1110.1	round 1	Metlakatla First Nation	4.10.5.2, p. 4.10-51	Marine Wildlife - Marine Mammals	Please provide acoustic information regarding disposal at sea and provide a figure that shows the 120 and 160dB isopleths associated with dredge disposal at Brown Passage. This is critical in order to understand the potential sonic limitations to marine mammal movement through Brown Pass to and from the open ocean.	As discussed on page 4.10-51 of the Application, and based on literature reported values (e.g., Todd et al. 2015), it is considered unlikely that the NOAA (n.d.) interim thresholds for behavioural disturbance (i.e., 120 and 160 dB re 1 µPa rms) will be exceeded during dredging and disposal at sea activities. As such, acoustic modelling of dredging and disposal at sea were not undertaken. This approach is in keeping with that taken on other recently-approved projects in northern BC. Aurora LNG maintains that the Application adequately characterizes potential residual effects of dredging and disposal at sea on marine mammals, and that additional quantitative modelling is unlikely to change the conclusions presented in the Application.
1111.1	round 1	Metlakatla First Nation	Table 4.10-9	Marine Wildlife - Marine Mammals	The principles guiding the determination of exclusion zones (in consultation with DFO) must include the creation of a corridor in which sound levels are below 160dB. This may require significant reductions in vessel speed within narrow channels.	Acoustic modelling of Project-related vessels in transit predicted that sound levels would drop below 160 dB re 1 µPa rms within 0.1 km of the vessel propellers based on conservative assumptions. Modelling assumed that LNG carriers were accompanied by two tugs (which will not occur beyond the boundaries of the PRPA) and that vessels were travelling at the maximum speed of 16 knots (30 km/hr) (while the average speeds throughout the PRPA will be 12 knots [22 km/hr]). Further details on vessel scenarios and acoustic modelling results are provided in Appendix P.
1112.1	round 1	Metlakatla First Nation	4.10.5.4	Marine Wildlife - Marine Mammals	The Application notes that the proposed upper-end LNG carrier transit speed within the RAA is 16kts. Literature from the US suggests that baleen whales have difficulty maintaining speeds over 10kt and may therefore have difficulty outrunning vessels travelling at top speed if startled or otherwise engaged in an activity (mating/foraging) that prevents early vessel detection. Speeds from triple island to the jetty should be maintained at no more than 10kts. This is expected to reduce behavioural changes associated with noise, as well, because noise from LNG carriers generally increases more than proportionally with increases in speed.	The relationship between vessel speed and strike risk was considered in the assessment (see Section 4.10.5.4) and the relationship between sound levels and vessel speeds is recognized. The Technical Review Process of Marine Terminal Systems and Transshipment Sites (TERMPOL) process, conducted by Transport Canada, will address vessel speeds and routing, in consideration of mariner safety, environmental effects, and feedback through consultation with PRPA, DFO, Aboriginal Groups, and others. Project-related vessels will proceed at a safe speed and respect any regionally-defined or PRPA-specific speed profiles that are applicable at the time of operations, subject to navigational safety. Aurora LNG is willing to collaborate in regional programs planned and developed by government and in conjunction with other proponents, regarding regional management of effects of vessel strikes on marine mammals in the RAA.
1113.1	round 1	Metlakatla First Nation	Appendix Q	Marine Wildlife - Marine Birds	Please explain the reasoning for the following methods: Why were there no shoreline stationary counts conducted on Tuck Island or the Kinahan Islands? Why were shoreline surveys only conducted for fall migration and summer, and only in one year? Why were vessel-based surveys conducted at different months for summer surveys (July 2014 vs. June 2015)? Why were vessel-based surveys only conducted once per season, with the exception of summer? Why were vessel-based surveys conducted to survey marine birds 300m on either side of the centreline? Standard is 300m total width, at 150m on either side of the centreline. Marbled murrelets are increasingly difficult to detect beyond 100m. Why were surveys conducted between 8am and 6pm? Marine birds are typically best to sample in the morning or dawn/dusk. Why were vessel-based surveys so concentrated in Chatham Sound, outside the RAA? More effort should have been taken to survey within the RAA. This was not explained. Why were results not shown by habitat type? Please show more information about the results of the survey and describe the importance/significance of the results. Why were vessel-based surveys conducted in a different pattern (continuous straight lines) during the February 2015 survey? Why were some habitat types not sampled during the July 2014, June 2015 and November 2014 vessel-based surveys?	Methods for shoreline stationary counts and vessel-based surveys are described in Section 4.1.2 and 4.2.2 of Appendix Q. Field studies for marine birds were completed to provide a record of occurrence and patterns in habitat use within the LAA and RAA. The scope and timing of field studies were consistent with recommendations within applicable sampling protocols referenced in Appendix Q. Shoreline stationary counts and vessel-based surveys were completed across different months, times of day, and at variable tide heights to account for seasonal, diurnal, or tidal patterns of use during overwintering, migration, and breeding periods. Although surveys were generally completed once per season, survey effort was replicated across and within habitat types in LAA and RAA. Surveys were completed in July 2014 and June 2015 to provide additional information about patterns in marine bird use of the LAA and RAA across the summer breeding period. To provide greater regional context, results of field studies were evaluated in consideration of regional datasets and information sources (see Appendix Q). Shoreline stationary counts were located to maximize survey coverage in habitats within the LAA. Specific placement of individual points was intended to survey across various nearshore environments within the LAA, targeting unique marine features. A shoreline stationary count was located on Spire Island (MBDI20) and included Tuck Island in its radius of detection (see Figure 2 of Appendix Q). Although no shoreline stationary counts were located on Kinahan Islands, vessel-based surveys included survey effort in adjacent marine habitats. Vessel transects were stratified across four primary habitat guilds to account for potential differences in marine bird habitatuse. Transects were distributed throughout the RAA but also Chatham Sound more broadly, to account for regional patterns in seasonal richness, abundance, and distribution. Transects placement was random within each guild to provide an indiscriminate sample of species presence, richness, abundance, and distribution. As noted in Appendix Q, the number and placement of transects completed in each season (including distribution across habitat guilds) varied based on constraints in weather and sea conditions. A complete summary of marine bird detections by habitat guild is provided in Appendix 3 and discussed in Section 4.2.3 of Appendix Q. Vessel-based survey methods (e.g., RIC 1997; Gjerdrum et al. 2012) recommend that observers scan out to 300 m ahead and to one side of the vessel. This can result in an underestimate of difficult to detect species (e.g., alcids) if surveying under challenging weather conditions, however a 300 m transect width better accounts for species that avoid transiting vessels that would also be underestimated using a narrower transect width (e.g., loons, diving ducks; RIC 1997, Gjerdrum et al. 2012). Detection of smaller species beyond 150 m is optimized by surveying during conditions were visibility is not compromised and through the use of skilled observers (see Appendix Q for details). References: Gjerdrum, C., D.A. Fifield, and S.I. Wilhelm. 2012. Eastern Canada Seabirds at Sea (ECSAS) Standardized Protocol for Pelagic Seabird Surveys from Moving and Stationary Platforms. Canadian Wildlife Service Technical Report Series No. 515. Atlantic Region. Resource Inventory Committee (RIC). 1997. Inventory Methods for Seabirds: cormorants, gulls, murres, storm-petrels, Ancient Murrelet, auks, puffins, and Pigeon Guillemot. Victoria, BC.
1114.1	round 1	Metlakatla First Nation	Appendix Q	Marine Wildlife - Marine Birds	Survey methodology was not well described. Nor were there justifications for locations chosen for surveys. Please elaborate on the methodology and provide justifications.	Methods for shore and vessel-based surveys are described in Section 4.1.2 and 4.2.2 of Appendix Q and are consistent with the level of information required based on the survey protocol standards referenced within each section. Shore-based points were located to maximize survey coverage in habitats within the LAA while preventing overlap of the observation radius of individual points to avoid duplication in survey effort. Specific placement of individual points were intended to survey across various nearshore environments within the LAA, targeting unique marine features (e.g., Delusion Bay, Casey Cove, surrounding islands and islets). Vessel transects were stratified across four primary habitat guilds to account for potential differences ir marine bird habitat use. Transects placement was random within each guild to provide an indiscriminate sample of species presence, richness, and abundance.
1115.1	round 1	Metlakatla First Nation	Appendix Q	Marine Wildlife - Marine Birds	Were shoreline surveys conducted within 2hrs of high tide at each survey location? Methodology only states that surveys were conducted between 8am and 4pm.	Consistent with sampling protocols referenced in Appendix Q, shore and vessel-based surveys were completed across different months, times of day, and at variable tide heights to account for seasonal, diurnal, or tidal patterns of use. Stationary shoreline points situated around mudflats (e.g., Delusion Bay, Casey Cove) were surveyed at mid- or high-tide, to optimize detection of shorebirds and dabbling ducks, as well as to facilitate access to survey locations.
1116.1	round 1	Metlakatla First Nation	Appendix Q	Marine Wildlife - Marine Birds	Were shoreline surveys conducted with spotting scopes and binoculars? 300m is a long distance to see with just binoculars and many species including marbled murrelet may be missed. Please provide more information, including the number of observers.	Shoreline surveys were completed using a combination of a spotting scope and binoculars to support species identification (including for species that are more difficult to detect at greater distances, such as marbled murrelet).
1117.1	round 1	Metlakatla First Nation	4.11.2.5	Marine Wildlife - Marine Birds	Please explain why Dodge Cove was not included in the LAA? This area looks to be within 1km of the MOF, thus should be included.	The LAA for marine birds includes a 1 km buffer around the proposed marine terminal, including the MOF. Dodge Cove is located just outside of this 1 km buffer (see Figure 4.11-1 in Section 4.11); however, Project studies included three shoreline stationary counts in Dodge Cove to understand marine bird presence, abundance, and distribution in this area. Given its proximity to the LAA, potential effects to marine birds using habitats in Dodge Cove are expected to be similar to those characterized for other areas within the LAA. A discussion of potential effects to nesting herons in Dodge Cove is also considered in Section 4.7 of the Application.
1118.1	round 1	Metlakatla First Nation	1.2	Proposed Project Overview	Please show the infrastructure for the natural gas delivery on the site maps. This context is important for determining the constructed layout and allows for a broader picture of the end product.	As noted in section 1.2.7.1 of the Application, natural gas will be delivered to the Project via a third party-owned pipeline, which is yet to be determined, and not in the scope of this Project. The feed gas pipeline will enter the PDA via a dedicated pipeline delivery station. It is expected that the marine-based feed gas pipeline would approach Digby Island from the south to avoid further disturbance to areas on Digby Island outside of the PDA. However, the exact location for landfall is subject to change since the pipeline supplier has not been selected.

1119.1	round 1	Metlakatla First Nation	4.11.3.1 and Table 4.11-7	Marine Wildlife - Marine Birds	Despite scoping in section 4.11.2 that lists Bird Conservation Region 5 and First Nations interests (section 4.11.3.2) as part of the scope, these species of interest have not been carried forward in the assessment. Please explain why priority species for BCR5 and harvestable marine birds of value to FNs have not been included in the assessment.	Sections 4.11.2.2 and 4.11.2.3 of the Application describe the Aboriginal Groups from which traditional knowledge and traditional use information was gathered, and how information was incorporated into the assessment. Section 4.11.3.2 provides a summary of findings of traditional ecological knowledge for marine birds and is described in more detail in Appendix Q of the Application. Traditional ecological knowledge provided on traditionally harvested species, seasons, and locations are used in combination with Project and regional studies, and scientific literature to determine the appropriate extent of spatial boundaries, characterize residual Project and cumulative effects, and to assign significance determinations. Species of cultural importance are discussed throughout Section 4.11.5 and 4.11.6 where there was an identified mechanism for interaction with Project activities and infrastructure. Additional details on the timing and location of marine bird harvesting practices are provided in Appendix S.2. Information on harvesting practices was used to support Section 4.11, Section 11, and Part C of the Application. The assessment also integrated information from the Bird Conservation Region 5 (BCR 5) Strategy (Environment Canada 2013), recognizing that the BCR 5 extends from the western Gulf of Alaska to northern California. The Application draws information on conservation objectives outlined in the Strategy that is relevant to marine bird species present, and habitats available, within the LAA and RAA. Priority species identified in the Strategy align with those presented in Section 4.11.3.2 and Appendix Q of the Application. Supporting field studies were developed in consideration of habitat requirements for priority species / species of management concern. The key threats identified for priority species in the Strategy are considered in the Application, where the Project has potential to contribute to residual effects (e.g., habitat change and alteration, mortality, and disturbance). Section 4.11.5.6 of the Application describes residual Project effects that have potential to interact cumulatively with other projects and activities within the RAA, including those identified in the Strategy (e.g., commercial fishing and by-catch, marine transportation). Environment Canada (2013) further outlines that BCR strategies are not intended to be highly prescriptive. Proponents are recommended to integrate local information, recommendations, and management practices. Accordingly, Aurora LNG incorporated information from regional data and information sources (e.g., land use plans, traditional ecological studies) into Section 4.11 of the Application. Mitigation measures are developed in consideration of other relevant provincial and federal regulations and best management practices. Reference: Environment Canada. 2013. Bird Conservation Strategy for Bird Conservation Region 5: Northern Pacific Rainforest. Canadian Wildlife Service, Environment Canada. Delta, British Columbia. 128 pp. + appendices.
1120.1	round 1	Metlakatla First Nation	4.11.4	Marine Wildlife - Marine Birds	Why is marine construction not considered a mortality risk? Effect of blasting on diving birds includes concussive force and pressure. This effect should be included in the assessment. Why is discharge to the marine environment under commissioning and start-up not considered as a change in habitat? Hydro-testing will include fresh water plus impurities in the pipe, which gets discharged to the marine environment. This poses a risk to change in environment for marine birds. Why is LNG shipping not considered a mortality risk? There is a risk that marine birds disoriented by lights or avoiding ships are not able to make it to a rest area or suitable landing site. Why has LNG production not been considered a risk to change in behaviour of marine birds? Flaring and lighting may cause marine birds to avoid the area, or be disoriented by the lights, changing their behaviour.	Effects of underwater noise to marine birds is primarily expected to result in sensory disturbance that could influence change in habitat use or change in behaviour, and is discussed in Sections 4.11.5.2 and 4.11.5.4 of the Application, respectively. As per mitigation 4.11.2, a Noise Management Plan and a Marine Activities Plan will be implemented to decrease the extent of in-air and underwater acoustic emissions during Project construction, and considers timing windows to reduce effects to key species (see Section 14.5 and 14.11 for details). Additional procedures related to blasting, pile driving, and dredging will be outlined in the Marine and Freshwater Resources Management Plan. The Plan will include measures to reduce disturbance to marine fish, which will, by extension, benefit marine birds (see Section 14.9). Recognizing that the detailed technical information and effects thresholds necessary to assess effects of noise levels encountered by marine birds is currently limited, the Application incorporates best-available information in scientific literature to characterize potential effects of underwater noise on marine birds (see Section 4.11 for applicable citations). Marine birds are likely to avoid areas of elevated underwater noise during all Project phases through behavioural adaptation, which in turn is expected to reduce the risk of noise-induced injury or mortality. As per mitigation 4.7.14, facility staff will document and report bird injuries or fatalities, including birds that would be potentially affected by underwater noise. Methods for waste discharge into the marine environment, and potential effects to the physical or chemical composition of marine waters is assessed in Section 4.5.15.3 of the Application. Changes in physical or chemical conditions, and resulting effects to marine bird prey, are considered as part of the assessment of change in habitat under Section 4.11.5.2 of the Application. Section 4.11.5.3 indicates that for marine birds, change in mortality risk for the Project is primarily associated with increased nighttime lighting at the LNG facility, marine terminal, and from berthed or transiting vessels (inclusive of LNG carriers). The assessment of change in mortality risk specifically addresses effects of disorientation that could result in stranding, injury, or mortality from all Project-related anthropogenic light sources. Section 4.11.5.4 further acknowledges that marine birds are also expected to adjust behaviour patterns, either through attraction to, or disorientation caused by, nighttime lighting at the marine terminal and at berthed or transiting vessels. However, because behaviour-related changes as a function of Project-related lighting can ultimately result in injury or mortality of marine birds, this mechanism for effect was assessed in Section 4.11.5.3.
