health and ways of life may be felt. The local communities rely on the ocean for sustenance, for employment and health. In the event of a grounding event, the implications could be severe to many in the local communities. This is particularly true for Bunker oil as you mention on page 9-38 "bunker oil is persistent in the environment". Please provide more information on how Nexen will manage these risks.	Section 9.9.3 recognizes the potential effects of spills resulting in localized closure to marine harvesting of country foods as well as commercial fishing (Community Health). Aurora LNG acknowledges a closure to marine harvesting may affect local communities. The predicted effects are expected to be limited in geographic extent to the LAA and short-term in duration (as defined in the characterization of residual effects tables for these VCs). Aurora LNG notes that the severity of potential effects, on marine fish and fish habitat, from a spill in the marine environment, will vary depending on various factors including the type and volume of material spilled, the location, weather (during and following the spill) and season, marine fish (and life stages) and habitat present; tidal influences, response time and response measures.
2828.1	round 1	Gitga'at First Nation	page 9-41 section 9.9.1	Accidents or Malfunctions	Community health: and in Human health: In the event of a spill of diesel or bunker oil you mention that a localized fishing ban will be implemented. There are people and groups who do not have choice on where to fish through house territories, size of boat or issues as simple as no mode of transportation or money and must harvest food close to where they live. A large spill would be catastrophic.	As described in Section 11.6 of the Application, Aurora LNG acknowledges that the potential cumulative effects of a vessel-to-vessel collision causing a release of diesel and/or bunker oil could be significant to Aboriginal Current Use and Aboriginal Physical and Cultural Heritage through the potential loss or change in quality of harvested resources, or culturally or spiritually important species.
2829.1	round 1	Gitga'at First Nation	9	Accidents or Malfunctions	It is not clear if future conditions due to climate change (e.g., sea level rise) were considered in the assessment?	The potential effects of climate change on the Project are assessed in Section 10 of the Application (Effects of the Environment on the Project).
2830.1	round 1	Gitga'at First Nation	Table 11.3-2	CEAA 2012	For "effects of changes to the environment on Aboriginal health", why wasn't change in Project-related vibrations assessed? And why wasn't change in light?	The residual effects to the environment on Aboriginal Health were assessed according to the methods outlined in Section 11.3.5.1 and in Figure 11.3-5 of the Application. These methods were based on guidance provided by the CEAA, and are consistent with those described in Figure 11-1 of the AIR. Aurora LNG determined that a change in light levels, which are considered in the Visual Quality VC, did not have potential to interact with Aboriginal Health; therefore, these effects were not carried forward in the assessment. The potential effects from a change in vibration levels are captured through the assessment and conclusions of theAcoustic Environment and related VC's, and was not included in the discussion on Aboriginal Health because conclusions in the Acoustic Environment VC apply equally to any person, Aboriginal or non-Aboriginal.
2831.1	round 1	Gitga'at First Nation	Table 11.3-2	CEAA 2012	Again, disagree with the limited scope of the assessment on "effects of changes to the environment on Aboriginal socio-economics".	As per CEAA 2012 5(1)(c), the focus of the assessment is on effects to the environment on the various CEAA 5(1)(c) factors. The residual effects to the environment on Aboriginal socio-economics were based on guidance provided by the CEAA, and are consistent with those described in Figure 11-1 of the AIR.
2832.1	round 1	Gitga'at First Nation	11.3.2.4	CEAA 2012	The boundaries of the combined VCs LAAs and RAAs were modified to reflect information on harvesting practices along the coastlines of Melville Island and Stephens Island, and to capture all of Lucy Islands. The map on page 11-31 (Figure 11.3-1), depicts a much larger area for the LAA boundary for Current Use, going all the way up to Lax Kw'alaams and down to Kitkatla. Why does it cut off the southern end of Stephens Island? This area is much closer to the proposed shipping route than a good portion of the LAA, and Gitga'at's Traditional Use and Occupancy Study identified extensive Gitga'at use of that area, including anchorages, clam harvesting, and fishing throughout.	The LAA boundaries established for all of the Section 5(1)(c) Effects include areas from Lax Kw'alaams south to Kitkatla. The LAA boundary for Current Use is larger, extending further west, as it also incorporates the LAA's established for; Marine Mammals and Marine Use and Navigable Waters (see figures 4.10-1 and 6.5-1 respectively). The LAA's established for the Marine Mammals and Marine Use and Navigable Waters include buffers around the shipping route of 6km and 5km buffers, respectively, and encompass the area where potential effects from the Project could occur. The southern end of Stephens Island was not included in the Current Use LAA as it is outside of the 6km buffer established around the shipping route.
2833.1	round 1	Gitga'at First Nation	Table 11.3-6, Table 11.3-34	CEAA 2012	For the characterization of residual effects of 'reversibility', the definition of reversible reads "residual effect is likely be reserved after activity completion and reclamation". The proponent concluded that effects of the Project on current use would be reversible (Table 11.3-34). While the proponent's use of the term reversible in the assessment is consistent with their definition, the question begs of whether the proponent's conceptualization of reversibility is appropriate in the context of Gitga'at's harvesting. As noted on p10 of the CEA Agency's most recent guidance on characterization of residual adverse effects, reversibility is about recovery of effects "within a reasonable timescale" (CEA Agency, 2015.*Determining Whether a Designated Project is Likely to Cause Significant Adverse Environmental Effects under the Canadian Environmental Assessment Act, 2012.* 11pp.). While best left to harvesters and Gitga'at as a community to decide, it would seem that several decades of loss of harvesting space (given the Project's proposed duration of "medium term" [see comment above], and potential lag effects due to possible perceptions of environmental degradation following decommissioning) might be a very damaging loss, especially considering some people's lifespans. Please justify your conception of 'reversibility' in the current use harvesting context, and whether it is meaningful and respectful to qualify the loss of harvesting opportunities for several decades as 'reversible'.	Aurora LNG is confident that the environmental assessment presented in the Application is fully compliant with all provincial and federal regulatory requirements. The Application, including Section 11.3, was developed in accordance with the Application Information Requirements (AIR) and informed by pre-application consultation with Aboriginal Groups (see the Aboriginal Consultation Reports). In accordance with the AIR, the definitions of reversibility relate to "whether or not the residual effect can be reversed once the physical work or activity causing the disturbance ceases." As described in Table 11.3-6, the definition of reversibility in the context of the assessment of CEAA 5(1)(c) effects considers whether the residual effect is likely to be reversed after "activity completion and reclamation", which includes decommissioning activities. Applying the characterization of reversibility is linked to the characterization of duration. The definition of "Medium-term" in Table 11.3-6 includes consideration of whether or not a residual effect restricts traditional use, such that the effects extend beyond a single generation (~ 25 years) and effectively remove the knowledge related to a practice at a particular site from the community's Traditional Knowledge. Determining whether or not the potential effect restricts (i.e. effectively prevents) the transfer of knowledge related to a practice at a particular site is the primary consideration in determining whether a potential effect (that is predicted to last beyond the construction phase) should be characterized as "medium-term" or "permanent". If the presence of the Project would prevent Gitga'at First Nation use of particular known sites, then traditional users' ability to share traditional knowledge about those sites would be deprived for the duration of the Project activity. In this case, for the purposes of this assessment, residual effects on land and resources relied on for such a traditional use, which would otherwise be considered "medium –term", are instead characterized as "permanent" and "irreversible" on the basis that the resulting restrictions on the site will prevent the ability to transfer traditional knowledge related to the site where the site is removed from usefor a generation (~ 25 years). However, if Project activities have the potential to affect (but don't prevent) use of the sites where the current use activities occur, then traditional knowledge transfer about the sites and resources harvested or used would not be considered restricted. In this case, the duration of effects is characterized as "medium-term" and "reversible".
2834.1	round 1	Gitga'at First Nation	Table 11.3-7, Table 11.3-34, Table 11.3-36, Table 11.3-37	CEAA 2012	For the characterization of residual effects of 'duration', the definition of 'medium-term' reads "residual effect extends through the duration of construction, operations and decommissioning", and goes on to read "Aurora LNG understands that residual effects that restrict TU and extend beyond a single generation (~25 years) can effectively remove a practice from the community's TK. Therefore, for the purposes of this assessment, residual effects on land and resources relied on for TU that last longer than a single generation (~25 years) will be considered permanent." - so considering that the operation phase is expected to be 25 years, i.e., "a single generation" and due to the permanence acknowledgement of Nexen with impacts lasting one generation, why is there a medium or long-term duration category? It is Gitga'at's view that any effect that exists in construction and continues into operation and decommissioning is permanent; the duration characterization of current use (Table 11.3-34), socio-economic conditions (Table 11.3-36), and physical and cultural heritage (Table 11.3-37) must be changed from "MT [medium-term]" to "P [permanent]", and the significance determination must be re-evaluated.	Aurora LNG acknowledges, as per the definition of "Medium-term" in Table 11.3-6, that residual effects that restrict traditional use and extend beyond a single generation (~ 25 years) can effectively remove a practice from the community's Traditional Knowledge. Therefore, for the purposes of this assessment, residual effects on land and resources relied on for traditional use that last longer than a single generation (~ 25 years) are considered permanent. Determining whether or not the potential effect "restricts" (i.e. effectively prevents) the transfer of knowledge related to a practice at a particular site is the primary consideration in determining whether a potential effect (that is predicted to last beyond the construction phase) should be characterized as "medium-term" or "permanent". If the presence of the Project would prevent Gitga'at First Nation use of particular known sites, then traditional users' ability to share traditional knowledge about those sites would be deprived for the duration of the Project activity. In this case, for the purposes of this assessment, residual effects on land and resources relied on for such a traditional use, which would otherwise be considered "medium –term", are instead characterized as "permanent" on the basis that removing the ability to transfer traditional knowledge related to the site would no longer be possible if the site is removed for a generation (~ 25 years). However, if Project activities have the potential to affect (but don't prevent) use of the sites where the current use activities occur, then traditional knowledge transfer about the sites and resources harvested or used would not be considered restricted. In this case, the duration of effects is characterized as "medium-term".

2835.1	round 1	Gitga'at First Nation	11.3.2.7	CEAA 2012	For Significance Threshold for Current Use, a residual effect exists if the current use activity is "no longer considered viable" - please define "viable". Further information is needed besides "the determination of viability is guided by information provided by Aboriginal Groups and applying professional judgment". Also, similar to comments in the socio-economic Part B VC's, this significance threshold lacks reference to what conditions are and are not acceptable to Gitga'at (and other Aboriginal groups) - please also incorporate stakeholder perspective on what constitutes viable/acceptable conditions, and please revise your effects assessment accordingly.	The Application, including Section 11.3, was developed in accordance with the Application Information Requirements (AIR) and informed by pre-application consultation with Aboriginal Groups (see the Aboriginal Consultation Reports). Aurora LNG acknowledges that Gitga'at First Nation may have differing views regarding significance and the associated threshold as it relates to predicted residual effects on Current Use. In the context of the significance threshold for Current Use, "viability" is the consideration of whether it remains realistically possible and/or feasible to continue to participate in a specific traditional use activity at, or near, current levels (potentially with some level of modification). In accordance with the AIR and the Canadian Environmental Assessment Agency (CEA Agency) document entitled "Reference Guide: Determining Whether a Project is Likely to Cause Significant Adverse Environmental Effects: A Framework" this evaluation considers the assessments of magnitude, geographic extent, duration, reversibility and context (i.e., resilience) for each of the measurable parameters identified for current use. In accordance with the AIR, professional judgement is applied as part of this evaluation in a manner that is consistent with the guidance provided in CEA Agency's document entitled "Technical Guidance for assessing the Current Use of Lands and Resources for Traditional Purposes under the Canadian Environmental Assessment Act, 2012" (December 2015) (see pg. 11). Aurora LNG is confident that the environmental assessment presented in the Application is fully compliant with all provincial and federal regulatory requirements. As a result, the re-assessment, as suggested, is neither warranted nor required.
2836.1	round 1	Gitga'at First Nation	11.3.2.7	CEAA 2012	For Significance Threshold for Aboriginal Health, Socio-Economic Conditions and Cultural and Physical Heritage a residual effect exists if "if a key component (Table 11.3-2) that is relevant... would have a substantial effect ... beyond that considered in the VC analysis in Part B of the Application, it would be considered significant" - this ambiguous, and further information is needed: a) who determines if a component is "key", and "relevant"? b) what constitutes "substantial effect"? measured by who?, and c) what "VC analysis in Part B". Also see comments on Table 11.3-2.	The significance thresholds for Aboriginal Health, Aboriginal Socio-Economic Conditions and Aboriginal Cultural and Physical Heritage were established in accordance with the Application Information Requirements (AIR) and informed by pre-Application consultation completed by Aurora LNG. Aurora LNG acknowledges that Gitga'at First Nation may have differing views regarding significance and the associated threshold as it relates to predicted residual effects on Aboriginal Health, Aboriginal Socio-Economic Conditions and Aboriginal Cultural and Physical Heritage. As indicated in the significance threshold for Aboriginal Health, Aboriginal Socio-Economic Conditions and Aboriginal Cultural and Physical Heritage (pg. 11-47), the key components identified as relevant for each of the three potential effects are identified in Table 11.3.2 (in the "Components included in Assessment" column), which also identifies the Part B VCs that each of the potential effects referenced (pg. 11, 25-26) As provided in Section 11.3.2.7, significance thresholds for Section 5(1)(c) effects were developed by considering feedback received from Aboriginal Groups, taking into account guidance provided by the Canadian Environmental Assessment Agency and the BC EAO, examining similar environmental assessments, and applying professional judgement (pg. 11-47). The consideration, as part of the significance determination, of whether a key component that is relevant to Aboriginal Health, Aboriginal Socio-Economic Conditions, and Aboriginal Cultural and Physical Heritage would have a substantial effect beyond that considered in the VC analysis in Part B of the Application was guided by information provided by Aboriginal Groups and applying professional judgment. In this context, professional judgement was applied in a manner that is consistent with the guidance provided in CEA Agency's document entitled "Technical Guidance for assessing the Current Use of Lands and Resources for Traditional Purposes under the Canadian Environmental Assessment Act, 2012" (December 2015) (see pg. 11).
2837.1	round 1	Gitga'at First Nation	11.3.2.7	CEAA 2012	Significance Thresholds for Residual Effects. Simply because an area is physically available for use does not mean that harvesters would be willing or comfortable using that area. This determination, made by outsiders, does not consider other reasons that are not included in these guidelines.	Please see the memo titled "Additional Information Regarding Methods Used to Consider Traditional Use Information in the Assessment of CEAA 5(1)(c) Factors and Aboriginal Interests" for further information and context related to the treatment of information provided by Aboriginal Groups, including information related to the reported use of the Project Development Area and the adjacent marine area, in Sections 11.3 and 12 of the Application.
2838.1	round 1	Gitga'at First Nation	11.3.3, Appendix S.2, 11.3.12, 11.4	CEAA 2012	As with some of the Part B VCs (e.g., Community Health, harvested foods), the baseline provides little sense of the actual context for further impacts of major project development. The baseline outlines what species are used but doesn't explore the history of colonization and industrialization on Aboriginal use and most importantly the acceptability of current conditions of use to Aboriginal groups in the area. This is not simply an academic issue but is critical for interpreting Project effects (i.e., further impacts on current use may be significant to Gitga'at but are not concluded as such in effects assessments). Further, the notion that harvesters can simply shift their activities to other harvesting grounds ignores the fact of unequal distribution of resources across the region and the limitations imposed by traditional governance boundaries, and also assumes that alternative sites are felt to be of adequate environmental quality. Also in the CEA where major Projects affecting a larger portion of the study area are examined, the proponent still describes that harvesters can just shift harvesting locations. The proponent seems to conclude that the larger RAA means that harvesters have an even larger space from which to shift their activities, thus repeating the issues of unequal distribution of resources, political boundaries, and available of suitable alternative sites raised above further. Please revise the baseline to reflect a deeper understanding of context and please revise the effects assessment and cumulative effects assessment accordingly.	The methods utilized to compile the Existing Condition section and to characterize residual effects were established in accordance with the Application Information Requirements (AIR) and informed by pre-Application consultation completed by Aurora LNG. Regarding the Existing Conditions section (Section 11.3.12.2), the AIR indicates that the Application will summarize relevant baseline conditions for each Aboriginal Group on Aboriginal traditional practices and the current use of lands and resources for traditional purposes that may interact with the proposed Project (pg. 11-9). The information presented in Section 11.3.12.2 (Existing Conditions for Gitga'at First Nation) is in alignment with the requirements of the AIR. Regarding characterizations for Current Use, the specific characterizations for Current Use presented in Section 11.3.12.3 (Assessment of CEAA 2012 5(1)(c) iii—Current Use of Lands and Resources for Traditional Purposes) were assessed based on the information contained in Section 11.3.12.2 and Section 9 (Gitga'at First Nation) of Appendix S.2 (Aboriginal Consultation) and the definitions identified in Section 11.3.2.5 (Residual Effects Description Criteria). Please also see the memo titled "Additional Information Regarding Methods Used to Consider Traditional Use Information in the Assessment of CEAA 5(1)(c) Factors and Aboriginal Interests" for further information and context related to the treatment of information provided by Aboriginal Groups, including information related to the reported use of the Project Development Area and the adjacent marine area, in Sections 11.3 and 12.5 of the Application. Aurora LNG is confident that the environmental assessment presented in the Application is fully compliant with all provincial and federal regulatory requirements. As a result, the re-assessment, as suggested, is neither warranted nor required.
2839.1	round 1	Gitga'at First Nation	11.3.4	CEAA 2012	Please provide more information for why "employment and expenditures" is not considered to impact Aboriginal Socio-Economics?	Section 11 of the Application addresses the assessment requirements of the CEAA 2012 (CEAA 2012) Section 5(1)(c). This section requires an assessment of residual effects on Aboriginal people that result from Project-generated changes to the environment. As such, the effects considered in the assessment of Section 5(1)(c) Effects are those that qualify as "effects to the environment" as defined by CEAA 2012. Effects that may affect Aboriginal people that are not "effects to the environment," such as employment and expenditures, are outside the scope of Section 11, and are considered in Part B of the Application.
2840.1	round 1	Gitga'at First Nation	11.3.5.1	CEAA 2012	It is stated "when interactions are found, identify if the predicted interactions would be different in an Aboriginal context when compared to those interactions described in the original VC section" - what is meant by "Aboriginal context"?	The assessment of CEAA 5(1)(c) effects considered whether the residual environmental effects identified in Part B VC assessments would be experienced differently by Aboriginal people than non-Aboriginal people by taking into account existing data from Aboriginal Groups on Current Use, Aboriginal Health, Aboriginal Socio-Economic Conditions, and Aboriginal Cultural and Physical Heritage. Existing conditions information for Gitga'at First Nation is presented in Section 11.3.12.2. These methods are outlined in Figure 11.3-5 and are consistent with those presented in Figure 11-1 of the AIR.
2841.1	round 1	Gitga'at First Nation	11.3.5.2	CEAA 2012	The assumption that resources harvested on or around Digby Island and in surrounding waters are not unique and can be harvested elsewhere within the LAA depending on protocols and availability is incorrect (and is not "conservative" as the text suggests). A particular species is not equivalent in all locations where it is harvested. Harvesting depends on a myriad of factors including weather, tides, seasonal abundance, quality and quantity at a specific location, proximity and ease of harvest, traditional conservation practices to prevent over harvesting and to allow re-growth, cultural teachings and variations in taste. One can't simply move to another area without it having an impact. This also ties to the last assumption that "all species identified through either Project specific TK and TU studies, or publicly available sources, are hunted, trapped, fished for, or gathered throughout the Current Use RAA." These further heighten Gitga'at's concerns regarding this section. No assumptions such as these should be made and Section 11.3 should be revised.	Information that provides context related to the assessment of the identified potential effects in the Application, including clarification regarding the assumptions utilized in the assessment, is provided in the technical memo entitled "Additional Information Regarding Methods Used to Consider Traditional Use Information in the Assessment of CEAA 5(1)(c) Factors and Aboriginal Interests" which will be filed with the BC EAO.
2842.1	round 1	Gitga'at First Nation	11.3.6.1	CEAA 2012	Due to linkages in Table 11.3-9 and Table 11.3-10, comments above in specific Part B VC apply. For example, we disagree with the methodology of only evaluating LNG carriers docked at the facility, as the shipping lane should be assessed.	The effects of LNG shipping, including LNG carriers and other supporting marine traffic such as tugs, were assessed in the following VC sections: Air Quality (section 4.2), Greenhouse Gases (Section 4.3); Water Quality (Section 4.5); Marine Fish and Fish Habitat (Section 4.9); Marine Mammals (Section 4.10); Marine Birds (Section 4.11); Community Health (Section 6.6); Marine Use and Navigable Waters (Section 6.5); and Human Health (Section 8). LNG carriers docked at the facility represent the most substantial potential effects. The effects of LNG shipping were not carried through certain VC assessments because LNG shipping are not predicted to have measurable effects based on the assessment findings of similar LNG projects (i.e., Pacific NorthWest LNG; LNG Canada). For VC assessments that did not consider effects from LNG shipping traffic, a description of why these effects were not brought forward in the assessment is provided in each of the relevant VC assessments. Aurora LNG believes that the assessment methods, analysis, and conclusions set out in the Application are fair and reasonable, and in compliance with the requirements of the AIR.
2843.1	round 1	Gitga'at First Nation	11.3.6.1	CEAA 2012	Table 11.3-9, Marine Use and Navigable Water, change in marine fisheries and other uses - please justify why "vegetation gathering" (e.g., seaweed) is not relevant?	As outlined in the AIR, Part B, Section 4.9 Marine Fish and Fish Habitat; Potential Project effects on Marine Fish and Fish Habitat, marine plants (e.g. eelgrass, seaweed, and kelps, SARA – listed species) are considered part of marine fish habitat. In regard to measurable parameters for the potential effect change in marine navigation, Section 6.5: Marine Use and Navigable Waters, Table 6.5-3: Potential Effects and Measurable Parameters for Marine Use and Navigable Waters, changes in Marine Fisheries and Other Uses does not address vegetation gathering, and is not applicable to seaweed gathering.
2844.1	round 1	Gitga'at First Nation	11.3.6.1	CEAA 2012	Table 11.3-10, Air Quality, change in ambient CAC concentrations - please justify why this is not relevant to important species that can be impacted by air quality impacts.	Project-related effects to species as a result of changes in air quality, where potential effects may exist, have been considered in relevant VC assessments and reiterated in the Section 11, as appropriate. While potential air quality effects were deemed relevant to the assessment of effects on use of spiritually or culturally important sites (in terms of a human's experience using those sites), air quality effects on spiritually or culturally important species are inferred through the results of relevant VC assessments. Additional Project specific information related to the species of spiritual or cultural importance can be found in the following VC assessments and TDRs: Wildlife Resources (Terrestrial) (Section 4.7 and Appendix J); Freshwater Fish and Fish Habitat (Section 4.8 and Appendix K); Marine Fish and Fish Habitat (Section 4.9 and Appendix L); Marine Mammals (Section 4.10 and Appendix N); Marine Birds (Section 4.11 and Appendix Q); and Vegetation and Wetland Resources (Section 4.6 and Appendix I).
2845.1	round 1	Gitga'at First Nation	11.3.6.1	CEAA 2012	Table 11.3-10, Acoustic Environment - please justify why this is not relevant to important species that can be impacted acoustics (e.g., killer whales).	The predicted Project-related effects to species as a result of potential changes in acoustics, where potential effects may exist, have been considered in the relevant VC assessments (for example, Wildlife Resources in Section 4.7 or Marine Mammals in Section 4.10) and reiterated in Section 11, as appropriate. The Acoustic Environment VC assessment (Section 4.4 of the Application) relates to potential changes to in-air sound levels only, and effects are considered from a human perspective. While potential acoustic-related effects were deemed relevant to the assessment of effects on use of spiritually or culturally important sites (in terms of a human's experience using those sites), acoustic-related effects on spiritually or culturally important species are inferred through the results of other relevant VC assessments. For example, potential changes to underwater sound levels are addressed in the Marine Mammals (Section 4.10) and Marine Fish and Fish Habitat (Section 4.9) assessments, and are reiterated in Section 11.3.12.3. Additional Project specific information related to the species of spiritual or cultural importance can be found in the following VC specific assessments and TDRs: Wildlife Resources (Terrestrial) (Section 4.7 and Appendix J); Freshwater Fish and Fish Habitat (Section 4.8 and Appendix K); Marine Fish and Fish Habitat (Section 4.9 and Appendix L); Marine Mammals (Section 4.10 and Appendix N); Marine Birds (Section 4.11 and Appendix Q); and Vegetation and Wetland Resources (Section 4.6 an Appendix I). The Prince Rupert – Aurora LNG Acoustic Monitoring Study (Appendix O), and the Aurora LNG Acoustic Study: Modelling of Underwater Sounds from Pile Driving, Rock Socket Drilling, and LNG Carrier Berthing and Transiting (Appendix P) also provide further information related to potential acoustic effects on species.
2846.1	round 1	Gitga'at First Nation	11.3.6.1	CEAA 2012	Table 11.3-11 - see comments in each of the Part B VCs comments above, including one of Gitga'at's overlying major concern with the Application in that evidence of effectiveness for many of the mitigation measures presented throughout the Application is missing. Also, there are not any Aboriginal-specific (including Gitga'at-specific) mitigation measures presented.	Aurora LNG is confident in the effectiveness of mitigation measures proposed in the Application to reduce adverse effects of the Project. Aurora LNG requested specific feedback on proposed mitigation measures from Gitga'at First Nation during Technical Workshops #4 and #5. Aurora LNG is currently reviewing feedback received to date on mitigation measures and any revised or new mitigation measures proposed will be included as part of an updated Table 16-1 and 16-2 to be submitted to the EAO on Day 90.
2847.1	round 1	Gitga'at First Nation	11.3.6.1	CEAA 2012	Will Nexen commit to follow-up monitoring programs to verify the accuracy of this assessment, and to determine if the mitigation measures presented in Part B (and referenced again in this section) are indeed effective? Gitga'at would like to be engaged in the development and implementation of follow-up monitoring programs.	Follow-up programs will be designed and implemented to assess the accuracy of the assessment predictions, and the effectiveness of mitigation measures. Section 15 of the Application outlines the proposed follow-up programs for the Project. Aurora LNG will engage with the appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of follow-up programs.
2848.1	round 1	Gitga'at First Nation	11.3.6.2	CEAA 2012	Again, shipping noise should be assessed.	The Aurora LNG Project shipping route distance to the nearest sensitive receptor (i.e., receptor ID R06, Barrett Rock) is 670 m. Based on the shipping noise effect from a similar application (PNW LNG), the predicted nighttime shipping sound level at receptor R06 would be less than 28.5 dBA. The nighttime sound level of 28.5 dBA is well below the nighttime existing sound level of 40 dBA at Barrett Rock presented in Table 4.4-7 of the Application. Further assessment of noise effects along the shipping route is therefore not required. Please see the "Sleep Disturbance and Speech Interference" technical memo for a discussion of the maximum noise level from sounding the marine horn on the LNG vessel during shipping activities. The technical memo will be filed with the BC EAO. The "Sleep Disturbance and Speech Interference" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2849.1	round 1	Gitga'at First Nation	11.3.6.2	CEAA 2012	Table 11.3-12 - see comments in each of the Part B VCs comments above, including one of Gitga'at's overlying major concern with the Application in that evidence of effectiveness for many of the mitigation measures presented throughout the Application is missing. Also, there are not any Aboriginal-specific (including Gitga'at-specific) mitigation measures presented.	Aurora LNG is confident in the effectiveness of mitigation measures proposed in the Application to reduce adverse effects of the Project. Aurora LNG requested specific feedback on proposed mitigation measures from Gitga'at First Nation during Technical Workshops #4 and #5. Aurora LNG is currently reviewing feedback received to date on mitigation measures and any revised or new mitigation measures proposed will be included as part of an updated Table 16-1 and 16-2 to be submitted to the EAO on Day 90.
2850.1	round 1	Gitga'at First Nation	11.3.6.3	CEAA 2012	Table 11.3-13 - see comments in each of the Part B VCs comments above, including one of Gitga'at's overlying major concern with the Application in that evidence of effectiveness for many of the mitigation measures presented throughout the Application is missing. Also, there are not any Aboriginal-specific (including Gitga'at-specific) mitigation measures presented.	Aurora LNG is confident in the effectiveness of mitigation measures proposed in the Application to reduce adverse effects of the Project. Aurora LNG requested specific feedback on proposed mitigation measures from Gitga'at First Nation during Technical Workshops #4 and #5. Aurora LNG is currently reviewing feedback received to date on mitigation measures and any revised or new mitigation measures proposed will be included as part of an updated Table 16-1 and 16-2 to be submitted to the EAO on Day 90.
2851.1	round 1	Gitga'at First Nation	11.3.12.2	CEAA 2012	p. 11-307 what consumption rates were used for Gitga'at?	In the Project specific study provided by Gitga'at First Nation to Aurora LNG, no details on the average consumption rate of traditional foods by community members were included. Please see the technical memo, "Supplemental Information for Traditional Marine Foods" for additional discussionon consumption rates for marine foods. This document will be filed with the BC EAO. The "Supplemental Information for Traditional Marine Foods" technical memo was presented to the Working Group in draft for a pre-read on April 18, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2852.1	round 1	Gitga'at First Nation	11.3.12.2	CEAA 2012	Existing Conditions - Socio-Economic Conditions (p. 11-308): this section has very minimal information. Please provide all of the information that was used to assess socio-economic impacts as they relate to CEAA 2012.	Information used to inform the assessment of Section 5(1)(c) effects for Gitga'at First Nation, including Socio-Economic Conditions, is presented in Section 5.2.3 of Economic Conditions and in Section 9 of the Aboriginal Consultation TDR (Appendix S2).
2853.1	round 1	Gitga'at First Nation	11.3.12.2	CEAA 2012	Due to linkages to Part B VCs, comments above apply - for Marine Birds, Marine Mammals, Wildlife (Terrestrial), Marine Fish and Fish Habitat, and Freshwater Fish and Fish Habitat.	Aurora LNG has assumed that the "comments above" is referring to the question put forth in the preceding comment. Information used to inform the assessment of Section 5(1)(c) effects for Gitga'at First Nation, including Wildlife (Terrestrial), Marine Mammals, Marine Birds, Marine Fish and Fish Habitat, and Freshwater Fish and Fish Habitat, is presented in Sections 4.7.3, 4.8.3, 4.9.3, 4.10.3, 4.11.3 and in Section 9 of the Aboriginal Consultation TDR (Appendix S2).
2854.1	round 1	Gitga'at First Nation	11.3.12.3	CEAA 2012	The "summary of effects (terrestrial and marine)" on p. 11-313 it is stated that "it is anticipated that any specific marine hunting practices would be able to continue, albeit at potentially reduced levels, and it is not anticipated that there will be a measurable change in current use of marine mammals, such that current use cannot continue". This seems to contradict p. 11-312 where noticeable change in current use of marine mammals is predicted. The conclusion for current use on p. 11-333 does not seem to align either. Please clarify.	The quoted text from page 11-313 will be updated to, "it is anticipated that marine hunting practices would be able to continue, albeit at potentially reduced levels. Although as described above, Gitga'at First Nation members may notice a change in marine mammals, it is not anticipated that there will be a measurable change in marine hunting practices such that current use cannot continue". An errata document is being created that will capture these corrections and it will be filed with the BC EAO.

2855.1	round 1	Gitga'at First Nation	11.3.12.3	CEAA 2012	p. 11-314 - what is meant by "0 m depth contours"?	Measuring the total channel width from 0 m depth contours means that the width of the channel was measured from the lowest astronomical tidal height, displayed on the area's nautical chart.
2856.1	round 1	Gitga'at First Nation	11.3.12.3	CEAA 2012	p. 11-315 - states "…safety and access to shoreline sites will be maintained with the implementation of the proposed mitigations": what mitigations exactly?	Safety and access to shoreline sites will be maintained through the implementation of proposed mitigation measures summarized in the Marine Use and Navigable Waters assessment (Section 6.5). Examples of proposed mitigation measures include:A Marine Activities Plan will be developed and implemented to communicate Project construction activities with marine users.Project-related marine traffic, including LNG carriers, will use the Coast Guard Marine Communication and Traffic System (MCTS) to provide notice of planned arrival time at Triple Island. Aurora LNG will encourage Aboriginal Groups to use the system to plan their routing and scheduling.LNG carriers will maintain safe operating distances from other marine craft.LNG carriers will strictly adhere to the prescribed route and passing restrictions.LNG carriers, tugs, and barges will not exceed a speed of 16 knots within the LAA.
2857.1	round 1	Gitga'at First Nation	11.3.12.3	CEAA 2012	p. 11-315 states "… because shipping has occurred along the shipping route for decades, it is expected that mariners will be accustomed to navigating around large vessel traffic" - as stated in other comments, Gitga'at disagrees with the use of this statement in the EA (also, consider the LNG carrier is a new vessel to the region). Therefore, the conclusion that "Gitga'at First Nation members are expected to experience little to no change from existing conditions" is not supported.	The Project will result in the addition of LNG carriers to marine shipping traffic; however LNG carrier vessels are similar with respect to their size, speed, and maneuverability to other large marine vessels currently traveling in the RAA, such as cruise ships and container vessels traveling to the Port of Prince Rupert. LNG carriers will also travel along the existing shipping route. Given proposed mitigations, it is unlikely that two LNG carriers transits per day (at full build out) associated with the Project would reduce access to sites located along the shipping route, as marine users will still be able to travel through the existing shipping lanes. For these reasons the assessment concludes that little to no change from existing conditions or alteration of behaviour to access marine or terrestrial hunting locations is anticipated .
2858.1	round 1	Gitga'at First Nation	11.3.12.3	CEAA 2012	p. 11-318 states "These effects are anticipated to be reversible following the removal of underwater sound sources and lighting, localized, and are expected to not jeopardize the ability of a fish to complete one or more of their life processes" - what is meant by this statement? What processes?	This terminology is drawn from the wording provided by DFO in their definition of serious harm to fish (DFO 2013). The intention of using this wording is to explicitly align Aurora LNG's assessment with regulatory guidance. Although DFO do not provide a strict definition of "life processes", Aurora LNG interprets this term to mean any aspect of a species' biology or life history that must be completed in order to successfully perpetuate the species. These processes are typically considered to include feeding and growth, reproduction, predator avoidance, and adjusting to environmental changes. Examples of life-history traits that would also fall within the scope of "life processes" include migration and any species-specific behaviours necessary to spawn or reproduce (e.g. courtship rituals or vocalizations). Reference: Fisheries and Oceans Canada (DFO). 2013. Fisheries Protection Policy Statement. Available at: http://www.dfo-mpo.gc.ca/pnw-ppe/pol/PolicyStatement-EnoncePolitique-eng.pdf. Accessed: July, 2016.
2859.1	round 1	Gitga'at First Nation	11.3.12.3	CEAA 2012	p. 11-318 states "Residual effects on fish behaviour are not anticipated to threaten the long-term persistence of a marine fish population" - was fish individuals or populations assessed? What evidence does Nexen have to justify this statement?	Please see Section 4.9 of the Application for a full assessment of effects on Marine Fish and Fish Habitat. Specifically, effects on fish were assessed by considering potential interactions between Project activities and fish or their habitats. Although interactions are mediated via interactions at an individual level, the importance of these effects lies in the extent to which they could result in adverse effects at the population level. Consequently, population effects are integral to the marine fish and fish habitats assessment. Specifically, fish populations are considered as part of the magnitude characterization of residual effects (Table 4.9-5) and the definition of significance for effects on marine fish and fish habitat (Page 4.9-17).
2860.1	round 1	Gitga'at First Nation	11.3.12.3	CEAA 2012	p. 11-318 - what about disposal at sea impacts at Brown Passage?	The discussion of potential effects on marine fish and fish habitat associated with 'disposal at sea' activities refers to potential effects at the proposed Brown Passage site. Potential effects associated with disposal of dredged materials at sea (at Brown Passage) are characterized under the 'change in habitat' effect, the 'change in mortality risk' effect, and the 'change in health' effect (Section 4.9 of the Application).
2861.1	round 1	Gitga'at First Nation	11.3.12.3	CEAA 2012	p. 11-319 states "… the loss of a limited number of individuals is not expected to threaten the long term persistence of a marine fish population…" - what evidence does Nexen have to justify this statement?	The concept that some individuals in a population can be lost without threatening the long-term persistence of that population is a fundamental principle in ecology, the basis of all food webs, and a foundational component in the management of wildlife hunts and fisheries. That is, if some individuals in a population die, the population itself does not necessarily suffer calamitous consequences. The productivity of the population is such that the loss of those individuals does not necessarily result in a long-term and precipitous decline in population levels. As mortality levels increase, the potential for population-level ramifications to occur also increases. Aurora LNG's assertion that Project effects will not threaten the long-term persistence of a marine fish population is based on the assessment, characterization (which considers the magnitude, geographic extent, frequency, duration, reversibility, and context of extent; Table 4.9-5), and likelihood of residual effects (please see Sections 4.9.5, pages 4.9-41 to 4.9-63, 4.9-69 to 4.9-78, 4.9-87 to 4.9-95, and 4.9-101 to 4.9-106).
2862.1	round 1	Gitga'at First Nation	11.3.12.3	CEAA 2012	p. 11-319 states "With offsetting, it is anticipated that current use can continue, and it is not anticipated that there will be a measurable change in current use of fish species"; more information is required on fish offsetting before statements/conclusions such as these can be made.	A Conceptual Fish Habitat Offsetting Plan was included as part of the Application. Please refer to Appendix V for details regarding the conceptual plan.
2863.1	round 1	Gitga'at First Nation	11.3.12.3	CEAA 2012	p. 11-319 in a few instances, Nexen describes that Gitga'at does not harvest freshwater fish in any streams within the PDA; these statements must be made with caution because it is does not mean that Gitga'at does not harvest anadromous species that use freshwater ecosystems within the PDA.	The referenced statements are included within the measurable parameter of quantity and quality of current traditional use locations where use will be affected. This measurable parameter is assessed based on traditional use locations identified by Gitga'at First Nation in Project specific or publicly available studieswhere use may be affected. As indicated in the Application, project specific information reports that Gitga'at First Nation members currently harvest both marine fish and intertidal species near the PDA and marine infrastructure exclusion zone, however information was not provided to indicate that freshwater streams within the PDA are used by members for fishing. Potential effects to anadromous species utilizing freshwater streams within the PDA was assessed in the Freshwater Fish and Fish Habitat VC and considered in the Current Use assessment through the measurable parameter of quantitative and qualitative changes in currently harvested species.
2864.1	round 1	Gitga'at First Nation	11.3.12.3	CEAA 2012	p. 11-321 "use of radar or other software that can broadcast real-time Automatic Identification Systems information will help fishers anticipate the movements of LNG carrier traffic and plan their responses accordingly" - does Nexen have data on how many Aboriginal boats (including personal, not just commercial) have said technology? How will conflicts between LNG vessels and tugs be resolved? Who will get out of the way for who?	Information regarding recreational and commercial boats, including boats operated by Aboriginal community members, can be acquired through the Department of Oceans. Commercial and Marine fisheries are managed by DFO using spatially-defined management areas, and recreational fishing is an activity enjoyed by local residents including Aboriginal community members. These activities are regulated by DFO under the BC Sport Fishing Regulations of the Fisheries Act. As described in Section 6.5: Marine Use and Navigable Waters, Traffic management procedures and protocols, pursuant to Section 56 of the Canada Marine Act are outlined in detail in the Prince Rupert Port Information Guide (PRPA 2015). Notable marine safety and security measures include the use of automated electronic harbour scheduling software, and the requirement to file detailed ship and cargo information prior to entering the port. Information is submitted electronically and simultaneously to the PRPA, TC and RCMP.
2865.1	round 1	Gitga'at First Nation	11.3.12.3	CEAA 2012	p. 11-326 the vagueness on the amount of "rocky substrate" (for kelp) that will be altered or lost due to dredging and marine construction is concerning. Due to the amount of dredging required, it is assumed that Nexen would know how much of that area is rocky or not? Please provide a refined estimate on the amount of kelp predicted to be alternated/lost from the Project.	Aurora LNG is of the opinion that the approach and level of detail provided in Section 4.9.5.2 ('change in habitat' effect, Marine Fish and Fish Habitat VC) is sufficient to support the assessment and characterization of anticipated kelp loss due to Project construction activities. The approach included applying the following conservative assumptions: i) that marine algae of cultural importance (such as kelp) existed in areas where physical conditions are appropriate for its growth (i.e., on rocky substrate), but for which data was not available (i.e., the absence of kelp observations from an area was not used to infer the absence of kelp), and ii) the upper limit of hard substrate was anticipated to be the amount of rocky habitat altered or lost (i.e., 35% for South Digby Island and 20% for Casey Cove). Aurora LNG acknowledges that the amount of rocky substrate and kelp anticipated to be altered or lost as a result of Project activities may be further refined during final engineering and design (e.g., from refining information around dredging activities), and if so, this information will be applied to further refine estimates of habitat alteration and losses during preparation of an application for a Fisheries Act authorization.
2866.1	round 1	Gitga'at First Nation	11.3.12.3	CEAA 2012	p. 11-330 states "However, the PDA will include a vegetated riparian buffer that avoids must of the identified archeological and heritage resources with highest significance located in the PDA" - "highest significance" for who?	As discussed in Section 7: Assessment of Potential Heritage Effects, 7.2.7.1 Significance of Project of Residual Effects, "While there are archaeological and heritage resources within the LAA/RAA, the Project activities that could affect them will be limited to the area outside the proposed buffer zone, thereby wholly or partially avoiding most of the archaeological or heritage resources in the PDA with the highest significance." Heritage resources, archaeological sites, and historic places are defined in accordance with applicable federal and provincial legislation. The provincial HCA automatically protects archaeological and heritage resources that pre‑date AD 1846 as well as Aboriginal rock art and human remains, regardless of their age. Section 5(1)(c) of the Canadian Environmental Assessment Act, 2012 (CEAA 2012) requires consideration of Aboriginal physical and cultural heritage and of any structure, site or thing that is of historical, archaeological, palaeontological or architectural significance and potential archaeological, cultural, and heritage resources have been identified as being of concern to regulators, Aboriginal Groups, stakeholders, and the public. Significance in this context is defined as per the BC Archaeological Impact Assessment Guidelines (Archaeology Branch 1998).
2867.1	round 1	Gitga'at First Nation	11.3.12.3, Table 11.3-34	CEAA 2012	Please justify why for 'current use (consumptive), Fishing' context has a moderate to high resilience?	An error was made in the characterization of residual effects on Gitga'at First Nation's Current Use fishing practices. The effects should have been characterized as having a low level of resilience. This change will be incorporated as an errata. An errata document is being created that will capture these corrections and it will be filed with the BC EAO.
2868.1	round 1	Gitga'at First Nation	11.3.12.4, Table 11.3-35	CEAA 2012	For both 'changes in human health from changes in marine harvested food quality' and 'changes to Aboriginal health from change in noise levels' duration is denoted as "ST[short-term] - LT[long-term]" - this large range seems inappropriate, please justify.	An error was made in the characterization of duration for "changes in human health from changes in marine harvested food quality" and "changes to Aboriginal health from change in noise levels". The duration of residual effects should have been characterized as medium-term in accordance with the definitions in Tables 11.3-6. An errata document will be prepared that will captures these corrections and it will be filed with the BC EAO.
2869.1	round 1	Gitga'at First Nation	11.3.12.5, Table 11.3-36	CEAA 2012	Please justify why 'changes as a result of changes to harvested foods' has moderate to high resilience? Especially considering that the current baseline conditions are already at a compromised state for some species.	An error was made in the characterization of residual effects on Gitga'at First Nation's Aboriginal Socio-Economic Conditions as a result of changes to harvested foods. The effects should have been characterized as having a low level of resilience. This change will be included in an errata document that is being prepared to capture these corrections and it will be filed with the BC EAO.
2870.1	round 1	Gitga'at First Nation	11.3.12.6, Table 11.3-37	CEAA 2012	For 'changes in consumptive land and resource use' context is denoted as "L [low resilience] - H [high resilience]" - this large range seems inappropriate, please justify.	The assessment of Aboriginal Physical and Cultural Heritage took into account the conclusions from the assessment of Current Use, including consumptive land and resource use. The characterization of residual effects on consumptive land and resource use was divided into separate hunting, fishing, trapping, and vegetation gathering subsections; each of these effects were characterized separately. As outlined in Table 11.3-34, residual effects for hunting were characterized as having a moderate resilience for the terrestrial environment and a low resilience for the marine environment; residual effects for fishing, trapping and vegetation gathering were characterized as having a medium to high resilience. Table 11.3-37 presents the characterization of residual effects on consumptive land and resource use as low to high to reflect these distinct characterizations.
2871.1	round 1	Gitga'at First Nation	11.4	CEAA 2012	What significance thresholds for this section were used? This information is required to review this section further.	As outlined in Section 11.3.2.7 of the Application, a cumulative residual effect on Current Use would be considered significant if the predicted effect results in a condition where participation by Aboriginal people in a current use activity is no longer viable within existing conditions. A cumulative residual effect on Aboriginal Health, Aboriginal Socio-Economic Conditions, and Aboriginal Cultural and Physical Heritage would be significant if a key component would have a substantial effect on Aboriginal people's health, socio-economics or cultural and physical heritage beyond that considered in the VC assessment in Part B of the Application. The significance determinations considered the magnitude, geographic extent, and duration of key components that could interact with CEAA 2012 5(1)(c) effects , as well as whether the residual effect on Current Use, Aboriginal Health, Aboriginal Socio-Economic Conditions, or Aboriginal Cultural and Physical Heritage takes place in a context that has low resilience as defined in Table 11.3‑6.
2872.1	round 1	Gitga'at First Nation	12	Aboriginal Consultation	The GFN traditional use study is illustrative of Gitga'at occupation and use of a defined study area. As noted in the past, the occupation and use information is not exhaustive as time and budget did not allow for interview of all community members.	While the information contained in the study helped Aurora LNG more fully understand Gitga'at First Nation's traditional use in the Project-area, Aurora LNG acknowledges the limitations of the study.
2873.1	round 1	Gitga'at First Nation	12	Aboriginal Consultation	Within Gitga'at's traditional use study, a listing of species is not necessarily exhaustive, hence each listing begins with "including." In the EA application "including" should always be used in listings as well.	Aurora LNG acknowledges this comment, and has included this change in the errata document that is being compiled and will be filed with the BC EAO.
2874.1	round 1	Gitga'at First Nation	12	Aboriginal Consultation	There are several statements that Gitga'at's use of the Study Area is by members who live in Prince Rupert. Nowhere is this statement made in the Gitga'at's traditional use report. Gitga'at's use of the Study Area is by members who live in a number of communities including Hartley Bay, Vancouver and Prince Rupert.	Aurora LNG acknowledges this comment, and has tried to reflect this understanding by using the broad term "Gitga'at First Nation members" throughout the assessment, which includes anyone who is part of Gitga'at First Nation, regardless of where they reside. Aurora LNG also considered potential effects on Gitga'at First Nation members travelling to or from Prince Rupert (see for example Section 12.5.9.8 starting on page 12-303).
2875.1	round 1	Gitga'at First Nation	12	Aboriginal Consultation	As stated in Gitga'at's traditional use study report, Gitga'at's use of the Study Area has been impacted over the years by external factors including land alienation, industrialization, pollution, government legislation and regulations, and commercial over-harvesting. It is incorrect to imply that Gitga'at members not using an area or a particular resource was a decision made outside of the above context. It is also incorrect for Nexen to assume that if an area is not currently being used, it will not be used in the future.	Aurora LNG appreciates that Gitga'at First Nation included information in its Project-specific study regarding the influence of external factors on Gitga'at First Nation use of the Project vicinity. Aurora LNG was able to incorporate this information into the assessment in several locations: see Section 12.5.9.5 (Changes in Harvested Species, page 12-277 and again on page 12-291), and Section 12.5.9.6 (page 12-300). As described in Section 12.5.9.5 (page 12-276), Aurora LNG assumes that Gitga'at First Nation would like to continue to use the Project vicinity for the same purposes, and in the same ways, as it currently uses the area. Aurora LNG also notes that some important marine resources are not currently available for harvesting and that Gitga'at First Nation would like to resume harvests in the future, even if these resources are not currently harvested.
2876.1	round 1	Gitga'at First Nation	12.1.1	Aboriginal Consultation	Principle 1 states that information received from Aboriginal Groups will be meaningfully considered - can you please describe Nexen's view of meaningful.	Aurora LNG amalgamated, in the Technical Data Report (see Appendix S2), all known Gitga'at First Nation culturally important sites, marine use information, species and locations used for hunting, trapping, fishing, and vegetation gathering, as well as information regarding Gitga'at First Nation infrastructure, businesses and services. From this dataset, Aurora LNG then incorporated this information about Gitga'at First Nation's use of the Project vicinity into the assessment in Part C. In acknowledgement of the nuanced and important context to Gitga'at First Nation's use of the area, Aurora LNG endeavored to incorporate direct quotes from Gitga'at First Nation into the assessment in Part C wherever possible. Gitga'at First Nation had the opportunity to review the draft Part C (and Section 11.3) prior to submission of the Application for screening review and to discuss any views or feedback at Technical Workshop #3, which was held on October 13-14, 2016. The views provided by Gitga'at First Nation as part of that workshop were incorporated into Sections 11.3 and 12.3 of the Application, in accordance with the AIR (see Tables 11.3-6 and 12.9-1). As noted in Table 12.9-1, in many cases feedback received from Gitga'at First Nation resulted in revisions to the final version of Part C submitted to the BC EAO. Aurora LNG believes the depth and scope of incorporation of Gitga'at First Nation information in Part C as described above is meaningful.
2877.1	round 1	Gitga'at First Nation	12.2.2	Aboriginal Consultation	Tsimshian Cultural Groups. This section has ignored the Gitga'at summary in the Gitga'at traditional use study. Southern Tsimshian is a recent construct of anthropologists and does not reflect Gitga'at's views. Gitga'at has a long history that is not only tied to the Douglas Channel region. Historically Gitga'at occupied villages on the Skeena River and in the Prince Rupert Harbour as set out in the traditional use study.	Aurora LNG acknowledged this concern in the preamble to the presentation of material in Section 12.2.2, and referenced Gitga'at First Nation's Project-specific use study: "However, divisions between Tsimshian groups are not recognized universally, and are not reflected in all ethnographic and historic records (Inglis 2016). These divisions are presented here to provide context." The assessment of effects on Gitga'at First Nation's Aboriginal Interests incorporates the information presented in Gitga'at First Nation's Project-specific study. Please see Section 12.5.9.3 for a direct quote from the study (on page 12-275) regarding past use and occupation of the Prince Rupert harbour region.

2878.1	round 1	Gitga'at First Nation	12.2.2.2-4	Aboriginal Consultation	This is a limited and simplistic discussion of Tsimshian social and political organization. Please provide more information.	In accordance with Section 12.2 of the AIR, Aurora LNG presented a "brief summary of publicly available and relevant information on ethnography, language, land use setting and planning, governance, economy, and Indian Reserves for Schedule B Aboriginal Groups" in Section 12.2 of the Application. Based on Project-specific studies provided by Aboriginal Groups, feedback received from Aboriginal Groups during consultation activities, and on information in the public domain, Aurora LNG understands that the Aboriginal Groups discussed in Section 12.2 share similarities in language, traditional harvesting practices, and over-arching social organization. As a result, Aurora LNG also provided a background section including, in brief, a discussion regarding the general cultural similarities among the Aboriginal Groups. Aurora LNG has also included a list of publicly available documents that provide detailed background information on the subjects summarized in Section 12.2 (see Seguin Anderson 2006; Halpin and Seguin 1990; Menzies 2011 for examples).
2879.1	round 1	Gitga'at First Nation	12.2.2.5	Aboriginal Consultation	This is too simplistic. Many resources harvested by Gitga'at members in the past and today are not mentioned including many varieties of fish (black cod, snapper, etc), sea mammals (seals and sea lions), and terrestrial animals (deer, bear, porcupines, etc.). There is no mention of trapping. Seasons of harvesting are much broader and more complicated than presented. For example clams and cockles are harvested primarily over the winter months (November through February). Others are harvested year round. Seagull eggs and abalone are not collected from beaches. Please provide more information.	The overview provided in Section 12.2.2.5 of the Application is meant to be a brief summary as required by the AIR (Section 12.2). A full description of Gitga'at First Nation use of the Project vicinity is included in Section 12.5.9.3. In addition, Aurora LNG amalgamated a dataset of known Gitga'at First Nation use (including, among other things, seasonal information and areas outside the Project Vicinity) in the Aboriginal Consultation Technical Data Report (See appendix S2, Section 9.5).
2880.1	round 1	Gitga'at First Nation	12.2.8.2	Aboriginal Consultation	The term Southern Tsimshian is a term recently developed by anthropologists. It is not recognized by Gitga'at as discussed in the Gitga'at's traditional use study.	Aurora LNG acknowledged this concern in the preamble to the presentation of material in Section 12.2.2, and referenced Gitga'at First Nation's Project-specific use study: "However, divisions between Tsimshian groups are not recognized universally, and are not reflected in all ethnographic and historic records (Inglis 2016). These divisions are presented here to provide context." The assessment of effects on Gitga'at First Nation's Aboriginal Interests incorporates the information presented in Gitga'at First Nation's Project-specific study. Please see Section 12.5.9.3 for a direct quote from the study (on page 12-275) regarding past use and occupation of the Prince Rupert harbour region.
2881.1	round 1	Gitga'at First Nation	12.2.8.6	Aboriginal Consultation	This section is very limited, e.g., where is fishing?	The importance of the commercial fishery to Gitga'at First Nation is described in Section 12.5.9.9 (Assessment of Effects on Gitga'at First Nation Economic Opportunities). Potential Project effects on Gitga'at First Nation commercial fishing are also described in that section.
2882.1	round 1	Gitga'at First Nation	12.3	Aboriginal Consultation	For clarity, this section should be revised to clearly describe what "Schedule B Aboriginal Groups" were involved in each of the activities and plans/reports (due to the Section 13 Orders).	The level of detail in Section 12.3 is in accordance with the AIR (Section 12.3) to provide a brief summary of: the Second Aboriginal Consultation Report (ACR#2) changes to the Aboriginal Consultation Plan as a result of feedback from Aboriginal Groups key issues raised by Schedule B Aboriginal Groups regarding the environmental assessment. For an in-depth description of the different consultation activities undertaken by Aurora LNG in the pre-Application phase, please see the ACR#2 in Appendix S1 of the Application. Consultation activities are described for each Aboriginal Group in that document. Aurora LNG will be providing a draft of Aboriginal Consultation Report #3 (i.e. the interim consultation report) at day 90 of the 180 day Application-review period (as per the EAO's letter of December 14, 2016). As part of the draft Aboriginal Consultation Report #3, Aurora LNG will report on its understanding of the status of issues/concerns resolution with Gitga'at First Nation for the issues/concerns recorded during all phases of the EA (in table format), including those identified in Aboriginal Consultation Report #2 and recorded as part of Technical Workshops #4 and #5. The final version of Aboriginal Consultation Report #3 will be submitted at day 120 of the 180 day Application-review period (as per the section 11 Order [as amended]).
2883.1	round 1	Gitga'at First Nation	12.3.6	Aboriginal Consultation	It is unclear to Gitga'at why two versions of Gitga'at's pre-application concerns exist in the Application, i.e., Appendix S.1, Table 10-1 and Table 12.3-6?	The various records of Gitga'at First Nation's pre-application concerns align with requirements for different documents. Table 10-1 in Appendix S1 represents a full list of Gitga'at First Nation concerns raised during pre-Application, including concerns not directly related to the Application. Table 12.3-6, as required by the AIR, summarizes key issues raised by Gitga'at First Nation regarding the environmental assessment (all sections). Another table (Table 12.9-1) presents Gitga'at First Nation's pre-Application views on Part C specifically.
2884.1	round 1	Gitga'at First Nation	12.4, 12.5.2.4	Aboriginal Consultation	Water quality is missing from Table 12.4-1 and Section 12.5.2.4 (and subsequently in Part C assessments). Please justify why.	Potential changes to water quality could affect the exercise of Gitga'at First Nation Aboriginal Interests through effects on species or habitats used for harvesting-related activities and cultural wellbeing. These effects have been considered in the relevant Part B VCs, which are listed in Table 12.4-1 and described in the assessments in Section 12.5.9.5 and 12.5.9.6.
2885.1	round 1	Gitga'at First Nation	12.5.1, 12.5.2	Aboriginal Consultation	The assessment of potential impacts on the exercise of Aboriginal title relies in part upon the availability of other areas within an Aboriginal group's traditional territory that activities can be shifted. Given a context of colonization, industrialization, continued degradation of natural resources and access, this assessment criterion seems inappropriate. Notwithstanding the previous issues, there are also other problems with shifting activity, namely traditional governance regimes that dictate who can harvest where, the dynamic nature of ecosystems, and the importance of most if not all marine space for harvesting. Please justify the assumption that Aboriginal people can simply shift harvesting or other traditional activities. This assumption was also made in Section 12.5.2.3 where the Project's "interference with the exercise of an Aboriginal Interest" by taking into account "the relative importance of the Project vicinity as well as the availability of other areas within the traditional territory of an Aboriginal Group where the meaningful exercise of Aboriginal Interests could reasonably occur". Please define "meaningful exercise" and "reasonably".	Please see the memo titled "Additional Information Regarding Methods Used to Consider Traditional Use Information in the Assessment of CEAA 5(1)(c) Factors and Aboriginal Interests" for further information and context related to the treatment of information provided by Aboriginal Groups, including information related to the reported use of the Project Development Area and the adjacent marine area, in Sections 11.3 and 12 of the Application. As indicated in Section 12.5.1, the AIR requires that Aurora LNG provide information regarding the following two factors when determining the degree to which the Project may result in residual effects on the exercise of Aboriginal Interests:the relative importance of the Project vicinity and its surroundings to the exercise of an Aboriginal Group's Aboriginal Interests, including any special characteristics or unique features of that area the relative availability of other areas in reasonable proximity, within the traditional territory of each Aboriginal Group, where the meaningful exercise of Aboriginal Interests could reasonably occur In Section 12.5.9.5 (harvesting-related Aboriginal Interests), Aurora LNG included the following text to highlight uncertainty around the availability of other areas: "The Gitga'at First Nation Report focused on Gitga'at First Nation use within the Project vicinity. As a result, Aurora LNG does not know if Gitga'at First Nation members harvest the same resources elsewhere in the traditional territory, nor how much the Project vicinity is preferred for the harvest of these marine species (relative to other available areas available to Gitga'at First Nation members)." (page 12-291) In Section 12.5.9.6 (cultural wellbeing), Aurora LNG included the following statement addressing the concerns raised by Gitga'at First Nation in this comment: "Aurora LNG understands that the Project vicinity may have unique importance and features not found elsewhere in Gitga'at First Nation traditional territory. Aurora LNG understands that the locations that are available to Gitga'at First Nation community members for cultural activities may be restricted by various factors including traditional governance, harvesting protocols, commercial or residential development (including private or restricted lands), and access." (page 12-300).
2886.1	round 1	Gitga'at First Nation	12.5.9.3	Aboriginal Consultation	This section is incomplete. Past use would have been more extensive than present as there was limited outside interference by settlers, industry and government. Present use has been impacted by land alienation, urban development, industrial activities, pollution, commercial activities, and federal and/or provincial land and resource legislation and regulations. Also, at times, the examples are not complete and do not set out the full range of species or locations used by Gitga'at. Future use will likely expand with increase in population and will continue to be impacted as noted above. Already Gitga'at members relate that they are not able to harvest enough for individual, community and other purposes. Also, (and again) harvesting in the Prince Rupert region is not limited to Gitga'at members who live there - Gitga'at members who live in Hartley Bay and other places also harvest in the Prince Rupert region. Please revise this section.	Description of Past Use: Based on the information available to Aurora LNG at the time of writing the Application, a description of Gitga'at First Nation past, present, and future use of the Project vicinity is included in Section 12.5.9.3. In addition, Aurora LNG amalgamated a dataset of known Gitga'at First Nation use (including, among other things, seasonal information and areas outside the Project Vicinity) in the Aboriginal Consultation Technical Data Report (See appendix S2, Section 9.5). Impact of External Factors on Present Use: Aurora LNG appreciated that Gitga'at First Nation included information in its Project-specific study regarding the influence of external factors on Gitga'at First Nation present use of the Project vicinity. Aurora LNG was able to incorporate this information into the assessment in several locations: Section 12.5.9.5 (Changes in Harvested Species, page 12-277 and again on page 12-291), and Section 12.5.9.6 (page 12-300). As described in Section 12.5.9.5 (page 12-276), Aurora LNG assumes that Gitga'at First Nation would like to continue to use the Project vicinity for the same purposes, and in the same ways, as it currently uses the area. Aurora LNG also notes that some important marine resources are not currently available for harvesting and that Gitga'at First Nation would like to resume harvests in the future, even if these resources are not currently harvested. Gitga'at First Nation Members Who Do Not Live in Prince Rupert: Aurora LNG acknowledges this comment and has tried to reflect this understanding by using the broad term "Gitga'at First Nation members" throughout the assessment, which includes anyone who is part of Gitga'at First Nation, regardless of where they reside. Aurora LNG also considered potential effects on Gitga'at First Nation members travelling to or from Prince Rupert (see for example Section 12.5.9.8 starting on page 12-303).
2887.1	round 1	Gitga'at First Nation	12.5.9.5	Aboriginal Consultation	Importance of Project Vicinity. Add seals to the list of species harvested in the vicinity of the PDA.	Aurora LNG has added seals to the list of species harvested in the vicinity of the PDA. This will be included in an errata document being compiled that will capture corrections and it will be filed with the BC EAO.
2888.1	round 1	Gitga'at First Nation	12.5.9.5	Aboriginal Consultation	On p12-278 (s.12.5.9.5) the proponent notes that the Gitga'at First Nation is concerned that resource users would shift their activity south into Gitga'at core territory. In response, the proponent noted that it "does not anticipate the presence of the Project will result in increased use of Gitga'at First Nation territory by other resource users." No rationale for this conclusion was provided, yet the proponent's methodology for this part of the application presumes that shifting of activities away from the Project site will occur and be a way that Aboriginal groups adapt to the Project. Please explain why resource users won't shift their activity southward into Gitga'at core territory.	Aurora LNG understands that the Project vicinity is valued by resource users for its close proximity to Prince Rupert, and because the area was historically a shared resource area among several house groups. As a result, Aurora LNG anticipates that resource users will continue to harvest in other areas close to Prince Rupert, in accordance with traditional governance protocols.
2889.1	round 1	Gitga'at First Nation	12.5.9.5 and 12.5.9.8	Aboriginal Consultation	On p12-286 (s.12.5.9.5) and again on p12-304 (s.12.5.9.8) the proponent takes the position that the Project's two vessel transits per day will not reduce access to harvesting sites along the shipping route or affect marine navigation because marine users will be able to avoid temporary Project marine traffic and continue with their activities. This argument is flawed because it ignores how there is already large vessel traffic in the area, and the Project will add to this traffic, never mind possible other future additions to this traffic. In other words, the Project will not operate in a void but will inevitably contribute to the CEs of other current and future shipping. Please revise the analysis to reflect the reality that the Project's shipping traffic will not occur in a void but will add to the CEs of existing and future large vessel traffic.	Aurora LNG has incorporated the Project's contributions to cumulative effects from shipping in the Changes in Harvesting Locations and Access Routes assessment in Section 12.5.9.5 (see page 12-286). The pre-existing shipping conditions in the region are considered in Section 12.5.9.8 on page 12-304.
2890.1	round 1	Gitga'at First Nation	12.5.9.5	Aboriginal Consultation	The proponent argues that the aesthetic effects of the Project will 'not considerably alter' existing conditions given that the Prince Rupert harbour area is already industrialized and already used for shipping (p12-291 (s.12.5.9.5). The proponent does not seem to be thinking about CEs and limits of acceptability, or more colloquially, what amount of straw will break the camel's back. Please revise the baseline and assessment to reflect an understanding of the level of acceptability of current conditions in the Prince Rupert harbour and how additional changes relate to this significance threshold.	Aurora LNG has incorporated the Project's contributions to cumulative effects from shipping in the Changes in Harvesting Locations and Access Routes assessment in Section 12.5.9.5 of the Application (see page 12-286). The pre-existing shipping conditions in the region are considered in Section 12.5.9.8 on page 12-304. Aurora LNG is unable to apply a defensible threshold in Part C to determine when an aesthetic effect could significantly alter the exercise of an Aboriginal Interest. This is because Aurora LNG cannot meaningfully measure or predict an individuals potential response to differing potential residual effects from the Project.
2891.1	round 1	Gitga'at First Nation	12.5.9.5	Aboriginal Consultation	The proponent expects that trollers and other types of fishers should be able to adapt to LNG carriers by temporarily moving out of the way (e.g., p12-286 (s.12.5.9.5)), yet no evidence was provided to support this assertion. Given that large vessel traffic has been active in the area for many years alongside commercial and traditional fishing, there should be evidence of how well the two marine uses co-exist. Please provide evidence supporting the assertion that large vessel traffic is not a problem for commercial and traditional fishers.	Aurora LNG did not conclude that large shipping traffic is "not a problem for commercial and traditional fishers." Rather, Aurora LNG has provided reasonable evidence to suggest that commercial and traditional fishing activities within the shipping lane could be interrupted by passing vessels, for up to a maximum of one hour per day. Furthermore, Aurora LNG incorporated additional input from Gitga'at First Nation (received during consultation), that "the potential effects on commercial fishing may be exacerbated because of the duration of commercial fishery openings. According to Gitga'at First Nation, the commercial openings for some salmon species are particularly short. Therefore, should a Project-related vessel require a salmon fisher to move gear during an already brief commercial opening, this could cause increased interference and have economic consequences." (Section 12.5.9.5, page 12-286).
2892.1	round 1	Gitga'at First Nation	12.5.9.5	Aboriginal Consultation	The proponent regularly seems to assume that all marine space is uniform in terms of harvesting opportunities. For example, on p12-286 (s.12.5.9.5) the proponent writes "[a] worst-case, unmitigated, and unlikely scenario is that a fisher might lose a total of one hour of fishing time per day because of interacting with both LNG carrier transits (daily incoming and outgoing). While unlikely, this scenario could have a low to medium magnitude effect on a fisher's one-day catch, and is not be anticipated to occur on a regular basis when all the mitigations are implemented (and considering the total area within the traditional territory available for fishing)." Yet marine space differs in numerous ways; while in general the entire region is important for harvesting, particular harvesting locations differ in terms of aesthetics, exposure to bad weather, marine habitat quality, and availability of target species (which can also vary year-to-year). Please revise baseline and effects assessment to incorporate an understanding of the non-uniform nature of harvesting grounds. In revising, please ensure adequate information is included for all mitigations presented. The assessment failed to acknowledge that specific fisheries (i.e., salmon) are only open during limited periods of time, measured in hours. Therefore, the loss of one hour of fishing effort can have a significant effect on harvest, sustenance, and economic gain. Mitigation measures should include scheduled vessel sailings outside of these time-sensitive fishery periods to not impact Aboriginal or commercial fisheries. This mitigation measure has been applied in other ports.	Incorporation of Preferred Harvesting Practices and Species: Aurora LNG has made substantial effort in Part C to identify and highlight preferred species and harvesting grounds and potential effects to those species and locations. Aurora LNG also presented additional information in the Aboriginal Consultation Technical Data Report (Appendix S2) about known Gitga'at First Nation harvesting practices. Additional Information for Mitigations: To reduce redundancy, only conclusions from Part B residual effects and cumulative effects are discussed in Part C. As such, the assessment of Aboriginal Interests does not include a reiteration of the existing conditions of relevant VCs, nor the mitigation measures, unless those mitigation measures are relevant in a way not already considered in the Part B VC assessment. For a full list of proposed mitigation measures, please see Part F of the Application. Acknowledgement of Limited-Duration Commercial Openings: Aurora LNG incorporated additional input from Gitga'at First Nation (received during consultation), that "the potential effects on commercial fishing may be exacerbated because of the duration of commercial fishery openings. According to Gitga'at First Nation, the commercial openings for some salmon species are particularly short. Therefore, should a Project-related vessel require a salmon fisher to move gear during an already brief commercial opening, this could cause increased interference and have economic consequences." (Section 12.5.9.5, page 12-286). Further information that provides context related to the assessment of the identified potential effects in the Application, including clarification regarding the assumptions utilized in the assessment, is provided in the technical memo entitled "Additional Information Regarding Methods Used to Consider Traditional Use Information in the Assessment of CEAA 5(1)(c) Factors and Aboriginal Interests" which will be filed with the BC EAO .
2893.1	round 1	Gitga'at First Nation	12.5.9.6	Aboriginal Consultation	See comments on the Community Health VC - more information, clarification and revision comments are provided in Section 6.6 so Gitga'at does not agree with the statement on p. 12-293 that "community wellbeing-related issues raised by Gitga'at First Nation are not discussed further in the assessment of cultural wellbeing".	The statement quoted in the comment is in reference to the following topics raised by Gitga'at First Nation during consultation: community safety, vulnerability, resilience, health, wellness, cohesion, dynamics, and social structure. These community well-being-related topics have been addressed in Section 6.6 of the Application in the following locations: Community Safety: Effects on community health and wellness from various factors related to community safety, including the presence of workers, workplace incidents, motor vehicle incidents, communicable diseases and STIs, and crime, are assessed in Section 6.6.5.3 on pages 6.6-51, 6.6-66 to 6.6-68, 6.6-70, 6.6-71. Vulnerability and Resilience: The effects on "stress and anxiety" and "personal health practices and coping skills" are assessed in Section 6.6.5.3 on pages 6.6-50, 6.6-52, 6.6-71 and 6.6-72. Health: All of Section 6.6, however the effects on "health status" are described specifically in Section 6.6.5.3 on page 6.6-50 and 6.6-65. Wellness: All of Section 6.6.5.3. Cohesion, Dynamics, and Social Structure: The effects on "income and social status", "income inequality", "social support networks", and "social environments" are assessed in Section 6.6.5.3 on pages 6.6-51, 6.6-52, 6.6-68 to 6.6-70. Effects on community health are also considered in the cumulative effects assessment in Section 6.6.6.3.
2894.1	round 1	Gitga'at First Nation	12.5.9.6	Aboriginal Consultation	p. 12-295 mentions the "marine safety and access to shoreline sites will be maintained with the implementation of the mitigations" - what mitigations?	Please see the mitigation measures numbered 6.5.1 to 6.5.9 in Table 16-1 (see Section 16, page 16-11).