1121.1	round 1	Metlakatla First Nation	4.11.4	Marine Wildlife - Marine Birds	How will wastes be treated during waste management? Will there be any disposal or discharge to the marine environment?	Methods for waste storage, treatment, disposal, and discharge into the marine environment, and potential effects to the physical or chemical composition of marine waters are assessed in Section 4.5.15.3 of the Application. Changes in physical or chemical conditions, and resulting effects to marine bird prey, are considered under Section 4.11.5.2 of the Application. Details regarding Project waste sources, anticipated waste streams, and disposal options will be described in the Waste Disposal Management Plan (see Section 14.14 of the Application).
1122.1	round 1	Metlakatla First Nation	4.11.5.2	Marine Wildlife - Marine Birds	A general assumption has been made that "most marine birds present in the LAA and RAA have secure populations and have access to other suitable marine habitats, marine birds are expected to demonstrate a moderate degree of resilience to change in habitat availability". However, 22 species of marine birds of management concern have been identified as potentially occurring in the LAA or RAA. These species do not have secure populations, or are at risk of having unsecure populations. In addition, species traditionally harvested by First Nations have not been included in the assessment (unless already of management concern). The inability to harvest traditionally harvested marine birds, either due to a decrease in availability, change in behaviour of the species, or because the added pressure of harvesting would be detrimental to the species, is in conflict with the rights of FNs to practice Aboriginal rights. Marine birds on the priority list for BCR5 (including species where an increase in population is desired) have also not been included. Please explain rationale for concluding that marine birds are expected to demonstrate a moderate degree of resilience.	Species of management concern and traditionally harvested species have been included in the assessment (see subsections within Section 4.11.3.2) and although there is some overlap, they are not necessarily representative of the same marine bird species or species groups. Traditional ecological knowledge provided on traditionally harvested species, seasons, and locations are used in combination with Project and regional studies and scientific literature to characterize residual Project and cumulative effects, and to assign significance determinations. The assessment also integrated information from the Bird Conservation Region 5 (BCR 5) Strategy (Environment Canada 2013), drawing information on conservation objectives outlined in the Strategy that is relevant to marine bird species present, and habitats available, within the LAA and RAA (see response to comment 776 for more information). As per Table 4.11-15, resilience was determined for marine bird species and species groups (including species of management concern and traditionally harvested species) based on the existing conditions, the potential for interaction with Project activities and infrastructure, the nature of that interaction, and the sensitivity of marine birds to respond. Given these criteria, marine birds were assessed to have moderate tolerance to change from existing conditions; the viability of local or regional populations was not expected to be affected by residual project effects. The prediction confidence is moderate or high (see Section 4.11.8) given some uncertainty over the degree to which some marine bird species may be affected by the Project. Information presented in Section 4.11 was carried forward to Section 11 (see Section 11.3.8.3 starting on page 11-123) and Part C (see Section 12.5.5.6) of the Application and considers the resilience of harvested species to residual Project and cumulative effects in combination with traditional harvesting practices. Reference: Environment Canada. 2013. Bird Conservation Strategy for Bird Conservation Region 5: Northern Pacific Rainforest. Canadian Wildlife Service, Environment Canada. Delta, British Columbia. 128 pp. + appendices.
1123.1	round 1	Metlakatla First Nation	4.11.5.2	Marine Wildlife - Marine Birds	Please provide the lowest noise levels that cause disturbance to marine birds. This information is important in determining potential effects on birds. Please show isopleth lines on a map of the project area, along with marine bird concentrations. Please show attenuation distance of underwater noise and model used to determine this.	Scientific understanding and recognition of the potential effects of underwater noise (i.e., behavioural and injury thresholds) on marine mammals have increased dramatically in recent decades. However, for other marine taxa (e.g., marine birds) there remain substantial limitations in current scientific understanding of this potential stressor. Recognizing that the detailed technical information and effects thresholds necessary to assess effects of noise levels encountered by marine birds, an acoustic model for marine birds was deemed inappropriate. The nature and extent of underwater noise effects are limited to species who spend a portion of their life cycle below the water surface (i.e., diving and pursuit foragers) that are likely to use marine habitats experiencing elevated noise levels. Recognizing that the detailed technical information and effects thresholds necessary to assess effects of noise levels encountered by marine birds is currently limited, the Application incorporates best-available information in scientific literature to characterize potential effects of underwater noise on marine birds (see Section 4.11 for applicable citations).
1124.1	round 1	Metlakatla First Nation	4.11.5.2	Marine Wildlife - Marine Birds	What is the rationale for determining that adverse effects are not expected on marine birds given that noise produced by the Project vessels is expected to be 206dB re 1uPa for transiting tugs and pile driving is expected to reach 230dB re1uPa, yet an expose level of 202dB can caused injury to marbled murrelet? This is a clear exceedance, yet the assessment claims that the noise produced by ships in the shipping lane "are well below the threshold expected to cause injury in diving bird species". What threshold is this if not the 202dB for marbled murrelet? At what dB level does noise cause disturbance or change in behaviour for marbled murrelet?	Effects of underwater noise to marine birds was expected to result in sensory disturbance that could influence change in habitat use or change in behaviour, and was discussed in Sections 4.11.5.2 and 4.11.5.4 of the Application, respectively. The assessment did indicate that underwater noise would result in an adverse residual effect of displacement or disturbance within each section. Given available scientific evidence, the SAIC (2011) concluded that terrestrial and marine mammals represent reasonable surrogates for characterizing auditory injuries to marbled murrelets, while thresholds for fish are useful for estimating non-auditory injuries. Based on that species extrapolation, the SAIC (2011) estimated that a continuous 24-hour sound exposure level (SEL) greater than 202 dB re 1uPa could cause disturbance or injury to marbled murrelet. However, the SAIC (2011) recommends this as a guideline given that the SEL threshold represents a 24-hour cumulative exposure period (i.e., an individual remains submerged and its distance to the noise source remains constant for a continuous 24-hour exposure period) and has limitations in its application for species that are a) mobile, and b) spend only a proportion of its daily cycle below the surface of the water. Detailed technical information on the nature and extent of underwater noise effects continue to be limited for marine birds. Although Project-related activities may result in underwater noise production above 202 dB re 1uPa, marbled murrelets or other marine bird species are not expected to be exposed for a sufficient period to sustain injury. Marine birds are likely to avoid areas of elevated underwater noise during all Project phases through behavioural adaptation, which in turn is expected to reduce the risk of noise-induced injury or mortality. As per mitigation 4.11.2, a Noise Management Plan and a Marine Activities Plan will be implemented to decrease the extent of in-air and underwater acoustic emissions during Project construction; these plans will consider timing windows to reduce effects to key species (see Section 14.5 and 14.11 for details). Additional procedures related to noise reduction for blasting, pile driving, and dredging will be outlined in the Marine and Freshwater Resources Management Plan. The Plan will include measures to reduce disturbance to marine fish, which will, by extension, benefit marine birds (see Section 14.9). Reference: Science Applications International Corporation (SAIC). 2011. Environmental science panel for marbled murrelet underwater noise injury threshold. Prepared for: US Navy, Bothell, WA. 34 pp.
1125.1	round 1	Metlakatla First Nation	4.11.5.3	Marine Wildlife - Marine Birds	Table 4.11-10: Mitigation for marine construction/operations is incomplete. Suggested mitigation measures include: -bubble curtain to limit risk of marine birds (and fish) from getting too close to pile driving operations or other appropriate mitigatins if bubble curtains are unfeasible in some locations; surveys/monitoring for birds during construction and operations; timing of works to avoid sensitive periods, such as when young are present (likely more susceptible to noise effects); shielding of the flare to prevent accidental mortality	As per mitigation 4.11.2, a Noise Management Plan and a Marine Activities Plan will be implemented to decrease the extent of in-air and underwater acoustic emissions during Project construction, and considers timing windows to reduce effects to key species (see Section 14.5 and 14.11 for details). Additional procedures related to blasting, pile driving, and dredging will be outlined in the Marine and Freshwater Resources Management Plan. The Plan will include measures to reduce disturbance to marine fish, which will, by extension, benefit marine birds (see Section 14.9). Section 1.2.5.1 describes the proposed flare system design and does not include a shielding mechanism, due to infrastructure constraints. However, maintenance flaring events will be scheduled during daylight hours to the extent practicable to reduce the potential of accidental mortality of marine birds (mitigation 4.7.20). Aurora LNG has further committed to limit exterior lighting, and use of directional or shielded lighting to reduce the risk of injury or mortality of marine birds during all Project phases (mitigation 4.7.9).
1126.1	round 1	Metlakatla First Nation	4.11.5.2 & 4.11.5.3	Marine Wildlife - Marine Birds	Please describe in-air noise effects on marine birds. Include information on pressure and vibration changes associated with flaring and how these will affect birds (vibration cavity of birds differs from humans, and as such, human-centric thresholds are not applicable).	Effects of in-air noise on marine birds are described in Sections 4.11.5.2 and 4.11.5.4. While flaring will contribute to noise production during Project operations, it is not expected to generate substantial noise for marine bird receptors unless they are in the immediate vicinity of an active flare, in which case individuals are likely sufficiently close to the pilot flare to be at risk of injury or mortality from collision with the flare stack or flame (see Figure 11 of Appendix C). Changes in mortality risk from injury or collision with the flare system are discussed in Section 4.11.5.3. While effects from sudden pressure changes (e.g., barotrauma) are well documented among bats, the unique respiratory anatomy of birds is thought to make them less susceptible to changes in pressure and is not expected to be a potential effect for marine birds (Baerwald et al. 2008). Aurora LNG has committed to mortality monitoring and reporting (mitigation 4.7.14). The Wildlife Management Plan will provide details on procedures for identifying, recording, and reporting on injuries or mortalities related to Project activities; where possible, Project personnel will be required to describe the cause of mortality. Reference: Baerwald, E.F., D;Amours, G.H., Klug, B.J., and Barclay, R.M.R. 2008. Barotrauma is a significant cause of bat fatalities at wind turbines. Current Biology, 18(16): 695-696.
1127.1	round 1	Metlakatla First Nation	4.11.5.3	Marine Wildlife - Marine Birds	Please describe how sudden pressure changes, sudden noise, burns and collisions related to flaring will affect marine birds.	Effects of flaring on marine birds are described in Section 4.11.5.3. While flaring will contribute to noise production during Project operations, it is not expected to generate substantial noise for marine bird receptors unless they are in the immediate vicinity of an active flare (see Figure 11 of Appendix C to see predicted noise levels of Project infrastructure within the PDA). If individuals are sufficiently close to the pilot flare to experience elevated noise levels, they're also likely sufficiently close to the pilot flare to be at risk of injury or mortality from collision with the flare stack or flame. While effects from sudden pressure changes (e.g., barotrauma) are well documented among bats, the unique respiratory anatomy of birds is thought to make them less susceptible to changes in pressure and is not expected to be a potential effect for marine birds (Baerwald et al. 2008). Aurora LNG has committed to mortality monitoring and reporting (mitigation 4.7.14). The Wildlife Management Plan will provide details on procedures for identifying, recording, and reporting on injuries or mortalities related to Project activities; where possible, Project personnel will be required to describe the cause of mortality. Reference: Baerwald, E.F., D;Amours, G.H., Klug, B.J., and Barclay, R.M.R. 2008. Barotrauma is a significant cause of bat fatalities at wind turbines. Current Biology, 18(16): 695-696.
1128.1	round 1	Metlakatla First Nation	4.11.5.3	Marine Wildlife - Marine Birds	Discussion of residual effects for change in mortality fails to mention discussion of underwater noise, as in the previous section. As shown in above comment, underwater noise is expected to exceed thresholds for marbled murrelet (and likely other species). Please include underwater noise in this discussion.	Effects of underwater noise to marine birds is primarily expected to result in sensory disturbance that could influence change in habitat use or change in behaviour, and is discussed in Sections 4.11.5.2 and 4.11.5.4 of the Application, respectively. As per mitigation 4.11.2, a Noise Management Plan and a Marine Activities Plan will be implemented to decrease the extent of in-air and underwater acoustic emissions during Project construction, and considers timing windows to reduce effects to key species (see Section 14.5 and 14.11 for details). Additional procedures related to blasting, pile driving, and dredging will be outlined in the Marine and Freshwater Resources Management Plan. The Plan will include measures to reduce disturbance to marine fish, which will, by extension, benefit marine birds (see Section 14.9). Scientific understanding and recognition of the potential effects of underwater noise (i.e., behavioural and injury thresholds) on marine mammals have increased dramatically in recent decades. However, for other marine taxa (e.g., marine birds) there remain substantial limitations in current scientific understanding of this potential stressor. The nature and extent of underwater noise effects are limited to species who spend a portion of their life cycle below the water surface (i.e., diving and pursuit foragers) that are likely to use marine habitats experiencing elevated noise levels. Recognizing that the detailed technical information and effects thresholds necessary to assess effects of noise levels encountered by marine birds is currently limited, the Application incorporates best-available information in scientific literature to characterize potential effects of underwater noise on marine birds (see Section 4.11 for applicable citations). Marine birds are likely to avoid areas of elevated underwater noise during all Project phases through behavioural adaptation, which in turn is expected to reduce the risk of noise-induced injury or mortality. As per mitigation 4.7.14, facility staff will document and report bird injuries or fatalities, including birds that would be potentially affected by underwater noise.

1129.1	round 1	Metlakatla First Nation	4.11.5.3	Marine Wildlife - Marine Birds	Table 4.11-11: Mitigation describes LNG carriers as having to maintain a distance of greater than 500m from known marine bird colonies, and 1km from Lucy Island. However, the existing shipping lane is 6km from Lucy Island. Limiting ships to >5km from Lucy Islands Conservancy would be more prudent.	Aurora LNG is committed to complying with available guidance provided by federal agencies, such as Environment and Climate Change Canada (ECCC). ECCC provides guidance to avoid disturbance to seabird and waterbird colonies in Canada and recommend that large vessels maintain a minimum distance of 500 m from marine bird colonies (ECCC 2016). Given the distance between the existing shipping lane and Lucy Island (approximately 6 km), LNG carriers for the Project are expected to exceed ECCC's recommendations and vessel-based disturbance to colonial breeding marine birds are expected to be low as a result of Project activities. Details of this mitigation measure will be provided in the Wildlife Management Plan (see Section 14.8 in Section 14). Reference: Environment and Climate Change Canada (ECCC). 2016. Guidelines to Avoid Disturbance to Seabird and Waterbird Colonies in Canada. Available at: https://www.ec.gc.ca/paomitmb/default.asp?lang=En&n=E3167D46-1. Accessed: March 2017.
1130.1	round 1	Metlakatla First Nation	4.11.5.3	Marine Wildlife - Marine Birds	Please describe wake effect of LNG carriers on marine habitats, including nesting areas. How will wake be attenuated (show on map)? How will this affect marine bird colonies 500m from the shipping lane?	Section 6.5.4.2 of the Application provides details on wake from operational shipping traffic. Waves generated by LNG carriers and escort tugs travelling at 12 knots will be less than 0.4 m high at the source vessel and is within the size range of naturally occurring waves in the region. Historical data collected at weather buoys operated by Environment and Climate Change Canada indicate the average wave heights in Hecate Strait were 1.8 m. The Project's shipping route passes through unconfined waters in Chatham Sound towards Hecate Strait, which lends itself to larger distances between transiting carriers and shoreline habitats. This will allow wake waves to grow smaller (attenuate) as they travel over distance. As outlined in Section 4.11.5, Environment and Climate Change Canada recommends that large vessels maintain distances greater than 500 m from breeding colonies to reduce disturbance effects while transiting. Because the Project's shipping route is located more than 1 km from the nearest marine bird colony, the disturbance caused by LNG carriers for the Project are expected to attenuate to levels representative of average ambient wave conditions within the LAA and RAA. Maintaining distance from active marine bird colonies will reduce the potential for disturbance, including flushing of breeding adults from active nests.