2895.1	round 1	Gitga'at First Nation	12.5.9.6	Aboriginal Consultation	p. 12-295 states "because shipping has occurred along the shipping route for decades, Aurora LNG anticipates that mariners will be somewhat accustomed to navigating around large vessel traffic" - as stated in other comments, Gitga'at disagrees with the use of this statement in the EA (also, consider that the LNG carrier is a new vessel to the region). This also ties to the conclusions made for cultural wellbeing.	Aurora LNG agrees that the Project would introduce new vessels to the region, as per the assessment in Section 6.5, Section 12.5.9.5, 12.5.9.6, and 12.5.9.8. Aurora LNG understands that Gitga'at First Nation disagrees with the statement that "mariners will be somewhat accustomed to navigating around large vessel traffic." However, given the present use of the region by large vessels (~548 to 700 large vessel visits per year into the Port of Prince Rupert), Aurora LNG is of the opinion that the statement is accurate. See Section 6.5.3.2 (Table 6.5-6) for more information about the current use of the region by large vessels.
2896.1	round 1	Gitga'at First Nation	12.5.9.6	Aboriginal Consultation	p. 12-299 - what is the "Indigenous Peoples policy"?	Aurora LNG's Indigenous Peoples Policy is described here: http://www.nexencnoocltd.com/en/ResponsibleDevelopment/SocialResponsibility/AboriginalRelations/IndigenousPolicy.aspx
2897.1	round 1	Gitga'at First Nation	12.5.9.7	Aboriginal Consultation	Not all traditional governance structures are house-based although the assessment has limited discussion to this. See discussion in Gitga'at's traditional use study.	Aurora LNG understands that traditional socio-political organization is more complex than just house groups. However, as described in Gitga'at First Nation's Use Study, "the wilp (house) is the fundamental political and land owning unit" and the chief of the house group manages "the use of the house territories and all associated rights" (p. 10), Aurora LNG believes this is an appropriate traditional governance structure to consider in the assessment of potential effects to Gitga'at First Nation traditional governance.
2898.1	round 1	Gitga'at First Nation	12.5.9	Aboriginal Consultation	In assessing potential impacts, this project is looked at in isolation from the history of development that has already negatively affected the ability of GFN members to harvest in preferred places, preferred species and in quantities needed for individual, family and community purposes. Cumulative effects should be considered	Aurora LNG disagrees with the statement that the Application looks at the Project in isolation from the history of development in the area, or that cumulative effects were not considered. Aurora LNG appreciates that Gitga'at First Nation included information in its Project-specific study regarding the influence of external factors on Gitga'at First Nation's present use of the Project vicinity. Aurora LNG was able to incorporate this information into the assessment in several locations: see Section 12.5.9.5 (Changes in Harvested Species, page 12-277 and again on page 12-291), and Section 12.5.9.6 (page 12-300). Cumulative effects were assessed for all VCs and effects on the CEAA 5(1)(c) factors (Section 11.4). Where cumulative effects on a VC have the potential to affect the exercise of Gitga'at First Nation's Aboriginal Interests, the conclusions from that VC have been incorporated into the assessment of effects in Section 12.5.9.
2899.1	round 1	Gitga'at First Nation	12.5.9.8	Aboriginal Consultation	On p12-305 (s.12.5.9.8) the proponent notes that marine berths will reduce channel width used by Gitga'at boaters by up to 35%. This number differs from those provided in the Marine Use and Navigable Waters section of the application (e.g., on p6.5-53 (s.6.5.5.2) the proponent says the southern terminal including control zone will occupy approximately 17% of the small vessel corridor). Please clarify how the number of 35% was calculated.	As described in Section 6.5.5.2 (on page 6.5-53) of the Application, "The northern berth and control zone spans approximately 35% of the width of the entire channel between Kaien and Digby islands (the total channel width, measured from the 0 m depth contours (chart datum), is approximately 1.4 km). The southern berth and control zone spans approximately 20% of the channel (the total width, measured from the 0 m depth contours (chart datum), is approximately 2.5 km)." The assessment in the Marine Use and Navigable Waters VC also calculates the percent of the "small vessel corridor" that will be overlapped by the proposed marine infrastructure: "The potential effect on marine navigation for smaller vessels is low because only 2% of marine terminal infrastructure lies within the small vessel corridor (see Figure 6.5-2). The northern berth is completely outside of this corridor and is therefore not expected to affect small vessel traffic. The southern terminal (including the control zone) will occupy approximately 17% of the small vessel corridor, leaving more than 80% of the available open to navigation." (page 6.5-53). Aurora LNG, in taking a conservative approach in the assessment of potential effects on Gitga'at First Nation use of marine travelways in Section 12.5.9.8, assumed that Gitga'at First Nation mariners may not only be in small boats. Therefore, the maximum potential interference (because of the proposed control zone around the northern berth) to Gitga'at First Nation marine travel could be up to 35% of the channel width.
2900.1	round 1	Gitga'at First Nation	12.5.9.8	Aboriginal Consultation	p. 12-304 states "because shipping has occurred along the shipping route for decades, Aurora LNG anticipates that mariners will be somewhat accustomed to navigating around large vessel traffic" - as stated in other comments, Gitga'at disagrees with the use of this statement in the EA (also, consider that the LNG carrier is a new vessel to the region).	Aurora LNG agrees that the Project would introduce new vessels to the region, as per the assessment in Section 6.5, Section 12.5.9.5, 12.5.9.6, and 12.5.9.8. Aurora LNG understands that Gitga'at First Nation disagrees with the statement that "mariners will be somewhat accustomed to navigating around large vessel traffic." However, given the present use of the region by large vessels (~548 to 700 large vessel visits per year into the Port of Prince Rupert), Aurora LNG is of the opinion that the statement is accurate. See Section 6.5.3.2 (Table 6.5-6) for more information about the current use of the region by large vessels.
2901.1	round 1	Gitga'at First Nation	12.5.9.9	Aboriginal Consultation	See comments on the Economic VC.	Comment noted.
2902.1	round 1	Gitga'at First Nation	15	Follow-up Programs and Compliance Reporting	Based on Nexen's confidence characterizations in the Application, it appears that Nexen does not have high confidence in some of the EA predictions. In these areas, Nexen should develop and implement monitoring programs. Please provide an updated list of follow-up monitoring programs proposed.	Aurora LNG has proposed follow-up programs for those VC assessments where there is predicted low confidence in the conclusion of potential residual adverse effects. The specific reasons for the low confidence would be due to identified uncertainties outlined in each VC assessment. For VC assessments that concluded moderate to high prediction confidence, these will be managed through the development of Environmental and Operational Management Plans (Section 14 of the Application) designed to verify compliance of the Project with commitments in the Application and conditions in an Environmental Assessment Certificate.
2903.1	round 1	ECCC	4.2.2.1	Air Quality	Marine and other emissions related to the project are subject to the Transboundary Notification Agreement between Canada and the US. A prescribed form (accessible at http://www.ec.gc.ca/air/default.asp?lang=En&n=5AE57A08-1) needs to be completed for any new air pollution source located within 100 km of the Canada/U.S. border that is expected to emit greater than 90 tonnes per year of any one of the common air pollutants. These common air pollutants are sulphur dioxide (SO2), nitrogen oxides (NOx), carbon monoxide (CO), total suspended particulates (TSP) and volatile organic compounds (VOC), where VOCs are defined as compounds containing at least one carbon atom, excluding carbon monoxide, carbon dioxide, methane and chlorofluorocarbons. Information Request In support of the requirement to assess project effects outside of Canada, ECCC requests that the proponent provide information that would facilitate transboundary notification and the assessment of project effects on US. ECCC also requests the proponent to revise its accounting of the regulatory and policy setting for the project to include reference to theTransboundary Notification Agreement and its relevance to the environmental assessment.	Aurora LNG will comply with requirements related to the Transboundary Notification Agreement between Canada and the US. Aurora LNG will complete and submit the requested form.
2904.1	round 1	ECCC	4.2.2.1	Air Quality	The North American Emission Control Area under the International Convention for the Prevention of Pollution from Ships (MARPOL) imposes certain emission controls for ships trading off the coast of Canda and US. These controls include a low sulphur fuel standard and nitrogen oxide (NOx) standards for marine diesel engines (e.g., a NOx Tier III standard applies to ships constructed since 2016). Recognition of Emission Control Area standards provide important context for the assessment of project effects on air quality. Information Request ECCC requests that the proponent revise its accounting of the regulatory and policy setting for the project to include reference to the Emission Control Area and its relevance to the environmental assessment.	Aurora LNG agrees that the North American Emission Control Area under the International Convention for the Prevention of Pollution from Ships (MARPOL) is an important regulatory consideration and is relevant to the environmental assessment. The emission control area requirements are included in the list of Project mitigation (Table 4.2-10, Air Quality). The NOx and low-sulphur fuel requirements associated with the emission control area regulation are discussed throughout the Air Quality TDR, and emission rates and dispersion modelling associated with marine vessels reflect these emission control area requirements.
2905.1	round 1	ECCC	4.2.2.5	Air Quality	In Section 4.2.2.5, the proponent states that "boundaries are sufficiently large to encompass [the area] influenced by major emission sources in the region" (p. 4.2-7). However, the assessment does not include marine emissons while vessels are underway, which are substantially larger than emissions from vessels maneuvering or at berth. Information Request ECCC requests that the proponent provide a complete accounting of project-related marine emissions to the limits of the territorial sea for inclusion in the effects assesment.	The approved Application Information Requirements (Section 4.2.2) notes that air quality will be assessed through dispersion modeling to determine the effects of the Project marine vessels and Project LNG Facility emissions on air quality for Project activities that occur near the LNG facility. This includes the LNG and support vessels when maneuvering and at berth which occur at the same time and in proximity to the LNG Facility emissions when it is operating at full capacity. Consistent with the AIR and as detailed in the final approved Detailed Model Plan (Appendix 1, Air Quality - TDR) the assessment was intentionally scoped to focus on the combined LNG Facility and marine vessel emissions near the facility to represent maximum potential effects on air quality in closest proximity to nearby communities and other sensitive receptors. The BC MOE approved the final Detailed Model Plan excluding separate modelling of Project LNG vessels when underway (at sea).
2906.1	round 1	ECCC	4.2.4	Air Quality	In Section 4.2.4 the proponent indicates that "transit of LNG carriers along the shipping route will be sporadic and short-term in duration (i.e. about 3 hours each way) and as such effects of emissions from shipping are not carried forward into the assessment." (p. 4.2-19). ECCC disagrees with this conclusion. Coast Guard/AIS data show there are 10-20 transits per day of large commercial vessels plus other vessels across the Regional Assessment Area (RAA) and transit times to the territorial sea limit would be greater than 3 hours. Moreover, in this region the vessels are using their main propulsion engines, which have much higher emissions than auxiliary engines. By excluding this vessel traffic and associated emissions for project and non-project marine vessels, the proponent underestimates marine emissions. In not fully accounting for vessel transit time during which main engines are employed, marine emissions are underestimated by 140-350% (annual basis). Information Request ECCC requests that the proponent include a full accounting of emissions from vessels in transit in the RAA (that is revised to extend to the territorial sea limit) to ensure a complete asessment of project effects on air quality and GHG including cumulative effects.	The approved Application Information Requirements (Section 4.2.2) notes that air quality will be assessed through dispersion modeling to determine the effects of the Project marine vessels and Project LNG Facility emissions on air quality for Project activities that occur near the LNG facility. This includes the LNG and support vessels when maneuvering and at berth which occur at the same time and in proximity to the LNG Facility emissions when it is operating at full capacity. Consistent with the AIR and as detailed in the final approved Detailed Model Plan (Appendix 1, Air Quality - TDR) the assessment was intentionally scoped to focus on the combined LNG Facility and marine vessel emissions near the facility to represent maximum potential effects on air quality in closest proximity to nearby communities and other sensitive receptors. The BC MOE approved the final Detailed Model Plan excluding separate modelling of Project LNG vessels when underway (at sea).
2907.1	round 1	ECCC	4.3.5.2	Greenhouse Gases	The proponent states that during operations "The formation CO2 in the form of acid gas is stripped off and sent to the thermal oxidizers for safety purposes." (p. 4.3-26) Information Request ECCC requests that the proponent explain why a fully oxidized stream would be sent to oxidation and describe the ultimate fate of the stripped formation CO2. If the stripped formation CO2 is vented, it should be confirmed whether it is accounted for in line 3 of Table 4.3-14 (GHG Emissions - Thermal oxidizers).	The acid gas sent to the thermal oxidizer is described in Table 14 of the GHG Technical Data Report (Appendix B of the Application). In Table 14, it demonstrates that the acid gas stream is made up of 0.0004 mol fraction of H2S. For safety purposes, the acid gas stream is sent to the thermal oxidizer to convert the H2S into SO2. CO2 content within the acid gas will be directed to the thermal oxidizer. However, as it is already in the form of CO2 it will not undergo further combustion. For this reason, the CO2 content of the acid gas has been identified to be formation CO2 that is received in the feed gas. Section 5.3 of the GHG Technical Data Report provides a breakdown of the thermal oxidizer calculations. Table 23 of the GHG Technical Data Report identifies that formation gas CO2 (i.e. the CO2 content of the acid gas) is included in line 3 of Table 4.3-14 of the Application.
2908.1	round 1	ECCC	4.3.10	Greenhouse Gases	The project is estimated to have a GHG emissions intensity of 0.28 tonne CO2e/tonne LNG produced. Information Request Given the requirement of another comparable project (Pacific Northwest LNG) to achieve a lower GHG emissions intensity (in the 0.21 to 0.22 range), ECCC requests that the proponent describe and evaluate opportunities to achieve a comparable emissions intensity level. If based on such an analysis, it is concluded by the proponent that such a level cannot be achieved, ECCC requests that the proponent identify what is unique about the Aurora LNG project that accounts for the higher intensity level.	Based on the conservative assumptions for Project design (i.e., simple cycle turbines and all onsite facility power) and feed gas composition (1.82% mol C02), the GHG emission carbon intensity has been estimated to be 0.28 tCO2e/t LNG produced. It has been conservatively assumed that the Project will not consume electricity through BC Hydro. If the Project were to connect to the BC Hydro grid, a reduction in the GHG intensity can be expected. Discussions are continuing with BC Hydro to determine if connection to the grid is a feasible option. Further, the carbon intensity will reduce once actual feed gas data is available. Other LNG projects in the region have presented the formation CO2 concentration in feed gas between 0.6 and 0.8% mol CO2. The current Aurora LNG Project design with a revised feed gas composition of 0.8% mol CO2 would result in a carbon intensity closer to 0.25 tCO2e/t LNG produced. The current Aurora LNG Project design with a revised feed gas composition of 0.6% mol CO2 would result in a carbon intensity closer to 0.24 tCO2e/t LNG produced. As the facility design advances through detailed engineering, efficiencies and optimum equipment selections are expected to result in reduced overall project operation emissions. For further information, regarding how changes of mol CO2 % in the feed gas can affect the GHG emission intensity, please refer to the technical memo "Feed Gas Carbon Dioxide (CO2) Content Impact on GHG Emissions for the Aurora LNG Application for an Environmental Assessment Certificate" which will be filed with the BC EAO.
2909.1	round 1	ECCC	Part E 14.4	Greenhouse Gases	The proponent references a GHG Management Plan and a review of best available technologies. Information Request ECCC requests that the proponent confirm that the proposed review will be ongoing during the life of the project as appropriate.	Section 4.3.5.2 of the Application states "A GHG Management Plan will be prepared to identify the requirements of relevant GHG reporting legislations and will contain continuous assessment of monitoring and management requirements applicable to the mitigations listed in Table 4.3-12 (i.e., requirements of a fugitive emission survey program). The management plan will also contain a Best Achievable Technology analysis." Further to this statement, Mitigation 4.3.6 states, "By continuously monitoring the requirements of GHG mitigations and relevant GHG reporting legislations, the Project will continue to implement best management practices."
2910.1	round 1	ECCC	Section 4.7 Appendix 2 in Appendix A	Air Quality	Marine emissions from vessels at anchor are a major contributor criteria to air contaminants and GHGs over the 24 hour anchorage period. However, the environmental assessment does not include a consideration of these emissions, and as a consequence, project-associated criteria air contaminants and GHG marine emissions are underestimated by about 30%. Information Request ECCC requests that the proponent account for emissions of vessels at anchor in the assessment of impacts on air quality and GHG.	The approved Application Information Requirements (Section 4.2.2) notes that air quality will be assessed through dispersion modeling to determine the effects of the Project marine vessels and Project LNG Facility emissions on air quality for Project activities that occur near the LNG facility. This includes the LNG and support vessels when maneuvering and at berth which occur at the same time and in proximity to the LNG Facility emissions when it is operating at full capacity. Consistent with the AIR and as detailed in the final approved Detailed Model Plan (Appendix 1, Air Quality - TDR) the assessment was intentionally scoped to focus on the combined LNG Facility and marine vessel emissions near the facility to represent maximum potential effects on air quality in closest proximity to nearby communities and other sensitive receptors. The BC MOE approved the final Detailed Model Plan excluding separate modelling of Project LNG vessels when underway (at sea). Section 5.4 of the GHG Technical Data Report (Appendix B of the Application) also discusses marine operations considered in the assessment.
2911.1	round 1	ECCC	Sections 5.3 and 5.5 in Appendix A	Air Quality	The proponent has not used the short-term marine emissions scenario for modelling maximum predicted concencentrations. However, the ambient air quality objective for NO2 is based on the 98th percentile of a 1-hr objective. Information request: ECCC requests that the proponent model the short-term emissions scenario (2 LNG carriers and 4 tugs at berth), including marine emissions from anchorage and underway within the LAA, and the effects be described with reference to the ambient air quality objectives (See Appendix A, Section 5.3, Table 14, and Section 5.5, Table 17)	The statement in the ECCC comment about Aurora LNG not using the short term emission scenario is incorrect. Aurora LNG used the short-term emission scenario (2 LNG carriers and 4 tugs at berth) to calculate the maximum 1-hour (98th percentile daily hourly maximum). As a result, it is not necessary to provide updated model predictions.

2912.1	round 1	ECCC	4.5.13.3	Water Quality	Dredging of marine sediments is proposed by the proponent for several project components. The proponent is planning to dispose of the top 0.5m dredgate in a land based on-site soil disposal facility. After construction is completed the soil storage area will be revegetated. The dredgate exceeds applicable sediment guidelines for arsenic, copper, PAHs and PCDD/Fs (Table 4.5-24). The proponent did not compare chemical concentrations to soil quality guidelines in support of proposed land disposal, but did specify that the concentrations do not exceed the BC Contaminated Sites Soil Relocation Standards (p. 4.5-56). Note that these standards are only applicable until October 31, 2017 (see BC Contaminated Sites Regulation (CSR) Stage 10 Omnibus Update). Information Request ECCC requests that the proponent provide the following information in support of the assessment of impacts to water quality that could result from upland disposal of dredgate, • a comparison of dredgate to applicable soil quality guidelines and - if dredgate exceeds applicable soil quality guidelines- • a prediction of contaminant concentrations in seepage and drainage water along with an assessment of whether the drainage/seepage has the potential to affect freshwater or marine water quality.	Sediment was compared to soil quality guidelines in Section 5.7 of the Marine Sediment and Water Quality Technical Data Report (Appendix F of the Application), with full details of this screening in Table 6-1, Appendix 6 of the Technical Data Report. Section 5.7 of Appendix F stated: "Outside of sodium and chloride, analytes compared to CSR Schedule 7 did not exceed Column II (soil relocation to non-agricultural land) standards. BC MOE Technical Guidance 20 states that if the land disposal site is a near-shore site (as would be expected in sites within the Project Development Area on Digby Island) and the remaining contaminants of concern do not exceed Schedule 7, Column II, no Contaminated Soil Relocation Agreement (CSRA) would be necessary for disposal of dredgeate on land." All applicable CSR Schedule 7 metal analytes were not analyzed in the baseline field program. Supplemental metal analysis will be conducted if required. Additional screening against revised contaminant criteria will also be conducted if necessary.
2913.1	round 1	ECCC	4.5, p. 23, Table 4.5.11	Water Quality	The proposed mitigation measures for reducing acidification/eutrophication effects on water quality are mitigation measures which limit SOx/NOx air emissions (see Table 4.5.11). Some of the proposed mitigation measures include complying with applicable legislation which is a legal requirement. Compliance with applicable legislation should not be considered as a project specific mitigation measure. For example, mitigation measure 4.2.7, refers to the Sulphur in Diesel Fuel Regulations (SOR/2002-254), which set maximum limits for sulphur in diesel fuel for use on-road, off-road, in rail (locomotives), vessels, and stationary engines. It is unlawful to use diesel with higher sulfur content. Hence using the low sulfur diesel should only be considered as project specific mitigation, if sulfur content would be considerablely lower than sulfur content in typically available diesel. Similar concepts apply also to mitigation measures 4.2. - 5,6, 9, 12 and possibly 4.2.10. Information Request ECCC requests that the proponent clarify if there is additional project-specific mitigation to be implemented in addressing predicted effects.	Aurora LNG is committing to numerous mitigation measures to manage potential effects of the Project, as summarized in Table 16-1 of the Application. Please see the "Mitigation Measures Categorization Table" technical memo which further categorizes the proposed mitigation measures to indicate whether a measure is outside of permitting requirements (legal requirement, industry standard/Best management practice and/or Aurora LNG additional mitigation measure). This technical memo will be filed with the BC EAO.
2914.1	round 1	ECCC	4.5.13.3, Table 4.5-24	Water Quality	Sediment arsenic and copper concentrations in the dredge areas exceed sediment quality guidelines. The proponent indicates that the elevated levels reflect naturally high background concentrations and does not assess potential impacts to water quality and fish. Information Request: ECCC requests that the proponent provide a rationale and supporting data demonstrating that arsenic and copper concentrations are naturally elevated.	The assessment of dredge material focused on sediment sampling within the dredge footprint and followed the Disposal and Sea criteria for characterizing sediments. Elevated arsenic and copper levels in soil of Skeena Region are documented in the Ministry of Environment Protocol 4: Determining Background Soil Quality, these levels are similar to those found in sediment from the assessment area. Elevated levels of copper and arsenic were found at all depths sampled, (down to 15 m below seabed), indicating that these metal concentrations predate industrial activity.
2915.1	round 1	ECCC	4.5.13.3, p. 4.5-54 and Appendix F	Water Quality	Sediment and water quality data is summarized in Section 4.5.13.3. Detailed data is referenced to be in Appendix F. Appendix F appears to be draft. Data tables and Figures were not included. Information Request ECCC requests that the proponent provide complete and final versions of the referenced data.	The incorrect version of this appendix was posted on e-PIC at the start of Application Review, and subsequently replaced with the correct, final version of Appendix F on February 3, 2017.
2916.1	round 1	ECCC	4.5.15.3, p. 4.5-62 and Section 1.2.5.3; pp. 1-26\28.	Water Quality	Freshwater for the proposed project will be provided through a desalination system. To meet the expected freshwater need of 9855 m3/day, desalination of 20,000 m3 of seawater per day is required (p. 1-26). At the intake, fish screens will be in place and intake water will be chlorinated. The effluent from the desalination plant will be combined with the power plant cooling water blow down and reject water from the desalination plant. The combined effluent will be discharged through the deep outfall into the marine environment at Charles Point. The proponent states that the temperature of the effluent will meet regulatory guidelines (provincial) outside of a small mixing zone (p. 1-28). Information Request ECCC requests that the proponent provide the following information in order to understand whether the desalination process could have an impact on water quality or fish in the marine environment: • Detailed explanation and drawings of desalination system to demonstrate that the fish screen and intake components of the desalination system have been designed to prevent exposure of fish to the chlorination process. • Detailed information on what the proponent considers a "small" mixing zone.	The desalination intake design is not yet finalized and will be completed during Front End Engineering Design. Under the Fisheries Act, the intake must be designed so that its operation does not result in serious harm to fish. The exact size of the deepwater outfall mixing zone is not yet known, and will be determined through modelling in the permitting phase. However, under the Fisheries Act, waste discharges within and outside the mixing zone cannot be acutely toxic to fish. Discharges from the deepwater outfall will require a permit under the Municipal Waste Regulation, which imposes limits on the extent and location of the mixing zone. For further details on waste discharges see the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2917.1	round 1	ECCC	4.5.15.3, p. 4.5-63, Table 4.5-26	Water Quality	Proposed mitigation measures to avoid/reduce change in physical or chemical composition of marine waters (Table 4.5-26) include complying with applicable legislation (e.g. 4.5.7). Similar to ECCC's comment regarding acidification/eutrophication mitigation measures, compliance with applicable law should not be considered a project-specific mitigation measure. Information Request ECCC requests that the proponent clarify the project-specific mitigation to be implemented in addressing predicted effects.	Details on mitigation measures for waste discharges to the marine environment are provided in the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2918.1	round 1	ECCC	4.5.15.3; p. 4.5 - 76	Water Quality	Marine sediment dispersion modelling did indicate temporary Total Suspended Solids (TSS) levels up to 218 mg/L in Casey Cove, and up to 67 and 72 mg/L in Berth 1 and 2 respectively. ECCC understands that TSS levels in Casey Cove near the dredging operations are predicted to exceed the applicable 5mg/L guideline for the duration of dredging activities (48 days). Suspended sediments are expected to contain PCDD/F, copper, arsenic and PAHs (see Table 4.5-24). ECCC understands that TSS modelling indicated that PCDD/F resuspension and re-settling does not lead to a wider distribution. ECCC also agrees that PCDD/F usually partion into the sediment, not into water column. However, if high levels of suspended sediment with PCDD/F are predicted, fish frequenting the area as well as other receptors may be exposed to PCDD/F. Information Request>ECCC requests that the proponent further investigate the potential effects of TSS, and its contaminants, on ecological receptors and report on its assessment findings.	The potential effects associated with exposure of marine fish to elevated TSS levels during dredging and disposal at sea activities are assessed under the 'change in health' effect (Section 4.9.5.5 of the Marine Fish and Fish Habitat assessment). The effects assessment also evaluated exposure of marine fish to potential contaminants of concern, including dioxins and furans (PCDD/Fs) in particular, based on the results of the Marine Water Quality assessment (Section 4.5 of the Application). The assessment concluded that the risk to marine fish from exposure to PCDD/Fs is considered low and similar to baseline conditions (see Appendix F, Marine Sediment and Water Quality TDR for baseline conditions). As stated in Section 4.5.13.3, concentrations of PCDD/Fs were above CCME ISQGs in some sediment samples. However, the distribution of these elevated levels was patchy; occurring in only 17 of the 81 samples. Of these 17 samples, 12 were surface samples, and the remaining five were from the top 0.2 m. These PCDD/F concentrations represent the current baseline conditions. The majority of sediment containing PCDD/Fs will be removed for land disposal (an estimated 3% of this sediment may escape during dredging; USACE 1984). The Project will not contribute PCDD/Fs to the environment. Since the highest PCDD/F concentrations were detected in the 0.5 m surface layer of sediment, benthic marine life such as crabs, clams, prawns and benthic fish are currently interacting (i.e., feeding, foraging and living) with the layer of sediment that would result in the highest possible PCDD/F concentrations in their tissues. There is no pathway for the removal of surface, and underlying sediment to 15 m depth to result in higher PCDD/F concentrations in the environment. As noted in Section 4.5.13.3, "sediment containing PCDD/Fs are predicted to settle in an area of similar concentrations.....much of the PCDD/F deposited in the surrounding area is anticipated to be covered subsequentlywith dispersed sediment of lower PCDD/F concentrations". Owing to the highly hydrophobic nature of PCDD/Fs, uptake by aquatic life from the water column is negligible compared to the uptake from food (which represents approximately 75% of PCDD/F uptake) and sediment (Cook et al. 1991). Further discussion on the risk to aquatic life from exposure to PCDD/Fs is provided in Section 4.5.15.3 of the Application. As noted in several previous studies of sediment in the Prince Rupert area, the presence of copper and arsenic above CCME interim sediment quality guidelines is widespread and related to natural occurrence (elevated concentrations in soils of the Skeena watershed). The metals are in particulate form, and not expected to be available for uptake. Marine organisms are already exposed to these metals, for example in the elevated TSS that occurs during annual freshet and in sediment, and no adverse effects from exposure to metals is anticipated. Table 4.5-24 indicates that total PAH levels are below the disposal at sea screening criterion of 2.5 mg/kg, but that some individual PAHs were higher than the interim sediment quality guidelines in some samples. Concentrations of these PAHs were well below the probable effects levels, at which adverse effects would be expected. Given the sporadic occurrence of samples with some elevated PAHs, and the low amounts of sediment released (3%) during dredging, no adverse effects to marine biota are anticipated. U.S. Army Corps of Engineers (USACE), 1984. Shore Protection Manual, 4th Ed. Report by Dept. of the Army, Waterways Experiment Station, Corps of Engineers, Coastal Engineering Research Center, For sale by the Supt. of Docs., U.S. G.P.O. in Vicksburg, Miss, Washington, DC.
2919.1	round 1	ECCC	4.5.15, p. 4.5-77	Water Quality	The proponent states that "with mitigation [4.5.8] the receiving marine waters will meet Canadian Council of Minsters of the Environment (CCME) and BC water quality guidelines (p. 4.5-77)". Mitigation measure 4.5.8 (see Table 4.5-26) states that waste discharges will comply with Fisheries Act and the CCME water quality guidelines for the protection of aquatic life. ECCC could not locate data for marine water quality predictions that demonstrate how guidelines are being met. Information Request ECCC requests that the proponent provide modelled/predicted data on the characterization of waste discharges at the discharge point and modelled/predicted data on the characterization of the marine receiving environment.	Waste characterization and modelling of waste discharge to the receiving environment will be conducted at the permitting stage. Further details on Project waste discharges, effects assessment, and associated regulations are provided in the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2920.1	round 1	ECCC	4.5.15, p. 4.5-78	Water Quality	The proponent summarizes the residual effects on marine water quality in terms of magnitude, geographic extent, frequency, duration, reversibility, context and likelihood (Table 4.5.28). Information Request ECCC requests that the proponent provide a rationale (or cross reference to a rationale) to support the assigned ranking in context of the characterization of residual effects as presented in Table 4.5.-21.>	The magnitude, extent, frequency, duration,reversibility, and likelihood of dredging effects were discussed in detail in Section 4.5.15.3, in the Dredging and Sediment Disposal sections. These sections describe the predicted concentration, and spatial and temporal range of, TSS and associated contaminants, generated during the proposed dredging and disposal at sea activities. Section 4.5.13.3, Waste Management - Construction, Operations, Decommissioning, describes how waste discharges will be subject to permit requirements that limit the magnitude, extent, frequency, and duration of effects. The summary section describes waste discharge effects as reversible because no further effects are expected when discharges end, given that discharges were subject to regulation designed to protect the marine environment. The context of the LAA is described as resilient in the summary, given the history of industrial activity in the area, and baseline water quality reflected in the PRPA monitoring program in Prince Rupert Harbour.
2921.1	round 1	ECCC	Application, 4.6.2.1; Appendix U, 3.4	Vegetation and Wetland Resources	The Application does not contain all the information needed to assess potential impacts to wetlands and functions including those situated within federal lands and waters or within the geographic scope of federal authorizations. The Wetland Compensation Plan provided by the proponent states that other than the 2 ha of red/blue-listed wetlands identified within the project development area (PDA), "the remainder of the wetlands in the project development area (PDA) are not considered to be ecologically important in the context of regional guidance from ECCC, and thus will not require compensation" (Appendix U, 3.4, pdf p. 19). This is an inaccurate interpretation of the regional guidance ECCC has provided. Estuaries (including mudflats), eelgrass beds, and other wetlands that would be directly impacted by the proposed Material Offloading Facility and the Marine Jetty need to be assessed. All wetlands in the intertidal zone of Digby Island are considered as "Continental Significance to Waterfowl" ; further, the presence of estuaries (including mudflats) and eelgrass beds have also been identified in the intertidal areas of Digby Island. These wetlands are designated as "ecologically important for the region", thus analysis of mitigation measures to maintain function is necessary. The Application identifies that construction activities may affect wetlands adjacent to the PDA (Application, 4.6.5.4, pdf p. 47), including estuarine (e.g. mudflats) and eelgrass habitats. Wetland functions in these areas, as a result, may also be adversely impacted. Information Request ECCC requests that the proponent provide the following details important to assessing potential impacts on wetlands and wetland functions: • identify and describe potentially impacted wetlands and their function that are within federal lands and waters or located within the geographic scope of federal authorizations • identify the spatial extent (in ha) of any potentially impacted wetlands (including estuaries, eelgrass beds, and other wetlands found within areas of "Continental Significance to Waterfowl" as identified by the Joint Venture).	Wetlands within Federal Lands and Waters include estuarine wetlands within the management jurisdiction of the Prince Rupert Port Authority, the boundaries of which correspond with the area of Continental Significance to Waterfowl identified by the Joint Ventures where these two management area designations intersect within the spatial boundaries of the Project. Estuarine wetlands have been assessed in the Application as follows: See Table 4.6-4 in section 4.6.2.5, and 4-9 in the AIR for the spatial boundaries of the vegetation and wetlands resources VC, which are distinct from the spatial boundaries of the marine fish and fish habitat VC.See section 4.6.1 of the AIR, which states that "eelgrass will be assessed as part of the 'Change in Habitat' effect under Marine Fish and Fish habitat VC in Section 4.9". Note that some eelgrass habitat presented in Section 4.9 is located well below the lower low water mark, and thus are considered subtidal marine habitat rather than estuarine intertidal wetlands. Estuarine wetlands are assessed in section 4.6.5.4 (and see Table 3 of Appendix I, Vegetation and Wetland Resources TDR). The spatial extent of potentially-affected wetlands and their functions are presented in sections 4.6 (wetlands other than eelgrass beds), and 4.9 (eelgrass beds) of the Application. The spatial extent of estuarine shore water wetlands (i.e., mudflats) that occur within the PDA will be determined when the design options for the materials offloading facility are finalized. Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Wetland Compensation Plan. The consultation will include the assessment of which habitat offsetting measures associated with marine fish habitat address the habitat functions of estuarine wetlands such as eelgrass and estuarine shore water (i.e., mudflats) to achieve no net loss of functions for these ecologically important wetlands. See the memo titled "Supplemental Information Regarding Estuarine Wetlands and Wetland Compensation " for additional details. This technical memo will be filed with the BC EAO.

2922.1	round 1	ECCC	4.6.2.1 and 4.9.5.2	Vegetation and Wetland Resources	In British Columbia, wetlands designated as ecologically or socio-economically important to a region include marine eelgrass beds of the Zostera species. Eelgrass beds serve as essential foraging habitat for a variety of marine-associated fauna during critical stages in their annual cycle (e.g. breeding, wintering, and migration). The Application lists various species at risk and migratory birds using eelgrass habitats adjacent to the project development area (PDA) (e.g. Casey Cove, eastern Digby Island). Although an assessment on eelgrass beds in relation to project impacts on marine fish and their habitat (Application, 4.9.5.2, pdf p. 30) has been presented, there is a lack of information in relation to species at risk and migratory birds, despite their heavy reliance on eelgrass beds in the project area. Information Request ECCC requests that the proponent provide the following information important to assessing impacts on eelgrass and related functions: • baseline studies involving a detailed eelgrass habitat functions assessment that includes surveys to assess for the relative abundance and distribution of migratory birds and species at risk (SARA-listed and COSEWIC-assessed) in relation to potentially impacted eelgrass beds and their associated riparian areas; • the identification and description of potential direct (e.g., removal of eelgrass beds) or indirect (e.g., permanent or temporary alteration of hydrological processes, smothering from sedimentation) impacts to eelgrass beds arising from project activities. In particular, the effects assessment should describe how the habitat functions identified in the baseline studies would be impacted by the project; • the measures that will be taken to avoid, minimize, or compensate for each identified impact along with a rationale justifing the measure chosen; • a consideration of eelgrass restoration for areas where impacts to eelgrass beds cannot be fully avoided (e.g., measures such as replanting the site with material removed during construction); and • an adaptive monitoring program that assesses the recovery of eelgrass beds and their functions (including migratory birds and species at risk).	Table 4.7-11 in section 4.7.5.2 of the Application presents the loss of estuarine marsh, mudflat, and beach communities, which include areas of intertidal eelgrass. See section 4.11.5.3 for the assessment of change in habitat for marine birds, which includes intertidal habitats within the wildlife LAA for migratory birds and species at risk. The unavoidable effects on eelgrass due to marine construction and dredging are presented in section 4.9.5.2 in accordance with the AIR (see response to comment #2578). See section 10.4.1.2 of Appendix V of the Application, Conceptual Fish Habitat Offsetting Plan for proposed compensation addressing the loss of eelgrass. Aurora LNG will consult with ECCC to confirm that the eelgrass offsetting measures in the Fish Habitat Offsetting Plan willalso offset the wetland habitat functions of intertidal eelgrass to achieve no net loss of functions for this type of ecologically important wetland (intertidal eelgrass beds). See memo titled "Supplemental Information Regarding Estuarine Wetlands and Wetland Compensation " for additional details. This technical memo will be filed with the BC EAO.
2923.1	round 1	ECCC	Appendix U, 4.2	Vegetation and Wetland Resources	The proponent has committed to a compensation ratio of 2:1 (Appendix U, 4.2, pdf p. 21). Compensation sites are generally required to be larger than the original wetland area impacted to compensate for the inherent uncertainty of replacing the loss of wetland functions and the lag time between the loss of wetland functions in the impacted wetland and gain in wetland functions in the compensation wetland. Therefore, compensation ratios are based on such factors as the probability of success of replacement of wetland functions, length of time required to bring a compensation site to functioning condition, the expertise of the compensation project proponent, and threats to the site. Information Request ECCC requests that the proponent provide the rationale and analysis used to determine that a compenstation ratio of 2:1 will be appropriate to mitigate effects and that case-specific circumstances were taken into account in the analysis.	The ratio presented in the Conceptual Wetland Compensation Plan (Appendix U of the Application), is based on the general regional guidance issued by Environment Canada (2014), which states that, "At a minimum, a compensation ratio of 2:1 is used; however, this ratio varies on a project-by-project basis. Consultation with the Canadian Wildlife Service is recommended to ensure the appropriate ratio is identified." Aurora LNG will consult with ECCC/CWS about the proposed compensation ratio, as indicated in the regional guidance. Reference: Environment Canada. 2014. Federal Policy on Wetland Conservation – Guidance for Application and Implementation in Environmental Assessment. Available at: https://a100.gov.bc.ca/appsdata/epic/documents/p403/d37786/1404937173815_193684738c554031afd3fe7a5b3bf6196c13620cba3241eac8c3f318682e8f7f.pdf. Accessed: June 2016.
2924.1	round 1	ECCC	Appendix U, 4.2	Vegetation and Wetland Resources	The location of the proposed wetland compensation is unclear in the Wetland Compensation Plan (Appendix U, 4.2, pdf p. 21). The proponent has also listed a number of "wetland compensation options" - including wetland creation - in conjunction with an ENGO (Appendix U, 5.1 and 5.2, pdf pp 22-23). The plan also states that "actual details of the monitoring program will be determined in consultation with Aurora LNG, ECCC/CWS, and Aboriginal groups" (Appendix U, 5.3, pdf p. 23), and thus it is currently unclear to what extent the proponent will commit to monitoring as part of its wetland compensation program. Information Request ECCC requests that the proponent: • clarify the location(s) in which the wetland compensation will be implemented, • identify the ENGOs that have potentially committed to collaborate as part of the Wetland Compensation Plan. • demonstrate that a variety of criteria and construction methods have been considered in construction and design planning. (e.g., such as Wetland Restoration and Construction, a Technical Guide, 2nd edition (2011) by Thomas R. Biebighauser) • provide an revised monitoring plan that includes criteria to assess compensation success of wetland function and habitat functions.	Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order regarding the development of the Wetland Compensation Plan includingabout the details of wetland compensation such as ecological wetland functions to be compensated, potential locations where it could be implemented, ENGOs that could potentially collaborate, design criteria, and monitoring criteria. See memo titled "Supplemental Information Regarding Estuarine Wetlands and Wetland Compensation" for additional details. This technical memo will be filed with the BC EAO.
2925.1	round 1	ECCC	Application, 4.2.2.2 and 4.7.5.4; Appendix J	Wildlife Resources (Terrestrial)	The proponent developed habitat suitability modelling for Marbled Murrelets (MAMU) following a four-class rating scheme in RIC guidelines developed in 1999 (Appendix J, 4.2.2.2, pdf p.30). This modelling method is not consistent with the contemporary finer-scale mapping approaches outlined in the MAMU recovery strategy (section 7.1.1 Geographic Location), such as Air Photo Interpretation (API) and Low-level Aerial Surveys (LLA). The proponent has not characterized the extent and quality of suitable nesting habitat for MAMU in much of the critical habitat polygons within the project area. This poses a challenge in reviewing the analysis and mitigation measures provided since the methods used are not comparable or to modelling used in the MAMU recovery strategy. The proponent has conducted detailed habitat assessments for MAMU in areas adjacent to audiovisual survey stations and to ground-truth the wildlife habitat suitability model developed for MAMU (Appendix J, 5.7.2.2, pdf p. 50). This habitat assessment was compared to key biophysical attributes of MAMU nesting habitat in accordance with the recovery strategy. Analysis of the habitat assessment in a preponderance of MAMU critical habitat polygons found within the LAA and adjacent areas (Appendix J, Figure 9, pdf p. 74) is lacking. Determining the presence of biophysical attributes based solely on the locations of audiovisual surveys and the proponent's wildlife habitat suitability modeling results are not sufficient to accurately characterize the extent and quality of MAMU suitable nesting habitat within and near the project area. The proponent recorded 7 MAMU detections during their audiovisual (AV) survey (Appendix J, Table 14, pdf p. 51). However, this type and effort of survey is not sufficient to accurately detect MAMU abundance and assess movement behaviour, as would, for example radar surveys that can detect silent murrelets in the dark over much larger areas (audiovisual observers tend to only detected 10-23% of all murrelets detected by radar). Further, the Proponent should consider implementing mapping and habitat ranking methodologies to characterize the extent and quality of MAMU SNH within and near the Project area nesting habitat, such as LLA and API, consistent with the MAMU recovery strategy (section 7.1.1 Geographic Location), and following widely accepted protocols (e.g. Burger 2004; Burger et al. 2009; McDonald and Leigh-spencer 2009). **References:** Burger AE (ed.) (2004) Standard methods for identifying and ranking nesting habitat of marbled murrelets (Brachyramphus marmoratus) in British Columbia using air photo interpretation and low-level aerial surveys. Report prepared for BC Ministry of Water, Land and Air Protection, Biodiversity Branch, Victoria, BC and BC Ministry of Forests, Vancouver Forest Region, Nanaimo, BC. 37 pp. URL:http://www.env.gov.bc.ca/wld/documents/fia_docs/mamu_standard.pdf Burger AE, Waterhouse FL, Donaldson A, Whittaker C, and Lank DB (2009) New methods for assessing Marbled Murrelet nesting habitat: air photo interpretation and low-level aerial surveys. BC Journal of Ecosystems and Management 10:4–14. URL: http://forrex.org/sites/default/files/publications/jem_archive/ISS50/vol10_no1_art2.pdf Cooper BA, Blaha RJ (2002) Comparisons of radar and audio-visual counts of Marbled Murrelets during inland forest surveys. Wildlife Society Bulletin 30:1182-1194. McDonald S, Leigh-Spencer S (2009) Summary of Marbled Murrelet habitat low-level aerial survey and mapping techniques. Report prepared for Western Forest Products Ltd., Campbell River, BC. 3 pp. URL: http://marbledmurrelet.forrex.org/sites/marbledmurrelet.forrex.org/files/docs/Summary_of_MAMU_Habitat_Low-level_Aerial_Surveys_Mar2009.pdf RISC (2006) Inventory methods for marbled murrelet radar surveys. Standards for components of British Columbia's biodiversity No. 10a."The proponent indicated that "high-disturbance activities during Project construction and operations (e.g. blasting and drilling, pile driving) are likely to result in a high degree of disturbance to marbled murrelet movement during daily trips between potential nesting sites and marine feeding habitat during the breeding season" (Application, 4.7.5.4, pdf p. 74). Given the residual effects on MAMU identified both with and outside of the PDA, it is crucial that the Proponent conduct a more thorough habitat assessment within the LAA (i.e. determining the presence of suitable nesting habitat), in particular in areas identified as critical habitat polygons, as well as collect additional data on their movement patterns and abundance. **Information Request :** ECCC requests that the proponent revise the habitat assessments using modelling methods (e.g. API and LLA) that are consistent with the MAMU recovery strategy, and employing survey methods, such as the use of radar, to ensure survey results accurately capture abundance and movement. The revised assessment should provide an analysis for the following: • biophysical attributes outlined in the recovery strategy; • where potential nesting platforms occur; • where there is an indication of likely MAMU nesting or the presence of a nest; and • where a nest site is confirmed. ECCC requests that the proponent characterize the extent and quality of MAMU suitable nesting habitat which is important to the evaluation of project-related impacts, development of mitigation measures, and determination of residual effect taking into account available guidance in the attached Memo 01 "Environment and Climate Change Canada Standard Guidance for Environmental Assessments: Marbled Murrelet (Brachyramphus marmoratus)" Please also note that ECCC's document "Checklist for Conducting the Five step Strategy for Identifying and Classifying Potential Marbled Murrelet Suitable Nesting Habitat for an Area of Interest" is currently in draft and can be requested from ECCC.	Aurora LNG has completed a comprehensive suite of studies to assess the suitability and availability of marbled murrelet nesting habitat within the PDA and LAA, and to identify potential nesting sites and birds as part of field studies completed for the Project. Additional information on marbled murrelet assessment approaches presented in the Application in the context of the recommendations put forward by Environment and Climate Change Canada has been prepared as a technical memo, entitled "Marbled Murrelet Suitable Nesting Habitat Assessment" and it will be filed with the BC EAO.
2926.1	round 1	ECCC	4.6.5.2	Vegetation and Wetland Resources	The proponent states that "the red-listed non-vascular plant, Sphagnum majus and the blue-listed non-vascular plant, Sphagnum centrale will be translocated from the known locations within the project development area (PDA)", and that they "are considered resilient because they can recover from translocation and persist in the terrestrial local assessment area (LAA) and regional assessment area (RAA)" (Application, Table 4.6-10, pdf p. 29). However, the proponent has not provided further details regarding a translocation strategy and associated monitoring plans, as well as references to support its analysis that the two listed plant species are expected to "recover from translocation and persist" (Application, 4.6.5.2, pdf p. 31). Information Request ECCC requests that the proponent provide further analysis and rationale used to determine that these two plant species can recover from translocation. If the analysis demonstrates that translocation is an appropriate mitigation measure, a translocation strategy is requested including a follow-up monitoring plan to evaluate the effectiveness of such mitigation measures. The strategy should include identification of specific suitable translocation areas that contain the climatic conditions and biophysical features needed for the plants to survive and persist in the area.	Guidelines for the Translocation of Plant Species at Risk (Maslovat 2009) notes that, "in some cases, translocations may be the only viable option. For example, translocation can be a useful tool to mitigate threats to plants in development areas where no other option is feasible." Avoidance is not feasible for Sphagnum centrale and Sphagnum majus because they are located within the PDA. If the Project proceeds, the risks of attempting translocation are limited because the populations would otherwise be lost as a result of clearing within the PDA. Aurora LNG considers this a potentially-viable mitigation measure considering the successful research trials and methods of peatland restoration and moss propagation that have been developed in conjunction with the horticultural/agricultural sector and oil & gas sectors in North America and Europe. Examples of research institutes with publications that address the restoration of Sphagnum spp. include, but are not limited to the following: Peatland Ecology Research Group at the University of Laval, http://www.gret-perg.ulaval.ca/ See: Quinty, F. and L. Rochefort, 2003. Peatland Restoration Guide, second edition. Canadian Sphagnum Peat Moss Association and New Brunswick Department of Natural Resources and Energy. Québec, Québec. Peatland Restoration program at the Northern Alberta Institute of Technology http://www.nait.ca/70709.htm See: Sobze, J., M. Gauthier and R. Thomas 2012. Peatland Restoration – Harvest and Transfer of Donor Material. Technical Note. Available at: http://www.nait.ca/docs/1_Donor_Site_Harvesting_and_Moss_Transfer.pdf Aurora LNG will prepare a Sphagnum Translocation and Monitoring Plan. This will include identification of suitable translocation sites with the specific climatic conditions and biophysical features needed for each of the two species to survive and persist, as well as a plan for monitoring the performance (survival, establishment, and growth) of the translocated populations during the growing season according to the Guidelines for Translocation of Plant Species at Risk (Maslovat 2009). Translocation results will be made available to the BC Conservation Data Centre in order to increase collective knowledge of the species.
2927.1	round 1	ECCC	4.6.5.3	Vegetation and Wetland Resources	The proponent describes old-growth forests in the project development area (PDA), local assessment area (LAA) and regional assessment area (RAA) as resilient, with the ability to recover from perturbation albeit taking over 200 years to develop, and that effects on old growth forest are considered as reversible (Application, 4.6.5.3, pdf p. 40). It is unclear how this determination was made with respect to project-related impacts, given the lack of supporting references, empirical evidence, or adequate justification. Occurrences of species at risk and migratory birds were detected in these old-growth forests, indicating their reliance on this habitat for nesting, breeding, and foraging. Impacts on species at risk and migratory bird using these old-growth forest as habitat during all stages of the annual cycle (breeding, wintering, and migratory) have not been assessed. Information Request ECCC requests that the proponent clarify and provide rationale on how: • old-growth forests in the project area are considered resilient in the context of project-related effects; • project impacts on old-growth forests are considered as reversible, given the amount of time old growth forests take to develop; and • effects on species at risk and migratory birds were taken into account when developing mitigation measures and determining residual effects for old-growth forests.	The scope of Section 4.6.5.3 of the Application is the assessment of change in abundance or condition of ecological communities of interest (including old forest). This does not include the associated wildlife functions of old forest. The wildlife habitat functions of old forest, including the reliance of species at risk and migratory birds, is assessed explicitly in the wildlife section (Section 4.7 of the Application). Wildlife species which require mature and old forest for parts of their life cycle include little brown myotis, marbled murrelet, and western toad, which are assessed quantitatively under Assessment of Change in Habitat in the Wildlife Section (Section 4.7.5.2 of the Application). The Application defines a valued component as resilient if there is "capacity for resources to recover from a perturbation, and consideration of the existing level of disturbance" (Table 4.6-5 of the Application). Technically, old forest can recover from perturbation and does so during natural disturbance events such as forest fires or windthrow, as well as following anthropogenic disturbance such as commercial timber harvesting activities. Project effects on old forest are considered reversible because forests develop old forest characteristics (including complex structure and regeneration of shade-tolerant species with similar composition to the overstory) after a certain period following a stand replacing disturbance. On the North Coast, this period is typically 250 years (BC MOFR and MOE 2010). Duration is a separate characterization of residual effects and the Application directly acknowledges that Project effects on old forest are only reversible in the long term duration (i.e., extends beyond the life of the Project) (see Table 4.6-5 for definitions of effects characterizations. References British Columbia Ministry of Forests and Range and Ministry of Environment (BC MOFR and MOE). 2010. Field manual for describing terrestrial ecosystems. 2nd ed. Forest Science Program, Victoria, BC Land Management Handbook. No. 25. British Columbia Ministry of Forests and Range and British Columbia Ministry of Environment.

2928.1	round 1	ECCC	4.6.5.4 and 4.6.2.1	Vegetation and Wetland Resources	The proponent has committed to implementing the “Marine and Freshwater Resources Management Plan” to mitigate effects on adjacent wetlands outside of the PDA, and that the Wetland Compensation Plan will ensure that these wetlands “will be periodically monitored to determine effectiveness of mitigation measures” (Application, Table 4.6, pdf p 49). However, it is unclear whether these mitigation measures and monitoring efforts will be planned and implemented in the context of potential impacts on species at risk and migratory birds. For instance, loss of freshwater watercourse within the PDA will likely alter hydrological regimes (e.g. salinity, soil deposit) in areas with estuarine mudflats and eelgrass habitats, such as Delusion Bay and Casey Cove, which are known to support numerous migratory birds and species at risk year-round. It is also important to note that waters (including shorelines) from Delusion Bay to the eastern shorelines and waters of Digby Island are part of an Important Bird Area (http://www.ibacanada.ca/maps/sites/BC124.pdf), which further underscores the significance of such estuarine wetland and eelgrass areas for bird species. Information Request: ECCC requests that the proponent identify mitigation measures for adjacent wetland areas outside of the PDA, taking into consideration how species at risk and migratory birds using such areas may be impacted by Project activities. In addition, the proponent should evaluate effectiveness of such mitigation measures via a follow-up monitoring program that includes a “Before-After-Control-Impact” study design for species at risk, migratory birds, and their habitat. The proponent should describe how long-term monitoring and follow-up will be undertaken at the proper scale, and that subsequent studies will be compatible with the baseline studies.	Mitigation measures for wetlands outside the PDA are presented in Table 4.6-13 'Mitigation Measures Proposed to Avoid or Reduce Change in Wetland Function'. See mitigation number 4.6.14, which states that "Wetlands immediately adjacent to the PDA will be periodically monitored to determine the effectiveness of mitigation measures, specifically in relation to wetland hydrology." The recommendations in this comment from ECCC have been noted. Mitigation measures that address species at risk and migratory birds are provided in Table 4.11-9 related to 'Mitigation Measures Proposed to Avoid or Reduce Change in Habitat for Marine Birds' and Table 4.7-10 related to 'Mitigation Measures Proposed to Avoid or Reduce Change in Habitat for Wildlife Resources (Terrestrial)' and Table 4.7-14 related to 'Mitigation Measures Proposed to Avoid or Reduce Change in Mortality Risk for Wildlife Resources (Terrestrial)' Section 14 summarizes the environmental management plans, including the Wildlife Management Plan, which in-turn includes management plans for identified species at risk such as various bat species and marbled murrelet. Aurora LNG will consult with regulators including ECCC and working group members on the development of the environmental management plans, including monitoring plans and follow-up programs developed as part of the Wetland Compensation Plan.
2929.1	round 1	ECCC	Application, 4.6.6.2; Appendix I; Appendix U	Vegetation and Wetland Resources	Information request: ECCC requests that the Proponent address the following items important to understanding how impacts have been assessed and are to be mitigated: • clarify as part of the Invasive Plants Management Plan how “the introduction or spread of invasive species will be mitigated to acceptable levels” (Application, 4.6.6.2, pdf pg. 60); • provide justification for how wetlands without the presence of lichen are “not considered to be particularly sensitive to higher concentrations of NO2 and SOs” (Appendix I, 3.1.4, pdf pg. 19); • clarify why the 3 “Area[s] with Ecologically Important Wetlands” within the PDA mapped in Figure 1 of Appendix U (i.e. CWHvh2/Em05, CWHvh2/Wf51, and CWHvh2/Ws54) were not shown in Figure 4 of Appendix I (pdf pg. 83); and • clarify whether the 3 identified red/blue-listed wetland communities (i.e. CWHvh2/Em05, CWHvh2/Wf51, and CWHvh2/Ws54) were included as part of the NO2 and soil acidification exceedance determination (Appendix I, Table 7 and Table 8) References: Jones, W, 2005. Peat fires: The dangers from a Fire Manager’s Point of View. Journal of the Royal Society of Western Australia, 88, 139-142.	"The introduction or spread of invasive species will be mitigated to acceptable levels" (Application, Section 4.6.6.2, pdf pg. 60) through the implementation of the Invasive Plants Management Plan. This plan will include best management practices which will meet the legal obligations under the Weed Control Act and Regulations, which prohibit the spread of noxious weeds on highways and prohibits using seeds with noxious weed seeds intermixed, and will meet the BC Oil and Gas Commission (BC OGC) Environmental Protection and Management Guideline (2015) requiring control of invasive species during all phases of a project. Best management practices will be included in the invasive plant management plan and will include those in the following references:Best Practices for Managing Invasive Plants on Roadsides. Published by BC Ministry of Transportation and Infrastructure; available as a pocket guide. Contains best practices for roadside workers that are equally applicable to road contractors in the oil and gas sector. http://www.th.gov.bc.ca/publications/eng_publications/environment/ManagingInvasivePlants.pdfThe Best Practices for Managing Invasive Plants on Oil and Gas Operations. Pocket guide developed for British Columbia's Oil and Gas workers. Contains information on key aquatic invasive species as well. http://prrd.bc.ca/services/environmental/weed_control/documents/PRINT-READY-OG-Guide_2013_FINAL.v2.pdfMinistry of Agriculture, Seven Steps to Managing Your Weeds. A Guide for Integrated Weed Management in British Columbia. http://www.agf.gov.bc.ca/weedsbc/pdf/7StepsToManagingYourWeeds.pdfMinistry of Forests, Lands and Natural Resource Operations, Invasive Alien Plant Program - Reference Guide Part 1 https://www.for.gov.bc.ca/hra/plants/RefGuide.htm Mitigation 4.6.5 will also be included in the Invasive Plant Management Plan. Mitigation: Temporary workspaces, reclaimed land, and other revegetation activities will be vegetated using certified weed-free native plant seed and traditional use species where practicable. Mitigation mechanism: Reclaiming temporary workspaces as soon as practicable reduces the chance that invasive species will grow and will minimize erosion and therefore soil loss. Wetlands without the presence of abundant lichen are "not considered to be particularly sensitive to higher concentrations of NO2 and SOs" (Appendix I, 3.1.4, pdf pg. 19) because, as stated in Section 3.1.4 of Appendix I of the Application, "lichens are particularly sensitive to NO2 and SO2 as they lack the protective cuticle that vascular plants have (WHO 2000; Bobbink and Hettelingh 2011)". Wetlands without lichen were not identified as particularly sensitive in the review of literature sources cited in Section 3.3.1 of Appendix I of the Application. The "Area[s] with Ecologically Important Wetlands" within the PDA mapped in Figure 1 of Appendix U of the Application (CWHvh2/Em05, CWHvh2/Wf51, and CWHvh2/Ws54) were not shown in Figure 4 of Appendix I of the Application (pdf pg. 83). Figure 4 of Appendix I displays the dominant ecosystem map code, which may not include the map codes of ecologically important wetlands when they are not the dominant component of a polygon. For this reason, differently themed figures were used in the application to pull out the relevant details for specific purposes. The red/blue-listed wetland communities CWHvh2/Em05 and CWHvh2/Wf51 are not included among communities sensitive to NO2 and SO2, and therefore were included in the general category Total Wetland. The red/blue-listed wetland communities CWHvh2/Em05 and CWHvh2/Wf51 are not identified as communities sensitive to NO2 or SO2 because they are not apt to support lichens; however, the CWHvh2/Ws54 would be included among ecosystems sensitive to this mechanism since it could support abundant lichen. All ecosystems were deemed sensitive to the mechanisms of acidification and eutrophication (Tables 8 and 9 of Appendix I of the Application), including the provincially red/blue listed communities.
2930.1	round 1	ECCC	4.6.7.1 and 4.6.5.5	Vegetation and Wetland Resources	The proponent determined that residual effects to wetland resources are predicted to be not significant, citing justifications such as “change in wetland function will not involve uncompensated net loss of wetland functions of ecologically important wetlands” (Application, 4.6.7.1, pdf p, 76). The proponent concluded project residual effects on wetland function during the construction phase using the follow criteria (Application, Table 4.6-14, pdf p.56): • Magnitude: medium • Geographic extent: PDA • Frequency: single event • Duration: long-term • Reversibility: reversible • Context: resilient • Likelihood: high However, residual effects on wetland functions may be higher than what the proponent has concluded, based on the following criteria: • Geographic extent: beyond the PDA, as the proponent has not adequately considered the adjacent wetland areas (e.g. intertidal coastal wetlands) • Reversibility: irreversible, as the conceptual Wetland Compensation Plan is ambiguous in its proposed mitigation measures to offset impacts to red and blue-listed wetlands that are likely difficult to compensate (i.e. swamps, fens) • Context: not resilient, as the Proponent has not provided adequate information and empirical evidence to justify the resilience of impacted wetlands Information Request ECCC recommends that the proponent expand the effects assessment on wetlands to include project interactions with the estuaries, eelgrass beds, and intertidal wetlands of “Continental Importance to Waterfowl”,	Wetlands within Federal Lands and Waters include estuarine wetlands within the management jurisdiction of the Prince Rupert Port Authority, the boundaries of which correspond with the area of Continental Significance to Waterfowl identified by the Joint Ventures where these two management area designations intersect within the spatial boundaries of the Project. Estuarine wetlands have been assessed in the Application as follows: See Table 4.6-4 in section 4.6.2.5, and 4-9 in the AIR for the spatial boundaries of the vegetation and wetlands resources VC, which are distinct from the spatial boundaries of the marine fish and fish habitat VC.See section 4.6.1 of the AIR, which states that "eelgrass will be assessed as part of the 'Change in Habitat' effect under Marine Fish and Fish habitat VC in Section 4.9". Note that some eelgrass habitat presented in Section 4.9 is located well below the lower low water mark, and thus are considered subtidal marine habitat rather than estuarine intertidal wetlands. Estuarine wetlands are assessed in section 4.6.5.4 (and see Table 3 of Appendix I, Vegetation and Wetland Resources TDR). The spatial extent of potentially-affected wetlands and their functions are presented in sections 4.6 (wetlands other than eelgrass beds), and 4.9 (eelgrass beds) of the Application. The spatial extent of estuarine shore water wetlands (i.e., mudflats) that occur within the PDA will be determined when the design options for the materials offloading facility are finalized. Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Wetland Compensation Plan. The consultation will include the assessment of which habitat offsetting measures associated with marine fish habitat address the habitat functions of estuarine wetlands such as eelgrass and estuarine shore water (i.e., mudflats) to achieve no net loss of functions for these ecologically important wetlands. See the memo titled "Supplemental Information Regarding Estuarine Wetlands and Wetland Compensation " for additional details. This technical memo will be filed with the BC EAO.
2931.1	round 1	ECCC	4.7.5.2 and 4.11.5.3	Wildlife Resources (Terrestrial)	Proposed flaring sites are directly adjacent to Delusion Bay, which consists of estuarine meadow/marsh/mudflat habitat (Application, Figure 4.7-2, pdf p. 26) of high ecological value for Pacific migratory and breeding waterfowl and shorebirds. The proponent recorded 10 species of shorebirds and waterfowl in Delusion Bay (Application, 4.6.5.4, pdf p. 53), as well as thousands of other individual birds in the surrounding areas (Appendix J; Appendix Q). In addition, the flaring sites are adjacent to one of the Proponent’s shorebird count stations that resulted in the second highest count : 120 birds (Appendix Q, Table 2-1, pdf p. 45). Further, the PDA is directly adjacent to the Big Bay South to Delusion Bay Important Bird Area (IBA), and is less than 10km from two others (i.e. the Lucy Islands IBA and the Kitkatla Channel IBA). Coastal estuarine and mudflat wetlands found in IBAs serve as crucial breeding and migratory stopover sites for millions of individual birds and are globally significant for congregatory species and colonial waterbird/seabird and waterfowl concentrations. While the proponent has conducted observer-based baseline surveys to determine local abundance and density of various avian species in the LAA, such information may not adequately characterize flaring and lighting-related impacts on avian species within and near the Project area. Additional data collected using instrument-based and/or remote sensing approaches (e.g. radar surveys) in conjunction with observer-based surveys would provide further species or guild-specific information across their annual cycle (i.e. breeding, wintering, and migration). Acquiring a more comprehensive baseline dataset would allow the proponent to develop mitigation appropriate to advoidance and reduction of bird and bat mortality potentially arising from flaring and lighting and effects. The proponent states in the Application that as part of the Wildlife Management Plan “facility staff will document or report bird injuries or fatalities related to Project activities” in relation to lighting-related impacts (Table 4.7-14, pdf p. 62; Table 4.11-10, pdf p. 31). However, such a monitoring plan is not a methodical procedure and thus may not suffice to accurately evaluate the effectiveness of any implemented mitigation in relation to flaring and lighting-related impacts on avian species. Information Request ECCC requests that the Proponent outline provisions for collecting baseline data (using methods such as instrument-based and/or remote sensing) to assess potential effects, due to flaring and lighting-related impacts on avian species that takes into account the following:: • flight direction, altitude, and behaviour of birds and bats; • time periods with high bird and bat movement rates (e.g. migratory season, breeding season); and • relative abundance.	Shoreline stationary count locations were located to maximize survey coverage across various nearshore environments within the LAA, targeting unique marine features (e.g., Delusion Bay, Casey Cove, surrounding islands and islets). For clarity, Section 4.1.3 of Appendix Q provides a description of the findings, indicating that bird abundance and richness was generally similar across points (with exceptions to stations reporting higher numbers of individuals and species described therein). Table 2-1 of Appendix Q provides a summary of individual species reported at each shoreline stationary count. Compared to other locations, counts completed in Delusion Bay (i.e., i.e., MBDI09 and MBDI10) recorded fewer individual birds and species but nonetheless indicate that habitats at those locations support use by shorebirds, ducks, grebes, loons, gulls, corvids, and eagles (for example). Current Project specific and regional data in combination with information available in scientific literature and professional judgement and experience are considered appropriate for characterizing existing conditions and assessing potential residual effects to marine birds. As per mitigation 4.7.20, Aurora LNG has committed to scheduling maintenance flaring events during daylight hours to the extent practicable to further reduce attraction by birds and bats to flare system infrastructure during nocturnal migration or foraging. Additionally, the marine riparian disturbance buffer of 30 m (mitigation 4.5.1) will be applied during all phases of the Project to retain shoreline habitats and limit noise and light dispersal, and is expected to further reduce potential for disturbance to avian species using shoreline and nearshore habitats in Delusion Bay. Aurora LNG has further committed to mortality monitoring and reporting (mitigation 4.7.14). The Wildlife Management Plan will provide details on procedures for identifying, recording, and reporting on injuries or mortalities related to Project activities, As part of the reporting, Project personnel will be required to describe the predicted cause of mortality, if known. Aurora LNG welcomes further discussion with Environment and Climate Change Canada on the development of the Wildlife Management Plan and the subsequent implementation of mitigation 4.7.14. To improve understanding of bat species presence and occurrence, and to support the development of the Bat Management Plan, additional information on seasonal activity patterns for bats has been prepared as a technical memo, entitled "Aurora LNG Project Bat Monitoring Program", which provides further information about activity patterns in Delusion Bay. The technical memo will be filed with the BC EAO.