1131.1	round 1	Metlakatla First Nation	4.11.5.3	Marine Wildlife - Marine Birds	Please describe monitoring programs to determine whether construction, operations or decommissioning are having an impact on marine birds.	Aurora LNG has committed to implementing standard mitigation measures, guidelines, and practices to avoid or reduce potential adverse effects of Project activities on marine birds during construction, operations, and decommissioning. These mitigation measures are described in Tables 4.11-9 (to avoid or reduce change in habitat), 4.11-10 (to avoid or reduce change in mortality risk), and 4.11-11 (to avoid or reduce change in behaviour for marine birds). To monitor potential effects of lighting on bird and bat mortality, facility personnel will be required to document and report injuries or fatalities related to Project activities (mitigation 4.7.14). As per mitigation 4.7.16, light-induced stranding's of migratory birds (including marine bird species) at the LNG facility, marine terminal, supporting infrastructure and facilities, and on berthed vessels will also be documented and reported. Reporting the extent to which birds are susceptible to light-induced mortality allows for monitoring and adaptive management of lighting mitigation measures, as necessary, throughout Project operations. Aurora LNG's framework for adaptive management is as follows: Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended). Full details will be described in the Wildlife Management Plan (see Section 14.8 of the Application).
1132.1	round 1	Metlakatla First Nation	4.11.6.3	Marine Wildlife - Marine Birds	Please describe resiliency of SAR to cumulative changes in habitat.	As per Table 4.11-5, resilience was determined for marine bird species and species groups (including species of management concern) based on the existing conditions, the potential for interaction with Project activities and infrastructure, the nature of that interaction, and the sensitivity of marine birds to respond to changes. Cumulative changes in habitat for marine bird species of management concern were assessed in Section 4.11.6.3. Given the criteria for resilience in Table 4.11-5, marine birds were assessed to have moderate tolerance to change from existing conditions; the viability of local or regional populations was not expected to be affected by residual Project and cumulative effects from change in habitat. The prediction confidence is high for residual Project and cumulative effects on change in marine bird habitat (see Section 4.11.8 of the Application), based on the availability of data used to characterize existing conditions in the LAA and RAA, the quality of available literature to understand the Project and cumulative effect mechanisms, the effectiveness of proposed mitigation measures, and professional judgement. The Project's residual effects, and its contribution to cumulative effects will be offset by implementation of the Fish Habitat Offsetting Plan. The Fish Habitat Offsetting Plan is expected to reduce regional changes to marine bird habitats, particularly in nearshore areas in the Prince Rupert region. Proposed mitigation measures for change in habitat have incorporated federal and provincial regulations and guidelines as well as measures that have been recommended or proven effective on similar projects in the RAA which will further reduce cumulative effects to marine bird habitats throughout the RAA.
1133.1	round 1	Metlakatla First Nation	4.11.7.1	Marine Wildlife - Marine Birds	Please describe population thresholds for SAR populations. At what point will populations be unable to rebound from loss of habitat or incidental mortalities? What percentage of SAR populations are affected by the Project? What about cumulative effects from other projects?	Significance thresholds for marine birds present the limits of an acceptable change in a measurable parameter or state of regional marine bird populations and are based on applicable legislation, regulatory guidance documents, or other management standards (including cultural use). Where thresholds are not set by legislation, policy, and regulatory guidance documents, a threshold has been developed based on existing data and information, scientific literature and professional judgement, and with the incorporation of available traditional ecological knowledge. Significance thresholds vary between species or species groups and potential effects. As described in Section 4.11.2.8 of the Application, a residual effect is considered significant if it affects the viability of local or regional marine bird populations. The viability of species can be affected by several factors, including reproduction, mortality, immigration, emigration, and habitat availability, where viability was defined in the Application as the long-term maintenance in abundance, diversity, or distribution of marine birds through natural recruitment. Species of management concern with potential to occur in the LAA and RAA are described in Section 4.11.3 (see Table 4.11-7). A total of 22 species of management concern were identified as having potential to interact with Project activities and infrastructure, the effects of which may act cumulatively with other projects and activities within the RAA. Potential residual Project and cumulative effects are described in Section 4.11.5 and 4.11.6, respectively. Species listed on Schedule 1 of the Species at Risk Act that are expected to interact with the Project, including mitigation measures for each, are listed in Table 4.11-13 of the Application. The number of affected species cannot be reported as a percentage, because regional populations for each of these species has potential to experience effects, however the degree will vary based on species presence, abundance, and distribution within the RAA and mechanisms for interaction with the Project.
1134.1	round 1	Metlakatla First Nation	4.11.7 & 4.11.8	Marine Wildlife - Marine Birds	Given the lack of discussion on in-air noise and dismissal of effects of underwater noise on marine birds, lack of discussion of marine birds of interest to FNs, lack of inclusion of priority birds for BCR5, and lack of fully comprehensive mitigation plans, we disagree in the significance and confidence predictions.	Effects of in-air and underwater noise on marine birds are described in Sections 4.11.5.2 and 4.11.5.4 of the Application. The assessment for marine birds considered results of acoustic models developed for the Project in combination with best-available information in scientific literature to characterize residual Project effects. As per mitigation 4.11.2, a Noise Management Plan and a Marine Activities Plan will be implemented to decrease the extent of in-air and underwater acoustic emissions during Project construction (see Section 14.5 and 14.11 for details). Additional procedures related to blasting, pile driving, and dredging will be outlined in the Marine and Freshwater Resources Management Plan. The Plan will include measures to reduce disturbance to marine fish, which will, by extension, benefit marine birds (see Section 14.9). Sections 4.11.2.2 and 4.11.2.3 describe the Aboriginal Groups from which traditional knowledge and traditional use information was gathered, and how information was incorporated into the assessment. Section 4.11.3.2 provides a summary of findings of traditional ecological knowledge for marine birds and is described in more detail in Appendix Q. Traditional ecological knowledge provided on traditionally harvested species, seasons, and locations are used in combination with Project and regional studies and scientific literature to inform the assessment. Species of cultural importance are discussed throughout Section 4.11.5 and 4.11.6 where there was an identified mechanism for interaction with Project activities and infrastructure. The assessment also integrated information from the Bird Conservation Region 5 (BCR 5) Strategy (Environment Canada 2013), recognizing that the BCR 5 extends from the western Gulf of Alaska to northern California. The Application draws information on conservation objectives outlined in the Strategy that is relevant to marine bird species present, and habitats available, within the LAA and RAA. Priority species identified in the Strategy align with those presented in Section 4.11.3.2 and Appendix Q of the Application and occur within the LAA and RAA. Supporting field studies were developed in consideration of habitat requirements for priority species / species of management concern. The key threats identified for priority species in the Strategy are considered in the Application, where the Project has potential to contribute to residual effects (e.g., habitat change and alteration, mortality, and disturbance). Section 4.11.5.6 of the Application describes residual Project effects that have potential to interact cumulatively with other projects and activities within the RAA, including those identified in the Strategy (e.g., commercial fishing and by-catch, marine transportation). As noted in Section 4.11.7, the Project is not expected to adversely affect the long-term viability of local or regional marine bird populations and Project effects are considered to be not significant. The prediction confidence was considered moderate or high given some uncertainty over the degree to which some marine bird species may be affected by Project activities or infrastructure. Reference: Environment Canada. 2013. Bird Conservation Strategy for Bird Conservation Region 5: Northern Pacific Rainforest. Canadian Wildlife Service, Environment Canada. Delta, British Columbia. 128 pp. + appendices.
1135.1	round 1	Metlakatla First Nation	4.11.9	Marine Wildlife - Marine Birds	Follow-up monitoring is an important part of large industry projects. Follow-up monitoring is recommended to confirm that Project related impacts are not causing significant impacts on marine birds, ensuring that mitigation measures are being followed, and allows for issues to be addressed in a timely matter. As such, a monitoring program and an adaptive management plan should be developed.	The criteria for proposed inclusion of a follow-up program are consistent with the Considerations for Developing a Follow-up Program as outlined in the Operational Policy Statement Follow-up Programs under the Canadian Environmental Assessment Act (Government of Canada, 2011). The criteria included a conclusion of potential residual adverse effect and either a low prediction confidence in that conclusion or uncertainty in a specific component of the VC assessment. In cases where the criteria are met, the proposed follow-up program will be used to verify the accuracy of assessment predictions. For VC assessments that concluded moderate to high prediction confidence, these will be managed through the development of Environmental and Operational Management Plans (Section 14) designed to verify compliance of the Project with commitments in the Application and conditions in an Environmental Assessment Certificate.
1136.1	round 1	Metlakatla First Nation	5	Economic Conditions	In the assessment, Metlakatla participation rate, employment and unemployment data is provided, referencing 2006 INAC data. Please clarify in the report whether this is on-reserve or total Metlakatla population data. The majority of Metlakalta members live off-reserve so on-reserve data is not an accurate representation of the membership. Please note as such in the assessment. In the paragraph that follows, data from the Metlakatla census is provided. Please clarify in the assessment if the employment %s are of total population or labour force. I believe the %s shown are of total popluation and therefore not an apples to apples comparison of other employment rate data shown in the assessment. Please also clarify Figure 5.2-5 accordingly. With reference to this statement: "While Metlakatla is interested in increasing overall employment across its membership, industrial development within the RAA has been identified as a concern with respect to local capacity (the ability to fill Metlakatla employment and volunteer positions)." Please clarify that competition from industrial development employers is the concern.	The 2006 participation rate, unemployment rate, and employment rate of Metlakatla First Nation from the AANDC First Nations Profile is based on data from census subdivisions affiliated with Metlakatla First Nation and does not capture off-reserve populations. Statistics Canada labour force metrics (upon which the AANDC data is based) are calculated as follows: Employment rate = % of persons over 15 employed Participation rate - % of total population 15 years and older participating in the labour force (whether employed or not) Unemployment rate = % of labour force that is unemployed Labour force information provided from Metlakatla First Nation is based on its own membership survey. As indicated in the last paragraph on page 5.2.34 of the Application, this information is based on a percentage of the total community membership. There was no intention to compare this information with the AANDC data.
1137.1	round 1	Metlakatla First Nation	5	Economic Conditions	The assessment states: "Within LAA communities, the labour pool of individuals with skills to operate and maintain an LNG facility is likely to be modest, a proportion of the operations workforce will be hired from outside the LAA." It is troubling to see this assumption included in the assessment when a major emphasis from Metlakatla has been on ensuring proper efforts are allocated to training of available Metlakatla workers. At the working group meeting, Metlakatla emphasized the importance of engaging First Nations in the operations training early so they will be ready for opportunities post-construction. Please revise this statement with language that sets a positive tone and ensures adequate resources are put toward early and substantial efforts toward operations training of FNs within the LAA.	The statement on page 5.2-57 indicating that a proportion of the operations workforce will be hired from outside the LAA reflects the reality that when the plant becomes operational the workforce will need to include some individuals experienced in LNG plant operations. However, it is anticipated that other individuals will be hired from local communities and it is expected that the proportion of operations jobs held by local residents will grow over time, as they acquire the skills and experience needed to operate an LNG facility. Aurora LNG remains committed to hiring appropriately qualified individuals from local communities for Project construction and operations.
1138.1	round 1	Metlakatla First Nation	5	Economic Conditions	Please emphasize the need to engage FN workers in training for operations jobs early in the process. We understand the training can take several years in some cases. It will be important to commit to recruitment and training with enough time to allow FNs participation.	Aurora LNG recognizes that it may take several years of training before individuals become qualified to work at an LNG plant. Aurora LNG will develop and implement a formal training strategy as part of its operational preparedness once the Project reaches a positive Final Investment Decision.
1139.1	round 1	Metlakatla First Nation	5	Economic Conditions	Please include mitigations with respect to employment laddering within the project construction cycle. Some FN workers may lack skills for certain jobs but over the course of the project, though on the job training, etc. may advance their skills to enable better employment positions. Laddering is an important feature of the employment and training strategy. Laddering strategies should also specifically mention the importance of sequeing construction employment to operations employment, with an emphasis on FN workers.	Mitigation 5.2-25 indicates that Aurora LNG will "identify potential shortages of workers with specific skill requirements, and work with training and education facilities, Aboriginal Groups, and local communities to increase opportunities for Aboriginal and local community members to obtain training required for Project participation." This mitigation signals Aurora LNG's support for training initiatives with Aboriginal Groups and local communities. Specific training strategies will be developed as part of human resources planning during detailed engineering. The suggestion of incorporating "laddering" into an employment and training strategy is noted.

1140.1	round 1	Metlakatla First Nation	5	Economic Conditions	The assessment suggests "Mitigation measures presented in Table 5.2-40 will substantially reduce the potential for adverse interactions between LNG carriers and commercial fishers." Yet, the mitigation efforts are fairly weak when considered in the context of the already threatened viability of Metlakatla fishers (MSS, 2013). Any incremental impact could have disproportionately negative effects on Metlakatla fishers; furthermore, Metlakalta has consistently emphasized commercial fishing viability is linked to the viability of subsisence harvest due to reliance on fishing vessels to gather other marine species: Losing commercial fishers (and their vessels) decreases capacity for subsistence gatherers. Even the slightest incremental impact to fishers has a compounding negative effect. The mitigation table should include strategies to address perceived risk of LNG carriers, take into account access routes and timing of fishers, and include a no net loss provision for commercial fisher capacity.	Please see the "Effects of Lost Fishing Time" technical memo which will be filed with the BC EAO.
1141.1	round 1	Metlakatla First Nation	5	Economic Conditions	The assessment states: "There is a low likelihood that there will be adverse cumulative effects for change in resource-based primary and subsistence economies due to the limited interaction between reasonably foreseeable projects and primary and subsistence economic activities, in consideration of available mitigation measures." Given the magnitude of proposed projects, majority of which have a a marine component, and coupled with the already threatened viability of Metlakatla commercial fishers (and secondary effects on subsistence harvesters) the claim of a low likelihood of adverse effects seems questionable. Recognition of likely adverse effects is more reasonable, if taking into account current levels of fisher/harvester viability and the magnitide of potential impacts from projects.	Please see the "Effects of Lost Fishing Time" technical memo which will be filed with the BC EAO.
1142.1	round 1	Metlakatla First Nation	5	Economic Conditions	The assessment indicates the prediction confidence for significance of effects on marine primary and subsistence economies is moderate due to "limited information on the size of Aboriginal fisheries within the areas that could be affected by Project activities." This admission suggests there is greater potential for effects to First Nations that have not been fully considered in the assessment. At minimum, a better understanding of First Nation activity should be a mitigation measure, potentially providing support to affected First Nations to undertake this work. Further, if data collection demonstrates adverse effects, there needs to be a commitment to mitigate the effects and/or offer acceptable offsets in lieu.	Aurora LNG is open to working with the Metlakatla First Nation to address any potential information gaps and welcomes additional information they can provide regarding Aboriginal Fisheries. As described in Section 6.5.3.3 of the Application, Aurora LNG will develop a Marine Activities Plan (Mitigation 6.5.2) to describe how the Project's marine activities will be managed to avoid or reduce effects on current marine users and other stakeholders. Aurora LNG proposes to develop this plan in consultation with regulatory agencies, Aboriginal Groups, marine users, and other interested stakeholders. The safe-shipping workshops, TERMPOL study, and participation on the Prince Rupert Port Authorities' Marine Construction and Coordination Committee could lead to recommendations regarding such issues as ship design/operation, terminal design, navigational routes, risks and accident avoidance, and pollution prevention. Additional information on the nature of the Marine Activities Plan will be shared as the plan is developed.
1143.1	round 1	Metlakatla First Nation	6.2	Visual Quality	The following aspects of the visual quality assessment are missing or not satisfactorally fulfilled and are required to conclude on the potential impacts of the project: - Visual impact of transiting LNG carriers, including at night, on land based viewers as well as seafarers and fishers; - visual impact of LNG terminal at night from multiple viewpoints, including sky glow effects at those locations who may be shielded from direct view of the terminal, but will still see skyglow. Nighttime lighting impacts should also be assessed during foggy conditions, when impacts may be visible for greater distances. - Visual impact of the LNG terminal for transitting vessels (how much of an average journey in and out of the harbour will boaters see?) - Visual impact from multiple viewpoints when flaring, during day and nightime hours.	Please see the following responses to this comment, by topic: 1. Visual impacts of transiting LNG carriers As discussed in Section 6.2.2.4 of the Application, the effects from shipping were not carried forward in the visual quality assessment because Project shipping will not result in a new visual element within the LAA (because it is already regularly visited by large marine traffic), and based on the EAC Application for the PNW LNG project (which would use similar sized ships, shipping frequency, and shipping route as for Aurora LNG) it was concluded that Project shipping will not introduce new visual elements or be visibly prominent from most viewpoints along the shipping route. 2. Visual impact of LNG terminal at night from multiple viewpoints, including skyglow effects at those locations who may be shielded from direct view of the terminal, but will still see the skyglow Aurora LNG will prepare a supplemental memo that includes additional night time renderings. Aurora LNG acknowledges that light emissions from the Project could contribute to the skyglow effect in the Prince Rupert area. However, through the use of shielded/directional lighting (mitigations 4.7.9 and 6.2.1), the Project's contributions to sky glow will be minimized where it is safe. 3. Nighttime impacts should be assessed during foggy conditions when impacts would be visible at greater distances Aurora LNG disagrees that lighting effects would be visible at greater distances during foggy conditions. Fog attenuates visible light, such that, depending on the thickness of the fog, the Project's light emissions would appear diffused or obscured. 4. Visual impact of the LNG terminal for transiting vessels (how much of an average journey in and out of the harbour will boaters see)? The length of time that the Project will be visibly apparent to boaters depends on their speed and direction of travel. Assuming that boaters are mainly looking forward, Project components would be visible for approximately 7 km as they leave Prince Rupert Harbour, travelling south. Based on Project components being potentially visibly prominent at 8 km distance (i.e. mid-ground view), for boaters entering Prince Rupert Harbour from the south, Project components would be visibly apparent for approximately 13 km of their travel route. 5. Visual impact from multiple viewpoints when flaring, during day and nighttime hours Aurora LNG will prepare a supplemental memo that includes renderings of flare events.
1144.1	round 1	Metlakatla First Nation	6.2	Visual Quality	Metlakatla members have serious concerns regarding the visual impact of this project. Though not chosen as priority viewpoints, for the purposes of consultation, high quality imagery and explanation will be needed from Nexen, describing the alterations in viewscape as a result of this project from multiple areas of concern, including Metlakatla Village, multiple locations in Prince Rupert, and from marine transit routes.	During the development of the Application, Aurora LNG consulted with Metlakatla First Nation regarding viewpoints to be considered in the assessment. The viewpoints selected for analysis were based partially on this consultation. It is not anticipated that the Project will be visible from Metlakatla Village due to distance and topographical/vegetation screening. While multiple viewpoints in Prince Rupert were considered, due to the orientation of Prince Rupert, the Project will not be visible from most residential or commercial receptors in the city. The Prince Rupert viewpoint selected for analysis (VP03) represents the "worst case" view of the Project from the city. As discussed in Section 6.2.2.4 of the Application, effects from shipping were not carried forward in the visual quality assessment because Project shipping will not result in a new visual element within the LAA (because it is already regularly visited by large marine traffic), and based on the Application for the PNW LNG project (which would use similar sized ships, shipping frequency, and shipping route as that of Aurora LNG) it was concluded that Project shipping will not be visibly prominent from most viewpoints along the shipping route.
1145.1	round 1	Metlakatla First Nation	6.03	Infrastructure and Services	The mitigation measures focus more so on strategies to manage workers while in camp, yet the impacts of concern are more related to when workers have time off and leave camp for nearby towns (Prince Rupert and Port Edward, where the majority of Metlakatla members live). The assessment claims the majority of workers will be FIFO but it is unclear how this will be managed and enforced, particularly when considering statements from Aurora to hire locally when possible. More stringent mitiation strategies are required to lessen potential impacts from workers during their time off. For example, the proponent could financially incent workers to travel home during time off rather than spending time off in town or recreating within an area already under pressure from recreational fishers and hunters. Other measures should be explored.	Fly-in/Fly-out (FIFO) workers are estimated to comprise 95% of the peak construction workforce with the remaining 5% expected to be hired from the LAA and RAA (see section 6.3.5.2 of the Application). Transportation of workers from their home communities to the Project site will be coordinated by Aurora LNG. Aurora LNG anticipates adopting a logistics policy that requires FIFO workers to be transported to and from the Project and their point of hire (i.e., home communities). This logistics policy combined with the closed-access camp policy (that workers will be expected to remain onsite for the duration of their shifts) will limit the opportunity FIFO workers have to interact in local communities. Aurora LNG acknowledges that this limits the potential for adverse effects but also reduces potential benefits of the Project on nearby communities. Where workers are hired from local communities, there exists potential for adverse effects when these workers are off shift. Through mitigation 6.3.3, all staff and contractors will be required to undertake worker orientation, including communication of expected behavior when transiting to/from local communities (i.e., a worker code of conduct) and cross-cultural awareness to help build awareness and respect of local concerns and customs to reinforce the importance of respectful conduct when in communities). Through this mitigation, Aurora LNG's will work to reduce the magnitude of adverse effects on infrastructure and services and community health when local workers are off shift and in local communities. Aurora LNG does not have control over the behavior and actions of workers when off duty and must therefore rely on communication of behavioral expectations to workers (such as those proposed through mitigation 6.3.3) to help reduce adverse effects of workers on local communities when off-shift.
1146.1	round 1	Metlakatla First Nation	6.3.5	Infrastructure and Services	The application says: Approximately 10% of construction management workforce will be hired from the LAA for the duration of construction; the remaining will commute on a FIFO basis. Please verify that local workers will return home to their local residences daily? At the Feb. working group meetings, it was indicated the local employees would be expected to stay in camp for their 2 week shifts. If local workers are required to stay in camp, this is a major barrier to local employment. Metlakatla has repeatedly requested Aurora work with Metlakatla to address barriers to employing members, including barriers associated with familial responsibilities, single parenthood, etc. Requiring local workers to stay in camp defeats the purpose of hiring local and elimates a huge portion of the potential workforce. Please verify expectations and work with Metlakatla to address employment barriers further.	As described in the assumptions list in Section 6.3.5.1 of the Application, construction workers are currently assumed to operate on a two weeks on two weeks off shift rotation, and local workers will be transported by Project-dedicated vessels and vehicles from and back to Prince Rupert. Workers will remain on-site for the duration of their shifts. In consideration of issues and concerns expressed by local residents and due to operational challenges related to the continual shuttling of workers from nearby communities and Digby Island, the accommodation camp is closed-access (meaning that Project employees will be expected to remain onsite). Aurora LNG acknowledges that this accommodation strategy, while effective at mitigating potential adverse effects on nearby communities, could have adverse effects on local employment (as noted by Metlakatla could be a barrier to employment). To increase local employment, Aurora LNG will inform local residents and Aboriginal Groups of job and procurement opportunities during all Project phases and develop work packages that consider the capacity and capabilities of local and regional businesses (see mitigation 5.2.1, Section 5.2). Through the community engagement plan, Aurora LNG will further engage in ongoing and meaningful engagement with Metlakatla First Nation to understand barriers to employment and complaints and concerns that may arise.
1147.1	round 1	Metlakatla First Nation	6.03	Infrastructure and Services	Given the lack of mitigations addressing workers that leave camp on days off and remain in the LAA, the estimated low to moderate magnitude residual effect is questionable.	Described in Section 6.3.5.2 of the Application, an estimated 95% of the peak construction workforce is expected to be comprised of fly-in/fly-out (FIFO) workers with the remaining 5% hired from the LAA and RAA. Of the 5%, 3% are anticipated to be local residents of the RAA and 2% in-migrating workers. Transportation of FIFO and local workers (includes current residents and those whom in-migrate to the LAA and RAA) from their home communities to the Project site will be coordinated by Aurora LNG. Aurora LNG anticipates adopting a logistics policy that requires FIFO workers to be transported to and from the Project and their point of hire (i.e., home communities). This logistics policy combined with the closed-access camp policy (that workers will be expected to remain onsite for the duration of their shifts) will limit the opportunity FIFO workers have to interact in local communities. When off-shift, current residents of the LAA and RAA will not contribute to incremental demand as they are already accounted for in baseline conditions. The 2% of the peak construction workforce anticipated to in-migrate will increase demand on infrastructure and services within the LAA and RAA. Aurora LNG is confident that combined, the camp and logistics policies and mitigation measures proposed in Section 6.3 of the Application will effectively manage adverse residual effects on infrastructure and services within the LAA from non-local workers.

1148.1	round 1	Metlakatla First Nation	6.03	Infrastructure and Services	The % of First Nations in core housing need is 2.5 times that of the non-Aboriginal population in Prince Rupert (table 6.3-12). Table 6.2-22 does not identify any mitigation measures that will increase supply of housing or address the upward pressure on housing prices due to increased demand, nor does the table identify any strategies specific to housing for First Nations, despite First Nations being much more vulnerable. There is mention in the assessment of new temporary accommodation and open space lodges that would accommodate 4000 workers/families but Metlakatla is not aware of those projects. We suggest the Proponent take an active role in the creation of housing solutions for direct, indirect and induced employment (and their families) in order to alleviate pressure on housing supply in the LAA and any associated upward pressure on housing prices. Based on the aforementioned, suggeseting "the Project will result in moderate magnitude residual effects within the LAA" seems unlikely; rather a high magnitude residual effect seems more likely and a adverse effect seems likely, suggesting a significant adverse effect.	Aurora LNG acknowledges that a greater percentage of Aboriginal residents within the LAA are in core housing need than non-Aboriginal residents (noted in Section 6.3.3.2 subsection 'Core Housing Need'). While First Nation-specific mitigation measures for changes in accommodations are not currently proposed, mitigation measures proposed in Table 6.3-22 apply to all population (Aboriginal and non-Aboriginal) within the LAA. Aurora LNG is confident that the proposed mitigations in Table 6.3-22, in consideration of workforce estimates (see Section 6.3.5.1 subsection 'Assumptions') and accommodation policies (i.e., a closed-access accommodation camp and expectations for workers to remain onsite for the duration of their shifts), will be effective at mitigating Project-related effects on accommodations. Implemented under the Social Management Plan (mitigation 6.3.1), the Worker Lodging Plan (mitigation 6.3.10) will integrate an adaptive management approach. Aurora LNG's framework for adaptive management is as follows: the social management plan, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plan will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended). Taken together, as characterized in Section 6.3.5.3, adverse residual effects during construction, operation and decommissioning on housing availability are anticipated to be moderate in magnitude (see Section 6.3.5.3). General information on housing availability within the LAA is provided in Section 6.3.3.2 subsection 'Housing Availability' with additional information on housing within the RAA provided in the 'Supplemental Baseline Information for Infrastructure and Services' technical memo. With respect to proposed open lodge space within the LAA, see Section 6.3.3.2 subsection "Temporary, Commercial and Workforce Accommodations". Additional consideration of issues and concerns related to cost of living is provided in Section 13.5.4 of the Application. Additional baseline information on housing and accommodations within the RAA is provided in the "Supplemental Baseline Information for Infrastructure and Services" technical memo which will be filed with the EAO.
1149.1	round 1	Metlakatla First Nation	6.03	Infrastructure and Services	The assessment indicates Prince Rupert hosptial is already at capacity. The assessment acknowledges there will be increased population due to direct, indirect and induced employment (and their families). The mitigations outlined in Table 6.3-26 do not identify strategies that will increase the supply of health care infrastructure and services in town (for those workers and their families not located in camp and for those workers that come into town on their days off). Given supply/demand dynamics, it is not clear how the project will avoid high magnitude residual effects and a high likelihood determinitation with respect to the changes in health care infrastructure and services. The suggestion is to include mitigation strategies that increase supply of services for the LAA.	Aurora LNG proposes to implement mitigation measures (see Table 6.3-26 of the Application) to reduce Project-related demand on health care infrastructure and services. Mitigation measures to increase the supply of health care infrastructure and services within the LAA and RAA are not proposed. Funding for health care infrastructure and services within the LAA is a provincial government responsibility. In-migrating workers, their spouses and dependents will be captured in population-level budgeting processes conducted by the provincial government with respect to health care funding. In BC, health care funding is distributed to health authorities following ministry staff identification of government commitments to health authorities, determination of the amount of funding that remains after making allocations to core-program commitments, and use of the population-based funding model tool to help allocate remaining funding (Auditor General of British Columbia 2013). Should the Project proceed, Aurora LNG will contribute to provincial tax bases providing resources to fund a wide variety of social and health services. Aurora LNG acknowledges that there will likely be a lag effect with respect to population change and adjustments to local and regional health care budgets. Adverse residual effects within the RAA are therefore characterized as moderate to high (see Section 6.3.5.5 of the Application). Auditor General of British Columbia. Health Funding Explained. Available at: http://www.bcauditor.com/book/export/html/775 . Accessed: March 1, 2017.
1150.1	round 1	Metlakatla First Nation	6.03	Infrastructure and Services	In the context of Metlakatla's previous comments about the magnitude and likelihood of adverse effects on health/infrastructure services and housing, it seems likely that additional demand from other projects would only exacerbate the magnitude and likelihood of cumulative effects, notwithstanding proponents taking an active role in the supply of health services and housing.	Assessed in Sections 6.3.6.4 (Cumulative Effects Assessment for Change in Accommodations) and Section 6.3.6.6 (Cumulative Effects Assessment for Change in Health Care Infrastructure and Services) of the Application, cumulative adverse effects with the Project are characterized as being high in magnitude compared to residual adverse effects (see Section 6.3.5.3 and 6.3.5.5) which range from moderate (change in accommodations) to moderate to high (change in health care infrastructure and services). Therefore, the characterization of cumulative effects does take into account that demand from other projects and physical activities would exacerbate the magnitude of effects. Further, as noted in Section 6.3.7 of the Application, cumulative adverse effects on accommodations and health care infrastructure and services are anticipated to be significant while Project-specific residual adverse effects on accommodation and health care infrastructure and services are anticipated to be not significant.
1151.1	round 1	Metlakatla First Nation	6.5.2.5	Marine Use and Navigable Waters	A figure identifying alternate routes has not been provided. It is inappropriate to exclude alternate routes from assessment without identifying their locations and quantifying what "infrequent" use means as part of an overall rationale for exclusion. This is particularly important if alternate routes used in inclement conditions will bring vessels into areas with high harvesting intensity or closer to conservancies where accidents or malfunctions may have greater adverse consequences.	The assessment of Marine Use and Navigable Waters was done using the primary shipping route. This choice was conservative because it represents the route that most large shipping traffic will use and therefore has the greatest potential for adverse effects to marine navigation and fisheries. As described in Section 6.5.2 of the Application, while alternative shipping routes exist, LNG carriers would only ever deviate from the prescribed route under extraneous circumstances (e.g., such as under the direction of the LNG carrier captain or marine pilot to avoid a collision or other emergency). As a result, the assessment focused on the primary shipping route.
1152.1	round 1	Metlakatla First Nation	6.5.3	Marine Use and Navigable Waters	It is inappropriate to suggest that "most invertebrate harvesting locations do not appear to overlap with the shipping route (mainly because they are harvested during low tide in the intertidal zone." In fact, harvesters working on foot in the intertidal zone have repeatedly expressed concern that vessel wake in specific local areas may cause a danger to harvesters. Since wave patterns are extremely difficult to predict, a robust monitoring and adaptive management program is required to identify any locations where wake appears to be a problem during operations and to develop additional mitigations.	If it is conservatively assumed that intertidal harvesters on foot are using both low tide periods in a day (this is unlikely, because the two low tides in a day are not often the same tidal height and, therefore, one is more suitable for harvesting than the other), and harvesting can be undertaken for two hours during each low tide (i.e., one hour on each side of each low), then approximately 17% (4/24 hours) of each day is available for intertidal harvesting. The potential for intertidal harvesters to interact with Project-related shipping is temporally restricted on a daily basis; for approximately 83% of each day, wake from Project-related shipping cannot interact with intertidal harvesters Section 6.5.4.2 states that the mean monthly average natural wave height in the Project area is assumed to be between 0.14 m and 1.8 m. The potential maximum wave height (immediately adjacent to the source vessel) of 0.4 m produced by LNG carriers and escort vessels at 12 knots is within the range of anticipated mean monthly average wave height in the Project area. The modeled wake height of LNG carriers (and other vessel types) indicates that wake-related waves attenuate as they travel further from the source vessel (Oceanic Consulting Corporation 2014). This means that the actual wave height at the shoreline is expected to be lower than the wake height at the source vessel, and within the natural wave height range currently experienced by intertidal harvesters. Project-related traffic will travel along the existing and established shipping route currently used by marine traffic (e.g., container ships, cargo ships, breakbulk ships, ferries) to enter and exit Prince Rupert harbour. The predicted wake-related wave height 300 m from the centreline of travel of a large loaded LNG carrier traveling 12 knots (and that modeled for 14 knots) is similar to those predicted for ore carriers, cruise ships, and BC Ferries vessels (Oceanic Consulting Corporation 2014), all of which call at the Port of Prince Rupert. Project-related wake effects are not expected to differ from the variable wave heights and conditions already experienced by intertidal harvesters, relating to natural weather patterns and existing shipping. Reference Oceanic Consulting Corporation. 2014. Kitimat Ship Wake Study. Prepared for: LNG Canada Development Inc.