2932.1	round 1	ECCC	Application, 4.7.5.2 and 4.11.5.3	Wildlife Resources (Terrestrial)	There is a lack of information regarding the development of mitigation measures for avoiding and minimizing flaring and/or lighting-related impacts especially given that 3 Important Bird Areas (IBAs) are in close proximity to the project development area (PDA). There is lack of information to understand how the proponent will avoid flaring and light-related impacts to avian species (especially during high risk periods for birds and bat species) through the use of best available technology and what measure would be implemented if avoidance of effects is not feasible. A post-construction monitoring plan has not been provided which is essential to assessing the effectiveness of mitigations measures. In relation to any navigational lighting requirements, in order to minimize the risk to avian species, the minimum amount of obstruction avoidance lighting should be used on tall structures. The use of only strobe lights at night, at the minimum intensity and minimum number of flashes per minute (longest duration between flashes) allowable by Transport Canada, is recommended. The use of solid-burning or slow pulsing warning lights at night should be avoided." ECCC recommends the Proponent include, as part of their Wildlife Management Plan, a post-construction monitoring strategy to assess the effectiveness of mitigation measures for flaring and lighting-related impacts on avian species. The Proponent should consider such things as the following: a. describe how lighting and flaring would be avoided or minimized to the extent possible when occurring at night (see above); b. identify potential high risk periods (see above), as well as specific structures, activities or locations that have the potential to contribute to avian mortality. This should take into account areas that are not able to be monitored due to substrate, health and safety concerns, etc.; c. monitor the effectiveness of mitigation in a scientifically-sound and methodical procedure (this can include, but not be limited to, monitoring bird movement and behaviour using a marine radar); and d. document monitoring results, including a demonstration of whether the mitigation measures have proven effective and if additional measures were required. The monitoring should identify corrections for searcher efficiency, carcass persistence (i.e. scavenging), and searchable area (i.e. that takes into account areas that are not able to be searched due to substrate, health and safety concerns, etc.), in consideration of the use of marine radar independently or in combination with any carcass searches (see Ronconi et al. 2015 and Day et al. 2015 for monitoring protocols). **Information Request** ECCC requests that the proponent describe how its plans for use of best available technology will avoid flaring and lighting-related impacts to avian species (e.g., use of enclosed flare systems). If avoidance is demonstrated as not feasible, the proponent is requested to identify mitigation measures it will implement (in addition to those outlined in Table 4.7-13 and 4.11-10) and to demonstrate the following items have been considered: • Minimizing the number of light installations; • Avoiding the use of solid burning or slow pulsing warning lights; • Avoiding or restricting the time of operation of decorative lights such as spotlights and floodlights that function to highlight the exterior features of buildings; and • Installing the flaring site such that the height of the gas flare (i.e. flaring boom) is out of the flight altitude range of avian species (Day et al. 2015). ECCC requests that the proponent describe how it plans to avoid high risk periods for bird and bat species during the following conditions: • humid, foggy, or rainy nights (illumination glow can draw birds and bats from distance); • spring and fall migration period with high bird movement; and • breeding season for seabirds, when adult birds disperse between their nesting colony and marine foraging areas from dusk to dawn daily (e.g. Marbled Murrelets). ECCC also requests that the proponent provide a post-construction monitoring plan that would allow the effectiveness of mitigation measures to be determined. **References:** Day RH, Rose JR, Prichard AK, Streever B (2015) Effects of gas flaring on the behavior of night-migrating birds at an artificial oil-production island, arctic Alaska. Arctic 68:367-379 Ronconi RA, Allard KA, Taylor PD (2015) Bird interactions with offshore oil and gas platforms: Review of impacts and monitoring techniques. Journal of Environmental Management 147:34-45.	Sections 4.7.5.3 and 4.11.5.3 of the Application discuss effects of lighting infrastructure, including flaring, on terrestrial and marine birds and bats; noting from literature that effects to passerines, and species within the family Alcidae and the order Procellariiformes are more susceptible to light-induced mortality than other species. Although the LAA is located in proximity to three important bird areas, not all species they support are likely to interact with lit infrastructure from the Project (noting, however, that Lucy Islands is located 13 km from the PDA boundary and supports breeding habitat for alcids as described in Appendix Q). Aurora LNG committed to a suite of mitigation measures to reduce the potential effects of lighting infrastructure on birds and bats during all project phases which were described in Sections 4.7.5 and 4.11.5. Proposed mitigations are consistent with the recommendations presented by Environment and Climate Change Canada, in this comment. As per mitigation 4.7.9, Aurora LNG has committed to limit exterior lighting, and use of directional or shielded lighting to reduce the risk of injury or mortality of marine birds during all Project phases. Aurora LNG considered placement options of the flare system within the PDA to reduce potential interaction with environmental valued components and to limit the amount of light dispersal (Table 1-26) . As per mitigation measure 4.7.20, flaring events associated with maintenance activitieswill be scheduled during daylight hours to the extent practicable to further reduce attraction by birds and bats to flare system infrastructure during nocturnal migration or foraging. To facilitate compliance with Project mitigation measures, educational materials provided to employees and contractors will include information on procedures for documenting bird injury or mortality, and handling and release of stranded birds (mitigations 4.7.13, 4.7.14, and 4.7.15). Educational materials will include information on lighting effects to migratory birds, including seasonal and weather-based sensitivities and best management practices for lighting types. The on-site Environmental Monitor(s) will be responsible for providing access to educational materials, training and advising staff, maintaining an accurate record of injury and mortality events, and communicating this record to applicable regulatory authorities at a prescribed interval. To monitor potential effects of lighting on bird and bat mortality, facility personnel will be required to report injuries or fatalities related to Project activities (mitigation 4.7.14). As per mitigation 4.7.16, light-induced stranding's at the LNG facility, marine terminal, supporting infrastructure and facilities, and on berthed vessels will also be documented and reported. To support mitigation measures 4.7.14 and 4.7.16, the Wildlife Management Plan will provide a description of the procedures for searching, documenting, and reporting bird and injuries and mortalities, as a means to evaluate patterns in use, lighting-based effects, and for monitoring the effectiveness of mitigation measures. Project personnel will be required to describe the cause of mortality, if known. The Wildlife Management Plan will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended).
2933.1	round 1	ECCC	4.7.5.2 and 4.11.5.3	Wildlife Resources (Terrestrial)	The proponent states that "if clearing or disturbance to terrestrial habitats is required during breeding bird periods, bird surveys will be conducted in advance by a qualified biologist to comply with the Migratory Birds Regulations of the Migratory Birds Convention Act and the BC Wildlife Act" (Application, Table 4.7-14, pdf p. 63; Application, Table 4.11-5, pdf p 33). Construction during the breeding and nesting period for migratory birds carries with it high risks of detrimental effects (incidental take) to migratory birds. Many bird nests are difficult to locate, even with highly trained observers. ECCC does not recommend that clearing occur during breeding and nesting bird periods, even with pre-clearing surveys. Nest search techniques are not recommended because, in most habitats, the ability to detect nests remains very low while the risk of disturbing active nests is high. Flushing nesting birds increases the risk of predation of the eggs or young, or may cause the adults to abandon the nest or the eggs. In many circumstances, incidental take is likely to still occur during clearing even when active nest searches are conducted prior to these activities. Information Request ECCC requests that the proponent describe the scientifically sound approach it will implement to determine migratory bird presence before any clearing occurs (regardless of time of year) with attention to the following considerations: • existing standards to be followed, including Resources Information Standards Committee (RISC) standards for inventory and survey methods of Forest and Grassland Birds, as well as other species-specific survey and inventory methods, selected in consultation with ECCC, where applicable for species that are often not detected using RISC guidelines (e.g. Common Nighthawk, Western Screech-Owl, etc.) • descriptions of how surveys will be carried out by an experienced, Qualified Professional in a manner that protects migratory birds and nests and avoids harming, killing or disturbing migratory birds or destroying or taking their nests or eggs.	Environment and Climate Change Canada (ECCC) provides guidance on the Avoidance of Detrimental Effects to Migratory Birds (Incidental Take) to facilitate compliance with the Migratory Birds Convention Act (ECCC 2017a). Aurora LNG has adopted this guidance in the development of Project mitigation measures to prevent the inadvertent harming, killing, disturbance or destruction of migratory birds, nests, and eggs. Consistent with ECCC's guidance on avoiding incidental take, Aurora LNG will avoid pre-construction clearing activities within the primary breeding bird window, using ECCC's General Nesting Periods of Migratory Birds in Canada (ECCC 2017b). As per mitigation 4.7.17, Aurora LNG has also committed to modifying the pre-construction clearing schedule to limit disturbance of other species (e.g., bald eagle from February 5 through August 31) whose nesting period extends beyond the regional primary nesting period. If clearing becomes required within the proposed PDA during the primary nesting period, a pre-clearing survey will be completed to identify breeding activity for migratory birds. For clarity, the nest search survey referred to in mitigation 4.7.18 is intended to apply non-intrusive (e.g., passive) monitoring and search methods to identify breeding activity while limiting disturbance to breeding migratory birds, consistent with recommendations from ECCC (2017a). To the extent feasible, breeding activity will be determined using passive survey methods (e.g., point counts following provincial RIC standards) to support discovery of an actual nest, or behavioural observations that suggest evidence of nesting activity (e.g., territorial behaviour, carrying nesting material). If necessary, these methods will be adapted to confirm presence and nesting of potentially occurring migratory birds that are more appropriately surveyed using other methods. As noted by ECCC (2017a), more systematic nest survey approaches (e.g., transects with passive monitoring along each) are appropriately applied in simple habitats (e.g., open habitats). Appropriate methodology would be applied based on the habitat type and with professional judgement of the qualified professional performing the survey. ECCC recommends that "Any nest found should be protected with a buffer zone determined by a setback distance appropriate to the species, the level of the disturbance and the landscape context, until the young have permanently left the vicinity of the nest" (ECCC 2017a). Consistent with this recommendation, mitigation 4.7.18 indicates that active nests identified prior to clearing and setbacks will be clearly marked to show the extent of allowable clearing until the nest is no longer active. Buffer distances will be based on direction from provincial and federal guidance and species-specific disturbance thresholds, in the context of site conditions (e.g., habitat type; type of construction activity). Evidence of nesting activity and professional judgment are sufficient to recommend mitigation measures (e.g., setbacks), even if a nest is not found. The Wildlife Management Plan will provide a detailed description of the procedures for searching, documenting, and reporting of active nests and will be consistent with applicable Environmental Assessment Certificate conditions. Aurora LNG will engage with ECCC during the development of the Wildlife Management Plan. References Environment and Climate Change Canada (ECCC). 2017a. Accessed: March 2017.
2934.1	round 1	ECCC	Application, 4.7.5.2	Wildlife Resources (Terrestrial)	The proponent has identified 19 ha of Marbled Murrelet (MAMU) critical habitat within the PDA, of which 5 ha will be retained through the Wetland Compensation Plan (Application, 4.7.5.2, pdf p. 49). MAMU critical habitat is the portion (approximately 70%) of 2002 levels of suitable nesting habitat across coastal British Columbia required for the survival and recovery of the species as specified by short and long term population and distribution objectives. According to the MAMU recovery strategy, the minimum nesting habitat retention level for the conservation region within which the project is located (i.e. Northern Mainland Coast) is 68%. However, as indicated in the above IR, it appears that the Proponent did not determine whether SNH for MAMU is present within or near the project area, in consultation with ECCC. Further, the Proponent has not indicated whether they have consulted with the provincial or federal authorities to determine if impacts to SNH would compromise the minimum nesting critical habitat retention level for the Northern Mainland Coast conservation region. If the minimum nesting critical habitat retention level is compromised from Project-related impacts, ECCC would advise that destruction of critical habitat is likely. With respect to this mitigation hierarchy, the environmental assessment should describe how the hierarchy was applied and provide a rationale for moving from avoidance to minimization to offset. Given the long time it takes for forests to develop the biophysical attributes necessary to support nesting, it may not be possible to fully compensate for impacts to the critical habitat of MAMU. This is because of the time lag between when impacts would occur and the time when compensated habitat would become suitable for nesting. Information Request ECCC requests that the proponent determine the presence of suitable nesting habitat within and near the local assessment area (LAA) and consult with provincial or federal authorities in evaluating whether impacts to suitable nesting habitat would compromise the minimum nesting critical habitat retention level for the Northern Mainland Coast conservation region. ECCC also requests that the proponent identify and describe measures to avoid, minimize, or offset for any potential impact identified. With respect to this mitigation hierarchy, the environmental assessment should describe how the hierarchy was applied and provide a rationale for moving from avoidance to minimization to offset. Consistent with ECCC's Operational Framework for Use of Conservation Allowances, considerations should be given to the use of compensation for the loss of MAMU habitat: http://www.ec.gc.ca/Publications/58A4AECD-A096-458C-B457-0E67CADF911D/OperationalFrameworkforUseofConservationAllowances.pdf	To support the assessment and characterization of residual effects to marbled murrelet, wildlife habitat assessments were completed to support the development of a detailed habitat suitability model to quantify and qualify nesting habitat suitability within the LAA. The habitat assessments were supplemented with audio-visual surveys and detailed habitat assessments to refine the prediction of potential effects on marbled murrelet habitat. Survey data was collected to determine evidence of breeding or occupied detections (i.e., marbled murrelets seen or heard landing, perching, or flying through or out of the forest canopy) and to further evaluate habitat attributes within preferred or identified critical habitat polygons (see Section 5.7.2 of Appendix J for details). No marbled murrelets were detected during audio-visual surveys and no 'high-likelihood' nesting habitat was identified during the detailed habitat assessments. Supported by Project field studies, Section 4.7.5.2 of the Application provides an estimate of direct and indirect loss of preferred breeding (i.e., suitable nesting) habitat and identified critical habitat for marbled murrelet within the LAA.The PDA overlaps with 77 ha of preferred nesting habitat and 19 ha of polygons containing marbled murrelet nesting critical habitat. After accounting for portions of the PDA retained by the vegetated riparian buffer, the Project is estimated to result in the direct removal of 61 ha of preferred and 14 ha of identified critical habitat (with overlap in extent between those two classifications; see Figure 9 of Appendix J). The majority of preferred and identified critical habitat is located in stands of old-growth forests located on the perimeter of Digby Island. After accounting for portions of the PDA retained by the vegetated riparian buffer, the net change in identified critical habitat was estimated to be 14 ha as a result of the Project. The Project residual effects in change in breeding habitat is likely to act cumulatively with other past, present, or reasonably foreseeable projects and physical activities. The Application included a quantitative assessment of cumulative effects to marbled murrelet habitat in Section 4.7.5.6. A GIS spatial analysis was used to estimate the residual cumulative effects of past, present, and reasonably foreseeable future projects and physical activities in combination with residual Project effects on murrelet habitat present within the RAA (see Section 4.7.5.6). The ecological modelling conducted for the RAA indicates 923 ha of mature or old coniferous forest will be removed by reasonably foreseeable future developments (Table 4.7-19). The Project's contribution to change in habitat accounts for less than 0.0001% of the habitat supply target for the Northern Mainland Coast population. The Project's contribution to cumulative effects is considered a conservative estimate given that: (a) the full extent of identified critical habitat polygons were used to estimate direct effects (Environment Canada 2014), (b) the majority of habitat is located within 500 m of shoreline and is therefore only 'moderately likely' to support nesting (Environment Canada 2014), (c) recent studies have shown positive trends in radar counts (and associated availability of nesting habitat) for the North Mainland Coast (Bertram et al. 2015), and (d) Aurora LNG is committed to implementing a Marbled Murrelet Management Plan to avoid or reduce potential Project effects to changes in nesting habitat. Results of this assessment suggest that the Project's residual effect and its contribution to cumulative change in habitat availability will not influence the long-term sustainability of the regional population. This is consistent with habitat management directives outlines in the proposed Recovery Strategy for Marbled Murrelet (Brachyramphus marmoratus) in Canada (Environment Canada 2014). Aurora LNG is committed to following a mitigation hierarchy to avoid, limit, and mitigate for potential effects to marbled murrelet and will implement options that result in avoiding or reducing effects to the species. Mitigation measures applicable to marbled murrelet are listed in Table 4.7-17. Some Project activities (e.g., vegetation clearing within the PDA) will result in direct and indirect loss of habitat, however, to reduce potential effects on nesting habitat, Aurora LNG will retain a marine riparian disturbance buffer. The riparian buffer will be a minimum of 30 m wide, but may extend beyond 30 m in some areas on the east side of Digby Island (see Figure 4.7-7). To further address direct loss of suitable nesting habitat, Aurora LNG has committed to developing a Marbled Murrelet Management Plan that will outline avoidance, reduction, mitigation, and monitoring measures to effects from Project construction and operation activities. The management plan will follow the Operational Framework for Use of Conservation Allowances, as it applies to the Project (Environment Canada 2012). Aurora LNG will consult with the appropriate regulatory agencies during the development of the Marbled Murrelet Management Plan. 2935.1	round 1	ECCC	Application 4.7.5.2 and 4.7.9; Appendix J	Wildlife Resources (Terrestrial)	The proponent has identified a Great Blue Heron fannini subspecies (GBH) rookery west of Dodge Cove (Application, 4.7.3, pdf p. 31), and has committed that "high-disturbance project-related activities (e.g. blasting, pile driving) will be avoided where practicable during the breeding window… within 500 m of the GBH rookery at Dodge Cove". The proponent states that this mitigation measure is "consistent with provincial guidelines (i.e. BC MOE 2014c)" (Application, Tables 4.7-10, 4.7-14, and 4.7-15). However, the provincial guidelines (BC MOE 2014) state that high disturbance activities such as "blasting or similarly excessive noises should not occur closer than 1000 m from a colony during the nesting window". Further, GBHs residing in developed urban areas may be more habituated to human disturbances. In comparison, those that nest and forage in undeveloped "pristine" landscapes are less tolerant (lower threshold) to human disturbance, including project activities, and as a result are more likely to abandon their nests. The proponent has "committed to monitoring the great blue heron rookery for changes in breeding activity when vegetation clearing for the Project construction overlaps with the breeding window for great blue herons". However, the Proponent did not indicate whether monitoring of the GBH rookery will also occur in other phases of the project, such as the operation phase (Application, 4.7.9, pdf p. 98). It is unclear why the Proponent has indicated that the GBH rookery is "approximately 500 m from the PDA boundary" (Application, 4.7.3, pdf p. 31). According to Figure 10 of Appendix J (pdf p. 75) and the "Regulatory Based on the summary for Bird Species of Known Presence on Digby Island" provided to ECCC on June 14, 2016 (pdf p. 3), it appears that the GBH rookery maybe approximately 300m away from the PDA boundary. With the already existing buffer radius for GBH nests outlined in provincial guidance documents (e.g. BC MOE 2014), having an accurate representation of the interaction between the rookery and project activities has important implications for assessing project effects and planning mitigation measures for GBH. Information Request ECCC requests that the proponent describe how it will meet its commitment to the setback distance outlined for GBH colonies in the provincial guidelines, "Develop with care 2014: Environmental guidelines for urban and rural land development in British Columbia" and the direction to avoid all project activities, in particular high disturbance ones (e.g. blasting, pile driving), within the 1000m buffer from the GBH rookery during the breeding window (Jan 15 – Sept 15). ECCC also requests that the proponent confirm provisions for monitoring the GBH rookery not only during project construction but also the operation phase. ECCC requests that the proponent clarify the apparent discrepancy in the reported distance between the GBH rookery and the PDA. Specifically, section 4.7.3 of the Application (pdf p. 31) indicates the distance is "approximately 500 m", whereas according to the Figure 10 of Appendix J (pdf p. 69) and the "Regulatory Summary for Bird Species of Known Presence on Digby Island" (pdf p. 3), the distance may be approximately 300 metres.	Aurora LNG is committed to maintaining setbacks to decrease the extent of sensory disturbance in the vicinity of active nesting sites for great blue heron and to reduce the potential for flushing during the nesting and rearing period. Aurora LNG acknowledges that Develop with Care recommends as a best management practice that excessive noises should not occur within 1,000 m of a great blue heron colony during the nesting window (BC MOE 2014). As per mitigation 4.7.4, high-disturbance Project-related activities (e.g., blasting, pile driving) will be avoided where practicable during the breeding window (i.e., January 15 through September 15) within 500 m of the great blue heron rookery at Dodge Cove. To address the uncertainty over the degree to which high disturbance activities occurring within 1,000 m of the heron rookery may result in disturbance displays by nesting herons (as per provincial guidelines), Aurora LNG has committed to monitoring for changes in breeding activity at the rookery if high disturbance activities for Project construction occur within 1,000 m of the rookery during the breeding window (January 15 to September 15 for great blue heron). Given the geography of the area and the fact that there is a ridge of land that visually separates the rookery from proposed road corridor it is unlikely that road construction activities will cause a change in breeding activity. Monitoring protocols will follow the Survey Protocol for Measurement of Nesting Productivity at Pacific Great Blue Heron Nesting Colonies (Vennesland and Norman 2006). Aurora LNG will apply an adaptive strategy to accommodate observed changes in breeding activity. Monitoring and adaptive approaches will be described in detail in the Wildlife Management Plan and be developed in consultation with the appropriate regulatory agencies. Activity in the road corridor will be highest during the construction phase of the Project due to road construction and transportation of the construction workforce to and from the airport and the site. Given that the rookery is located in a rural area, in close proximity to existing anthropogenic disturbances in Dodge Cove, operational activities are not expected to cause effects beyond which those that the rookery is already exposed to; accordingly, additional monitoring during the operational phase is currently not proposed. The rookery is located approximately 300 m from the PDA boundary, as is depicted on Figure 4.7-7, but is over 500 m from the nearest project component (i.e., access road) where the extent of clearing is expected. To address concerns from Dodge Cove related to the location of the access road relative to the Dodge Cove watershed, Aurora LNG has revised the access road right of way to move it further west (please see the technical memo "Dodge Cove Water Supply and Watershed" which will be filed with the BC EAO), which also increases the distance between the right of way and the heron rookery . An errata document has been created that captures revisions to Figure 4.7-7 for clarity of buffer extents, and it will be filed with the BC EAO. 2936.1	round 1	ECCC	Appendix J-3	Wildlife Resources (Terrestrial)	The proponent conducted point counts for breeding birds throughout the PDA and LAA at 49 stations over the course of two years (June 22-24, 2014, July 1-3, 2014 and May 26-31, 2015). It is not clear from the Application how many times point counts were conducted at each station. In addition, while the proponent has provided what appears to be a sum of individuals per habitat type (Appendix J-3: Table 3-1, pdf p. 123) information on survey effort and area covered is lacking Establishing an accurate baseline that reflects natural inter-annual variation is important for assessing potential project impacts, focusing mitigation and monitoring, and addressing potential cumulative impacts. It is also important to note that a key purpose of collecting baseline data is to determine the presence of any biodiversity or distribution hotspots. ECCC guiding principles on this subject are found in Hanson et al. 2009, A framework for the scientific assessment of potential project impacts on birds - CWS Technical Report series No. 508. Available online at: http://publications.gc.ca/site/archivee-archived.html?url=http://publications.gc.ca/collections/collection_2010/ec/CW69-5-508-eng.pdf . However, it is not evident from the Application how many times point counts were conducted at each station. In addition, the Proponent provides what appears to be a sum of individuals per habitat type (Appendix J-3: Table 3-1, pdf pg. 123) without providing any proportional information including survey effort and area covered. This lack of information does not allow for accurate effects assessment, making it challenging to evaluate results of future monitoring and mitigation efforts for migratory bird species (see Hanson et al. 2009 for details). ECCC requests: • Clarification on sampling effort for point count surveys and stations; and • That, for each wildlife habitat community type identified throughout the LAA, the Proponent use appropriate baseline data to provide density and abundance estimates of migratory birds, particularly species at risk. This will allow a more accurate assessment of potential effects and plan for future monitoring and mitigation efforts on site. Details for how to most appropriately conduct these analyses can be found in Hanson et al 2009.	Breeding bird surveys followed protocols for point-count methods outlined in Inventory Methods for Swallows and Swifts (RIC 1998), Inventory Methods for Forest and Grassland Songbirds (RIC 1999a), Inventory Methods for Woodpeckers (RIC 1999b). In Appendix J, Section 5.5.2 provides an overview of the methods used to complete breeding bird surveys. As indicated therein, surveys were completed once across 49 point-count stations; individual surveys were 10 minutes in length for a total of 490 minutes of survey effort (or 10 minutes per station). Each station had a 100 m radius. To determine abundance and distribution of breeding songbird species among wildlife habitat communities present within the LAA, effort (number of surveyed stations), the average number of individuals, and the average number of species detected during point-count surveys was analyzed by wildlife habitat community. Point-count stations were distributed across six primary wildlife habitat communities within the LAA. The average number of species and individuals (mean ± standard deviation) recorded in each wildlife community are summarized in Table 12 of Appendix J. Presenting breeding bird survey data by wildlife habitat community was intended to support the assessment of change in habitat in Section 4.7, considering the relative availability of habitats in comparison to observed presence, abundance, and richness observed during field studies. This approach further facilitates characterizing residual effects and making a determination of ecological significance. This practice is consistent with the ecosystem approach, as recommended in Hanson et al. 2009. References: Hanson, A., I. Goudie, A. Lang, C. Gjerdrum, R. Cotter, and G. Donaldson. 2009. A framework for the scientific assessment of potential project impacts on birds. Canadian Wildlife Service Technical Report Series No. 508. Atlantic Region. 61 pp. Resources Inventory Committee (RIC). 1998. Inventory Methods for Swallows and Swifts. Ministry of Environment, Lands and Parks. Victoria, BC. Resources Inventory Committee (RIC).1999a. Inventory Methods for Forest and Grassland Songbirds. Ministry of Environment, Lands and Parks. Victoria, BC. Resources Inventory Committee (RIC).1999b. Inventory Methods for Woodpeckers. Ministry of Environment, Lands and Parks. Victoria, BC.
2937.1	round 1	ECCC	Appendix J, 3.3	Wildlife Resources (Terrestrial)	While the proponent did not detect Olive-sided Flycatchers (OSFL) in the LAA, the proponent does indicate that the species was observed on or near Digby Island in previous studies and projects (Appendix J, Table 2, pdf p 22). The precise locations of OSFL have not been provided. This information is required to determine potential project-related impacts and mitigation measures for this SARA-listed species. The posted recovery strategy for OSFL does not include a description of critical habitat because of a lack of adequate information. A schedule of studies is presently in place to obtain the necessary information for the identification of critical habitat. As such, an amended recovery strategy with finalized critical habitat may become available within a timeframe that overlaps with that of project activities. Presently, there is a lack of data related to OSFL presence and abundance in large portions of its range. Without this information any model used to predict critical habitat with current data may have a limited ability to do so in these areas (ECCC 2016). Reference: ECCC. 2016. Recovery Strategy for the Olive-sided Flycatcher (Contopus cooperi) in Canada. Species at Risk Act Recovery Strategy Series. Environment Canada, Ottawa. vii + 52 pp. Information Request ECCC requests that the proponent identify the precise locations in which OSFLs were previously detected on/near Digby Island, using available resources from other studies and projects (as indicated in Table 2 of Appendix J) and supplement this information through additional surveys within the LAA (in particular within the PDA) to better determine OSFL presence and relative abundance. In this regard, the proponent is encouraged to contact ECCC during the assessment process for updated and publicly available critical habitat information and to facilitate the timely exchange of data important to understanding potential impacts and necessary mitigation.	For clarity, Table 2 of Appendix J was intended to indicate which species are known or are likely to occur on Digby Island based on a combination of habitat requirements present within the LAA and documented occurrences from regional occurrence records. Although forested habitats on Digby Island are within the breeding range of olive-sided flycatcher, and meet requirements for nesting activities, there are no documented occurrences of the species regionally (see Table 1-2 of Appendix J). To improve prediction confidence in the occurrence of, and potential Project effects to olive-sided flycatcher, additional information on species presence has been prepared as a technical memorandum, entitled "Wildlife Passive Acoustic Monitoring Program" and it will be filed with the BC EAO. Given that there were no records of detection of olive-sided flycatcher with the additional analysis provided within the memorandum, the assessment of potential Project residual effects provided in Section 4.7 of the Application remains unchanged in consideration of the additional information. Aurora LNG acknowledges that the current recovery strategy for olive-sided flycatcher includes a schedule of studies to obtain information for characterization of critical habitat. Aurora LNG will continue to monitor for potential changes in habitat designations that overlap with the Project boundaries. The field studies collected for the Project, however, contribute to the bank of existing regional data (i.e., 11 datasets spanning data collected between 1972 and 2014) that provide information to the Environment and Climate Change Canada about potential for presence and abundance of the species in this area, relative to other locations in British Columbia. Project data can be provided to the agency, upon request, to support recovery objectives.
2938.1	round 1	ECCC	Appendix J, 4.2 and 5.8	Wildlife Resources (Terrestrial)	While Myotis spp. were incidentally detected within/near the PDA, the proponent has not conducted specific surveys targeted at federally-listed bat species, including the Little Brown Myotis (Appendix J, 5.8.3.1, pdf p. 55). Survey efforts in this case is likely unable to provide sound baseline data (e.g. abundance, distribution, habitat use) or detect seasonal and inter-annual variations. As depicted by the proponent's modeling work, the amount of suitable habitat in the area suggests Little Brown Bats are likely to be present and thus subject to project-related impacts. In Appendix J, Table 5 "Rating Assumptions for Species Habitat Suitability Models" (pdf p. 31) and Appendix J-2 Species Accounts, Little Brown Myotis (pdf p. 108), the proponent states that High Suitability (1) habitats include "Open-canopy mature- or old- growth forest (structural stage 6 or 7) in proximity to foraging habitat and/or movement corridors." ECCC agrees with the importance of these habitats and their location "adjacent to feeding areas such as open water wetlands, streams and forest edges." However, ECCC notes that no surveys for suitable foraging habitat or movement corridors were conducted in the PDA or LAA. Information Request ECCC requests that the proponent • conduct baseline studies for federally-listed bat species that include: desktop surveys (see, for example, Bat Acoustic Monitoring Portal http://databasin.org/groups/59d81a3951fd4915909efacbe2317efb) in combination with field surveys; • conduct field surveys employing methodologies such as radio telemetry, visual surveys, and acoustic monitoring for use in acquiring baseline information on locations of hibernacula and maternity roosting sites taking into account provincial inventory standards, published methodologies, and provincial best management practices for guidance on surveying methodologies; • conduct surveys that account for inter-annual variations, in areas identified as quality hibernacula and roosting habitats (determined, for instance, via habitat suitability modeling) while following decontamination protocols to avoid contamination and spread of White Nose Syndrome in bats (For resources on White Nose Syndrome see http://www.cwhc-rcsf.ca/wns_resources.php); • identify and describe mitigation measures to avoid, minimize, or compensate (in that order of hierarchy, from most to least preferred) for each potential impact identified, consistent with the Little Brown Bat Recovery Strategy, and taking into consideration the Best Management Practices for Bats in BC (http://a100.gov.bc.ca/pub/eirs/viewDocumentDetail.do?fromStatic=true&repository=BDP&documentId=12460); • field verify Roosting Habitat Suitability Modeling for Little Brown Myotis (Appendix J, Figure 5, pdf p. 70) sung the collected baseline data ECCC requests that - in cases where maternity sites or hibernacula are identified - the proponent describe provisions for identifying, implementing and monitoring appropriate buffers to protect these habitats throughout all phases of the project, noting that the size of the buffer will depend on specific disturbance and site conditions. ECCC requests that the proponent provide additional details on how suitable foraging habitat or movement corridors were determined within the PDA and LAA in order to accurately inform the Little Brown Myotis habitat suitability modeling.	Aurora LNG has committed to implementing several bat-specific mitigations; measures applicable to little brown myotis (and other bat species) are listed in Table 4.7-17. Aurora LNG will adhere to a mitigation hierarchy to avoid, limit, and mitigate for potential effects to wildlife resources. Accordingly, the Project has proposed a Bat Management Plan that will specifically outline avoidance, reduction, mitigation, and monitoring measures to limit potential effects to bats from change in habitat or mortality risk from Project construction and operation activities. Aurora LNG will engage with appropriate regulatory agencies regarding the development of this plan. Collectively, these measures are expected to limit the Project's contribution to cumulative effects on little brown myotis and support the current objective to maintain current population levels in western Canada, in accordance with provincial and federal management objectives (Environment Canada 2015). Incidental information on bat occurrence was collected concurrently during marbled murrelet dawn audiovisual surveys in July 2015. Recordings of bat vocalizations indicated the potential presence of little brown myotis within the PDA and LAA. To improve understanding of bat species presence, seasonal occurrence, and patterns in habitat use (e.g., foraging and movement) within the LAA, and to support the development of the Bat Management Plan, additional studies were completed, and information on seasonal activity patterns for bats has been prepared as a technical memo entitled "Aurora LNG Project Bat Monitoring Program" and it will be filed with the BC EAO. Opportunities for winter hibernaculum in rocky outcrops or underground caverns or caves within the PDA or LAA were not identified during field studies. Wildlife habitat community models, supported by ground-truthed vegetation and wildlife habitat assessments, did not classify any portions of the PDA or LAA as a primarily rock-based community type (see Section 4.1 of Appendix J). Additional field studies for wildlife resources did not identify winter hibernacula features. It is expected that habitats within the PDA and LAA primarily support summer roosting and foraging habitat for bats. Accordingly, proposed project mitigations, including the Bat Management Plan will be tailored to address species, habitats, and seasonal patterns in use that have potential to be affected by Project activities and infrastructure. Reference: Environment Canada. 2015. Recovery Strategy for Little Brown Myotis (Myotis lucifugus), Northern Myotis (Myotis septentrionalis), and Tri-colored Bat (Perimyotis subflavus) in Canada [Proposed]. Species at Risk Act Recovery Strategy Series. Environment Canada, Ottawa. ix + 110 pp.

2939.1	round 1	ECCC	Appendix J, 5	Wildlife Resources (Terrestrial)	The proponent did not conduct baseline surveys targeting Common Nighthawks (SARA-listed Threatened). The species' nocturnal habits preclude their detection during surveys such as the breeding bird survey conducted by the proponent. The Application indicated Common Nighthawks are unlikely to occur within the LAA due to their habitat requirements and range (Appendix J, 3.3, pdf p. 20). This is not consistent with the Common Nighthawk recovery strategy that states that the species "breeds in a wide range of open habitats including… wetlands (e.g. bogs, marshes, lakeshores, and riverbanks), [and] gravelly or rocky areas." These habitat types are found within the project area, in particular bog wetlands (Application, 4.07, pdf p. 26). The recovery strategy also identified loss of insect-producing habitats as one of its threats, via wetland destruction, drainage of wetland and peat extraction. Given the amount of wetland and other potentially suitable habitat found within the project area, project-related activities may adversely impact the Common Nighthawk. An analysis of these effects is lacking. Information Request ECCC requests that the proponent conduct surveys for the Common Nighthawk in support of the environmental assessment given its SARA-listed status and the presence of suitable habitat conditions. In designing an appropriate baseline information collection program for Common Nighthawks, the Canadian Nightjar Survey Protocol (draft): http://wildresearch.ca/wp-content/uploads/2013/11/National-Nightjar-Survey-Protocol-Draft-WildResearch2.pdf is a helpful reference to be considered.	Common nighthawk is known to use a range of habitats for breeding, including beaches, logged areas, woodland clearings, grasslands, rock outcrops, and gravel rooftops (Brigham et al. 2011). Nest sites preferentially include logged areas, bare sand, fields, and gravel roofs, but can also include marshes, bogs, and river banks (Brigham et al. 2011, Environment Canada 2016). The determination that common nighthawks were unlikely to occur within the LAA was based on a comprehensive review of regional occurrence records, with secondary consideration that preferred breeding habitat is limited within the LAA (recognizing that bog habitat may still provide some nesting opportunity; Environment Canada 2016). As part of characterizing existing conditions for birds within the LAA, Aurora LNG compiled regional data across 11 datasets spanning 43 years of data (i.e., 1972 through 2014) (see Table 1-2 of Appendix J). Across all of the regional bird records, there has only beena single occurrence of common nighthawk in the Prince Rupert area, a single vocal detection near Lelu Island (PNW LNG 2014). To improve prediction confidence of potential Project effects to common nighthawk, additional information on species presence has been prepared as a technical memorandum, entitled "Wildlife Passive Acoustic Monitoring Program" and it will be filed with the BC EAO. A single record of nighthawk was recorded calling on July 27, 2014 as part of the Passive Acoustic Monitoring Program field studies completed. Nighthawks are crepuscular aerial foragers that feed over water and forest canopies. Although not well documented, birds may travel moderate distances from nesting sites to suitable foraging areas (Brigham et al. 2011). Species presence during field studies could indicate that foraging habitat is located within the LAA. Given that nighthawks are known to display some degree of fidelity to nesting sites, it is expected that regional and Project records would include more frequent detections if the species were breeding locally (Environment Canada 2016). With the additional analysis, the infrequency of detection for this species does not modify the assessment of potential Project residual effects provided in Section 4.7 of the Application. References: Brigham, R.M., Ng, J., Poulin, R.G., and Grindal S.D. 2011. Common Nighthawk (Chordeiles minor), The Birds of North America (P. G. Rodewald, Ed.). Ithaca: Cornell Lab of Ornithology. Available at: https://birdsna.org/Species-Account/bna/species/comnig. Accessed: March 2017. Environment Canada. 2016. Recovery Strategy for the Common Nighthawk (Chordeiles minor) in Canada. Species at Risk Act Recovery Strategy Series. Environment Canada, Ottawa. vii + 49 pp. Pacific NorthWest LNG (PNW LNG). 2014. Pacific Northwest LNG: Technical Data Report—Terrestrial Wildlife and Marine Birds. Prepared by Stantec Consulting Ltd., Burnaby, BC. 121 pp.
2940.1	round 1	ECCC	Appendix J, 5	Wildlife Resources (Terrestrial)	Unlike most other amphibians, Western Toads are known to spend only a short amount of time in ponds to breed. Metamorphosis is usually complete by late July or early August; the toadlets then disperse up to several kilometers en masse to terrestrial habitats – in aggregations of tens of thousands (COSEWIC 2012). These migration corridors include marshes and riparian areas surrounding breeding sites, as well as forests, meadows, shrub lands, open forest patches. Protection of these migration corridors is important to ensure safe movement of adults between breeding and terrestrial habitats. The proponent conducted pond-dwelling amphibian surveys during late May and June, and detected juveniles at low numbers (1 - 25) at various locations across the LAA (Appendix J, 5.3.3, pdf p. 41). It appears that the proponent's surveys have not adequately taken into account terrestrial habitats that are crucial during other stages of Western Toad's life cycle such as the post-metamorphosis migration period or wintering habitat. ECCC also notes that the Proponent has conducted habitat suitability modeling for only the breeding habitat of Western Toad, but did not include any habitat types used for migration and wintering in their modeling. **Information Request** ECCC requests that the proponent: • conduct surveys at appropriate time of the year to identify migration corridors used annually by Western Toads, between breeding and terrestrial habitat, as well as to identify migratory timing windows, recognizing that inter-annual variability exists in Western Toad migratory movements; • use field data collected during surveys to verify breeding season habitat suitability models; • conduct an effects assessment for terrestrial habitat for Western Toads within the LSA within a buffer of 150–290 m (depending on buffer identified during baseline) plus a 50 m buffer surrounding all breeding ponds identified during baseline studies (Semlitsch and Bodie 2003; Bartelt et al. 2004). The effects assessment should include a description of all potential direct or indirect impacts to Western Toad arising from project activities; and • conduct habitat suitability modeling that takes into account all life stages in the annual cycle, including the migratory and wintering season. ECCC requests that the proponent identify appropriate mitigation measures be put in place to protect breeding and terrestrial habitat as well as migration corridors. Mitigation measures may include, but should not be limited to: setting speed limits on the road, avoidance of the area during the migration period, installation of signs to identify migration corridors, installation of wildlife crossings, fencing and access control measures. ECCC further requests that the proponent identify and describe measures to avoid, minimize, or offset for each potential impact identified, consistent with the Western Toad Management Plan (2016). and the mitigation hierarchy with a full rationale provided for moving from avoidance to minimization to offset. Please see attached Memo 03 "Environment and Climate Change Canada Standard Guidance for Environmental Assessments: Western Toad (Anaxyrus boreas)" for further details. **References:** Bartelt P.E, Peterson C.R., Klaver R.W. 2004. Sexual Differences in the Post-Breeding Movements and Habitats Selected by Western Toads (Bufo Boreas) in Southeastern Idaho. Herpetologica 60(4):455-467. COSEWIC. 2012. COSEWIC assessment and status report on the Western Toad Anaxyrus boreas in Canada. Committee on the Status of Endangered Wildlife in Canada. Ottawa. xiv + 71 pp. Semlitsch R.D., and Bodie J.R. 2003. Biological Criteria for Buffer Zones around Wetlands and Riparian Habitats for Amphibians and Reptiles. Conservation Biology 17(5): 1219–1228.	Field studies for wildlife resources are considered sufficient to characterize presence and use of habitats within the PDA and LAA by western toad. Pond-dwelling amphibian field studies completed for the Project were completed in accordance with provincial guidelines scheduled to occur within the breeding period for western toad. Based on visual detections and habitat requirements, western toad was identified as a focal species with potential to interact with Project activities and infrastructure. Accordingly, the Application has considered potential effects to western toad and includes appropriate supporting mitigation measures to avoid, reduce, or mitigate for potential residual effects. Table 4.7-17 outlines the mitigation measures that Aurora LNG has committed to as a means to avoid, reduce, or mitigate potential Project effects. These include habitat protection, traffic speed and volume, and drift fencing installation measures. Aggregation at breeding ponds and post-breeding dispersal by adult and juvenile toads varies depending on latitude, elevation, and environmental conditions (e.g., ice break up) in any given year (COSEWIC 2012). Accordingly, the restricted activity period (mitigation 4.7.17) that Aurora LNG identified in Section 4.7 extends from March 1 to August 15 to accommodate interannual variation in the timing of both breeding and migration. Scheduling vegetation clearing outside of the restricted activity period for amphibians will reduce the risk of mortality or injury of breeding amphibians. Based on the documented occurrence and habitat availability of western toad from field studies and habitat suitability modelling provided in Appendix J of the Application, in combination with the expected efficacy of the proposed mitigations, Aurora LNG is not planning to undertake additional western toad surveys at this time. Guidelines for restricted activity periods to protect amphibians will be followed where practicable (BC MOE 2014; BC MFLNRO 2014). Clearing activities will occur outside of the breeding season for amphibians (March 1 through August 15), where possible. In accordance with mitigation measure 4.7.19, if clearing or disturbance of open water wetland sites within the PDA cannot avoid the amphibian breeding period, salvage will be completed subject to permit approval under the BC Wildlife Act. Procedures for amphibian salvage will be outlined in the Wildlife Management Plan and will be conducted following Best Management Practices for Amphibian and Reptile Salvages in British Columbia (BC MFLNRO 2016). Amphibian salvage during the breeding season is expected to be an effective means of reducing the likelihood of mortality as individuals are concentrated at breeding locations, and the ability to detect and capture individuals of all life stages (e.g., eggs, tadpoles or larvae, juveniles, or adults) is improved. Salvaged individuals will be relocated, subject to applicable permits, to proximal areas of suitable habitat beyond the PDA boundaries. Wetland habitats on Digby Island with similar habitat attributes and/or where western toads were previously detected will be preferred relocation areas. The species selected for habitat suitability modelling were determined to be good candidates for species-specific models, in part, because they each require a suite of habitat features that are best assessed at the species level (rather than at the community level). Provincial standards advise planners to select species for suitability modelling where there is a strong understanding of the relationship between habitat characteristics and species whose life requisites (e.g., breeding, feeding) compare well with terrestrial ecosystem map units (RIC 1999). While breeding habitats for western toad are well understood and can be reliably built into a species-specific habitat suitability model, less is understood about migration and overwintering habitats, and models for those habitat types may not be adequately supported using the criteria identified in RIC (1999). Despite this, western toad observations during Project field studies show a reasonable verification of the habitat suitability model (Figures 6 and 10 of Appendix J of the Application). Western toads were detected more frequently and in larger numbers in, or adjacent to high and moderate suitability polygons within the LAA. Adult and juvenile dispersing western toads were observed during Project field studies. Toads appeared to have some association with riparian corridors within the LAA, however, no large migration events were observed in these areas. Given that the LAA is primarily comprised of interspersion of mature or old coniferous forest, shrub-dominated bog, and treed swamp or bog, it is expected that western toad disperse from breeding habitats using forested, wetland, and riparian habitat features across the landscape. However, Aurora LNG is committed to reducing potential for toad mortality. Accordingly, Aurora LNG has committed to installing drift fencing to direct dispersal movements towards wildlife crossing features (e.g., culverts) and away from Project infrastructure to reduce interaction with Project activities (e.g., vehicle traffic). Drift fencing will be installed along riparian corridors that intersect with the access road. References: BC Ministry of Environment (BC MOE). 2014. 2941.1	round 1	ECCC	Appendix J, 5.3	Wildlife Resources (Terrestrial)	The proponent conducted breeding bird surveys at 49 stations across the LAA in various wildlife habitat communities. The number of survey stations is not adequate for some habitat communities. For example, only 2 stations were situated in the 152 ha of "Young or Seral Coniferous Forest", and no survey stations in the 65 ha of "Estuarine Meadow/Marsh/Mudflats" (Appendix J, Table 12, pdf p. 47). It also appears that the proponent did not conduct breeding bird surveys in a majority of the PDA, that is, the western and northern portions where large areas of wetlands and old growth forests were identified (Appendix J, Figure 8, pdf p. 73). This information is required to access potential effects and identify appropriate mitigations measures. Information Request ECCC requests that the proponent update the baseline information to account for wildlife habitat communities that were not fully represented during the breeding bird survey, including "Young or Seral Coniferous Forest" and "Estuarine Meadow/Marsh/Mudflats". Further, ECCC requests that the proponent conduct breeding bird surveys in the western and northern portions of the PDA, where breeding bird information (e.g. abundance, habitat usage) have not been properly characterized in the baseline survey. The additional baseline data should be incorporated in the effects assessment so as to refine impact predictions and identification of mitigation and monitoring measures.	Breeding bird point-count survey locations were placed to provide survey effort that was generally proportional to the relative availability of each wildlife habitat community within the LAA. Sampling effort included surveys in young or seral forests within the LAA. Where possible, point-count stations were located in contiguous habitat to appropriately sample for species expected to be associated with any single community.Due to the size and shape of most young or seral forest community polygons, the observation radius for a single point count would intersect other adjacent wildlife habitat communities limit sampling within a contiguous habitat type (see Figure 8 of Appendix J). To limit bias in interpreting species presence, abundance, and habitat associations, every attempt was made to locate individual stations within a single habitat community.Survey effort included point-count stations in both the PDA and LAA. As noted in Table 12 of Appendix J, the majority of survey effort included sampling of mature or old coniferous forest and shrub-dominated bog. Sampling effort in these communities was expected to be representative of general species presence, abundance, and use of these same communities wherever they occur throughout the LAA, including areas that were not specifically sampled during Project field studies. The Estuarine Meadow/Marsh/Mudflats community is tidally influenced and is regularly inundated with saltwater and hence, provides negligible breeding opportunities for terrestrial bird species. These habitats were specifically surveyed for bird presence, richness, and abundance, as part of shoreline stationary counts completed to support the assessment of marine birds (see Appendix Q).
2942.1	round 1	ECCC	Appendix J, 5.4	Wildlife Resources (Terrestrial)	The Western Screech-Owl is COSEWIC-assessed as Threatened and SARA-listed as Special Concern. The proponent conducted nocturnal raptor surveys between May 26 and June 1, 2015 (Appendix J, pdf p 44), and did not detect the presence of Western Screech-Owls. This may not be the appropriate or reliable survey window because response rate to call-playbacks is likely low during this time period – i.e. beginning of incubation and nesting period (Kissling and Lewis 2009; RIC 2006). Response rates are known to be substantially higher during courtship and territory establishment. This peak calling period determined from Kissling and Lewis (2009) was between April 9 and May 8 in Southeast Alaska. Given that the proposed project is situated at a lower latitude, peak calling period may be even earlier. The proponent broadcasted the calls of various nocturnal raptor species for each sample station within the same night (Appendix J, pdf p 44). However, methods outlined in the Inventory Methods for Owl Surveys (RIC 2006) – which the proponent had reportedly followed for their baseline surveys – stated that "the use of multi-species call-playback techniques is no longer an acceptable method of surveying for owls", as multi-species call-playback may inhibit response from smaller owls, including Western Screech-Owls (Olson et al. 2005). Though the habitat suitability models for Western Screech-Owl appear to be well-constructed, the nocturnal raptor call-playback survey stations were situated in areas categorized as "anthropogenic" (Appendix J, Figure 8 pdf p 73), as well as in areas where "habitat suitability class" for Western Screech-Owls was rated as "Nil" or "Low" (Appendix J, Figure 4, pdf p. 69). Western Screech-Owls are typically found in low elevation riparian forests adjacent to bogs or large streams. Survey stations were situated outside of the PDA (Appendix J, Figure No. 8 pdf p. 73), which may not allow for a thorough evaluation of potential impacts from project activities. It is important that baseline data for Western Screech-Owls be collected accurately – i.e. in the appropriate time period, without its response being potentially inhibited from other nocturnal raptor species, and in suitable habitat types – so that false negatives are minimized (i.e. not detecting an owl when it is in fact present). Having reliable baseline data would allow the proponent to determine the species' existing conditions (e.g. abundance and distribution), and assess effects, mitigation measures, and residual effects resulting from project activities. **References:** Kissling ML and SB Lewis 2009. Distribution, abundance, and ecology of forest owls in Southeast Alaska. U.S. Fish and Wildlife Service, Juneau Field Office, Alaska, and Alaska Department of Fish and Game, Division of Wildlife Conservation, Douglas, Alaska. 215pp. Olson GS, Anthony RG, Forsman ED, Ackers SH, Loschl PJ, Reid JA, Dugger KM, Glenn EM and WR Ripple 2005. Modeling of site occupancy dynamics for northern spotted owls, with emphasis on the effects of barred owls. Journal of Wildlife Management 69:918-932. Resources Inventory Committee (RIC). 2006. Inventory Methods for Owl Surveys. Ministry of environment, Lands and Parks. Victoria, BC. **Information Request** ECCC requests that the proponent conduct targeted surveys within the project area for the Western Screech-owl which includes the following design considerations: - surveys are conducted during periods when the species in the region is reliably known to be responsive (i.e. courtship and territory establishment periods); - single-species call play-back, consistent with the Inventory Methods for Owl Surveys (RIC 2006) are conducted, as opposed to broadcasting calls in conjunction with other species; - surveys are conducted where habitat would be suitable for the species and survey transects are both within the PDA and the terrestrial component of 1.5km buffer extending from the PDA (within the LAA). and - in the event that surveys cannot be conducted due to safety and feasibility issues (e.g., late at night in dense forest), use of recording devices such as Autonomous Recording Units (ARUs) may be appropriate with advice from ECCC and other Western Screech-Owl kennicottii experts. ECCC requests that the proponent verify habitat suitability models using collected field data in order to best assess potential effects of the project to Western Screech-Owl in the PDA and LAA.	As described in Appendix J, nocturnal raptor call-playback stations were located in habitats expected to support target species and included survey effort adjacent to contiguous stands of young, mature or old-growth forest (see Figure 8 of Appendix J). Site selection was expected to target habitats within the PDA and LAA likely to support breeding by western screech-owl. Station NRAP7 was the only station that was positioned within habitat classed as 'anthropogenic', because it was situated adjacent to the railway line on Kaien Island (due to access constraints). Vocalizations of nocturnal raptors in forested stands on Kaien Island east the railway line would have been within the detection limits for this location, and survey data at this location contributes to understanding potential presence of western screech-owl in the LAA. To improve prediction confidence of potential Project effects to western screech-owl, additional information on species presence has been prepared as a technical memorandum, entitled "Wildlife Passive Acoustic Monitoring Program" and it will be filed with the BC EAO. Additional data presented in this memorandum provide further spatial and temporal survey coverage for potential presence of the species. Although there was no detection of western screech-owl during field studies (including the additional data provided in the memorandum), the assessment of wildlife resources also considers how change in habitat will potentially affect the species through the habitat suitability model developed for the species (see Section 4.2.3 of Appendix J and Section 4.7.5.2 of the Application). Table 4.7-17 outlines mitigation measures that Aurora LNG has developed, in part, to avoid, reduce, or mitigate potential effects from Project activities or infrastructure on western screech-owl. The assessment of potential Project residual effects provided in Section 4.7 of the Application remains unchanged in consideration of the additional information.