1153.1	round 1	Metlakatla First Nation	6.5.3	Marine Use and Navigable Waters	See comment above #809	It is not clear what this comment refers to.
1154.1	round 1	Metlakatla First Nation	Table 6.5-12	Marine Use and Navigable Waters	First Nations have consistently indicated concern about the effects of dredge disposal traffic on marine fisheries and other uses. Please provide a rationale for its exclusion from consideration and assessment.	Dredging and disposal at sea activities will be limited to the DFO least risk timing window (November 30 to February 15) and is planned to take place over two years. See Appendix G (Technical Memorandum - Aurora LNG: MOF and Terminal Dredge Modelling) and Appendix H (Technical Memorandum - Aurora LNG: Disposal at Sea Modelling) for additional dredge timing information. Table 6.5-12 indicates that dredging was identified as a construction-related physical activity that could affect marine use and navigable waters. In the context of the operational life of the Project, dredging will occur over a relatively short period during the construction phase, barges will be located outside of major navigation routes during loading, and barges will travel at relatively slow speeds while under way. For these reasons, the effects of dredge-related traffic was not assessed further (see rationale provided in Section 6.5.4.1). However, see the "Effects of Additional Project-related Traffic" technical memo for additional information on dredge-related marine traffic. The technical memo will be filed with the BC EAO.
1155.1	round 1	Metlakatla First Nation	6.5.4.1	Marine Use and Navigable Waters	The Application states that smaller vessels associated with construction "were not carried forward in the assessment of marine use and navigable waters because this vessel traffic does not represent the worst case scenario for potential adverse effects." Failure to include these vessels significantly underrepresents effects to efficiency of movement, access to berthing, and potential for vessel accidents due to vessel congestion between Digby and Kaien Island. To adequately assess effects; both vessel types need to be included in the assessment; numbers, however, should be disaggregated to identify increases in number of small vessels. This is of particular interest and relevance to harvesters in smaller vessels.	See the "Small Craft Assessment" technical memo which will be filed with the BC EAO.
1156.1	round 1	Metlakatla First Nation	6.5.4.1	Marine Use and Navigable Waters	Please provide duration (weeks or months) for disposal, season, and number of seasons, and use this information to provide a robust rationale for the decision not to assess the potential adverse effects of dredging traffic on marine use.	See the "Effects of Additional Project-Related Traffic" technical memo which will be filed with the BC EAO.
1157.1	round 1	Metlakatla First Nation	6.5.4.2	Marine Use and Navigable Waters	It is inappropriate to suggest that "most invertebrate harvesting locations do not appear to overlap with the shipping route (mainly because they are harvested during low tide in the intertidal zone." In fact, harvesters working on foot in the intertidal zone have repeatedly expressed concern that vessel wake in specific local areas may cause a danger to harvesters. Since wave patterns are extremely difficult to predict, a robust monitoring and adaptive management program is required to identify any locations where wake appears to be a problem during operations and to develop additional mitigations. Rather than stating that "no further assessment of vessel wake is warranted", it is appropriate to state that the complexities of modelling suggest uncertainty regarding effects; an adaptive management program is therefore required.	If it is conservatively assumed that intertidal harvesters on foot are using both low tide periods in a day (this is unlikely, because the two low tides in a day are not often the same tidal height and, therefore, one is more suitable for harvesting than the other), and harvesting can be undertaken for two hours during each low tide (i.e., one hour on each side of each low), then approximately 17% (4/24 hours) of each day is available for intertidal harvesting. The potential for intertidal harvesters to interact with Project-related shipping is temporally restricted on a daily basis; for approximately 83% of each day, wake from Project-related shipping cannot interact with intertidal harvesters Section 6.5.4.2 states that the mean monthly average natural wave height in the Project area is assumed to be between 0.14 m and 1.8 m. The potential maximum wave height (immediately adjacent to the source vessel) of 0.4 m produced by LNG carriers and escort vessels at 12 knots is within the range of anticipated mean monthly average wave height in the Project area. The modeled wake height of LNG carriers (and other vessel types) indicates that wake-related waves attenuate as they travel further from the source vessel (Oceanic Consulting Corporation 2014). This means that the actual wave height at the shoreline is expected to be lower than the wake height at the source vessel, and within the natural wave height range currently experienced by intertidal harvesters. Project-related traffic will travel along the existing and established shipping route currently used by marine traffic (e.g., container ships, cargo ships, breakbulk ships, ferries) to enter and exit Prince Rupert harbour. The predicted wake-related wave height 300 m from the centreline of travel of a large loaded LNG carrier traveling 12 knots (and that modeled for 14 knots) is similar to those predicted for ore carriers, cruise ships, and BC Ferries vessels (Oceanic Consulting Corporation 2014), all of which call at the Port of Prince Rupert. Project-related wake effects are not expected to differ from the variable wave heights and conditions already experienced by intertidal harvesters, relating to natural weather patterns and existing shipping. Reference Oceanic Consulting Corporation. 2014. Kitimat Ship Wake Study. Prepared for: LNG Canada Development Inc.
1158.1	round 1	Metlakatla First Nation	6.5.4.3	Marine Use and Navigable Waters	A figure identifying alternate routes has not been provided. It is inappropriate to exclude alternate routes from assessment without identifying their locations and quantifying what "infrequent" use means as part of an overall rationale for exclusion. This is particularly important if alternate routes used in inclement conditions will bring vessels into areas with high harvesting intensity or closer to conservancies where accidents or malfunctions may have greater adverse consequences.	The assessment of Marine Use and Navigable Waters was done using the primary shipping route. This choice was conservative because it represents the route that most large shipping traffic will use and therefore has the greatest potential for adverse effects to marine navigation and fisheries. As described in Section 6.5.2 of the Application, while alternative shipping routes exist, LNG carriers would only ever deviate from the prescribed route under extraneous circumstances (e.g., such as under the direction of the LNG carrier captain or marine pilot to avoid a collision or other emergency). As a result, the assessment focused on the primary shipping route.
1159.1	round 1	Metlakatla First Nation	6.5.5.1	Marine Use and Navigable Waters	See comment associated with section 6.5.4.1. Effects of carriers and small vessels must each be assessed; data on each should be disaggregated to understand individual effects by vessel size class ("large size" versus "other")	Please see the "Small Craft Assessment" technical memo which will be filed with the BC EAO.
1160.1	round 1	Metlakatla First Nation	6.05	Marine Use and Navigable Waters	The assessment states: "The assessment begins by determining if two key conditions are met: 1) if the fishing grounds overlap with the shipping route, and 2) if the fishing techniques used (i.e., fishing gear type or local fishing practices) could interact with shipping traffic." Travel routes TO and FROM fishing grounds (not just fishing grounds themselves) also need to be considered because impeded travel routes are tantamount to loss of fishing grounds.	See the "Effects of Lost Fishing Time" technical memo for a description of the anticipated conditions required for an LNG carrier-fishing vessel interaction. The technical memo will be filed with the BC EAO. Given the proposed mitigation measures related to marine traffic described in Table 6.5-13, and because Project-related traffic will travel along the existing and established shipping route currently used by other marine traffic (e.g., container ships, cargo ships, breakbulk ships, ferries) to access the Port of Prince Rupert, Project-related traffic is not expected to substantially impede access travel routes over current conditions. The assessment of Metlakatla First Nation's current use fishing practices (see Section 11.3.8.3 of the Application) considered the quantity (area) and quality of current access routes where use will be affected and determined that, with the implementation of the proposed mitigation measures, it is unlikely that Project-related marine traffic will reduce access to fishing sites along the shipping route, as marine users will still be able to travel through the existing shipping lanes. Aurora LNG welcomes further discussions with Metlakatla First Nation to better understand the community concerns.
1161.1	round 1	Metlakatla First Nation	Table 6.5-13	Marine Use and Navigable Waters	All of these mitigations assume smaller vessels must give way to larger (LNG) vessels. While this is appropriate mariner behaviour, it does not address the fact that changing behaviour to accommodate LNG vessels requires a deviation from preferred routing or activities. This represents an adverse effect on the exercise of traditional rights and must be addressed in Part C of the application.	Given the proposed mitigation measures related to marine traffic described in Table 6.5-13, and because Project-related traffic will travel along the existing and established shipping route currently used by other marine traffic (e.g., container ships, cargo ships, breakbulk ships, ferries) to access the Port of Prince Rupert, Project-related traffic is not expected to require deviation from preferred marine routes or activities. The assessment of effects on Metlakatla First Nation's harvesting-related Aboriginal Interests (Section 12.5.5.6) considered effects resulting from Project-related shipping activities. Because shipping has occurred along the shipping route for decades, it is expected that smaller vessel mariners will be accustomed to navigating around large vessel traffic. Given the proposed mitigation, it is unlikely that two LNG carrier transits per day associated with the Project would reduce access to current traditional use sites located along the shipping route, as marine users will still be able to travel through the existing shipping lanes. Travel routes to current traditional use locations that overlap with the Project shipping route are expected to maintain their current level of safety and access after the application of mitigation measures. Aurora LNG welcomes further discussion with Metlakatla First Nation to better understand their community concerns.
1162.1	round 1	Metlakatla First Nation	6.5.5.2	Marine Use and Navigable Waters	The Application notes that 17% of the small vessel corridor will be alienated. The Application does not, however, indicate how many more small vessels will be using this corridor during the 5-year construction period. It is not possible, therefore, to fully assess the effects of the project on marine use. Vessel congestion in the reduced small vessel corridor may be considerable and needs to be quantified before it can be dismissed from consideration.	See the "Small Craft Assessment" technical memo which will be filed with the BC EAO.

1163.1	round 1	Metlakatla First Nation	6.5.5.3	Marine Use and Navigable Waters	The Application notes that "a fisher may lose a total of one hour of fishing per day). This is a misleading statement because among other things, it implies fishing occurs year round. Harvesting windows for many species are considerably smaller and weather conditions and tides further limit fishing opportunity, thus a one-hour limitation is most definitely more significant than implied.	See the "Effects of Lost Fishing Time" technical memo which will be filed with the BC EAO.
1164.1	round 1	Metlakatla First Nation	6.05	Marine Use and Navigable Waters	A potentially effective mitigation would be to understand diurnal and seasonal travel patterns of First Nation fishers and avoid having LNG carriers enter the harbour area during those times.	Aurora LNG acknowledges this mitigation measure suggestion. In addition, Aurora LNG requested and received specific feedback on proposed mitigation measures from Metlakatla First Nation during Technical Workshops #4 and #5. Aurora LNG is currently reviewing feedback received to date on mitigation measures and any revised or new mitigation measures proposed will be included as part of an updated Table 16-1 and 16-2 to be submitted to the BC EAO on Day 90. As described in Section 6.5.3.3 of the Application, Aurora LNG will develop a Marine Activities Plan (Mitigation 6.5.2) to describe how the Project's marine activities will be managed to avoid or reduce effects on current marine users and other stakeholders. Aurora LNG will engage with regulatory agencies, Aboriginal Groups, marine users, and other interested stakeholders in the development of this plan. Additional input to the planning process will result from the safe-shipping workshops and the recommendations from the TERMPOL study.
1165.1	round 1	Metlakatla First Nation	Table 6.5-15	Marine Use and Navigable Waters	Given the exclusion of small construction vessels from assessment, Metlakatla feels that the determination of magnitude of residual effects of construction is not accurate.	See the "Effects of Additional Project-Related Traffic" technical memo which will be filed with the BC EAO.
1166.1	round 1	Metlakatla First Nation	6.5.6.3	Marine Use and Navigable Waters	Given the exclusion of small construction vessels from assessment, Metlakatla feels that the determination of magnitude of residual effects of construction is not accurate.	See the "Effects of Additional Project-Related Traffic" technical memo which will be filed with the BC EAO.
1167.1	round 1	Metlakatla First Nation	6.5.6.5	Marine Use and Navigable Waters	Given the exclusion of small construction vessels from assessment, Metlakatla feels that the determination of magnitude of residual effects of construction is not accurate.	See the "Effects of Additional Project-Related Traffic" technical memo which will be filed with the BC EAO.
1168.1	round 1	Metlakatla First Nation	6.05	Marine Use and Navigable Waters	Because only fishing grounds and not travel routes to/from fishing grounds are considered, an accurate characterization and likelihood determination is not possible. The same comment applies to cumulative effects characteriziation and likelihood determination.	See the "Effects of Lost Fishing Time" technical memo for a description of the anticipated conditions required for an LNG carrier-fishing vessel interaction. The technical memo will be filed with the BC EAO. Given the proposed mitigation measures related to marine traffic described in Table 6.5-13, and because Project-related traffic will travel along the existing and established shipping route currently used by other marine traffic (e.g., container ships, cargo ships, breakbulk ships, ferries) to access the Port of Prince Rupert, Project-related traffic is not expected to substantially impede access travel routes over current conditions. The assessment of Metlakatla First Nation's current use fishing practices (see Section 11.3.8.3 of the Application) considered the quantity (area) and quality of current access routes where use will be affected and determined that, with the implementation of the proposed mitigation measures, it is unlikely that Project-related marine traffic will reduce access to fishing sites along the shipping route, as marine users will still be able to travel through the existing shipping lanes. Aurora LNG welcomes further discussions with Metlakatla First Nation to better understand the community concerns.
1169.1	round 1	Metlakatla First Nation	6.06	Community Health	Metlakatla has consistently commented that in the context of community health, volume of food harvested or consumption levels are not adequate as measurable parameters in the absence of a consideration of participation levels. Theoretically, a few people could harvest a great volume of food while majority of people are not practicing harvesting methods or "getting out on the water/land". Metlakatla's socio-economic work shows that a key aspect to communtiy well being is participating in food, social and ceremonial (FSC) activities. Metlakatla provided data on FSC participation rates. Adverse effects to FSC participation reduces overall communtiy well being, knowledge transfer, individual health of members, and social fabric. It is important to consider participation rates in the assessment to get an accurate assessment of how the proect affects First Nation community health.	As per responses to screening comment #251 on the draft Application Information Requirements (AIR), in accordance with AIR requirements (specifically Table 6-9) and identified in Table 6.6-2, measurable parameters to be considered in the qualitative assessment of change in harvested foods include volume of foods harvested and harvested food consumption. Consideration of (FSC) participation rates are not a requirement of the AIR. Noted in screening comment #251 of the draft AIR, Section 11.3 addresses specific requirements of CEAA 2012 regarding the effects of the environment on Aboriginal peoples, commonly referred to as the 5(1)(c) effects (i.e., health and socio-economic conditions, physical and cultural heritage, current use of lands and resources for traditional purposes, and any structure, site or thing that is of historical, archaeological, paleontological or architectural significance). In addition, Section 12 assesses how the project could potentially affect the interests of Schedule B Aboriginal Groups. Section 11.3.8.3 assesses Metlakatla First Nation members' ability to conduct traditional practices within their traditional territory due to changes in consumptive land and resource use for traditional purposes and changes in non-consumptive land and resource use for traditional purposes. Section 11.3.8.4 assesses how Metlakatla member health may be affected by changes in air quality, harvested food quality or quantity, and noise levels. Section 11.3.8.5 assesses how Metlakatla socio-economic conditions may be affected by changes to visual quality, the acoustic environment, or harvested foods. Section 11.3.8.6 assesses how Metlakatla physical and cultural heritage may be affected by changes to archaeological and heritage resources, and changes to consumptive and non-consumptive use of lands and resources for traditional purposes. Section 12 assesses effects on Metlakatla First Nation Cultural Wellbeing (see Section 12.5.5.7) including consideration of participation in cultural and spiritual activities (see the subsection 'Change in Locations, Landforms, Natural Features and Access Routes Associated with Cultural and Spiritual Use or Place Name-Names") and cultural transmission (see subsection 'Interruption to Cultural Transmission Between Generations'). Through mitigation 6.3.11, Aurora LNG will engage with local communities and Aboriginal Groups to address community concerns associated with the Project. Issues and concerns related to Project-influenced changes in participation rates, should they occur, could be further addressed through this mitigation measure.