2943.1	round 1	ECCC	Appendix J, 5.4	Wildlife Resources (Terrestrial)	The Northern Goshawk laingii subspecies (Northern Goshawk) is SARA-listed as Threatened with a recovery strategy in development. These species are habitat specialists limited to dense forests with mature and old-growth structures including large trees and multiple canopy layering (Lewis et al. 2006; Greenwald et al. 2005). Diurnal raptor call-playback surveys (including for Northern Goshawk) were conducted by the proponent on only the perimeter of Digby Island "due to access constraints" (Appendix J, 5.4.2.2, pdf p. 44). These survey locations were consequently located at the edge of forest patches (Appendix J, Figure 8, pdf p. 73), which is not considered as suitable habitat to reliably detect Northern Goshawks during the surveyed period (RISC 2001). It is important that baseline data for Northern Goshawks be collected accurately (e.g. in suitable habitat types) so that false negatives are minimized (i.e. not detecting a bird when it is in fact present). Having reliable baseline data would allow the proponent to determine the species' existing conditions (e.g. abundance and distribution), to assess potential effects and to identify appropriate mitigation measures and monitoring programs. ECCC brings to the attention of the Proponent that the Northern Goshawk recovery is currently in development. References: Greenwald DN, Crocker-Bedford DC, Broberg L, Suckling KF, and Tibbitts T (2005) A review of northern goshawk habitat selection in the home range and implications for forest management in the western United States. Wildlife Society Bulletin 33:120–129. Lewis SB, Titus K, Fuller MR (2006) Northern goshawk diet during the nesting season in southeast Alaska. Journal of Wildlife Management 70:1151-1160. Information Request ECCC requests that the proponent conduct targeted surveys for the Northern Goshawk within the project area following widely accepted protocols (e.g. RISC), and in habitat types known to be suitable for Northern Goshawks (i.e. dense forest canopies). In addition, the survey transects should be both within the PDA and the terrestrial component of 1.5km buffer extending from the PDA (within the LAA). ECCC requests the proponent provide details on the measures are taken to avoid or lessen any Project-related effects on the species, and to monitor them.	As described in Appendix J, diurnal raptor call-playback stations were located in habitats expected to support target species and included survey effort in contiguous stands of mature or old-growth forest. Site selection was expected to target habitats within the PDA and LAA most likely to support breeding by northern goshawk. To improve prediction confidence of potential Project effects to northern goshawk, additional information on species presence has been prepared as a technical memorandum, entitled "Wildlife Passive Acoustic Monitoring Program" and it will be filed with the BC EAO. Although there was no detection of northern goshawk during field studies (including the additional data provided in the memorandum), the assessment of wildlife resources also considers how change in habitat will potentially affect the species through the wildlife habitat community model (see Section 4.1.3 of Appendix J and Section 4.7.5.2 of the Application). Table 4.7-17 outlines mitigation measures that Aurora LNG has developed, in part, to avoid, reduce, or mitigate potential effects from Project activities or infrastructure on northern goshawk. The assessment of potential Project residual effects provided in Section 4.7 of the Application remains unchanged in consideration of the additional information. Aurora LNG acknowledges that a recovery strategy for northern goshawk is scheduled for development. Aurora LNG will consult with Environment and Climate Change Canada regarding any changes to potential Project effects as a result of information provided in the recovery strategy, if applicable.
2944.1	round 1	ECCC	Application, 4.7.3.2; Appendix J-1	Wildlife Resources (Terrestrial)	The proponent did not including Black Swift (COSEWIC-listed Endangered) as a federally-listed species potentially occurring within the local assessment area (LAA) and regional assessment area (RAA) (Application, Table 4.7-7, pdf p. 23). These species may be listed within a timeframe that overlaps with project construction and operation. The distribution of the species has the potential to occur within the project area (COSEWIC 2015). While the proponent did not detect Black Swift, the proponent does indicate in Appendix J that these species have been observed several times within/near the project area by the BC Breeding Bird Atlas, eBird, and the North American Breeding Bird Survey (Table 1-2 of Appendix 1). References: COSEWIC (2015) COSEWIC assessment and status report on the Black Swift Cypseloides niger in Canada. Committee on the Status of Endangered Wildlife in Canada. Ottawa. x + 50 pp. Information Request ECCC requests that the proponent conduct a survey for the species and an effects assessment based on survey results with reference to the attached Memo 02 "Black Swift – baseline survey protocol and effects assessment for Environmental Assessment".	Black swift is an uncommon migrant to the region and is most likely to occur within the LAA during breeding between June and August (Lowther and Collins 2002; Bird Studies Canada 2017). During the breeding season, black swifts nest on ledges or shallow caves in steep rock faces, usually behind waterfalls (Lowther and Collins 2002). An overview of wildlife habitat communities available within the LAA for wildlife resources is described in Section 4 of Appendix J of the Application. Habitats that meet the criteria to support nesting activities for black swift are not located within the LAA; accordingly, black swifts are not expected to interact with Project activities and infrastructure. The determination that black swifts occur in the LAA infrequently was based on a comprehensive review of regional occurrence records and consideration that preferred nesting habitat is not available within the LAA. As part of characterizing existing conditions for birds within the LAA, Aurora LNG compiled regional data across 11 datasets spanning 43 years of data (i.e., 1972 through 2014) (see Table 1-2 of Appendix J of the Application). Across all regional bird records, occurrences of this species are uncommon. However, potential effects of the Project on migratory birds, including black swift, are assessed in Section 4.7 of the Application. Potential effects to black swift from Project activities and infrastructure are considered to be accurately represented in Section 4.7. Aurora LNG has committed to several mitigations to reduce the potential for residual effects to migratory birds, and these are considered beneficial in reducing effects to potentially occurring black swifts, in Sections 4.11.5.2, 4.11.5.3, and 4.11.5.4. References: Lowther, P. E. and Collins, C.T. 2002. Black Swift (Cypseloides niger), The Birds of North America (P. G. Rodewald, Ed.). Ithaca: Cornell Lab of Ornithology. Data accessed from NatureCounts, a node of the Avian Knowledge Network, Bird Studies Canada. Available at: http://www.naturecounts.ca/. Accessed: March 2017.
2945.1	round 1	ECCC	Appendix Q, 4.1; Application 4.7.5.2	Wildlife Resources (Terrestrial)	The proponent detected the presence of Great Blue Herons fannini subspecies (GBH) on the west and south sides of the PDA - i.e. Dodge Cove, Charles Point, Delusion Bay, Tremayne Bay (Appendix Q, Table 2-1, ; Appendix J, Figure 10, pdf p. 75). However, the proponent did not indicate the tidal levels during the surveys, a critical factor to consider when determining GBH abundance along the coast. GBH tend to forage in the intertidal zone at low and medium tides from early spring to late summer, and are rarely present on the foreshore at high tides (RISC 1998; Huang et al. 2015). While the proponent reportedly followed the RISC protocols, it is unclear whether surveys were conducted during low or medium tides when the abundance and presence of GBH can be more reliably determined. While GBH use open intertidal habitats in the summer months for foraging, these year-round residents switch to upland areas (e.g. marshes, grassy habitats, riversides) for foraging during late fall, winter, and early spring (Butler et al. 1997; ECCC 2016). GBH detections described in the Application were primarily located along the shoreline and during the summer months; however, it is unclear whether GBH surveys were conducted in upland foraging habitat and in other months of the year. Providing more comprehensive baseline data that captures annual and inter-annual spatial and seasonal variation of GBH ecology (e.g. movement, foraging requirement) would enable a reliable evaluation of potential project impacts and facilitate identification of mitigation and design of effects monitoring programs. The proponent indicated that its assessment will "incorporate information about presence and seasonal use of the heron rookery site and adjacent marine foraging habitats near Dodge Cove in developing mitigation measures" (Application, Table 4.11-2, pdf p 5), and that it will implement "a variable width shoreline setback" on the east side of Digby Island (Application, 4.7.5.2, pdf p. 43). However, it is unclear whether the foraging requirements of GBH (or other bird species) were considered when establishing this shoreline setback distance and whether the effectiveness of such mitigation measures will be assessed during and after construction (e.g., by comparing changes in GBH abundance). References: Butler, R. W. 1997. The great blue heron. – UBC Press. Huang AC, Essak M, O'Connor MI (2015) Top–down control by great blue herons Ardea herodias regulates seagrass-associated epifauna. Oikos 124:1492-1501 Information Request ECCC requests that the proponent: - identify the tidal level during the surveys conducted for GBH - and if these were not documented at the time of surveys - conduct a baseline survey in the appropriate time periods that would allow for reliable detection of GBH abundance, taking into account tidal levels and consistent with accepted protocols (e.g. RISC); - clarify / confirm that surveys were conducted in upland foraging habitat and accounted for seasonal variation including confirmation that GBH life stage requirements were considered (e.g. critical foraging areas during various months of the year during surveys); and - provide a monitoring plan that would allow the effectiveness of the proposed shoreline setback distances to be evaluated in relation to the foraging needs of GBH (and other birds using the area) with indices directly related to the response of GBH (e.g., changes in GBH abundance along any potentially impacted shoreline habitat, changes in foraging behaviour in relation to project-related disturbance).	Please note that the great blue heron observations shown on Figure 10 of Appendix J represent incidental records. Additional heron detections were recorded during marine bird surveys and described in Appendix Q. The information below provides a combined summary of heron observations across terrestrial and marine field studies. Consistent with sampling protocols referenced in Appendix Q, stationary shoreline counts were completed across different months, times of day, and at variable tide heights to account for seasonal, diurnal, or tidal patterns of use. Stationary shoreline points situated around mudflats (e.g., Delusion Bay, Casey Cove) were surveyed to optimize detection as well as to facilitate access to survey locations. Recognizing that surveys within two-hours of high tide is the best observation period for shorebirds, but may limit detection of other bird species that are more reliant on exposed mudflat, surveys were timed to coincide with mid to high-tide cycles to improve detection across multiple taxa. Note that for habitats in Delusion Bay, a modest decrease in tide height provides substantial access to mudflat habitat. A summary of heron observations within the LAA relative to the tide level is provided in the table below. Tide stage was not recorded as part of incidental records because observations were not completed during periods of targeted detection.Date (dd/mm/yy)LocationNumber of HeronsBehaviourTide Stage04/06/14Delusion Bay2ForagingIncidental05/06/14Delusion Bay2ForagingIncidental24/06/14Dodge Cove1FlyingIncidental01/07/14Charles Point (MBDI05)1FlyingMid – Rising01/07/14Dodge Cove (MBDI01)3Loafing on shoreMid – Rising03/07/17Auriol Point20Loafing on shoreIncidental03/07/14Gribell Islet10Loafing on shoreIncidental03/07/14Dodge Cove (MBDI02)2FlyingMid – Rising17/11/14Tremayne Bay (MBDI14)1Loafing on shoreMid – Falling18/11/14Dodge Cove (MBDI02)4Loafing on shoreMid – Falling Wildlife habitat community modelling identified 15 wildlife habitat communities within the LAA, but did not include upland grass, marsh or riverine habitat. The wildlife habitat communities present within the LAA were used to assess potential Project effects to the wildlife species assemblages that occupy them, including great blue heron. Methods and findings of the wildlife habitat community models are provided in Section 4.1 of Appendix J and carried forward in Section 4.7.5.2 of the Application. Because suitable upland habitat was not identified in the LAA, survey effort focused on coastal areas of greatest use. While outside of the LAA, the incidental records of herons on the north end of Digby Island were located in or adjacent to upland grass habitat. Although these detections occurred in July, this area of Digby Island may represent important heron habitat during other parts of their annual cycle as well. With respect to great blue heron, the riparian buffer will be a minimum of 30 m wide, but extend beyond 30 m in some areas on the east side of Digby Island resulting in greater retention of forested and shoreline habitat to support roosting and foraging opportunities. Given the width of the riparian buffer on the east side of Digby Island, this area is expected to retain habitat function during Project construction and operation.
2946.1	round 1	ECCC	Appendix Q, 4.1	Marine Wildlife - Marine Birds	The proponent detected the highest number of marine birds on Spire Island (MBDI20) of all survey stations (Appendix Q, Table 2-1, pdf p. 45) . Nearby islands (e.g. Metford Island, Tuck Island), which are situated in close proximity to the marine jetty as well, may also have high abundance and diversity of marine birds along the shoreline. The Application is lacking shoreline marine bird surveys in these islands. Noise and lighting from construction and operation of the marine jetty has the potential to affect birds in the area. Information Request: ECCC requests that surveys be updated to include shoreline marine bird surveys to characterize the abundance and diversity on islands near the proposed marine jetty, such as Metford Island and Tuck Island. This analysis will allow the effects assessments to be strengthened and appropriate mitigation measures for project effects (e.g. noise, lighting) to be identified.	Shoreline stationary counts were located to maximize survey coverage in habitats within the LAA. Specific placement of individual points was intended to survey across various nearshore environments within the LAA, targeting unique marine features. Some portions of the LAA were deemed unsuitable for placement of a survey location due to accessibility, safety, and to limit unnecessary disturbance to birds using rocky shoals and islets for roosting (consistent with Environment and Climate Change Canada's Avoidance Guidelines; ECCC 2017). A shoreline stationary count was located on Spire Island (MBDI20) and included Tuck Island in its radius of detection (see Figure 2 of Appendix Q). Although Metford Island is just beyond the observation radius of MBDI20 and others, marine bird presence and abundance is represented by survey coverage for similar rocky shoals and islets within the LAA, including Spire and Tuck Island.Proposed Project mitigation measures were developed in consideration of marine bird use of these collective habitats in the southern section of the LAA. References: Environment and Climate Change Canada (ECCC). 2017. Avoidance Guidelines. Available at: http://www.ec.gc.ca/paom-itmb/default.asp?lang=En&n=AB36A082-1. Accessed: March 2017.
2947.1	round 1	ECCC	Appendix Q, 4.3	Marine Wildlife - Marine Birds	The red-necked phalarope is COSEWIC-designated as a species of Special Concern. The proponent found a single large congregation of 3041 individuals of red-necked phalaropes reported as an "incidental observation" (Appendix Q, 4.3.3, pdf p. 18). A single flock of this size is unusually large for red-necked phalaropes (Tracy et al. 2002), and therefore could indicate that the area of observation serves as an important migration staging site for refueling. However, the proponent did not indicate the location of this observation relative to the PDA, and whether the birds were feeding in, roosting at, or flying by this area. While the phalaropes may have only been there for a short period of time (i.e. stopover for migration), understanding the exact location of this flock is of importance to the effects assessment and to identification of appropriate mitigation. Reference: Tracy, Diane M., Douglas Schamel and James Dale. (2002). Red Phalarope (Phalaropus fulicarius), The Birds of North America (P. G. Rodewald, Ed.). Ithaca: Cornell Lab of Ornithology; Retrieved from the Birds of North America: https://birdsna.org/Species-Account/bna/species/redpha1 DOI: 10.2173/bna.698 Information Request ECCC requests that the proponent prepare a species-specific effects assessment for red-necked phalarope which includes the following: • clarity on where the 3041 individuals were reportedly observed (Appendix Q, 4.3.3, pdf p. 18); • clarity on how the location was used (e.g. feeding, roosting, flying by); and • a survey conducted in accordance with the RISC standard ("Shorebirds Version 1.1") to determine whether other potentially important migration staging areas exist within the LAA and RAA during other times of their migration season. ECCC requests that for each project phase, the proponent describe the project's potential effects on the red-neck phalatrhope and its habitat taking into account a current understanding of species ecology .	The record of 3,041 red-necked phalaropes is a total sum of five separate incidental observations made during vessel-based surveys in July 2014, and included a single detection of 3,000 individuals on July 9, 2014. This large congregation was observed in deep-farshore waters outside of the RAA, approximately 1 km east of Grey Islet in Orifalmme Passage. Birds were recorded as resting on the water. Field studies for marine birds were completed to provide a record of occurrence and patterns in habitat use within the LAA and RAA. The scope and timing of field studies were consistent with recommendations within applicable sampling protocols referenced in Appendix Q (Gjerdrum et al. 2012; RIC 1997a,b). Shoreline stationary counts and vessel-based surveys were completed across different months, times of day, and at variable tide heights to account for seasonal, diurnal, or tidal patterns of use during overwintering, migration, and breeding periods. Although surveys were generally completed once per season, survey effort was replicated across and within habitat types in LAA and RAA. To provide greater regional context, results of field studies were evaluated in consideration of regional datasets and information sources (see Appendix Q). Shoreline stationary counts were located to maximize survey coverage in habitats within the LAA. Specific placement of individual points was intended to survey across various nearshore environments within the LAA, targeting unique marine features. Vessel transects were stratified across four primary habitat guilds to account for potential differences in marine bird habitat use. Transects placement was random within each guild to provide an indiscriminate sample of species presence, richness, abundance, and distribution. As noted in Appendix Q, the number and placement of transects completed in each season (including distribution across habitat guilds) varied based on constraints in weather and sea conditions. A complete summary of marine bird detections by habitat guild is provided in Appendix 3 and discussed in Section 4.2.3 of Appendix Q. Collectively, field studies for marine birds are considered sufficient to characterize seasonal presence and use of habitats within the LAA and RAA. The large congregation of red-necked phalarope was located outside of the RAA, suggesting that the species has access to a range of valuable foraging and staging habitats beyond the area where residual Project effects are predicted to occur. Accordingly, potential effects to red-necked phalarope from Project activities and infrastructure are accurately represented in Section 4.11. Aurora LNG has committed to several mitigations to reduce the potential for residual effects to marine birds, including red-necked phalarope, in Sections 4.11.5.2, 4.11.5.3, and 4.11.5.4. 2948.1	round 1	ECCC	Appendix Q, 4.3	Marine Wildlife - Marine Birds	The proponent reports that two large congregations of 2520 surf scoters were observed in April 2015 and 120 in February 2015 (Appendix Q, Table 4-1, pdf p. 53), which suggest that these areas of observation may serve as important overwintering or migration stopover sites for the species. For example, during molt, winter, and spring migration periods, large numbers of surf scoters often feed in seagrass beds. Scoters flush easily, and thus repeated physical disturbance by boat traffic could affect them through exclusion from important feeding sites and/or reduction in energy stores as occurs in other waterfowl (Anderson et al. 2015). However, the proponent did not indicate the precise location of these observations relative the PDA and whether the birds were feeding in, roosting at, or flying by this area. Understanding the exact location of these congregations is important to the effects assessment and identification of mitigation measures for any project-related impacts. Reference: Anderson, Eric M., Rian D. Dickson, Erika K. Lok, Eric C. Palm, Jean-Pierre L. Savard, Daniel Bordage and Austin Reed. (2015). Surf Scoter (Melanitta perspicillata), The Birds of North America (P. G. Rodewald, Ed.). Ithaca: Cornell Lab of Ornithology; Retrieved from the Birds of North America: https://birdsna.org/Species-Account/bna/species/sursco Information Request: ECCC requests that the proponent • identify the precise locations of the two congregations of surf scoters observed in April and February 2015 in relation to the project area; • indicate how the locations were being used (e.g. feeding, roosting, flying past); and • conduct a survey in accordance with the RISC standard ("Inventory Methods for Waterfowl and Allied Species") to determine whether other potentially important overwintering or migration staging areas exist within the LAA and RAA during other times of the year. ECCC further requests that the proponent consider the additional findings on surf scoters and: • refine its assessment of the project's potential effect on the species and its habitat • develop mitigation measures to reduce the project's potential impacts on the species, and • describe the follow-up monitoring it will conduct to determine mitigation effectiveness.	The congregation of 120 surf scoters was recorded during vessel-based surveys on February 7, 2015. The group of scoters was recorded incidentally between transect surveys in deep-farshore waters outside of the RAA, approximately 2 km northeast of Stephens Passage (see Figure 5 of Appendix Q for location). This group of birds was reported as resting on the water. The congregation of 2,520 surf scoters was recorded as an incidental detection during vessel-based surveys on April 10, 2015. The group of scoters was recorded on a transect located outside of the marine bird RAA, directly north of Tugwell Island (in the shallow-farshore habitat guild) and were demonstrating foraging behaviour (see Figure 6 of Appendix Q for transect location). Observations of large groups of surf scoter are common in the Prince Rupert region and are also reflected across regional datasets reported in Appendix 1 of Appendix Q (e.g., BC Coastal Waterbird Surveys and Christmas Bird Counts). Scoters use habitats in the LAA, RAA, and broader region for foraging, staging, and overwintering. Exceptionally large congregations can coincide with herring spawn (Lok et al. 2012). The large group of scoters observed in April 2015 likely reflects movements to local spawning events for forage. Field studies for marine birds were completed to provide a record of occurrence and patterns in habitat use within the LAA and RAA. The scope and timing of field studies were consistent with recommendations within applicable sampling protocols referenced in Appendix Q (Gjerdrum et al. 2012; RIC 1997). Shoreline stationary counts and vessel-based surveys were completed across different months, times of day, and at variable tide heights to account for seasonal, diurnal, or tidal patterns of use during overwintering, migration, and breeding periods. Although surveys were generally completed once per season, survey effort was replicated across and within habitat types in LAA and RAA. To provide greater regional context, results of field studies were evaluated in consideration of regional datasets and information sources (see Appendix Q). Shoreline stationary counts were located to maximize survey coverage in habitats within the LAA. Specific placement of individual points was intended to survey across various nearshore environments within the LAA, targeting unique marine features. Vessel transects were stratified across four primary habitat guilds to account for potential differences in marine bird habitat use. Transect placement was random within each guild to provide an indiscriminate sample of species presence, richness, abundance, and distribution. As noted in Appendix Q, the number and placement of transects completed in each season (including distribution across habitat guilds) varied based on constraints in weather and sea conditions. A complete summary of marine bird detections by habitat guild is provided in Appendix 3 and discussed in Section 4.2.3 of Appendix Q. Collectively, field studies for marine birds are considered sufficient to characterize seasonal presence and use of habitats within the LAA and RAA. Both detections of surf scoter were in locations outside of the RAA, suggesting that the species has access to a range of valuable foraging, staging, and overwintering habitats beyond the area where residual Project effects are predicted to occur. Accordingly, potential effects to surf scoters from Project activities and infrastructure are accurately represented in Section 4.11. Aurora LNG has committed to several mitigations to reduce the potential for residual effects to marine birds, including surf scoter, in Sections 4.11.5.2, 4.11.5.3, and 4.11.5.4. 2949.1	round 1	ECCC	Appendix U, 4.2	Vegetation and Wetland Resources	The location of the proposed wetland compensation is unclear in the Wetland Compensation Plan (Appendix U, 4.2, pdf p. 21). In addition, the proponent has listed a number of "wetland compensation options" in conjunction with an ENGO, including wetland creation (Appendix U, 5.1 and 5.2, pdf pg. 22-23). With regards to monitoring, the plan also states that "actual details of the monitoring program will be determined in consultation with Aurora LNG, ECCC/CWS, and Aboriginal groups" (Appendix U, 5.3, pdf pg. 23), and thus it is currently unclear to what extent the Proponent will commit to monitoring as part of its wetland compensation program. Information Request Based on the above, ECCC requests that the proponent: • specify the location(s) in which the wetland compensation will be implemented, and provide a scientifically-sound rationale for how this would be appropriate in achieving no-net-loss goal of wetland function; • provide a list of the ENGOs which have committed to or may potentially commit to collaborate as part of the Wetland Compensation Plan. • demonstrate that a variety of criteria and construction methods were carefully considered in construction and design planning for any wetland creation (such as for e.g. Wetland Restoration and Construction, a Technical Guide, 2nd edition (2011) by Thomas R. Biebighauser) • elaborate and provide more comprehensive information on the proposed monitoring plan. The plan should include monitoring criteria that provide a quantitative benchmark to assess compensation success for wetland functions (including habitat functions). The proponent should also provide in its plan the time scale of the monitoring program and rationale that it is sufficient to ensure effectiveness of the compensation efforts in the long-term. ECCC requests that the proponent appropriately consider compensation sites, activities and monitoring for any wetlands within the project area (including mudflats and eelgrass beds; see above IRs) - not only for the 2 ha of red/blue-listed wetlands identified in the PDA	Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order regarding the development of the Wetland Compensation Plan.Details to be developed include potential compensation locations, ENGOs that could potentially collaborate, design criteria, and monitoring criteria (including duration of the monitoring program). Aurora LNG will engage with ECCC to determine the extent that the estuarine habitat offsetting measures for marine fish and fish habitat also compensate for the wetland habitat functions of intertidal wetlands, including eelgrass and mudflats, to achieve no net loss of functions for these ecologically important wetlands. The request to consider compensation sites, activities, and monitoring for "any wetlands within the project area (including mudflats and eelgrass beds; see above IRs) - not only for the 2 ha of red/blue-listed wetlands identified in the PDA" has been noted; however, this request exceeds the scope of guidance issued by Environment Canada (2014). See also the memo titled "Supplemental Information Regarding Estuarine Wetlands and Wetland Compensation " for additional details. This technical memo will be filed with the BC EAO. Reference: Environment Canada. 2014. Federal Policy on Wetland Conservation – Guidance for Application and Implementation in Environmental Assessment. Available at: https://a100.gov.bc.ca/appsdata/epic/documents/p403/d37786/1404937173815_193684738c554031afd3fe7a5b3bf6196c13620cba3241eac8c3f318682e8f7f.pdf. Accessed: June 2016.
2950.1	round 1	ECCC	4.8.3.2, pp. 29-30	Water Quality	Water quality baseline data (pH, temperature, dissolved oxygen, conductivity and turbidity) were collected in 2014 and 2015. Total suspended solids (TSS) were also measured for use in Acidification/Eutrophication modelling. In this Section (p. 30), the proponent refers to detailed water quality data provided in Appendix K, except for TSS data which is cited as available in Section 4.5. ECCC could not locate water quality data or detailed discussion as per the references provided by the proponent. It is not clear where water quality baseline data can be found: Detailed information on the general baseline water quality parameters could not be located in Appendix K. For TSS data Section 4.5 (4.5.2.4., p. 4) refers back to Section 4.8. Information Request ECCC requests that the proponent provide the detailed data or references and all information/water quality data that was not included but is referenced in the Application.	Detailed water chemistry, including TSS results for the lakes and streams measured in 2015 and 2016 as part of the eutrophication and acidification assessment are provided in Table 1-1 of Appendix E.Aurora LNG acknowledges that detailed water quality data was not provided in Appendix K. A "Water Quality In-situ Data (Freshwater)" technical memorandum has been compiled containing the water quality data that is missing from the Freshwater Fish and Fish Habitat section and Appendix K and it will be filed with the BC EAO. The " Water Quality In-situ Data (Freshwater)" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting. It should be noted that Freshwater Fish and Fish Habitat did not collect TSS data during the baseline assessments. As per the Resource Inventory Committee (RIC) Standards (Reconnaissance (1:20,000) Fish and Fish Habitat Inventory: Standards and Procedures), turbidity was assessed visually (turbid (T), moderately turbid (M), lightly turbid (L), clear (C)) and recorded as a snapshot view of the current water clarity conditions.
2951.1	round 1	ECCC	4.8.3.2, pp. 30	Water Quality	The proponent states that "the wide variability in the in-situ water quality parameters is likely a result of seasonal differences during the field program (Section 4.3.3.2, p. 30)". Information Request ECCC requests that the proponent explain how it assessed water quality under changing seasonal conditions if baseline data represents only one point in time. ECCC further requests that the proponent indicate whether it has or will consider the option of collecting baseline data for all relevant parameters over an extended period of time (minimum one year) to assess whether forecasted SOx/NOx air emissions from the project will affect water quality in all seasons and in "worst case" conditions.	In situ water quality data described in Section 4.8 of the Application were collected as part of the Freshwater Fish and Fish Habitat baseline assessment. These data were collected at locations in the LAA where fish surveys and fish sampling were completed. The variability in the in situ water quality data relates to the data collected in the different seasons (spring, summer, and fall (i.e., May, August-September, October 2014 and March-April 2015)), as part of the Freshwater Fish and Fish Habitat Program. Water quality data for the acidification and eutrophication assessment (Section 4.5 of the Application) were collected in separate field programs, as different locations and different parameters and sampling methods were required. There are no planned effluent discharges to lakes or streams, so for general assessment of freshwater quality, as part of fish habitat assessment, seasonal water quality data is not needed. For freshwater quality related to the potential for acidification and eutrophication, it has been common practice in other regional assessments to sample lakes during fall turnover to capture fully mixed conditions that represent times of maximum nutrient concentrations. Seasonal baseline data for identified areas of concern (e.g., lakes with predicted critical load exceedances) should be collected as part of future regional monitoring programs.
2952.1	round 1	ECCC	4.8.4, Table 4.8.9. and pp 4.8-34	Water Quality	Section 4.8.4 lists the project interaction with Freshwater Fish and Fish Habitat. Potential Acidification/Eutrophication of freshwater habitat is not listed as a project interaction because a biologically relevant change in pH is not predicted in Section 4.5.7.1. Although the proponent's modeling does not indicate a relevant change in pH, the potential for a project interaction remains. Should pH or eutrophication predictions require revision based on the comments from expert reviewers, it is important that the effect to fish and fish habitat also be re-evaluated. Information request ECCC requests that the proponent list all potential project interactions in Table 4.8.9 for assessment. For project components assessed in detail in Section 4.5., ECCC requests that the proponent make the appropriate cross-references to help ensure the assessment of potential effects on fish and fish habitat is complete.	Aurora LNG acknowledges the comment about Table 4.8-9. This table will be updated in an errata to recognize the potential project interaction between Freshwater Fish and Fish Habitat and LNG Production during operations to address the concerns about possible acidification and eutrophication. Additional information will be provided to clarify why this is not considered a project interaction for Freshwater Fish and Fish Habitat. As mentioned in the comment / information request, the predictions of the modelling does not indicate a relevant change in pH related to fish health, and this remains correct. An errata will contain the updated table, along with the clearer justification for why it is not considered to be a project interaction for Freshwater Fish and Fish Habitat. An errata document has been created is being compiled that captures these corrections and it will be filed with the BC EAO.
2953.1	round 1	ECCC	4.9.6.6	Marine Fish and Fish Habitat	The report indicates that the Prince Rupert Port Authority (PRPA) or ECCC may regulate construction schedules to mitigate potential cumulative effects on marine fish health. Specifically, the proponent has stated that "if there is temporal overlap in the construction schedules for these projects, the PRPA, which has jurisdiction in the area, or ECCC, which has jurisdiction over the disposal at sea location, may require adjustments to construction schedules to mitigate potential cumulative effects on marine fish health." (p. 4.9-117). Cumulative effects are not explicitly considered under the Disposal at Sea provisions of the Canadian Environmental Protection Act, and as such, the disposal at sea permitting process should not be identified as a mitigation measure. While ECCC would request input from other government departments, local First Nations, and public interest stakeholders on various aspects of dipsosal at sea permitting; cumulative effects are not directly addressed. Information Request ECCC requests that the proponent provide an assessment of cumulative effects related to potential temporal overlap in project construction schedules along with options for managing those effects.	The assessment of residual cumulative effects for changes in marine fish health (Section 4.9.6.6 of the Marine Fish and Fish Habitat VC) did not assume that the construction schedules of reasonably foreseeable future projects would not overlap with that of Aurora LNG. As stated on Page 4.9-188, "If construction schedules do overlap with the Project, a relatively larger area within the RAA could be affected by suspended sediment, which could affect the health of a greater number of marine fish, or, result in longer-duration effects on individual fish if they happen to migrate through multiple sediment plumes." The characterization of residual cumulative effects for changes in marine fish health considered the possibility that construction schedules could overlap, and did not assume that regulatory agencies would schedule project works to avoid overlap.
2954.1	round 1	ECCC	4.9.3.2	Vegetation and Wetland Resources	Estuarine mudflats are by definition a wetland under the Canadian Wetland Classification System (CWCS 1991; see attached Annex 1 for further details). It is unclear whether estuarine mudflats adjacent to the PDA were categorized as wetland areas. For instance, the proponent states that Delusion Bay is "primarily mudflat habitat" (Application, 4.9, pdf p 25) while Figure 1 of the Wetland Compensation Plan (pdf p 29) describes Delusion Bay as having <50% wetland coverage. Information Request ECCC requests that the proponent provide the following information that allows for a fuller understanding of the wetlands that could be impacted by the project 1. a clear accounting of estuarine mudflats as wetlands (e.g. Delusion Bay) within the project area 2. the spatial extent (in ha) to which estuarine mudflats are expected to be affected by project activities 3. mitigation measures to maintain wetland function taking into consideration the annual cycle (breeding, wintering, and migration) of species at risk and migratory birds using the wetland as habitats.	Mudflat habitat located from 2m below mean tidal water elevation up to the mean high water elevation within the greater Skeena estuary could be considered a type of shallow water wetland called, 'estuarine shore water wetlands' by the Canadian Wetland Classification System. Existing conditions and potential effects on intertidal wetlands including mudflats and eelgrass are addressed by the Marine Fish and Fish Habitat VC (Section 4.09 of the Application) and the Marine Birds VC (Section 4.11 of the Application). The latte addresses potential effects on species at risk and migratory birds due to loss of habitat including eelgrass and mudflats.The assessment includes the area captured under the definition for estuarine shore water wetlands. No direct effects on estuarine wetlands within Delusion Bay are anticipated due to the fact that no Project infrastructure is located in that bay, and that a buffer will be applied to the marine riparian area along the shoreline of Delusion Bay. Based on assumptions stated in the memo titled, "Supplemental Information Regarding Estuarine Wetlands and Wetland Compensation ", a conservative estimate of the area of intertidal estuarine wetlands within the PDA is 2.8 ha, which includes both eelgrass and estuarine shore water wetlands located within the footprint of the materials offloading facility (concrete caission option), and marine jetty. This technical memo will be filed with the BC EAO. Mitigation measures that address species at risk and migratory birds are provided in the Application, in Table 4.11-9 related to Mitigation Measures Proposed to Avoid or Reduce Change in Habitat for marine birds and Table 4.7-10 related to Mitigation Measures Proposed to Avoid or Reduce Change in Habitat for Wildlife Resources (Terrestrial). In response to comments received, a new mitigation measure has been added: Mitigation 4.6.16 commits to monitoring wildlife habitat attributes for species and risk and migratory birds in wetlands subject to the no net loss goal of the Federal Policy that are immediately adjacent to the PDA. This is documented in the technical memo 'Mitigation Measures Categorization Table" which will be filed with the BC EAO. Section 14 summarizes the environmental management plans, including the Wildlife Management Plan, which includes management plans for identified species at risk (bats and marbled murrelet). Aurora LNG will consult with ECCC to determine the degree to which the offsetting measures associated with marine fish and fish habitat address the habitat functions of estuarine wetlands such as eelgrass and estuarine shore water wetlands (i.e., mudflats) to achieve no net loss of functions for these ecologically important wetlands.
2955.1	round 1	DFO	4.8	Freshwater Fish and Fish Habitat	1. Is Aurora LNG planning to do any in-water works (i.e. infilling) during spawning season or when eggs are expected to be in the gravel? Does the Proponent plan any measures to mitigate the death of fish from infilling during spawning or when eggs are expected to be in the gravels? If so, can these measures be provided?	The majority of the suitable spawning habitat identified within the local assessment area is located in watercourse reaches J1-J5, and J1.1. These watercourses are to be retained with associated riparian areas and all construction near these watercourses will occur outside of the riparian reserve zone. Detailed timing of project components has not yet been determined; however, the following considerations will be given to construction work in relation to potential spawning activity: Areas of suitable or potential spawning within watercourses to be infilled will be identified and assessed in detail prior to construction planning. If there is potential that construction activity is required to take place outside of the window of least risk for instream works, then measures to prevent fish from accessing these areas (e.g., exclusion fencing), will be implemented prior to spawning season to prevent fish from spawning in these reaches. If necessary, fish salvage activities to remove fish, eggs, or other life stages of fish in these reaches will be conducted prior to any infilling activities.