1170.1	round 1	Metlakatla First Nation	6.06	Community Health	This part of the assessment needs to link back to changes to marine fisheries and specifically Metlakatla's previous comment about the need to consider LNG shipping impeding access to and from harvesting grounds (not just the grounds themselves). An adverse effect on ability to access fishing grounds will have a corollary effect on harvest levels.	The assessment of change in harvested foods provided in Section 6.6 of the Application (Community Health) as well as the assessment of change in marine fisheries and other uses provided in Section 6.5 of the Application (Marine Use and Navigable Waters), which informs the assessment of change in harvested foods provided in Section 6.6, both consider changes in access to and from harvesting grounds as well as changes in access to grounds themselves. In Section 6.6, the assessment of change in harvested foods considers effects on access (to and from grounds as well as on grounds themselves) through the effect mechanism 'change in accessibility to harvested foods (marine and terrestrial)' as identified in Table 6.6-2. This effect mechanism results in the identification of potential interactions, among others, between LNG shipping (i.e., changes in access to and from harvesting grounds) and marine construction (i.e., changes in accesses to harvesting grounds themselves) and the potential effect change in harvested foods as identified in Table 6.6-17 (Project Interactions with Community Health). These interactions, among others, are assessed in Section 6.6.5.4 of the Application. Similarly, informing the assessment of change in harvested foods (Section 6.6.5.4), Section 6.5 (Marine Use and Navigable Waters) considers effect mechanisms related to shipping and the construction and operation of marine infrastructure in assessment of change in marine fisheries as measured through the 'shipping traffic (ships per year)' and 'fisheries area affected' (see Table 6.5-3 of the Application). Marine construction and LNG shipping are identified as interactions with the potential effect - change in marine fisheries and other uses. These interactions are assessed in Section 6.5.5.3 of the Application.
1171.1	round 1	Metlakatla First Nation	6.06	Community Health	The "stay in camp" policy will do little to address impacts to community health from workers spending their time off in LAA communities. Mitigations that financially incent workers to return to their home communities during time off is a more effective strategy that should be considered.	Fly-in/Fly-out (FIFO) workers are estimated to comprise 95% of the peak construction workforce with the remaining 5% expected to be hired from the LAA and RAA (see section 6.3.5.2 of the Application). Transportation of workers from their home communities to the Project site will be coordinated by Aurora LNG. Aurora LNG anticipates adopting a logistics policy that requires FIFO workers to be transported to and from the Project and their point of hire (i.e., home communities). This logistics policy combined with the closed-access camp policy (that workers will be expected to remain onsite for the duration of their shifts) will limit the opportunity FIFO workers have to interact in local communities. Aurora LNG acknowledges that this limits the potential for adverse effects but also reduces potential benefits of the Project on nearby communities. Where workers are hired from local communities, there exists potential for adverse effects when these workers are off shift. Through mitigation 6.3.3, all staff and contractors will be required to undertake worker orientation, including communication of expected behavior when transiting to/from local communities (i.e., a worker code of conduct) and cross-cultural awareness to help build awareness and respect of local concerns and customs to reinforce the importance of respectful conduct when in communities). Through this mitigation, Aurora LNG's will work to reduce the magnitude of adverse effects on infrastructure and services and community health when local workers are off shift and in local communities. Aurora LNG does not have control over the behavior and actions of workers when off duty and must therefore rely on communication of behavioral expectations to workers (such as those proposed through mitigation 6.3.3) to help reduce adverse effects of workers on local communities when off-shift.
1172.1	round 1	Metlakatla First Nation	6.06	Community Health	Based on Nexen's assessment, a high magnitude of adverse effects on community health during construction within Prince Rupert and Port Edward seems more likely.	Residual effect characterizations provided in Section 6.3.5 and summarized in Section 6.6.5.3 of the Application take into consideration factors such as the Project's location on Digby Island (without fixed link to Prince Rupert), local and in-migrant employment estimates (see Section 6.3.5.2), camp policies (closed-access), logistics planning (that fly-in/fly-out workers will be transported to and from points of hire at the beginning and end of their work shifts), and the proposed mitigation measures in the characterization of adverse residual effects. Given the above, due to the proximity of the Project to Dodge Cove and Crippen Cove, residents in these communities are predicted to experience high magnitude effects on change in community health and wellness during construction and decommissioning and moderate magnitude effects during operation. For remaining communities within the LAA, including Port Edward and Prince Rupert, adverse residual effects on change in community health and wellness are predicted to be moderate during construction and decommissioning and low during operation.
1173.1	round 1	Metlakatla First Nation	6.06	Community Health	An effective potential mitigation could be providing an offset for reductions on harvest activities due to the project, e.g. increasing the capacity for First Nation people to access harvest areas and partake in marine and terrestrial harvest activities through provision of equipment.	Aurora LNG is confident that the suite of mitigation measures proposed in Table 6.6-21 of the Application will effectively manage adverse residual effects on change in harvested foods. The provision of equipment to increase capacity of First Nation members to partake in harvesting areas is not currently proposed.
1174.1	round 1	Metlakatla First Nation	6.06	Community Health	An accurate characterization is not possible without consideration of how the project affects FSC participation rates.	As per responses to screening comment #251 on the draft Application Information Requirements (AIR), in accordance with AIR requirements (specifically Table 6-9) and identified in Table 6.6-2, measurable parameters to be considered in the qualitative assessment of change in harvested foods include volume of foods harvested and harvested food consumption. Consideration of (FSC) participation rates are not a requirement of the AIR. Noted in screening comment #251 of the draft AIR, Section 11.3 addresses specific requirements of CEAA 2012 regarding the effects of the environment on Aboriginal peoples, commonly referred to as the 5(1)(c) effects (i.e., health and socio-economic conditions, physical and cultural heritage, current use of lands and resources for traditional purposes, and any structure, site or thing that is of historical, archaeological, paleontological or architectural significance). In addition, Section 12 assesses how the project could potentially affect the interests of Schedule B Aboriginal Groups. Section 11.3.8.3 assesses Metlakatla First Nation members' ability to conduct traditional practices within their traditional territory due to changes in consumptive land and resource use for traditional purposes and changes in non-consumptive land and resource use for traditional purposes. Section 11.3.8.4 assesses how Metlakatla member health may be affected by changes in air quality, harvested food quality or quantity, and noise levels. Section 11.3.8.5 assesses how Metlakatla socio-economic conditions may be affected by changes to visual quality, the acoustic environment, or harvested foods. Section 11.3.8.6 assesses how Metlakatla physical and cultural heritage may be affected by changes to archaeological and heritage resources, and changes to consumptive and non-consumptive use of lands and resources for traditional purposes. Section 12 assesses effects on Metlakatla First Nation Cultural Wellbeing (see Section 12.5.5.7) including consideration of participation in cultural and spiritual activities (see the subsection 'Change in Locations, Landforms, Natural Features and Access Routes Associated with Cultural and Spiritual Use or Place Name-Names") and cultural transmission (see subsection 'Interruption to Cultural Transmission Between Generations'). Through mitigation 6.3.11, Aurora LNG will engage with local communities and Aboriginal Groups to address community concerns associated with the Project. Issues and concerns related to Project-influenced changes in participation rates, should they occur, could be further addressed through this mitigation measure.

1175.1	round 1	Metlakatla First Nation	7.2.2.4, second paragraph	Heritage	"Any potential effects on archaeological and heritage resources are most likely to occur during the construction phase when ground disturbance and tree removal will occur". Metlakatla disagrees- potential effects are just as likely during the pre-construction phase (geotech program, ESA program), operation phase (increased public use of area resulting in rutting and looting due to development), and decommissioning phase (building demolition and reclaimation). These other phases of the project need to be scoped into the assessment in Chapter 7.	Potential Project interactions with archaeological and heritage resources are only anticipated to occur during activities that result in tree removal or ground disturbance (including dredging) during the construction phase. The operation and decommissioning phases are not anticipated to result in additional tree removal or ground disturbance (including dredging) outside of the area affected during the construction phase, and therefore do not have potential to cause a measurable interaction with archaeological and heritage resources. Access to archaeological sites within the LAA/RAA by members of the public is not anticipated to increase during the construction and operation phases, as there will be on-site security services and restricted access to the PDA. Access to archaeological sites by project personnel is not anticipated (see mitigation 6.4.4). Therefore, tree removal or ground disturbance related to increased human presence are not anticipated and human presence is unlikely to cause a measurable interaction with archaeological and heritage resources.
1176.1	round 1	Metlakatla First Nation	7.2.2.4, Table 7-2, second column	Heritage	The pre-construction, operation and decommissioning phases should be discussed in this table and assessed in Chapter 7.	Potential Project interactions with archaeological and heritage resources are only anticipated to occur during activities that result in tree removal or ground disturbance (including dredging) during the construction phase. The operation and decommissioning phases are not anticipated to result in additional tree removal or ground disturbance (including dredging) outside of the area affected during the construction phase, and therefore do not have potential to cause a measurable interaction with archaeological and heritage resources. There is no pre-construction phase within the scope of the environmental assessment; however, the term is used in Section 7 when referring to a mitigation measure that could occur prior to construction phase. An errata documentis being compiled that captures these corrections and it will be filed with the BC EAO.
1177.1	round 1	Metlakatla First Nation	7.2.2.5, Table 7-3, second row	Heritage	RAA is incorrectly defined and should minimally be set to the Borden block level (16 x 16 km area) or, better, at the broader coast Tsimshian Territory level. RAA is meant to "provide context for the assessment of potential project effects" and is often "used as the spatial boundary for the assessment of potential cumulative effects" (EAO Valued Component Guidelines). A broader area than just the LAA/PDA is required to properly evaluate site significance. For example, at the LAA/PDA level there may be five shell middens. The decision may be made to avoid four and destroy one. At the LAA level, this feels comfortable - you've preserved four of five! However, when using a broader, and we would argue more appropriate RAA, we may find out that there are only five midden sites across the entire Borden block or the entire coastal Tsimshian territory. Now all of a sudden the loss of the one shell midden is more concerning, maybe to the point where all five should be preserved.	The regional archaeology and heritage setting relative to the Project is addressed in the permitted archaeological impact assessment reporting, completed in accordance with regulatory guidelines. Within the Application process, the AIR describes the LAA and RAA as being the Project Development Area and this is consistent with what is included in the Application, Section 7.2.2.5. The LAA and RAA are used to assess effects during all project phases; however, only construction activities are predicted to have an effect on this VC because vegetation clearing and ground disturbance with the potential to impact archaeological and heritage resources will be completed during the construction phase. In accordance with the AIR, an assessment of cumulative effects on archaeological and heritage resources was not undertaken as the following two conditions were not met: 1) proposed Project is assessed as having residual effects on the VC and 2) residual effects could act cumulatively with residual effects of other past, present, or reasonably foreseeable future physical activities. Further assessment of cumulative effects on archaeological and heritage resources is not warranted because the Project effects on archaeological and heritage resources will be mitigated prior to alteration. As a result, there are no predicted residual effects to archaeological and heritage resources. Consequently, the Project is not expected to interact cumulatively with potential residual effects from other projects or activities.
1178.1	round 1	Metlakatla First Nation	7.2.2.5, Temporal Boundaries	Heritage	As previously mentioned, the pre-construction phase should be added to the bulleted list and included in the assessment.	There is no pre-construction phase within the scope of the environmental assessment; however, the term is used in Section 7 when referring to a mitigation measure that could occur prior to construction phase. An errata documentis being compiled that captures these corrections and it will be filed with the BC EAO.
1179.1	round 1	Metlakatla First Nation	7.2.2.6, Table 7-4, first row (Magnitude), fourth column	Heritage	For the low magnatiude definition - site significance is not important but rather information loss to an archaeological site is. The wording should be revised to state "A measureable change but is limited to a small amount of information loss at an archaeological or heritage site." This change would also better match the contents of the 'Likelihood' section that follows.	Negligible magnitude is defined as "no measurable change from existing (baseline) conditions (i.e., no loss of information"). Low, moderate and high magnitude are defined in reference to site significance and previous disturbance that could create an effect (i.e., a loss of information) relative to existing conditions. Therefore, the wording will not be revised.
1180.1	round 1	Metlakatla First Nation	7.2.2.6, Table 7-4, first row (Magnitude), fourth column	Heritage	For moderate magnatiude definition - site significance is not important but rather information loss to an archaeological site is. Please revise current wording to read "A measureable change but is limited to a moderate amount of information loss at an archaeological or heritage site." This change would also better match the 'Likelihood' section that follows.	Negligible magnitude is defined as "no measurable change from existing (baseline) conditions (i.e., no loss of information"). Low, moderate and high magnitude are defined in reference to site significance and previous disturbance that could create an effect (i.e., a loss of information) relative to existing conditions. Therefore, a revision to the chapter is not considered warranted.
1181.1	round 1	Metlakatla First Nation	7.2.2.6, Table 7-4, first row (Magnitude), fourth column	Heritage	For high magnatiude definition - site significance is not important but rather information loss to an archaeological site. Please revise current wording to read "A measureable change but is limited to a high amount of information loss at an archaeological or heritage site." This change would also make this entry better match the 'Likelihood' section that follows.	Negligible magnitude is defined as "no measurable change from existing (baseline) conditions (i.e., no loss of information"). Low, moderate and high magnitude are defined in reference to site significance and previous disturbance that could create an effect (i.e., a loss of information) relative to existing conditions. Therefore, a revision to the chapter is not considered warranted.
1182.1	round 1	Metlakatla First Nation	7.2.2.6, Table 7-4, second row (Geographic Extent), fourth column	Heritage	As mentioned above, additional discussions are required to address the RAA's geographic extent.	The regional setting for archaeology and heritage is addressed in the permitted AIA report (Appendix W). The AIA was completed in accordance with regulatory guidelines and considers appropriate regional data to assess the significance of, and potential effects to, sites situated in the LAA/RAA.Within the Application process, the AIR describes the LAA and RAA as being the Project Development Area and this is consistent with what is included in the Application, Section 7.2.2.5. The LAA and RAA are used to assess effects during all project phases; however, only construction activities are predicted to have an effect on this VC because vegetation clearing and ground disturbance with the potential to impact archaeological and heritage resources will be completed during the construction phase.
1183.1	round 1	Metlakatla First Nation	7.2.2.6, Table 7-4, third row (Frequency), fourth column	Heritage	To the definition of 'Multiple irregular events', pre-construction, operation, and decommissioning phases in addition to the construction phase need to be considered.	Potential Project interactions with archaeological and heritage resources are only anticipated to occur during activities that result in tree removal or ground disturbance (including dredging) during the construction phase. The operation and decommissioning phases are not anticipated to result in additional tree removal or ground disturbance (including dredging) outside of the area affected during the construction phase, and therefore do not have potential to cause a measurable interaction with archaeological and heritage resources. Access to archaeological sites within the LAA/RAA by members of the public is not anticipated to increase during the construction and operation phases, as there will be on-site security services and restricted access to the PDA. Access to archaeological sites by project personnel is not anticipated (see mitigation 6.4.4). Therefore, tree removal or ground disturbance related to increased human presence are not anticipated and human presence is unlikely to cause a measurable interaction with archaeological and heritage resources
1184.1	round 1	Metlakatla First Nation	7.2.2.6, Table 7-4, third row (Frequency), fourth column	Heritage	To the definition of "Continuous" need to ensure this is from the pre-construction phase through to decommissioning so that it is clear what the life of the Project is referring to.	The term "continuous" in Table 7-4 is defined as "occurs continuously throughout the life of the Project", which is the construction, operations and decommissioning phases. There is no pre-construction phase, however, the term is used in Section 7 when referring to a mitigation measure that could occur prior to construction phase. An errata documentis being compiled that captures these corrections and it will be filed with the BC EAO.
1185.1	round 1	Metlakatla First Nation	7.2.2.6, Table 7-4 (Context), 4th column	Heritage	"Disturbed" archaeological sites may not be in their original primary context however there is still an opportunity for data recovery (eg. artifact analysis) and in the case of shell midden, potential for ancestral remains.	The qualitative categories ("disturbed", "undisturbed") in Table 7-4 refer to a site's research potential based on the extent to which it may have been adversely affected by human activity, and does not preclude analysis of finds from disturbed contexts.