2956.1	round 1	DFO	4.9	Marine Fish and Fish Habitat	"2. Currently, the Proponent is only planning to offset the loss of habitats that have limited availability at both Casey Cove and South Digby Island. DFO would like to note that all habitats impacted, including those relatively common in the PDA (i.e., subtidal mud) contribute to the productivity of commercial, recreational and aboriginal fisheries. "	Comment noted. Aurora LNG plans to offset any and all instances of residual serious harm to fish, as per the definition in the Fisheries Act. Specifically: the death of fish; a permanent alteration to fish habitat of a spatial scale, duration or intensity that limits or diminishes the ability of fish to use such habitats as spawning grounds, or as nursery, rearing, or food supply areas, or as a migration corridor, or any other area in order to carry out one or more of their life processes; the destruction of fish habitat of a spatial scale, duration, or intensity that fish can no longer rely upon such habitats for use as spawning grounds, or as nursery, rearing, or food supply areas, or as a migration corridor, or any other area in order to carry out one or more of their life processes. Calculations of offsetting requirements have been based on Aurora LNG's interpretation of this legislated definition of serious harm to fish. Aurora LNG asserts that not all alterations or losses of habitats "that contribute to the productivity of commercial, recreational and Aboriginal fisheries" species would meet the definition of serious harm to fish. This assertion underpins the rationale for not proposing offsetting for some habitat impacts. Aurora LNG will continue to engage with Fisheries and Oceans Canada to develop and finalize the Project's Fish Habitat Offsetting Plan, including quantification of serious harm to fish and associated offsetting requirements.
2957.1	round 1	DFO	4.9	Marine Fish and Fish Habitat	3. The Proponent states that the risk of residual effects is considered 'high' for the change in mortality to fish. Is the Proponent planning any measures to mitigate the death of fish from infilling, dredging and pile installation? If so, could these measures be provided?	Yes, Aurora LNG is proposing several mitigation measures to reduce the potential for death of fish during dredging and pile installation. These measures are described in Table 4.9-18 of the Marine Fish and Fish Habitat VC, and include:Mitigation # 4.9.4: Pile installation procedures will follow the Best Management Practices for Pile Driving and Related Operations (BC Marine and Pile Driving Contractors Association and DFO 2003). Mitigation # 4.9.8: Dredging and Disposal activities will be conducted during DFO's least risk timing window (November 30 to February 15) (DFO 2014). Mitigation # 4.9.11: During impact pile driving, enclosed bubble curtains will be installed around piles to provide noise attenuation and reduce underwater sound levels emitted to the marine environment. Mitigation # 4.9.12: A ramp-up procedure will be used for impact pile driving that will involve the steady and gradual build-up of underwater acoustic energy output from a lower energy level to full output. Mitigation # 4.9.14: An Environmental Monitor will be onsite during active in-water impact pile driving and underwater blasting to monitor for fish kills. If a fish kill is observed, the activity will be temporarily suspended and additional mitigation measures will be discussed with DFO. References: BC Marine and Pile Driving Contractors Association and DFO. 2003. Best Management Practices for PileDriving and Related Operations in British Columbia. 2958.1	round 1	DFO	4.9	Marine Fish and Fish Habitat	4. The Proponent concludes that propeller wash associated with the Project (Construction, operation, and decommissioning) is not expected to cause any changes to marine fish habitat including eelgrass habitat. How did the proponent arrive at this determination? Did the Proponents analyses include modelling?	Propeller wash was not modelled; however, modelling was conducted for sediment dispersal caused by dredging at the same locations where propeller wash would occur. Several insights from this modelling support theassertion assessment that propeller wash is not expected to affect marine habitat, especially eelgrass. The amounts of sediment being resuspended (i.e., total suspended solid [TSS] concentrations) and subsequently deposited ion by dredging would be far greater than via propeller wash. Importantly, even these comparatively high TSS and deposition levels (and distances) associated with dredging are not expected to adversely affect fish habitat, including eelgrass. Productivity and mortality of eelgrass shoots decline when at least 25% of the photosynthetic surface is rapidly buried (Mills and Fonesca 2003). Eelgrass shoot length is reported in Appendix L, Section 5.4, and is (on average): Casey Cove - 51 cm; south Digby Island - 46 cm. Therefore, 25% coverage (again, occurring instantaneously) would be, respectively, 12.75 cm and 11.5 cm. Theresults of the sediment dispersion model(Technical Memorandum Aurora LNG: MOF and Terminal Dredge Modelling, Appendix G) predict that deposition beyond dredge boundaries(where remaining eelgrass could be affected) will be less thanare expected to be lower than 1 cm in Casey Cove and, therefore, well below the smallest possible depth for a 25% coverage. At South Digby, maximum cumulative sediment deposition is predicted to be less than 1 cm within 500 m (northern berth) or 200 m (southern berth) of the LNG jetty dredge areas. Consequently, there is very low likelihood that eelgrass will experience anything close to the 25% coverage postulated to affect growth and mortality(as reported by Mills and Fonesca [2003]) as a result of sediment dispersal caused by dredging. Therefore, adverse effects to eelgrass associated with sediment deposition from dredging activities, and propeller wash, are not expected. Theresults of the sediment dispersion modelling(Appendix G) also predicts that TSS concentrations fall rapidly with distance from the source of sediment disturbance, and that once the disturbance activity ceases, concentrations drop almost immediately. Effects on eelgrass as a result of TSS-mediated reductions in light penetration (and, hence, photosynthetic rates) are also not expected to occur as a result of dredging. Given the amount of sedimentexpectedlikely to be resuspended as a result of any instance of propeller wash is likely to be orders of magnitude smaller than what is predicted during dredging, it is deemedhighly unlikely that effects on eelgrass will be incurred via propeller wash. Although propeller wash is expected to occur repeatedly, any instance of resuspended sediment caused by this mechanism is expected to bevery short-lived, and occurring over ahighlylimited area. Reference: Mills, K. E. and M. S. Fonseca. 2003. Mortality and productivity of eelgrass Zostera marina under conditions of experimental burial with two sediment types. Marine Ecology Progress Series 255: 127-134.
2959.1	round 1	DFO	4.9	Marine Fish and Fish Habitat	5. Is the Proponent planning any measures to mitigate impacts from propeller wash during construction, operations and decommissioning? If so, could these measures be provided?	To mitigate the potential effects of propeller wash on marine fish and fish habitats, Aurora LNG will investigate various potential mitigation options including the use of tugs equipped with propulsion systems that reduce sediment scour (see mitigation measure # 4.5.6 in Table 4.5-26, Marine Water Quality VC) and potentially laying concrete mats on the sea floor to reduce potential for scour. It is expected the technical and economic feasibility of these options will be investigated during detailed design and will include additional discussions with DFO.
2960.1	round 1	DFO	4.9	Marine Fish and Fish Habitat	6. Is the Proponent planning any measures while pile driving to mitigate impacts to juvenile salmonids during juvenile outmigration from the Skeena River? If so, please provide these measures in the application.	Yes, Aurora LNG is proposing several mitigation measures to reduce potential effects to juvenile salmon outmigrating from the Skeena River during pile installation. These measures are described in Table 4.9-18 of the Marine Fish and Fish Habitat VC, and include:Mitigation # 4.9.4: Pile installation procedures will follow the Best Management Practices for Pile Driving and Related Operations (BC Marine and Pile Driving Contractors Association and DFO 2003). Mitigation # 4.9.11: During impact pile driving, enclosed bubble curtains will be installed around piles to provide noise attenuation and reduce underwater sound levels emitted to the marine environment. Mitigation # 4.9.12: A ramp-up procedure will be used for impact pile driving that will involve the steady and gradual build-up of underwater acoustic energy output from a lower energy level to full output. Mitigation # 4.9.14: An Environmental Monitor will be onsite during active in-water impact pile driving and underwater blasting to monitor for fish kills. If a fish kill is observed, the activity will be temporarily suspended and additional mitigation measures will be discussed with DFO. References: BC Marine and Pile Driving Contractors Association and DFO. 2003. Best Management Practices for PileDriving and Related Operations in British Columbia. Available at: https://a100.gov.bc.ca/appsdata/epic/documents/p351/d32211/1273516310337_a8f9af96262d9ff325e4452109b72a5c6e2c4828796e47dd8ed0c732bc322dfb.pdf Accessed: July, 2016.
2961.1	round 1	DFO	4.9	Marine Fish and Fish Habitat	7. The construction of offsets may result in adverse effects on existing marine and freshwater habitats. Did the Proponent consider adverse effects to existing habitats from the development of offsets when determining Project offset requirements?	Aurora LNG acknowledges that construction of marine offsetting features may result in serious harm to fish through the permanent alteration or destruction of existing habitats. Aurora LNG will seek to avoid or minimize such serious harm to fish through the careful placement of offsets; however, where this cannot be avoided, additional offsetting will be provided. Aurora LNG will continue to consult with DFO on the proposed fish habitat offsetting program during Application review and subsequently in Project design.
2962.1	round 1	DFO	4.9	Marine Fish and Fish Habitat	8. Northern abalone, which is endangered, is potentially in the PDA. The Proponent has not provided any information on abalone in the application. DFO has standard recommended protocols for assessing project related impacts to abalone. Has or will the Proponent be assessing abalone with this protocol?	Aurora LNG deemed the likelihood of Northern abalone occurring within the PDA as "low" (see Table 4.9-7). This determination was based on the following: Lack of suitable habitat. Habitat requirements for Northern abalone are described in the Action Plan for Northern Abalone (Haliotis kamtschatkana) in Canada (DFO 2012). While certain habitat requirements for abalone are met at the south end of Digby Island (e.g., presence of rocky habitats between 0 and 10 m chart datum, presence of macroalgae), seawater salinity in the area is below that required for abalone due to freshwater runoff from the Skeena River. As stated in Section 2.2.4 of the Action Plan for Northern Abalone, "Abalone require a water column with salinity > 30 ppt, and are therefore not found near areas of freshwater run-off or in estuarine habitats". Salinity measurements for south Digby Island are available from two permanent water quality stations monitored four times per year by the Prince Rupert Port Authority.Raw data obtained by Aurora LNG for sampling conducted in May 2015 at these two stations indicate salinity values ranging from 21.51 ppt (at 1 m depth) to 27.90 ppt (at 10 m depth). These data indicate that, at least seasonally, salinity at south Digby Island is below that required by abalone.No field observations. Aurora LNG conducted extensive field surveys to characterize marine habitats and associated biota within the PDA. This included intertidal transect surveys, subtidal remotely operated vehicle surveys, marine fish surveys, and an eelgrass survey, covering Casey Cove, east Digby Island, south Digby Island, and Delusion Bay (for details, see Appendix L: Marine Fish and Fish Habitat Technical Data Report). No abalone were observed during any of these field surveys. Based on the above information, Aurora LNG believes that there is a low likelihood of abalone occurring within the PDA. Nevertheless, Aurora LNG does recognize that there is potential for abalone to occur in the PDA. Currently there are no plans to conduct a dedicated abalone survey. However, additional follow-up programs may be identified during ongoing regulatory consultation and engagement. If a Northern abalone survey is deemed necessary, the standard recommended protocols will be followed (DFO 2016). References: Fisheries and Oceans Canada (DFO). 2012. 2963.1	round 1	DFO	4.11	Marine Wildlife - Marine Mammals	9. The application states that underwater noise levels associated with rock socket drilling are proposed to be above thresholds that cause behavioural response changes in marine mammals at a distance of up to 7km. Why are no mitigation measures proposed for this activity?	As discussed during the meeting with DFO April 25, 2017 rock socket drilling will produce lower underwater noise emissions than impact pile driving and is similar in nature to vibratory pile installation. Underwater noise levels as a result of rock socket drilling exceed the behavioural response thresholds modeled to a maximum of 3.9 km (using the R95% extent; Appendix P, Aurora LNG Acoustic Study: Modelling of Underwater Sounds from Pile Driving, Rock Socket Drilling, and LNG Carrier Berthing and Transiting, pg. 27). The modeled levels of underwater noise from rock socket drilling, when compared to the injury thresholds as proposed by Southall et al. 2007, did not reach the peak pressure level injury thresholds for any functional hearing group and only reached the SELcum threshold for pinnipeds (in water) at distances of < 0.01 km from the sound source (using the R95% extent; Appendix P, Aurora LNG Acoustic Study: Modelling of Underwater Sounds from Pile Driving, Rock Socket Drilling, and LNG Carrier Berthing and Transiting, pg. 26 & 27). The levels of underwater noise from rock socket drilling, as modeled, also did not reach the National Marine Fisheries Service (2016) SPLrms pinniped (in water) or cetacean injury thresholds. Typically, the application of mitigation measures and subsequent monitoring of a marine mammal exclusion zone during construction is required due to the potential for an activity to result in the injury of marine mammals. Due to the similarity between rock socket drilling and vibratory pile installation, for which specific mitigation and monitoring are typically not required, and underwater noise modeling that reports an exceedance of marine mammal injury thresholds at a distance of <0.01 km, additional mitigation measures specific to rock socket drilling have not been recommended.
2964.1	round 1	DFO	4.11	Marine Wildlife - Marine Mammals	10. The Proponent has determined pile driving will result in significant residual effects to harbour porpoise. Can the Proponent provide mitigation measures to further reduce the impacts from pile driving to marine mammals in the area? If so, can these measures be provided in the application?	As discussed during the meeting with DFO April 25, 2017further mitigation measures will be explored (e.g., double bubble curtain, hydrosound dampener)to reduce the extent of underwater noise that exceeds the NOAA interim behavioural threshold for impulsive noise (160 dB re 1 µPa SPLrms) as a result of impact pile driving. As noted in the assessment, impact pile driving will occur only during daylight hours, and an underwater noise field verification program will be conducted to verify predicted sound pressure levels and the size of the exclusion zone. As part of the Marine and Freshwater Resources Management Plan a monitoring program will be developed and implemented to effectively monitor and enforce the agreed upon exclusion zone during in-water impact pile driving.
2965.1	round 1	ECCC	GHG Upstream Report	Greenhouse Gases	"Issue Background and Justification: The questions raised in this IR and any other comments provided to the Proponent will likely lead the Proponent to change assumptions, data, methods and conclusions, or the way they are presented in the report. Comment 1: ECCC requests that the proponent provide a revised version of the upstream GHG assessement report that is complete and incorporates all ECCC information requests."	Please see revised report: "Review of Upstream Greenhouse Gas Emissions Estimates". This report will be filed with the BC EAO.
2966.1	round 1	ECCC	GHG Upstream Report	Greenhouse Gases	Issue Background and Justification: If Aurora just sources from the western Canada gas grid, it likely contains some Alberta gas. ECCC'S original upstream assessments assumed a certain amount of Alberta gas. This assumption was revised for the PNW assessement because the proponent owns the upstream assets and was able to confirm that its facility would only source gas from its own Montney assets. Montney Basin has very low formation CO2 amounts, which results in a lower CO2 emission intensity factor. Aurora did not indicate sourcing of the gas, or at least provide a rationale or justification for using BC-only gas. Therefore, unless demonstrated otherwise, it is preferable to use ECCC's original assumption that a certain amount of Alberta gas is included in the source. This would result in a higher upstream emissions factor is higher because the upstream emissions factor is higher with Alberta shale gas, than it is with BC shale gas. Unless a change is made, the emissions may be under-estimated. Comment: ECCC requests that the proponent explain the basis for the assumption that 100% BC gas will be used? Previous LNG upstream assessments assumed partial gas supply from Alberta in Montney basin, unless it was demonstrated that the supply was only from BC. If there are unique gas-sourcing aspects to the project, these should be stipulated. Including Alberta gas will likely result in a higher emission factor and higher emissions.	Aurora LNG is confident that the assumption in its "Review of Upstream Greenhouse Gas Emissions Estimates" that 100% of the natural gas will be sourced from basins in northeastern BC is supported by the current circumstances surrounding the Project. As indicated in its Application to the National Energy Board (NEB) for a 25-year export licence (November 29, 2013), the Aurora LNG joint venture currently has shale gas resources within three British Columbia supply basins: the Liard, Horn River and Cordova basins. Aurora LNG is of the view that this diversified portfolio of shale gas assets will allow it to address a key project risk of production deliverability inherent in any LNG project through a prudent approach to developing secured assets to fulfill long-term supply commitments. Furthermore, Aurora LNG notes that this assumption is generally consistent with the assumptions relied on by the NEB in its Canada's Energy Future 2016 reporting. As part of the analysis regarding the "Liquefied Natural gas Export Case" in Chapter 11 of the primary report issued in January of 2016, it is assumed that the majority of the production (93% in the Reference Case) is produced in the Montney basin (BC and Alberta), with the remainder of the production from the Horn River Basin, Liard Basin, and Cordova Embayment (see pg. 104-105).

2967.1	round 1	ECCC	GHG Upstream Report	Greenhouse Gases	Issue Background and Justification: The fourth paragraph of the executive summary notes that emissions are not necessarily incremental. It is important to state the baseline that is being used for comparison to make such a claim. For example, compared to a scenario in which no LNG projects are built, building this project would result in increased natural gas production largely equal to the throughput (and on-site energy use) of the project. ECCC's position would be that this would all be incremental production, compared to that baseline, because if projects represent a new source of demand for upstream production or, in the case of a pipeline, represents the sole means by which to transport upstream production, the Project would be expected to cause incremental upstream production and associated GHG emissions. In this case, the Project would represent a new source of demand. The next section could then discuss the incremental emissions in relation to the production projections, noting that some LNG production is already reflected in the NEB projections. The report should not conclude that, if the Project is not built, another will be built. While NEB projections show that some LNG capacity (or a lot under the high LNG case) could be built, this is only a projection and the future may be different. Again, this matter relates to the baseline chosen for comparison in assessing the conditions for incrementality. Comment: ECCC requests that the proponent clarify what baseline scenario they are using as a comparison to assess conditions for incrementality? It is not clearly supported that, if this project were not built, other LNG projects would be, particularly if one were assessing incrementality relative to a baseline in which no LNG projects were built. Please reconsider its inclusion in the report and adjust the discussion on incrementality to reflect the fact that upstream production from the project is likely incremental to a scenario in which no LNG project is built.	The Review of Upstream Greenhouse Gas Emissions Estimates report has been revised to explicitly define "incrementality" (see pg. 22) and address the potential upstream GHG emissions associated with predicted LNG production in the three NEB scenarios discussed (see Section 3.4.5). The analysis in Section 3.4.5 (Discussion on Incrementality of Project GHG Emissions) describes the proportion of upstream GHG emissions associated with Aurora LNG production that are not accounted in each of the three NEB scenarios. This section of the revised report is also drafted to reflect Aurora LNG's view the most suitable NEB scenario to assess incrementality based on is the Reference Case (Scenario 2), which is based on a moderate view of future energy prices and economic growth, as opposed to the other two cases (No LNG and High LNG) which are sensitivities developed to capture the uncertainty related to eventual volumes of LNG exports. Regarding incrementality, as part of the analysis in Section 3.4.5, the revised report makes reference to a key uncertainty that the NEB Energy Futures 2016 report identifies in relation to proposed changes to domestic energy and climate policy. Such unaccounted for policy considerations (e.g. coal phase-out initiatives, carbon pricing, GHG cap and trade systems), many of which would favour natural gas use over more GHG intensive fuel sources, could have a profound outcome on the upstream resources relevant to the Project. As indicated in the revised report, these considerations could result in increases in domestic gas prices, which would result in all or a portion of the upstream resource being developed, regardless of the advancement of Canadian LNG projects, a consideration which would suggest that such GHG emissions would not be directly attributable to the Project being constructed (i.e. incremental).The Executive Summary has been revised to capture this additional information and analysis.
2968.1	round 1	ECCC	GHG Upstream Report	Greenhouse Gases	Issue Background and Justification: Table 1 (pg 5) only goes to 2035 and this is comparable to when the proponent expects the project to reach full capacity. Is it possible to extend Pembina B.C. Shale Scenario Tool breakdown beyond 2035? Comment: ECCC requests that the data, if available, be used by the proponent or provided to ECCC?	The Pembina Tool can be used to forecast emissions beyond 2035. However, the accuracy of the forecasts becomes less reliable if extended too far into the future. The Aurora Upstream Assessment has included a 10 year forecast using ECCC data as well as Pembina data. This same approach was taken by ECCC in the reports prepared for other LNG projects proposed in BC. However, to acknowledge this request, the Aurora Upstream Assessment has been updated to forecast emissions to 2040. Please see the updated version of "Review of Upstream Greenhouse Gas Emissions Estimates".
2969.1	round 1	ECCC	GHG Upstream Report	Greenhouse Gases	Issue Background and Justification: The information presented in table 2 of Section 2.3 and surrounding paragaphs suggests that the Pembina B.C. Shale Scenario Tool accounts for the same activities as the ECCC Emissions Forecast, but does not clearly state it. It would be important to clearly state this. Further, the fact that the emission factor is lower in the Pembina B.C. Shale Scenario Tool may lead some readers to misinterpret the table or question if all activities are included in the Pembina B.C. Shale Scenario Tool. Comment: ECCC requests that the proponent clearly states that production, processing and tranmission activities are inlcuded in the emission factor and emission estimates, though not broken out in the Pembina B.C. Shale Scenario Tool.	This request for additional clarity on what activities are included in the Pembina BC Shale Scenario Tool has been added to the updated upstream GHG assessment. Please refer to updated report "Review of Upstream Greenhouse Gas Emissions Estimates". This report will be filed with the BC EAO.
2970.1	round 1	ECCC	GHG Upstream Report	Greenhouse Gases	Issue Background and Justification: The proponent provided a good discussion of how varying levels of LNG production in the NEB's forecasts would influence overall natural gas development. The report puts the associated upstream production from the project in context with projected production and notes, in Scenario 2, where the expected upstream production associated with the project exceeds the expected production growth in the reference case. While this section discusses scenarios and the potential incrementality of upstream production associated with the project, the authors do not specify the baseline used to determine whether production is incremental leading the reader to wonder "if the upstream production is incremental, what is it incremental to?" The section seems to assess conditions for incrementality relative to the NEB's production projections. However, that comparison is only one approach. Compared to a scenario in which no LNG projects are built (Scenario 1), building the Project would lead to incremental production largely equal to the Project's throughput because the project represents a new source of demand. This is never explicitly stated in the report. Scenario 1 appears to be an appropriate baseline scenario. The authors could relate Scenarios 2 and 3 to Scenario 1 in discussing the upstream impacts of the project. For example, the authors could compare the upstream production from a scenario in which only the project is built to one in which no project is built (Scenario 1). The report should not conclude that, if the Project is not built, another will be built. While NEB projections show that some LNG capacity (or a lot under the high LNG case) could be built, this is only a projection and the future may be different. Comment: ECCC requests that the proponent clarify what baseline scenario they are using as a comparison to assess conditions for incrementality? It is not clearly supported that, if this project were not built, other LNG projects would be, particularly if one were assessing incrementality relative to a baseline in which no LNG projects were built. Please reconsider its inclusion in the report and adjust the discussion on incrementality to reflect the fact that upstream production from the project is likely incremental to a scenario in which no LNG project is built.	The Review of Upstream Greenhouse Gas Emissions Estimates report has been revised to explicitly define "incrementality" (see pg. 22) and address the potential upstream GHG emissions associated with predicted LNG production in the three NEB scenarios discussed (see Section 3.4.5). The analysis in Section 3.4.5 (Discussion on Incrementality of Project GHG Emissions) describes the proportion of upstream GHG emissions associated with Aurora LNG production that are not accounted in each of the three NEB scenarios. This section of the revised report is also drafted to reflect Aurora LNG's view the most suitable NEB scenario to assess incrementality based on is the Reference Case (Scenario 2), which is based on a moderate view of future energy prices and economic growth, as opposed to the other two cases (No LNG and High LNG) which are sensitivities developed to capture the uncertainty related to eventual volumes of LNG exports. Regarding incrementality, as part of the analysis in Section 3.4.5, the revised report makes reference to a key uncertainty that the NEB Energy Futures 2016 report identifies in relation to proposed changes to domestic energy and climate policy. Such unaccounted for policy considerations (e.g. coal phase-out initiatives, carbon pricing, GHG cap and trade systems), many of which would favour natural gas use over more GHG intensive fuel sources, could have a profound outcome on the upstream resources relevant to the Project. As indicated in the revised report, these considerations could result in increases in domestic gas prices, which would result in all or a portion of the upstream resource being developed, regardless of the advancement of Canadian LNG projects, a consideration which would suggest that such GHG emissions would not be directly attributable to the Project being constructed (i.e. incremental). Also see the revisions to Sections 3.4.1, 3.4.2 and 3.4.3.
2971.1	round 1	ECCC	GHG Upstream Report	Greenhouse Gases	Issue Background and Justification: The section concludes that the increase in Canadian natural gas production from 2015 to 2040 in the NEB's reference case represents 91% of Aurora's capacity. The previous paragraph relates the Aurora LNG capacity to total expected LNG capacity, noting that forecast LNG production growth between 2015 and 2040 would represent 73% of Aurora's capacity. This is likely a more representative figure since the 91% comparison implies that Aurora also uses the natural gas volumes expected to meet Canada's demand growth. Comment: ECCC requests that the proponent provide more detail on the consequences to their analysis of using the 91% figure? For example, the 73% figure does not rely on other assumptions related to sources of supply for Canadian domestic demand growth. The proponent should specifically identify the quantity of upstream production expected as a result of the project in m3/d terms, not just provide a comparison to NEB projections based on a percentage.	Potential incremental annual upstream GHG estimates, expressed in mega-tonnes of CO2e, have been provided for each of the three scenarios addressed in sections 3.4.3 - 3.4.5 of the revised Review of Upstream Greenhouse Gas Emissions Estimates report
2972.1	round 1	ECCC	GHG Upstream Report	Greenhouse Gases	Issue Background and Justification: Section notes that scenario assumes that LNG capacity would be built and operated by another LNG developer. Important to consider that NEB Forecasts only include LNG export volumes and do not specify which projects supply these volumes. In fact, based on the finding of this section, if the proponent's project were not built, around 10% less natural gas production would be required in Canada based on the forecast under the reference case. Furthermore, the point that "another project would be built and operated" is not an effective means to characterize this scenario. As noted above, a more useful approach would be to compare a scenario in which ONLY the Aurora project were built to one in which no LNG facilities were built (Scenario 1). This would give a clearer view as to the amount of incremental upstream production associated with the project and the associated emissions. Comment: It is not clearly supported that, if this project were not built, other LNG projects would be, particularly if one were assessing incrementality relative to a baseline in which no LNG projects were built. Please reconsider its inclusion in the report and adjust the discussion on incrementality to reflect the fact that upstream production from the project is likely incremental to a scenario in which no LNG project is built.	The Review of Upstream Greenhouse Gas Emissions Estimates report has been revised to explicitly define "incrementality" (see pg. 22). "Incremental" is defined as any additional upstream GHG emissions that would be directly attributable to the Project being constructed (i.e. not the emissions that could occur even if the Project were not built). See revisions to Sections 3.4.1, 3.4.2 and 3.4.3 and the new Section 3.4.5. Section 3.4.5 (Discussion on Incrementality of Project GHG Emissions) address the potential upstream GHG emissions associated with predicted LNG production in the three NEB scenarios discussed. This analysis describes the proportion of upstream GHG emissions associated with Aurora LNG production that are not accounted in each of the three NEB scenarios. This section of the revised report is also drafted to reflect Aurora LNG's view the most suitable NEB scenario to assess incrementality based on is the Reference Case (Scenario 2), which is based on a moderate view of future energy prices and economic growth, as opposed to the other two cases (No LNG and High LNG) which are sensitivities developed to capture the uncertainty related to eventual volumes of LNG exports. Regarding incrementality, as part of the analysis in Section 3.4.5, the revised report makes reference to a key uncertainty that the NEB Energy Futures 2016 report identifies in relation to proposed changes to domestic energy and climate policy. Such unaccounted for policy considerations (e.g. coal phase-out initiatives, carbon pricing, GHG cap and trade systems), many of which would favour natural gas use over more GHG intensive fuel sources, could have a profound outcome on the upstream resources relevant to the Project. As indicated in the revised report, these considerations could result in increases in domestic gas prices, which would result in all or a portion of the upstream resource being developed, regardless of the advancement of Canadian LNG projects, a consideration which would suggest that such GHG emissions would not be directly attributable to the Project being constructed (i.e. incremental).
2973.1	round 1	ECCC	GHG Upstream Report	Greenhouse Gases	Issue Background and Justification: Document cites the conversion from LNG to m3/d in a number of sections, but it is not framed consistently which gives the reader the impression that the conversion could be done differently in different sections. Final paragraph misinterprets the use of the term incremental natural gas production and should likely read "In summary, natural gas production growth in Canada…" As above, the same change could be considered for the final sentence in the paragraph, which should likely read "The magnitude of Canadian natural gas production and LNG growth depends on…" Finally, the paragraph ends with the phrase "and will occur regardless of whether or not the project is constructed". As noted above, the report should not conclude that, if the Project is not built, another will be built. While NEB projections show that some LNG capacity (or a lot under the high LNG case) could be built, this is only a projection and the future may be different. Comment: ECCC requests that the proponent confirm the volume conversions in the document to ensure they are consistently undertaken given uncertainty created in the text? Proponent should consider suggested wording change "in summary, natural gas production growth in Canada...." ECCC requests that the proponent adjust wording of the document to clearly use the term incremental in cases where they are referring to upstream production growth that is enabled by the Project. Proponent should consider wording change for the final sentence in the paragraph, which should likely read "The magnitude of Canadian natural gas production and LNG growth depends on…" It is not clearly supported that, if this project were not built, other LNG projects would be, particularly if one were assessing incrementality relative to a baseline in which no LNG projects were built. Please reconsider its inclusion in the report and adjust the discussion on incrementality to reflect the fact that upstream production from the project is likely incremental to a scenario in which no LNG project is built.	Volume conversions used in sections 3.3.1, 3.3.3, and 3.3.4 of the report were based on the NEB conversion factor of 1 billion cubic metres of natural gas per day (Bcf/d) = 7.495 million tonnes of LNG per year (i.e. 1.0 billion cubic metres of natural gas = 0.73 tonnes of LNG). In the scenario analyses in sections 3.4.1 to 3.4.3, the GHG conversion factor within Pembina's B.C. Shale Scenario Tool was used, which has as a slightly different conversion factor of 1.0 billion cubic metres of natural gas per 0.74 million tonnes of LNG). For consistency, the report will be revised so that the Pembina conversion factor is used throughout. The Review of Upstream Greenhouse Gas Emissions Estimates report has been revised to explicitly define "incrementality" (see pg. 22). "Incremental" is defined as any additional upstream GHG emissions that would be directly attributable to the Project being constructed (i.e. not the emissions that could occur even if the Project were not built). See revisions to Sections 3.4.1, 3.4.2 and 3.4.3 and the new Section 3.4.5 (Discussion on Incrementality of Project GHG Emissions).
2974.1	round 1	ECCC	GHG Upstream Report	Greenhouse Gases	Issue Background and Justification: The section seems to compare the direct GHG emissions of the project to overall Canadian emissions. Recommend considering using the information laid out in the scenario analysis to relate potential upstream emissions to forecast emissions. For example, Scenario 2 finds that LNG production would have to be 37% higher than under the NEB reference to accommodate the Aurora project. Thus, building the project would be expected to increase total GHG emissions beyond the reference case by the emissions associated with that amount of production, provided domestic demand remains constant. Previous analyses undertaken by ECCC, in particular the Tower Birch pipeline, have used the global section to discuss the degree to which incremental production from the project (Aurora built versus a scenario where no LNG project is built) would either i) displace other sources of global natural gas/LNG supply or ii) add to total supply and potentially affect price. The upstream emissions impact based on displacement would be the difference in upstream emissions between the production supplying Aurora and production supplying another LNG plant in the world. The addition to global LNG supply would be expected to affect LNG prices and could affect overall demand. This would then better lead into the discussion on life-cycle impacts and the potential to displace coal-fired electricity generation (the downstream impacts) since the portion of incremental production that adds to total supply would add the full life-cycle of emissions. While the discussion of life-cycle emissions (natural gas versus coal) is out of scope of the upstream assessment, the proponent may feel it provides important context. Comment: ECCC request that the authors include a discussion of upstream emissions in the Canadian and Global context section as outlined in the methodology shared for reference.	The Review of Upstream Greenhouse Gas Emissions Estimates report has been revised to explicitly define "incrementality" (see pg. 22) and address the potential upstream GHG emissions associated with predicted LNG production in the three NEB scenarios discussed (see Section 3.4.5). The new Section 3.4.5 (Discussion on Incrementality of Project GHG Emissions) includes additional wording that discusses how changes in Canadian natural gas demand not captured by the NEB's estimate in its 2016 Energy Futures report (such as future climate policies and programs) could also affect the incrementality of upstream GHG emissions associated with the Aurora LNG project. Additional wording on upstream GHG emissions associated with the Project has been provided in Section 3.6 (Conclusions) of the revised report. Aurora LNG maintains that because LNG is a global commodity in which supply is generally balanced with demand, over the long term, building the project will result in equivalent LNG capacity being displaced (i.e. not built) elsewhere. Therefore, the net effect of the project on global GHG emissions will depend on the relative GHG intensity of the Project and its upstream gas supply relative to the GHG intensity of the displaced capacity.

2975.1	round 1	ECCC	GHG Upstream Report	Greenhouse Gases	Issue Background and Justification: The document confuses “incremental” production with production growth in the projections from the NEB. Sentence could read: “Natural gas production growth in Canada…” Document ends with note that “emissions may occur regardless of whether the Project is built because they ultimately depend on the extent of growth in demand or Canadian natural gas”. As noted above, the project represents a new source of demand for natural gas and, therefore, the upstream emissions associated with it are largely incremental to a scenario without the project that assumes no other project is built (Scenario 1). However, current NEB projections from its reference case factor in LNG growth equivalent to 73% of the Aurora project at full build. So, around 73% of upstream emissions from the project are accounted for in the reference case, and the upstream emissions associated with the production for the entire project are covered if one examines the NEB’s high LNG case. The upstream production from the Project is incremental, but a large amount of LNG supply is already factored into Canada’s natural gas production and emissions projections. However, even in comparing the upstream production impact to the NEB reference case, building the Project would lead to an increase in upstream natural gas production beyond what is currently projected. This section comes to the conclusion: “However, these incremental emissions may occur regardless of whether the project is built because they ultimately depend on the extent of growth in demand for Canadian natural gas products”. The emissions from the project are incremental, and they would not occur if the project is not built when comparing to a baseline in which no LNG facilities are built. The issue of growth in Canadian domestic demand, as projected by the NEB, and demand induced by the project are separate. Specifically, upstream GHG emissions would increase as a result of the construction of the project, because it would represent a new source of demand, and induce incremental natural gas production relative to a scenario in which no other LNG project is built. Comment: ECCC requests that the proponent clarify what baseline scenario they are using as a comparison to assess conditions for incrementality? Proponent should consider suggested wording change “Natural gas production growth in Canada…” It is not clearly supported that, if this project were not built, other LNG projects would be, particularly if one were assessing incrementality relative to a baseline in which no LNG projects were built. Please reconsider its inclusion in the report and adjust the discussion on incrementality to reflect the fact that upstream production from the project is likely incremental to a scenario in which no LNG project is built.	The Review of Upstream Greenhouse Gas Emissions Estimates report has been revised to explicitly define "incrementality" (see pg. 22) and address the potential upstream GHG emissions associated with predicted LNG production in the three NEB scenarios discussed (see Section 3.4.5). The analysis in Section 3.4.5 (Discussion on Incrementality of Project GHG Emissions) describes the proportion of upstream GHG emissions associated with Aurora LNG production that are not accounted in each of the three NEB scenarios. This section of the revised report is also drafted to reflect Aurora LNG’s view the most suitable NEB scenario to assess incrementality based on is the Reference Case (Scenario 2), which is based on a moderate view of future energy prices and economic growth, as opposed to the other two cases (No LNG and High LNG) which are sensitivities developed to capture the uncertainty related to eventual volumes of LNG exports. Regarding incrementality, as part of the analysis in Section 3.4.5, the revised report makes reference to a key uncertainty that the NEB Energy Futures 2016 report identifies in relation to proposed changes to domestic energy and climate policy. Such unaccounted for policy considerations (e.g. coal phase-out initiatives, carbon pricing, GHG cap and trade systems), many of which would favour natural gas use over more GHG intensive fuel sources, could have a profound outcome on the upstream resources relevant to the Project. As indicated in the revised report, these considerations could result in increases in domestic gas prices, which would result in all or a portion of the upstream resource being developed, regardless of the advancement of Canadian LNG projects, a consideration which would suggest that such GHG emissions would not be directly attributable to the Project being constructed (i.e. incremental). Section 3.6 (Conclusions) has been revised to capture this additional information and analysis.
2976.1	round 1	CEAA	GHG Upstream Report	Greenhouse Gases	• The report did not estimate emissions using the LNG Greenhouse Gas Life Cycle Analysis Report issued by the Government of British Columbia as suggested in the ECCC methodology.	The LNG Greenhouse Gas Life Cycle Analysis Reports was not cited in the Aurora LNG Upstream Assessment because in the Review of Related Upstream Greenhouse Gas Emissions Estimates for the Pacific NorthWest LNG Project (ECCC 2016), it states "this study is less appropriate to use as a reference for an analysis of upstream-only emissions." As this statement came directly from ECCC (the authors of the report), it was not considered to be an appropriate reference for a like-project such as Aurora LNG.
2977.1	round 1	CEAA	GHG Upstream Report	Greenhouse Gases	• The report did not provide a numeric estimate of the potential impact of GHG emissions associated with the project on global emissions.	The purpose of the Upstream Assessment, as per the guidance published in Part 1 of the Gazette on March 19, 2016, is to evaluate the potential upstream emissions. Upstream emissions were defined to be "all activities from the point of resource extraction to the project under review" (Government of Canada. 2016). Therefore, completing a numeric estimate of the project emission on global GHG levels is not part of the scope of this assessment.
2978.1	round 1	CEAA	GHG Upstream Report	Greenhouse Gases	• Since Nexen has not yet determined the natural gas feed source, or the specific information regarding the pipeline, a number of assumptions were made regarding upstream components associated with the project.	Comment noted.
2979.1	round 1	CEAA	GHG Upstream Report	Greenhouse Gases	• While the report concludes that natural gas production equivalent to the project would likely occur globally even if the project is not built, it does not conclude as to whether this production level would likely occur in Canada.	Correct, as discussed in Section 3.3.5 there are numerous other proposed LNG projects worldwide, and it is not possible to predict where the next LNG project approved for construction will be located.
2980.1	round 1	CEAA	GHG Upstream Report	Greenhouse Gases	• The report does not quantify the % contribution of upstream GHG emissions to provincial and national outputs, and while the Gazette guidance does not require such a comparison, it is useful information to have since it provides valuable contextual information to help the public understand the relative magnitude of the project’s environmental impacts.	The percent contribution of upstream emissions to provincial and national inventory totals is not required by the ECCC methodology, as published in Part 1 of the Gazette on March 19, 2016. Aurora LNG cannot comment on the forecast of provincial and national inventory totals to make comparisons to the forecasted upstream emissions. Many factors outside of this Project may affect the provincial and national inventory totals; therefore this was considered to be outside of the scope of this assessment.
2981.1	round 1	WG Action Item - April 19, 2017		Air Quality	Provide estimates of the amount and types of waste that would be produced and incinerated at the construction camp, as well as the air emissions anticipated to be generated from the incinerator. Information should reflect actual operational values based on similar-sized incinerators. These values will then be used to determine if the operations phase is still the worst case or if additional air dispersion modelling is required during the EA to assess potential effects on VCs.	See Section 6.3.5.2 of the Application for additional information on solid waste management. The preferred option is to utilize existing permitted waste facilities for the various Project waste streams. Aurora LNG is considering the use of an incinerator for potential food wastes from the worker accommodation. Aurora LNG intends to limit the size of the incinerator to below the BC MOE defined threshold of 400kg/hr and to limit the incinerated waste streams to organic food wastes. The incinerator, if utilized, will help to limit potential food waste odors that could attract wildlife or other pests. Please see the "Assessment of Work Camp Waste Incineration" technical memo which will be filed with the BC EAO.
2982.1	round 1	WG Action Item - April 19, 2017		Air Quality	Develop a draft modelling plan (including timelines) to assess the plume rise for the ground flare during the EA process to be approved by MOE.	Aurora LNG provided MOE with a draft ground flare model plan on May 8, 2017, and held a conference call with MOE on May 10 to confirm approach and clarify technical details. The outcome of this conference call was MOE providing verbal approval of the modelling plan and approach. Please refer to the technical memo "Ground-Flare Dispersion Model Assessment" for the results of the ground flare modelling, which will be filed with the BC EAO.
2983.1	round 1	WG Action Item - April 19, 2017		Air Quality	Provide OGC with additional information regarding what flaring will look like during commissioning, including a range for frequency of flaring activities.	Commissioning of a liquefaction train is expected to typically occur over a two week period with start-up taking approximately one day although it is not expected that flaring activity would occur for that entire duration. Commissioning is a controlled activity so it will be planned and managed to minimize the flaring events. The flare usage is dependent on commissioning of different systems e.g. utilities, storage, pretreatment, liquefaction, etc. which can be planned to occur simultaneously or sequentially to optimize the commissioning schedule. The Aurora LNG facility will adopt the latest technologies such as efficient turbine drivers and liquefaction technology; which are important criteria to minimize the flaring. Aurora LNG has not determined the final configurations of the facility so the flare length and duration cannot be predicted during the commissioning activity where the flaring rates can vary up to normal design loads. Aurora LNG will engage with the BC Oil and Gas Commission during the LNG Facility application process and will provide more detailed information regarding flaring activity expected while commissioning the facility once the Project has progressed into front end engineering and design.
2984.1	round 1	WG Action Item - April 19, 2017		Air Quality	Request a license agreement from ECCC for MEIT version 4.1.0.	Aurora LNG forwarded the PDF version user manual and PDF version summary document of the ECCC 4.1.0 version MEIT database to the BC EAO and ECCC on May 11, 2017. Aurora LNG asked ECCC to advise the BC EAO on whether the BC EAO can post those two PDF version files.
2985.1	round 1	WG Action Item - April 19, 2017		Human Health	Display the grid points spatially on a map and identify the maximum point of impingement for 1-hour NO2 concentration (based on the 98th percentile of the daily 1-hour maximum) for Digby Island, Prince Rupert and Port Edward.	Please refer to the technical memo titled "Maximum Points of Impingement (MPOI) for 1-Hour Nitrogen Dioxide Concentrations", which will be filed with the BC EAO.
2986.1	round 1	WG Action Item - April 19, 2017		Air Quality	Provide a clear description of how best technology/standards in Project design would meet a potential reduction in AAQOs in the future.	Aurora LNG will assess relevant current regulations such as AAQO's as part of the facility basis of design while in front end engineering and design. The basis of design will also consider any publicly announced expected changes to relevant regulations (e.g AAQO's) to ensure that the facility will meet the regulatory requirements anticipated to form part of facility operational permits. If changes to regulations occur during the facility design period, the options to adjust technology or standards are varied. However, once the facility is constructed and in operation, the potential options to meet emission permit changes related to AAQO's would likely be limited to adjusting the feed gas composition and/or considering the installation of customized scrubber units.
2987.1	round 1	WG Action Item - April 19, 2017		Marine Water Quality	Share the tables in the marine TDR that compare the maximum concentrations of COPCs in sediment with the CCME Interim Sediment Quality Guideline (ISQG).	The technical memo "Supplemental Information for Traditional Marine Foods", which will be filed with the BC EAO, includes the requested screening table. This screening table includes the number of sediment samples, CCME ISQG and PEL, and measured concentrations (min, max, 95% UCLM) in the sediment for metals, polycyclic aromatic hydrocarbons, polychlorinated biphenyls and dioxins and furans.
2988.1	round 1	WG Action Item - April 19, 2017		Human Health	Provide a revised calculation of health risk using an agreed-upon maximum consumption rate. Appropriate consumption rates to be informed in consultation with MOH and HC with reasonable time for Aboriginal groups to share known consumption rates for their communities for consideration. If no further rates are provided by Aboriginal Groups, or they are not substantially different from those identified in consultation with MoH and HC, the latter will suffice.	Please refer to the technical memo titled "Supplemental Information for Traditional Marine Foods", which will be filed with the BC EAO.
2989.1	round 1	WG Action Item - April 19, 2017		Water Quality	Provide a table that shows the numbering/naming nomenclature of fisheries streams that correspond with the same streams considered in the streams assessed for acidification/eutrophication.	Please see the technical memo "Additional Information about Eutrophication and Acidification in Freshwater" for a cross-referencing of naming/numbering. The technical memo will be filed with the BC EAO.
2990.1	round 1	WG Action Item - April 19, 2017		Water Quality	Update the draft access road and Dodge Cove watershed memo to describe that some Dodge Cove residences have copper piping while others have PVC piping. Also note that the predicted change in pH due to the Project would not alter the current effectiveness of existing filter systems in the Dodge Cove residences.	Please refer to the technical memo titled "Dodge Cove Drinking Water Supply and Watershed", which will be filed with the BC EAO.
2991.1	round 1	WG Action Item - April 19, 2017		Water Quality	Provide additional information on the desalinization facility and anticipated effluents from the power plant/cooling towers, and review existing technologies currently being used for these components. Consider which potential contaminants could cause harm and complete a literature review of which guidelines may be applicable in the absence of provincial guidelines .	Please see the technical memo "Discharges to the Marine Environment" which will be filed with the BC EAO.
2992.1	round 1	WG Action Item - April 21, 2017		Marine Water Quality	Regarding the draft Aurora LNG Memo “Discharges to the Marine Environment” • if the effluent assessment relies on a 200 m Initial Dilution Zone, Aurora LNG needs to provide specific examples of where a 200 m IDZ has been used in the province, identify the circumstances that might have justified a larger IDZ, and identify any special management plans or monitoring programs that were required to support a larger IDZ.	In the absence of previous discussions with MOE regarding an Initial Dilution Zone (IDZ), the draft memo (Discharges to the Marine Environment) mentioned a 100 or 200 m IDZ (we are aware of a 200 m IDZ approved in freshwater in northwestern British Columbia), but acknowledge that 100 m is more common. The memo "Discharges to the Marine Environment" has been revised.
2993.1	round 1	WG Action Item - April 21, 2017		Water Quality	Nutrient Nitrogen in Lakes • It is necessary to show the calculations used to estimate the concentration of nitrogen in the lakes. It is not possible to review the estimates without clearly showing the calculations.	Please see the revised technical memo "Additional Information about Eutrophication and Acidification in Freshwater" which will be filed with the BC EAO.
2994.1	round 1	WG Action Item - April 21, 2017		Water Quality	Access Road and Dodge Cove Watershed • The average annual water pH of the Dodge Cove reservoir is reported as 4.34 pH units. This value requires additional information about the sample size and the variability of pH measurements.	The "Dodge Cover Water Supply and Watershed" technical memo was presented to the Working Group in draft for pre-read on April 17, 2017 under the title of "Access Road and Dodge Cove Watershed." The memo was updated as a result of the discussion during the Working Group meeting and this comment, to clarify that the measurement of water pH in the Dodge Cover reservoir was based on a single point value measured in October 2015 and does not represent an annual average.
2995.1	round 1	WG Action Item - April 21, 2017		Water Quality	Water Quality In-Situ Data (Freshwater) • This memorandum requires a map showing the locations of sample sites. It also requires information about the turbidity classes, specifically, what are the range of values used to delineate C, L, M and H?	The technical memo "Water Quality In-situ Data (Freshwater)" has been updated to reference the site map in Appendix M of the Application, showing the sampling locations for water quality completed by Triton/Khtada field crews are shown. The memo will be filed with the BC EAO.
2996.1	round 1	WG Action Item - April 24, 2017		Acoustic Environment	Include information in the memo regarding the potential avoidance of previously-used areas due to increased noise levels.	Please see the technical memo "Low Frequency Noise Assessment" for information regarding previously-used areas. This technical memo will be filed with the BC EAO.
2997.1	round 1	WG Action Item - April 24, 2017		Acoustic Environment	Confirm the procedure for hearing protection of workers on LNG vessels.	There are no specific provincial publications outlining hearing protection requirements on LNG vessels operating in British Columbia waters. Recommendations from Transport Canada for hearing protection of crew members will be considered on the LNG vessels. Transport Canada publication TP5021E ""Personal Safety on Ships"" recommends the use of proper hearing protectors when working in noisy environments on a ship. The Transport Canada publication TP 3685 ""Standards Respecting Noise Control and Hearing Protection in Canada Towboats"" provide additional information on hearing protection requirements on towboats that can be applied on a LNG carrier. Any crew member entering any space of the ship where the sound level is 85 dB(A) or more shall use a hearing protector of appropriate quality (Class A, B or C as defined in CSA Standard Z94.2-1979), as follows: in spaces where the level is not in excess of 95 dB(A), the protector shall be of Class A, B or C; in spaces where the level exceeds 95 dB(A) but is not in excess of 100 dB(A), the protector shall be of Class A or B; in spaces where the level exceeds 100 dB(A), the protector shall be of Class A.
2998.1	round 1	WG Action Item - April 24, 2017		Acoustic Environment	Update the cumulative noise assessment memo to reflect the discussion regarding the consideration of Altagas, Canpotex and Prince Rupert LNG in the cumulative effects assessment of noise.	Please see the revised technical memo "Cumulative Noise Assessment" which will be filed with the BC EAO.
2999.1	round 1	WG Action Item - April 24, 2017		Acoustic Environment	Update low frequency noise assessment memo to reflect the discussion regarding potential noise effects on the west side of Digby Island.	Please see the revised technical memo "Low Frequency Noise Assessment" which has been updated to include receptors on the west side of Digby Island. The technical memo will be filed with the BC EAO.

3000.1	round 1	WG Action Item - April 24, 2017		Acoustic Environment	Confirm with Stantec's wildlife expert that potential effects of low frequency noise on wildlife were considered.	Wildlife-related literature has primarily centered on A-weighted decibel noise effects as it represents the most common weighting used in noise measurement. There is limited information available on the effects of C-weighted decibel noise to wildlife. Although there is limited information available on effects of C-weighted decibel noise to wildlife, a discussion on potential effects to human receptors is provided in Section 4.4 of the Application. The low frequency noise effect analyses for construction and operation are summarized in Table 4.4-17 to Table 4.4-18. The results indicate no predicted exceedances when compared to the ANSI 12.9 standard threshold for human receptors. Section 4.7.5.2 of the Application considered the potential indirect effects of change in habitat and incorporated information on noise-based effects available in scientific literature, for species occurring within the LAA (or for similar species whose effects are expected to be representative).
3001.1	round 1	WG Action Item - April 24, 2017		Acoustic Environment	Update sleep memo to include response to EAO's question: the noise of all four trains operating together was considered for the assessment, and that this is a worst-case (or more conservative) scenario than the levels of noise from construction of trains 3 and 4 overlapping with facility operations. Update the sleep memo regarding the potential avoidance of traditional use/camping sites due to increased noise levels.	Please see the revised technical memo "Sleep Disturbance and Speech Interference" which has been updated to reflect this request. The technical memo will be filed with the BC EAO.
3002.1	round 1	WG Action Item - April 24, 2017		Acoustic Environment	Review Gitxaala comment 1853 and add reference to sleep disturbance memo if appropriate.	References to the technical memos "Low Frequency Noise Assessment" and "Sleep Disturbance and Speech Interference" have been included in response to the noted comment #2196.1.
3003.1	round 1	WG Action Item - April 28, 2017		Marine	Determine if it's possible to correlate subsurface sediment type and bathymetry and the potential presence of coral.	Aurora LNG has reviewed the publically available data for the Chatham Sound region to determine whether it is possible to test for a correlation between benthic habitat type, bathymetry, and the presence of cold-water corals and glass sponges. Based on this review, Aurora LNG has determined that, for the following reasons, such a test cannot be performed at this time. Limited spatial distribution of data on cold-water corals and glass sponges. While detailed data on the distribution of corals and sponges was collected during baseline field surveys for the Prince Rupert Gas Transmission Project (McGregor GeoSciences Ltd. [McGregor] 2014), the data are limited to four north-south oriented corridors in the northern and eastern areas of Chatham Sound. This study used multibeam echo sounder and side scan sonar to identify benthic habitat features characteristic of biogenic sponge reefs. Dense aggregations of mounds (potential sponge reefs) were identified in water depths between 40 and 200 m, and were most concentrated to the east of Melville Island, Dunria Island and Baron Island (i.e., between Melville Island and the Tsimpsean Peninsula). Such detailed data are not available for the majority of Chatham Sound. Lack of detailed data for benthic habitat type and bathymetry. The available data for benthic habitat types and bathymetry in the region are coarse, and do not identify fine-scale features that might influence the presence/absence of sponges and corals (e.g., rocky outcrops or ridges). Higher-resolution data are available for areas within the corridors studied by McGregor (2014); however, observed correlation between habitat type, bathymetry, and presence of corals and sponges within these corridors cannot be extrapolated to the wider region without comparably high-resolution data for the particular areas of interest (e.g., at the candidate disposal at sea sites).Variable growth forms of glass sponges. Glass sponges require a hard substrate for attachment, and are often found on rocky substrates (e.g., bedrock, boulders). However, sponges also grow as reefs (bioherms), whereby successive generations of sponges settle and grow on the silica skeletons of dead sponges (Chu and Leys 2010). These reefs may occur in areas that lack bathymetric complexity, and may be surrounded by otherwise featureless soft sediment seafloor habitats. Given these variable growth forms, habitat type (e.g., rocky vs. soft sediment) may not be a good predictor of sponge presence. Indeed, many of the sponge reefs identified by McGregor (2014) were surrounded by relatively flat, featureless soft sediment habitat. Given the above, it is not possible to confidently predict the potential distribution of corals and sponges across Chatham Sound. However, as part of the disposal at sea permitting process, Aurora LNG will undertake detailed investigations including subtidal remotely operated vehicle (ROV) surveys at the specific candidate disposal at sea sites that are carried forward for disposal at sea permitting. These intensive surveys will provide site-specific information on the potential presence of corals and sponges at the selected sites, will support further assessment of potential environmental effects, and should allow the proposed candidate site to be refined to avoid the identified areas.. Appendix L-4 to Application for Environmental Assessment Certificate. 87 pp + Appendices.
3004.1	round 1	WG Action Item - April 28, 2017		Marine	Engage with commercial fishers to discuss suitability of alternative disposal sites and potential interactions with commercial fisheries.	Aurora LNG will engage with commercial fishers as part of its ongoing review of potential candidate DAS sites.
3005.1	round 1	WG Action Item - April 28, 2017		Marine	Consider including PNCIMA information on salmon migratory patterns and critical rearing habitat for juvenile salmon in the Skeena Estuary in the DAS constraint maps.	Aurora LNG has reviewed the PNCIMA publications (http://www.pncima.org/site/about-pncima/document-library/pncima-publications.html) for information on salmon migratory patterns and critical rearing habitat for juvenile salmon in the Chatham Sound / Skeena Estuary region. While no spatial data were located, Aurora LNG identified pertinent information in a PNCIMA report authored by Hyatt et al. (2007), titled 'Ecosystem Overview: Pacific North Coast Integrated Management Area (PNCIMA) - Appendix I: Pacific Salmon'. Sections 4.4 and 4.5 of this report describe migratory routes and important rearing habitats within the PNCIMA area. Regarding salmon migratory routes, the report states: "Although the detailed migratory routes and timing variations of individual stocks and species are known in only the most general terms, it is clear that key zones of egress and ingress (potential Ecologically and Biologically Significant Areas) may be initially identified in association with the watersheds within PNCIMA that support the largest populations of salmon. The distribution and abundance of spawning salmon may be used as a crude, first approximation of the relative importance of key marine zones in PNCIMA for actively migrating juvenile and adult salmon." Given that the Skeena River is a major producer of salmon on the north coast of BC, proximity to the mouth of the Skeena River can be used as a proxy for the relative importance of marine habitats for migrating juvenile and adult salmon. Areas that fall within migratory corridors to and from the Skeena River (i.e., between the mouth of the Skeena River and offshore habitats) can also be considered important habitats for migrating salmon. Aurora LNG has considered this information in its analysis of potential candidate sites for disposal at sea, as presented in the technical memo "Analysis of Alternative Sites for Disposal at Sea", which will be filed with the BC EAO. Regarding important rearing habitats for juvenile salmon, the Hyatt et al. (2007) report provides the following general description of salmon habitat utilization within Queen Charlotte Basin (QCB), which includes Chatham Sound and the Skeena Estuary: "The diverse marine habitats that salmon utilize in the QCB are created by complex, seasonal interactions among bathymetry, wind, freshwater runoff, and tidal currents that control both the circulation of water and its properties within the QCB (Thomson 1981). Although the detailed patterns of salmon utilization of these varied marine habitats are less well studied than their use of freshwater habitats, several generalizations are possible. From a salmon habitat perspective, the waters of the QCB may be viewed as consisting of: (1) transitional, estuarine staging, and rearing areas for juvenile and adult stages of all species (e.g., coastal inlets and major estuaries of the Nass and Skeena rivers); (2) upwelling areas of productive underwater shoals and banks that are especially important as rearing areas for aggregations of sub-adult coho and Chinook salmon (Dogfish, North Island, Goose and Cook banks); (3) continental-shelf, surface-water eddies that may entrain juvenile salmon and plankton for periods of days to weeks (e.g., clockwise rotating Rose Spit Eddy and the counter-clockwise flowing Queen Charlotte Sound Eddy, Crawford et al. 1995); and (4) advection zones along the continental shelf where surface waters move rapidly seaward as filaments or plumes with replacement from depth by upwelling nutrient rich waters." From the above description, most of the waters of Chatham Sound, particularly nearshore areas close to the mouth of the Skeena River, would be considered transitional, estuarine staging, and rearing areas for juvenile salmon. In recognition of this, Aurora LNG has committed to restricting disposal at sea activities to the DFO least-risk work window for the Lower Skeena Region, which is from November 30 to February 15. This window coincides with a period of low abundance of juvenile salmon in the coastal waters of Chatham Sound, when most juveniles are found farther offshore, over the continental shelf. Restricting disposal at sea activities to this window will substantially reduce potential effects to rearing juvenile salmon. References: Hyatt, K., M.S. Johannes, and M. Stockwell. 2007. Ecosystem Overview: Pacific North Coast Integrated Management Area (PNCIMA) - Appendix I: Pacific Salmon. Canadian Technical Report of Fisheries and Aquatic Sciences 2667.
3006.1	round 1	WG Action Item - April 28, 2017		Marine	Share the references for the two 2006 PNCIMA reports completed by Clark and Jamieson.	The process for identifying DFO Important Areas (IAs) for the Pacific North Coast Integrated Management Area (PNCIMA) is described in the following two references. They are both available online here: http://www.pncima.org/site/about-pncima/document-library.html Clarke, C.L. and G.S. Jamieson. 2006. Identification of Ecologically and Biologically Significant Areas in the Pacific North Coast Integrated Management Area: Phase I – Identification of Important Areas. Canadian Technical Report of Fisheries and Aquatic Sciences 2678. Clarke, C.L. and G.S. Jamieson. 2006. Identification of Ecologically and Biologically Significant Areas in the Pacific North Coast Integrated Management Area: Phase II – Final Report. Canadian Technical Report of Fisheries and Aquatic Sciences 2686.
3007.1	round 1	WG Action Item - April 28, 2017		Marine	Confirm if there are any marine heritage sites identified in traditional use studies that have not been carried forward into the DAS siting analysis.	Aurora LNG reviewed the traditional use studies completed by Aboriginal Groups for the Project to identify marine heritage sites that might overlap with the four candidate disposal at sea sites identified in the technical memo "Analysis of Alternative Sites for Disposal at Sea", which will be filed with the BC EAO. This review did not identify any traditional marine heritage sites that would overlap with the four identified candidate disposal at sea sites.
3008.1	round 1	WG Action Item - April 28, 2017		Marine	Develop a technical memo that compares Brown Passage with one or more identified alternative DAS sites using the additional constraints layers discussed in this meeting. Nexen will engage with appropriate agencies and Aboriginal groups regarding the DAS site alternatives. This process would inform the selection of one or more preferred DAS sites, which would then be assessed against the five pillars for the EA.	Please see the "Analysis of Alternative Sites for Disposal at Sea" technical memo which will be filed with the BC EAO.
3009.1	round 1	WG Action Item - April 28, 2017		Marine	Develop a work plan for addressing DAS including a schedule of key tasks, a description of the outcomes of each tasks, and how EAO, Aboriginal groups and agencies will be involved.	Aurora LNG has developed the "Aurora LNG - Disposal at Sea Workplan" technical memo outlining the proposed workplan for DAS permitting. It is based on the four phases of the ECCC DAS permitting process, with the expectation that the majority of Phase 1 of the ECCC process would fall within the Application Review process under BC EAO. This technical memo will be filed with the BC EAO.
3010.1	round 1	WG Action Item - April 28, 2017		Fish Habitat Offsetting Plan	Provide a technical memo with more information regarding the characterization of residual serious harm to fish and the suitability of the proposed conceptual offsetting measures to offset residual serious harm to fish	Please see the "Assessment of Project Effects and Proposed Offsetting for Residual Serious Harm to Fish" technical memo which will be filed with the BC EAO.
3011.1	round 1	WG Action Item - April 28, 2017		Wetland Compensation	Provide clarity on working group comments 2578, 2587, 2606 and 2611.	Please see the technical memo "Supplemental Information Regarding Estuarine Wetlands and Wetland Compensation" which will be filed with the BC EAO.
3012.1	round 1	WG Action Item - April 28, 2017		Wetland Compensation	Provide a memo that provides additional information regarding the extent and functions of intertidal estuarine wetlands in the PDA, and including Delusion Bay and how adjacent wetlands may be affected and a plan for compensation. Clarify which components of the wetland compensation requirement are addressed by the Fish Habitat Offsetting Plan and which are to be addressed by the wetland compensation plan. Provide additional information about monitoring and mitigation for wetlands adjacent to the Project development area.	Please see the technical memo "Supplemental Information Regarding Estuarine Wetlands and Wetland Compensation" which will be filed with the BC EAO.
3013.1	round 1	EAO		Human Health	See attached memo "Aurora LNG Digby Island Project - Information Request (May 19, 2017) - Air Emissions and Human Health Effects"	Please see the "Maximum Points of Impingement for 1-Hour Nitrogen Dioxide Concentrations" technical memo, which will be filed with the BC EAO.
3014.1	round 1	EAO	8.0	Human Health	The Ministry of Health has further input on the consumption rates applied in your re-analysis expected for May 31st. In careful consideration of the MOH feedback, the EAO would like Nexen's re-analysis to include both the adjusted rates you provided in your May 9th note below, as well as the 220 g/day suggested by MOH. I understand that the 220 g/day would also align with the rate applied in the LNG Canada analysis. This approach to considering a range of consumption rates will be helpful to move forward in our assessment on this topic.	Please see the "Supplemental Information for Traditional Marine Foods" technical memo, which will be filed with the BC EAO. The "Supplemental Information for Traditional Marine Foods" technical memo was presented to the Working Group in draft for a pre-read on April 18, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
3015.1	round 1	CAS	GHG Upstream Report	GHG Upstream Report	In March 2016, ECCC published suggested methodology for estimating the upstream GHG emissions from major projects undergoing federal environmental assessments. Emissions estimates were later developed for the Woodfibre LNG and Pacific Northwest LNG projects using this methodology. , These assessments, and the current one completed for Aurora LNG, highlight certain challenges inherent to the estimation of upstream emissions and its use in environmental assessments to determine the potential implications of a specific project on national or global GHGs. First, ECCC's natural gas upstream emissions estimates do not vary over time, which is inconsistent with observed trends in British Columbia (B.C.) and unlikely to represent the actual emissions associated with the project. Provincially reported GHG and natural gas production data show clear declines in the GHG-intensity of natural gas produced in BC between 2000-2015. These declines are due to a number of factors, including the shift from conventional gas production to tight and shale gas production (with typically lower GHG-intensities), and the use of newer production techniques and technologies. Similarly, the methodology and emissions factors used to develop the estimates do not take into account recent climate policy announcements that will influence natural gas upstream emissions over the project's operational lifetime. For example, B.C.'s Climate Leadership Plan includes direction for the development and enforcement of standards to reduce methane emissions in the upstream prior to the Aurora project coming on-line. Changes in natural gas supply as well as any provincial GHG reduction policies put in place will impact the amount of upstream GHG emissions in the future. As the ECCC analysis does not take these potential changes into account, the total expected upstream GHG emissions from a specific project may be overestimated when forecasted over its lifetime. As such, the estimates provided can be considered a higher-end estimate of the maximum potential annual emissions associated with a facility. The estimates may not be representative of the annual upstream emissions later on in the project's lifetime or indicative of the actual impact of the project on global greenhouse gas emissions. In terms of the project's potential impact on global GHGs, as Aurora notes, both downstream GHG emissions impacts (including fuel switching from coal-fired power plants to natural gas plants) and the counter-factual scenario (where other projects may come on-line if the Aurora project is not developed) would need to be considered to determine the net result of the project on global GHGs.	Aurora LNG notes the CAS comments on the published ECCC methodology. However, the intent and scope of this assessment was to evaluate upstream emissions as provided in the methodology, where upstream includes, as defined by ECCC, "all industrial activities from the point of resource extraction to the project under review." A review of downstream GHG emissions is therefore outside of the scope of this assessment.

3016.1	round 1	MNGD	GHG Upstream Report	GHG Upstream Report	B.C.'s Ministry of Natural Gas Development (MNGD)has completed internal analyses to determine the potential upstream emissions from proposed major projects in the province. Given the uncertainties associated with forecasting potential upstream emissions as described above, ranges in potential emissions are preferred by MNGD. These ranges can broadly account for potential variations that could occur between projects, including the source of the feedstock natural gas, the production techniques, and technologies used at the wellsites that produce that feedstock. For example, projects that receive the majority of their feedstock from the Montney basin (which has much lower formation CO2) would be on the low end of the range, while projects that receive their feedstock from areas with higher formation CO2 (including the Horn River Basin and the Liard Basin) would be at the high end of the range. Given Aurora LNG's description that the source of their feedstock gas would be from "proprietary and third party gas" and given the state of their partner's holdings in areas such as the Horn River Basin, it is reasonable to assume that upstream emissions associated with the project would be higher than projects that source their feedstock gas from areas with lower formation CO2. The estimates provided in the Aurora LNG report are in line with the ranges developed by MNGD and can be considered a reasonable estimate of the potential annual upstream GHG emissions associated with the project. As stated previously, these estimates are most applicable in the near term of a project's life, as changes to production techniques and technologies, as well as government policy, will reduce these values over time. In particular, carbon capture and sequestration (CCS) projects would greatly reduce the emissions intensity of natural gas produced in the Horn River Basin. MNGD was directed in the B.C. Climate Leadership Plan to complete the regulatory policy framework to ensure CCS projects, like those being considered for the Horn River Basin, can proceed. It should be noted that there will be uncertainty associated with all of these estimates, given the use of average, province-wide emissions factors as opposed to project-specific emission factors. The level of detail provided in the analyses and the results obtained may be appropriate for the purposes of this interim approach to this specific environmental assessment. More accurate estimates would require significantly more analysis to better understand the exact production and throughput characteristics for the project. Taking these uncertainties into account, compared to the MNGD analysis, the estimates provided by Aurora can be considered a reasonable higher-end estimate of the maximum potential annual emissions associated with the project. It is expected that over the project's life, the upstream emissions associated with the project will decrease due to changes in production techniques, the use of new technologies and additional government policies to reduce GHGs.	It is agreed that the Review of Upstream Greenhouse Gas Emissions estimates are a "reasonable higher-end estimate of the maximum potential annual emissions associated with the project." Given that Project specific details about upstream sources are not finalized yet, the "Review of Upstream Greenhouse Gas Emissions" utilized average emission factors from Environment and Climate Change Canada (ECCC) and The Pembina Institute as opposed to project-specific emission factors. To this effect, ranges in upstream emission estimates are limited to ECCC and Pembina data, as presented in the Application. Further details are not available to add additional Project-specific prospective ranges. in upstream emissions. Aurora LNG agrees that actual project upstream emissions will decrease "due to changes in production techniques, the use of new technologies and additional government policies to reduce GHGs."
3017.1	round 1	Gitga'at First Nation	12.3 and Appendix S.1	Aboriginal Consultation	"This comment was made during screening, and stills stands. Please respond. ""Gitga'at First Nation has the following comments on Appendix S1 (Aboriginal Consultation Report #2), which should also be considered throughout the Application where Appendix S1 is referenced: • Gitga'at First Nation has not been provided the opportunity to review and comment on the Aboriginal Consultation Plan (ACP). However, as described in Section 1.3 the ACP has been amended, so Gitga'at First Nation requests that the ACP be amended to reflect the recent Section 13 Order, and any other amendments identified during Gitga'at First Nation's review of the ACP. This is important because the Aboriginal Consultation Objectives outlined in Table 3-1, to date, have not been afforded to Gitga'at First Nation. • The Aboriginal Interests listed in Table 2-1 for Gitga'at First Nation are limited; for example, terrestrial harvesting, use of trails and travelways, and traditional governance are also Aboriginal Interests. Gitga'at First Nation should be consulted on this table. • A note should be added to Table 4-1 that no "Early Engagement" was conducted with Gitga'at First Nation. Also the specific "Pre-Application Consultation" activities conducted with Gitga'at First Nation should be clear as not of the activities listed included Gitga'at. • A list of technical workshops, field trips and attendees should be added to Section 4.2.3.1 and 4.2.3.3 as Gitga'at First Nation was not included. • The statement in Section 4.2.3.3 that "Aurora LNG has held meetings with Gitga'at to provide similar information" is incorrect; to date no such meeting has taken place. • No "Additional Workshops" in a one-on-one setting with Gitga'at First Nation occurred to review baseline information, and as such, Aurora LNG interpreted and incorporated information provided by Gitga'at on their own. • To date, Gitga'at First Nation has not been engaged in "Consultation on Related Authorizations during the Reporting Period" (Section 4.3.1). • Section 4.3.2 lists that "Aurora LNG provided a number of employment opportunities that provided economic benefits and built capacity for Aboriginal community members in the Prince Rupert area"; what opportunities have been provided to Gitga'at First Nation? • Section 10.2.2.1 states "… Aurora LNG worked with Gitga'at to develop a technical workshop with Gitga'at to discuss the topics that are relevant to Gitga'at, which include topics covered with the other Aboriginal Groups as part of the Technical Workshops held to date"; this did not occur so this statement should be removed. • Section 10.2.2.3 states "… Aurora LNG worked with Gitga'at to develop workshops on October 13 and 14, 2016. The topics covered during these workshops included topics that were covered with the other Aboriginal Groups as part of the First and Second Workshops"; this statement is misleading as Aurora LNG set the agenda for the October 13 and 14 workshops, focusing on drafts Section 11.3 and Part C. • Gitga'at First Nation requested to be consulted in identifying high value viewpoints (Table 10-1); however, this did not occur. • As commented throughout the screening Table of Concordance, Gitga'at First Nation continues to request Aurora LNG to assess impacts to Economic Conditions, Infrastructure and Services, and Community Health in Hartley Bay (listed in Table 10-1). • The Aboriginal Groups involved in the activities, and recipients of the reports listed in Appendix 1 should be listed. Also the dates of such activities and report sharing should be provided.""	During screening, the EAO provided guidance that "Gitga'at's comments are not screening level; however, please consider the feedback in updates to the ACR." As such, this comment was not included in the table of responses to screening comments. Aurora LNG will continue to track the views and feedback received from Gitga'at First Nation (including specific issues related to ACR #2), Aurora LNG's response to these views and feedback as well as the status of any outstanding items. The results of this process will be reported on in ACR #3. Aurora LNG will provide a draft of ACR #3 to Aboriginal Groups for review and comment before it is submitted.
3018.1	round 1	Gitga'at First Nation	12.3 and Appendix S.2	Aboriginal Consultation	"This comment was made during screening, and stills stands (Note, thank you for sending the full version for Application Review). Gitga'at First Nation was not provided the opportunity to review and comment on the Aboriginal Consultation Plan, and the Aboriginal Consultation Report #1. The Aboriginal Consultation Plan should be amended to include the recent Section 13 Order. In addition, Gitga'at First Nation has the following screening comments on Appendix S2 (Aboriginal Consultation), which should be considered throughout the Application where Appendix S2 is referenced: • This Appendix is missing Figures. • Table 9-5 is limited and missing other Gitga'at First Nation Businesses. • Gitga'at First Nation should have been provided the opportunity review this table prior to Aurora LNG submitting Application for screening. During the October 13 and 14th workshop with Aurora LNG, this Appendix was not provided. • Table 9-8 has limited information, and references LNG Canada 2014b and Inglis 2014 – what about the Traditional Use and Occupancy Study completed for this Project, i.e., Inglis 2016? • For Gitga'at First Nation to effectively screen this Appendix, the full version should be provided and not the public version."	During screening, the EAO provided guidance that "Gitga'at's comments are not screening level; however, please consider the feedback in updates to the ACR." As such, this comment was not included in the table of responses to screening comments. Aurora LNG will continue to track the views and feedback received from Gitga'at First Nation (including specific issues related to ACR #2), Aurora LNG's response to these views and feedback as well as the status of any outstanding items. The results of this process will be reported on in ACR #3. Aurora LNG will provide a draft of ACR #3 to Aboriginal Groups for review and comment before it is submitted.