1186.1	round 1	Metlakatla First Nation	7.2.4, second paragraph	Heritage	Add pre-construction, operation, and decommissioning to phases mentioned in the project.	Potential Project interactions with archaeological and heritage resources are only anticipated to occur during activities that result in tree removal or ground disturbance (including dredging) during the construction phase. The operation and decommissioning phases are not anticipated to result in additional tree removal or ground disturbance (including dredging) outside of the area affected during the construction phase, and therefore do not have potential to cause a measurable interaction with archaeological and heritage resources. There is no pre-construction phase within the scope of the environmental assessment; however, the term is used in Section 7 when referring to a mitigation measure that could occur prior to construction phase. An errata documentis being compiled that captures these corrections and it will be filed with the BC EAO.
1187.1	round 1	Metlakatla First Nation	7.2.4, Table 7-6, Operations	Heritage	Add "Public Access and Use of the Development and Surrounding Area" and check it off as a potential effect. The development will result in a significant increase in human activity in the area, increasing the liklihood of pedestrian/off road vehicle-related disturbance to sites and the potential for looting of archaeological resources.	Potential Project interactions with archaeological and heritage resources are only anticipated to occur during activities that result in tree removal or ground disturbance (including dredging) during the construction phase. Access to archaeological sites within the LAA/RAA by members of the public is not anticipated to increase during the construction and operation phases, as there will be on-site security services and restricted access to the PDA. Access to archaeological sites by project personnel is not anticipated (see mitigation 6.4.4). Therefore, tree removal or ground disturbance related to increased human presence are not anticipated and human presence is unlikely to cause a measurable interaction with archaeological and heritage resources.
1188.1	round 1	Metlakatla First Nation	7.2.4, Table 7-6, Decommissioning and Abandonment, first row	Heritage	The "Dismantaling of land-based and marine infrastructure" has the potential to impact archaeological and heritage resources, and therefore should checkmarked instead of a dash. Please ensure this is fully assessed.	Dismantling of land-based and marine infrastructure is not anticipated to result in additional tree removal or ground disturbance (including dredging) outside of the area affected during the construction phase, and therefore do not have potential to cause a measurable interaction with archaeological and heritage resources additional to that which occurs during the construction phase.
1189.1	round 1	Metlakatla First Nation	7.2.4, Table 7-6, Decommissioning and Abandonment, second row	Heritage	The "Remediation and reclamation of the site" has the potential to impact archaeological and heritage resources, and therefore should be a checkmark instead of a dash; this impact should be fully assessed.	Remediation and reclamation of the site is not anticipated to result in additional tree removal or ground disturbance (including dredging) outside of the area affected during the construction phase, and therefore do not have potential to cause a measurable interaction with archaeological and heritage resources additional to that which occurs during the construction phase.
1190.1	round 1	Metlakatla First Nation	7.2.5.1, Assumptions	Heritage	Until the RAA's geographic boundary is adjusted and studied, it is premature to say the potential effects at the RAA level are well understood.	The regional archaeology and heritage setting relative to the Project is addressed in the permitted archaeological impact assessment reporting, completed in accordance with regulatory guidelines. Within the Application process, the AIR describes the LAA and RAA as being the Project Development Area and this is consistent with what is included in the Application, Section 7.2.2.5. The LAA and RAA are used to assess effects during all project phases; however, only construction activities are predicted to have an effect on this VC because vegetation clearing and ground disturbance with the potential to impact archaeological and heritage resources will be completed during the construction phase. In accordance with the AIR, an assessment of cumulative effects on archaeological and heritage resources was not undertaken as the following two conditions were not met: 1) proposed Project is assessed as having residual effects on the VC and 2) residual effects could act cumulatively with residual effects of other past, present, or reasonably foreseeable future physical activities. Further assessment of cumulative effects on archaeological and heritage resources is not warranted because the Project effects on archaeological and heritage resources will be mitigated prior to alteration. As a result, there are no predicted residual effects to archaeological and heritage resources. Consequently, the Project is not expected to interact cumulatively with potential residual effects from other projects or activities.
1191.1	round 1	Metlakatla First Nation	7.2.5.2, Project Mechanisms section, first paragraph	Heritage	Should include mention and discussion of pre-construction, operation, and decommissioning phases of project.	Potential Project interactions with archaeological and heritage resources are only anticipated to occur during activities that result in tree removal or ground disturbance (including dredging) during the construction phase. The operation and decommissioning phases are not anticipated to result in additional tree removal or ground disturbance (including dredging) outside of the area affected during the construction phase, and therefore do not have potential to cause a measurable interaction with archaeological and heritage resources. There is no pre-construction phase within the scope of the environmental assessment; however, the term is used in Section 7 when referring to a mitigation measure that could occur prior to construction phase. An errata documentis being compiled that captures these corrections and it will be filed with the BC EAO.
1192.1	round 1	Metlakatla First Nation	7.2.5.2, Mitigation For Loss section, last paragraph	Heritage	Local users beyond Aboriginal groups (e.g. Dodge Cove inhabitants) should also be consulted about mitigation for non-protected heritage resources	Aurora LNG's public consultation activities, including with residents of Dodge Cove, are described in Section 13 of the Application, and Aurora LNG will continue to conduct ongoing public engagement throughout the project life cycle. Aurora LNG welcomes further discussions with Dodge Cove regarding non-protected heritage resources.
1193.1	round 1	Metlakatla First Nation	7.2.5.2 Table 7-7, first row, fifth column	Heritage	Pre-construction phase appears. As per other comments listed in this table, the pre-construction phase needs to be discussed throughout the document not just here.	Potential Project interactions with archaeological and heritage resources are only anticipated to occur during activities that result in tree removal or ground disturbance (including dredging) during the construction phase. The operation and decommissioning phases are not anticipated to result in additional tree removal or ground disturbance (including dredging) outside of the area affected during the construction phase, and therefore do not have potential to cause a measurable interaction with archaeological and heritage resources. There is no pre-construction phase within the scope of the environmental assessment; however, the term is used in Section 7 when referring to a mitigation measure that could occur prior to construction phase. An errata documentis being compiled that captures these corrections and it will be filed with the BC EAO.

1194.1	round 1	Metlakatla First Nation	7.2.5.2 Characterization of Residual section, second paragraph	Heritage	A general comment on mitigation strategy - if your avoidance strategy includes the creation of 'islands' or archaeological sites surrounded by otherwise developed or cleared land, these islanded sites should be subject to additional mitigation measures such as systematic data recovery as people will be drawn to these islands like magnets, thereby significantly increasing the likelihood of post-construction site disturbance through human-induced erosion and/or looting.	The Archaeology Branch (FLNRO) will determine the mitigation measures for protected archaeological sites, including sites surrounded by otherwise developed or cleared land. However, access to archaeological sites within the LAA/RAA by members of the public is not anticipated to increase during the construction and operation phases, as there will be on-site security services and restricted access to the PDA. Access to archaeological sites by project personnel is not anticipated (see mitigation 6.4.4). Therefore, tree removal or ground disturbance related to increased human presence are not anticipated and human presence is unlikely to cause a measurable interaction with archaeological and heritage resources. Aurora LNG welcomes further discussion with Metlakatla First Nation during preparation of the Archaeological and Heritage Resources Management Plan.
1195.1	round 1	Metlakatla First Nation	7.2.5.3, Table 7-9	Heritage	A row must be added for the pre-construction phase, which must be assessed.	Potential Project interactions with archaeological and heritage resources are only anticipated to occur during activities that result in tree removal or ground disturbance (including dredging) during the construction phase. The operation and decommissioning phases are not anticipated to result in additional tree removal or ground disturbance (including dredging) outside of the area affected during the construction phase, and therefore do not have potential to cause a measurable interaction with archaeological and heritage resources. There is no pre-construction phase within the scope of the environmental assessment; however, the term is used in Section 7 when referring to a mitigation measure that could occur prior to construction phase. An errata documentis being compiled that captures these corrections and it will be filed with the BC EAO.
1196.1	round 1	Metlakatla First Nation	7.2.5.3, Table 7-9, second row	Heritage	As previously discussed, there are Operations related residual effects and this table and this chapter should discuss and assess them accordingly.	Potential Project interactions with archaeological and heritage resources are only anticipated to occur during activities that result in tree removal or ground disturbance (including dredging) during the construction phase. The operation and decommissioning phases are not anticipated to result in additional tree removal or ground disturbance (including dredging) outside of the area affected during the construction phase, and therefore do not have potential to cause a measurable interaction with archaeological and heritage resources. Access to archaeological sites within the LAA/RAA by members of the public is not anticipated to increase during the construction and operation phases, as there will be on-site security services and restricted access to the PDA. Access to archaeological sites by project personnel is not anticipated (see mitigation 6.4.4). Therefore, tree removal or ground disturbance related to increased human presence are not anticipated and human presence is unlikely to cause a measurable interaction with archaeological and heritage resources.
1197.1	round 1	Metlakatla First Nation	7.2.5.3, Table 7-9, third row	Heritage	As previously discussed there are Decommissioning and Abandonment related residual effects and the table and this chapter should assess and discuss them accordingly.	Potential Project interactions with archaeological and heritage resources are only anticipated to occur during activities that result in tree removal or ground disturbance (including dredging) during the construction phase. The operation and decommissioning phases are not anticipated to result in additional tree removal or ground disturbance (including dredging) outside of the area affected during the construction phase, and therefore do not have potential to cause a measurable interaction with archaeological and heritage resources. Access to archaeological sites within the LAA/RAA by members of the public is not anticipated to increase during the construction and operation phases, as there will be on-site security services and restricted access to the PDA. Access to archaeological sites by project personnel is not anticipated (see mitigation 6.4.4). Therefore, tree removal or ground disturbance related to increased human presence are not anticipated and human presence is unlikely to cause a measurable interaction with archaeological and heritage resources.
1198.1	round 1	Metlakatla First Nation	7.2.6, 7.2.7	Heritage	Metlakatla firmly disagrees with the conclusions in these two sections. There are cumulative effects at the broader RAA level and therefore a proper discussion of cumulative effects has not occurred. How many of each site type exist within the RAA (Borden block or coastal Tsimshian Territory) and how many of each have already been disturbed by development? Does the number of each site type or the number of remaining intact sites per site type suggest a cumulative effects concern? This must be properly explored and commented on.	In accordance with the AIR, an assessment of cumulative effects on archaeological and heritage resources was not undertaken as the following two conditions were not met: 1) proposed Project is assessed as having residual effects on the VC and 2) residual effects could act cumulatively with residual effects of other past, present, or reasonably foreseeable future physical activities. Further assessment of cumulative effects on archaeological and heritage resources is not warranted because the Project effects on archaeological and heritage resources will be mitigated prior to alteration. As a result, there are no predicted residual effects to archaeological and heritage resources. Consequently, the Project is not expected to interact cumulatively with potential residual effects from other projects or activities.
1199.1	round 1	Metlakatla First Nation	7.2.10	Heritage	Metlakatla has low confidence in the conclusions at this time because a proper RAA was not used for the study, nor were the cumulative effects of the development properly explored and discussed in this assessment.	The regional archaeology and heritage setting relative to the Project is addressed in the permitted archaeological impact assessment reporting, completed in accordance with regulatory guidelines. Within the Application process, the AIR describes the LAA and RAA as being the Project Development Area and this is consistent with what is included in the Application, Section 7.2.2.5. The LAA and RAA are used to assess effects during all project phases; however, only construction activities are predicted to have an effect on this VC because vegetation clearing and ground disturbance with the potential to impact archaeological and heritage resources will be completed during the construction phase. In accordance with the AIR, an assessment of cumulative effects on archaeological and heritage resources was not undertaken as the following two conditions were not met: 1) proposed Project is assessed as having residual effects on the VC and 2) residual effects could act cumulatively with residual effects of other past, present, or reasonably foreseeable future physical activities. Further assessment of cumulative effects on archaeological and heritage resources is not warranted because the Project effects on archaeological and heritage resources will be mitigated prior to alteration. As a result, there are no predicted residual effects to archaeological and heritage resources. Consequently, the Project is not expected to interact cumulatively with potential residual effects from other projects or activities.
1200.1	round 1	Metlakatla First Nation	7.3.1, Table 7-10	Heritage	Add rows for pre-construction, operations, and decommissioning phases to the table.	Potential Project interactions with archaeological and heritage resources are only anticipated to occur during activities that result in tree removal or ground disturbance (including dredging) during the construction phase. The operation and decommissioning phases are not anticipated to result in additional tree removal or ground disturbance (including dredging) outside of the area affected during the construction phase, and therefore do not have potential to cause a measurable interaction with archaeological and heritage resources. There is no pre-construction phase within the scope of the environmental assessment; however, the term is used in Section 7 when referring to a mitigation measure that could occur prior to construction phase. An errata documentis being compiled that captures these corrections and it will be filed with the BC EAO.
1201.1	round 1	Metlakatla First Nation	7.2.3.1	Heritage	On page 7-16, the archaeological potential model was not conducted under AIA permit 2013-0101. It was conducted under the Kleanza AOA in 2014. This AOA is discussed earlier in section 7.2.3.1 but not included in table 7-5 or referenced properly here.	Aurora LNG received a draft of Kleanza's AOA report which is dated to 2015; therefore, no change specific to citations or reference to this report is required. However, a correction has been captured in the errata document that clarifies the scope of work that Triton and Kleanza conducted in 2013 and 2015. An errata documentis being compiled that captures these corrections and it will be filed with the BC EAO.
1202.1	round 1	Metlakatla First Nation	7.2.3.1	Heritage	On page 7-17, paragraph 1, there is currently no clear understanding provided in this chapter how TK/TU information has been evaluated and defined as a cultural heritage resource, and how potential and residual effects interact specifically with TU/TK resources as well as project interactions described in subsequent sections below.	Section 7.2.3.1 of the Application lists the TK/TU studies that were available at the time of assessment. These studies were reviewed for information that could inform the archaeological and heritage resources effects assessment, in particular, information regarding traditional land use sites, activity areas and place names in the LAA/RAA. Sections 11.3 and 12.5.5 also consider Metlakatla First Nation's TK/TU information as it pertains to CEAA 2012 and Aboriginal Interests.
1203.1	round 1	Metlakatla First Nation	7.2.3.2	Heritage	Recent work by the MSS has identified a number of archaeology sites withint the shoreline of the PDA. Further work is required to delineate and assess potential impacts of the project on these archaeological features.	Aurora LNG looks forward to reviewing any new data that MSS has, and incorporating it in the Archaeological and Heritage Resources Management Plan, where applicable.
1204.1	round 1	Metlakatla First Nation	7.2.4, Table 7-6	Heritage	In table 7-6, construction potential effects, first row, an indirect impact to sub-surface archaeological sites includes change in water table as soils are removed and/or depressed by the addition of material; this should be included in the assessment.	As outlined in Section 4.6-1.1, existing hydrological regimes and natural flow patterns will be maintained where practicable, and stormwater collection, treatment, and disposal will be managed during the construction and operations phases. Accordingly, there is no anticipated effects to archaeological sites through change in ground water conditions.
1205.1	round 1	Metlakatla First Nation	7.2.4, Table 7-6	Heritage	In table 7-6, operations potential effects, fourth row, why is there no potential effect identified? Vessel wake discussed in 7.2.2.2 was identified as a concern to potentially impact archeological sites.	The potential for wake effects from vessels was considered in this assessment (Section 7.2.5.2). The conclusion is that wake waves generated by LNG carriers and associated escort tugs are not expected to have adverse effects on archaeological and heritage resources within marine intertidal areas. In the exposed or semi-exposed waters of Chatham Sound, wake waves generated by LNG carriers will generally be masked by natural background waves. This was determined based upon a report produced for LNG Canada that predicted that wake generated by LNG carriers and escort tugs travelling at 12 knots will be less than 0.4 m high (at the source vessel), which is within the size range of naturally occurring waves in the region.Shorelines along the shipping route from Prince Rupert Harbour to the Triple Island pilot station are adapted to moderate to high levels of wave exposure, and are not expected to be affected by vessel wake associated with the Project. This is consistent with the findings of the Environmental Assessment Certificate Application for the LNG Canada Export Terminal that determined that shipping traffic associated with that project would not result in new wave effects on coastal sites.
1206.1	round 1	Metlakatla First Nation	7.2.4	Heritage	First paragraph following table 7-6, page 7-20, Disposal at sea is identified in table 7-6 above as having the potential effect of the "loss of information about or alteration to site contents or context". What rational is provided to consider this effect as non-interactive? In our experience, dredging of intertidal sediments that are in association with a sub-surface archaeological site are monitored if the possibility for buried archaeological deposits are present. Erosion of the intertidal zone may include buried archaeological deposits. Sea level curves in the Prince Rupert region also suggest that sites older than 9,000BP are below our current sea level. See Letham et al. (2016) Postglacial relative sea-level history of the Prince Rupert area, British Columbia, Canada. Quaternary Science Reviews 153:156-191 for further information.	Potential Project interactions with archaeological and heritage resources are only anticipated to occur during activities that result in tree removal or ground disturbance. Dredging is considered interactive as it will result in ground disturbance, however disposal at sea is considered non-interactive as it is anticipated to cap rather than disturb sediments (Section 7.2.4). The archaeological assessment considered available, published data on sea-level curves for the region. All indicated post-Pleistocene relative sea levels to be above modern sea levels (e.g. Shugar et al. 2014. Post-glacial sea-level change along the Pacific coast of North America. Quaternary Science Reviews 97:170-192). The reference provided in the comment, published in November 2016, post-dates the Environmental Assessment.
1207.1	round 1	Metlakatla First Nation	7.2.5.3, Table 7-9	Heritage	In table 7-9, column 2 Magnitude, Construction, Metlakatla disagrees that mitigation in the form of data collection offsets resdiual effects for the permenant removal of an archaeological and/or heritage site. Often only a small percentage of data from an archaeological site can be rigorously collected given time and budget constraints. TU/TK should be evaluated to understand the magnitude of loss not only directly but indirectly to metlakatla.	Aurora LNG acknowledges this as an ongoing concern of Metlakatla First Nation, and is exploring additional opportunities to further address these concerns, and welcomes the opportunity to discuss this matter further. Aurora LNG is confident that the correct approach to mitigating the loss of information about or alteration to site contents or contexts resulting from construction of the Project has been employed. Avoidance is recognized as being the preferred option, and the majority of the archaeological sites with high significance within the PDA are situated within the proposed buffer (Figure 7-1 and Figure 7-2). If avoidance is not feasible, a program of systematic data recovery and/or archaeological monitoring will take place under a Section 12 alteration permit issued for HCA protected sites. Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Archaeological and Heritage Resources Management Plan. The success of the measures that are ultimately determined through this engagement is predicted to be high. Therefore, with the implementation of mitigation measures 7.1.1 to 7.1.3, residual effects are assessed to be not significant.
1208.1	round 1	Metlakatla First Nation	Application, 8.2.3.2.3	Human Health	Consumptions rates of Dungeness crabs and horse clams were taken from a First Nations Food Nutrition & Environment Study (Chan et al., 2011). The study solicited information from First Nation communities across the province, including some along the BC coast. The Metlakatla FN did not participate in the Chan et al study. Please confirm/verify that the consumption rates taken from this study are relevant and applicable to the Metlakatla FN.	Refer to the document titled, "Supplemental Information for Traditional Marine Foods", which will be filed with the BC EAO. The "Supplemental Information for Traditional Marine Foods" technical memo was presented to the Working Group in draft for a pre-read on April 18, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
1209.1	round 1	Metlakatla First Nation	Application, 8.2.3.2.3	Human Health	The recommended maximum weekly intake value was estimated for each food type for a toddler and adult. Consumption of a food type up to this value consistently throughout the year is assumed to be safe (i.e. without a health concern). Please provide a sample calculation with the values for each input parameter, with justification for each value. Is it considered safe for an individual to consume up to the RMWI for multiple food types?	The "Supplemental Information for Traditional Marine Foods" technical memo has been created that includes responses to this comment and it will be filed with the BC EAO. The "Supplemental Information for Traditional Marine Foods" technical memo was presented to the Working Group in draft for a pre-read on April 18, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
1210.1	round 1	Metlakatla First Nation	Application, 8.2.5.1.2	Human Health	The Application notes that a key assumption related to air emissions is that the operations phase at full build-out has the greatest emission rates and emission volumes of airborne COPCs among all Project Phases. During construction and decommissioning, the site activities are quite different than during operations (movement of fill, paving, construction of facilities, installation of utilities, etc.); subsequently, the emission sources and airborne COPCs could be significantly different than during operations. Verify this assumption is correct given the different types of equipment, site activities, and potential for different airborne COPCs as a result of construction/decommissioning specific activities. Additionally, during construction, there would be days where emissions would be higher than others. An evaluation of the emissions should include average and peak emission days.	The potential health risk associated with the construction phase was not assessed in the Application because the amount of PM10 and PM2.5 produced was similar between the construction and project-alone phase. For example, the Air Quality TDR (Appendix A of the Application), Table 13 (page 21) shows the relative emissions of sulphur dioxide, nitrous oxides, PM10 and PM2.5 for the construction and operations phases. Emissions of sulphur dioxide and nitrous oxides are substantially greater in the operations phase. The average annual emissions of PM10 and PM2.5 during the construction phase and project-alone phase. - Construction PM10 emissions = 21.5 tonnes/year. - Construction PM2.5 emissions = 20.9 tonnes/year. - Project operations PM10 emissions = 19.2 tonnes/year. - Project operations PM2.5 emissions = 18.4 tonnes/year. Based on the results of the Human Health assessment (Chapter 8 of the Application), Table 8.2-9 (page 8-34), the potential change in health risk from particulate matter in the operations phase is negligible. In locations such as Dodge Cove (i.e., Receptor ID: D-337D, D-372F and D-385) and the worker camp within the Project fenceline (i.e., Receptor ID: IF-1764, IF-1825, and IF-385), the concentration ratio increases marginally from 0.00 to 0.04 above the Base Case. There are negligible changes in the health risk to people from particulate matter in the communities that are closest to the proposed Project. People in communities more distal from the proposed Project (e.g., Prince Rupert, Port Edward, Metlakatla Village) would experience even lower exposures. Given this information, it is logical to conclude that the assessment of particulate matter in the operations phase (i.e. Application Case) would provide sufficient information to conclude a similar degree of health risk in the construction phase. For other types of substances belonging to the class of chemicals known as volatile organic compounds (VOC), which includes acrolein, benzene, 1,3-butadiene...etc.,,refer to the technical memorandum, "Volatile Organic Compounds and Human Health Assessment" which will be filed with the BC EAO. The "Volatile Organic Compounds and Human Health Assessment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.

1211.1	round 1	Metlakatla First Nation	Application, 8.2.5.2.1	Human Health	The Application indicates construction activities include the use of heavy equipment and vehicles during site clearing and grading, construction of new roads, and mobilization of materials to Digby Island. US EPA mobile source air toxics considers the following national and regional scale cancer risk drivers: acrolein, benzene, 1,3-butadiene, diesel particulate matter plus diesel exhaust organic gases (diesel PM), formaldehyde, naphthalene, and polycyclic organic matter. These substances should be included in the HHRA or a rationale provided as to why it is suitable to exclude these as airborne COPCs?	The potential health risk associated with the construction phase was not assessed in the Application because the amount of PM10 and PM2.5 produced was similar between the construction and project-alone phase. For example, the Air Quality TDR (Appendix A of the Application), Table 13 (page 21) provides the average annual emissions of PM10 and PM2.5 during the construction phase and project-alone phase. - Construction PM10 emissions = 21.5 tonnes/year. - Construction PM2.5 emissions = 20.9 tonnes/year. - Project operations PM10 emissions = 19.2 tonnes/year. - Project operations PM2.5 emissions = 18.4 tonnes/year. Based on the results of the Human Health assessment (Chapter 8 of the Application), Table 8.2-9 (page 8-34), the potential change in health risk from particulate matter in the operations phase is negligible. In locations such as Dodge Cove (i.e., Receptor ID: D-337D, D-372F and D-385) and the worker camp within the Project fenceline (i.e., Receptor ID: IF-1764, IF-1825, and IF-385), the concentration ratio increases marginally from 0.00 to 0.04 above the Base Case. There are negligible changes in the health risk to people from particulate matter in the communities that are closest to the proposed Project. People in communities more distal from the proposed Project (e.g., Prince Rupert, Port Edward, Metlakatla Village) would experience even lower exposures. Given this information, it is logical to conclude that the assessment of particulate matter in the operations phase (i.e. Application Case) would provide sufficient information to conclude a similar degree of health risk in the construction phase. For other types of substances belonging to the class of chemicals known as volatile organic compounds (VOC), which includes acrolein, benzene, 1,3-butadiene...etc..., refer to the technical memorandum, "Volatile Organic Compounds and Human Health Assessment" which will be filed with the BC EAO. The "Volatile Organic Compounds and Human Health Assessment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
1212.1	round 1	Metlakatla First Nation	Application, 8.2.3.2.1	Human Health	The Application indicates 29 gridpoints were selected to represent human receptor locations. Do any of these correspond to the maximum points of impingement (highest air concentration predicted to occur over land and over water)? The MPOI may be important considerations for short-term exposures to airborne contaminants.	Among the 1,905 land-based gridpoints identified in the human health chapter, the sub-set of 29 gridpoints representing human receptor locations (i.e., populated areas) do not correspond to the maximum point of impingement (MPOI). The location of the MPOI for a criteria air contaminant is a function of its proximity toan emission source. Therefore, the MPOI for any given criteria air contaminant will likely be located immediately adjacent to the Aurora LNG fenceline, or another project within the Prince Rupert and Port Edward area. The location of the MPOI is not a human receptor location for one or both of the following reasons: 1. The location is over water. 2. The location is not populated, or may be zoned for non-residential land use (e.g., industrial land use). As part of the April 19, 2017 working group meeting, Aurora LNG has agreed to provide the map locations of the MPOI for 1-hour NO2. Refer to the document titled, "Maximum Points of Impingement for 1-hour Nitrogen Dioxide Concentrations", which will be filed with the BC EAO.
1213.1	round 1	Metlakatla First Nation	Application, 8.2.5.2.3	Human Health	The Application indicates the potential effects to human health from changes to air quality during construction and decommissioning phases of the Project would be substantially lower than the operations phase. Please verify this is correct since the emission sources during construction/decommissioning may be significantly different than during operations.	The information in the Application regarding changes to air quality between the three Project phases is correct. The emissions during the construction phase are primarily associated with diesel-powered equipment, but the emission volumes are deemed to be highly unlikely to change the ambient air quality of the airshed, and therefore, are not identified in the Application Information Requirements for the Human Health VC. The potential health risk associated with the construction phase was not assessed in the Application because the amount of PM10 and PM2.5 produced was similar between the construction and project-alone phase. For example, the Air Quality TDR (Appendix A of the Application), Table 13 (page 21) provides the average annual emissions of PM10 and PM2.5 during the construction phase and project-alone phase. - Construction PM10 emissions = 21.5 tonnes/year. - Construction PM2.5 emissions = 20.9 tonnes/year. - Project operations PM10 emissions = 19.2 tonnes/year. - Project operations PM2.5 emissions = 18.4 tonnes/year. Based on the results of the Human Health assessment (Chapter 8 of the Application), Table 8.2-9 (page 8-34), the potential change in health risk from particulate matter in the operations phase is negligible. In locations such as Dodge Cove (i.e., Receptor ID: D-337D, D-372F and D-385) and the worker camp within the Project fenceline (i.e., Receptor ID: IF-1764, IF-1825, and IF-385), the concentration ratio increases marginally from 0.00 to 0.04 above the Base Case. There are negligible changes in the health risk to people from particulate matter in the communities that are closest to the proposed Project. People in communities more distal from the proposed Project (e.g., Prince Rupert, Port Edward, Metlakatla Village) would experience even lower exposures. Given this information, it is logical to conclude that the assessment of particulate matter in the operations phase (i.e. Application Case) would provide sufficient information to conclude a similar degree of health risk in the construction phase. For other types of substances belonging to the class of chemicals known as volatile organic compounds (VOC), which includes acrolein, benzene, 1,3-butadiene...etc..., refer to the technical memorandum, "Volatile Organic Compounds and Human Health Assessment" which will be filed with the BC EAO. The "Volatile Organic Compounds and Human Health Assessment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
1214.1	round 1	Metlakatla First Nation	8.2.2.5.1 & Table 8.2-3	Human Health	The spatial boundaries established for air quality and harvested food quality are based on models used to assess air quality and sediment plume dispersion. For the assessment of human health from harvested food quality, were these boundaries used for the cumulative effects assessment? If yes, is this appropriate since marine food harvesting could occur throughout the region, thus exposure would occur from a number of locations.	The assessment of human health from marine harvested food quality applies the same spatial boundary established for air quality and harvested food quality based on models used to assess air quality and sediment plume dispersion including for the cumulative effects assessment. If an individual also harvests from multiple locations outside of the RAA (area within which the potential for cumulative effects are considered), exposure to chemical substances in those foods are considered to be independent and not affected by the Project on a cumulative basis.
1215.1	round 1	Metlakatla First Nation	Application, Table 8.2-11	Human Health	The Application indicates interactions between Project residual effects and residual effects of other projects are not expected. Please explain how the potential for an individual to harvest food from a number of sites, including at/near this Project then at other Project sites, was assessed taking into consideration the areal extent of traditional food harvesting areas.	A cumulative effects assessment evaluates project interactions that overlap (spatially and or temporally) with those of other known or proposed projects. In the case of marine harvested foods, no other past, present or reasonably foreseeable future projects were identified in the vicinity of the proposed Project dredge footprint and surrounding sediment plume area that would overlap spatially or temporally (i.e., no other dredging or similar activities were identified in the area of the predicted plume or within the same time period). If there are no spatial or temporal overlaps of activities from other projects that could affect marine food quality, the effects would be assessed independently for each project because the effects are not cumulative.
1216.1	round 1	Metlakatla First Nation	HH TDR, 4.1.2	Human Health	The TDR states that CCME ISQGs were used for screening purposes to select COPCs in lieu of environmental quality guidelines applicable to seafood quality for the protection of human health. Is this appropriate and protective of human health? There are instances where something is not toxic to sediment/aquatic life but would be toxic to human health (e.g. red tides).	As noted, there are no sediment quality guidelines for the protection of human health from any provincial, federal or international regulatory agency. Screening for chemicals is not intended to be an indicator that is protective of human health, since the purpose of screening is only to identify chemicals of potential concern. The risk assessment evaluates the exposure to chemicals of potential concern to quantify the health risk, through the application of health-based exposure benchmarks. There are many substances that exhibit various degrees of toxicity (or no toxicity) to animals and plants, which is why there are environmental guidelines specific to the protection of various forms of life (e.g., marine aquatic life, freshwater aquatic life, humans).
1217.1	round 1	Metlakatla First Nation	HH TDR, 5.1 and Table 2	Human Health	The TDR states health-based BC MOE AAQOs were used in this risk assessment. Air quality objectives are used to guide air-management decisions and may not be suitable to use in a human health risk assessment. TRVs used in most human health risk assessments typically consider "toxicity-based" and "persistence and bioaccumulation-based" criteria. Please provide a rationale for the use of each screening criteria in this risk assessment.	The BC Ministry of Environment indicates that "Air quality objectives are limits on the acceptable presence of contaminants in the atmosphere, established by government agencies to protect human health and the environment." http://www.bcairquality.ca/regulatory/air-objectives-standards.html Further guidance on the application of provincial air quality objectives for sulphur dioxide indicate that, "A provincial interim ambient air quality objective of 75 ppb (1-hour) was adopted in 2014 to provide a health-based tool". http://www.bcairquality.ca/pdf/so2_aqo-implementation_guide.pdf The use of the BC MOE AAQOs as guides for air management decisions does not exclude its application in health-based assessments.
1218.1	round 1	Metlakatla First Nation	HH TDR, 6.2.4, 6.3.2.1 and 6.3.2.2	Human Health	Please provide a sample calculation for the estimated daily intakes, non-carcinogenic and carcinogenic risk estimates, showing site-specific and assumed input values.	The "Supplemental Information for Traditional Marine Foods" technical memo has been created that includes responses to this comment and it will be filed with the BC EAO. The "Supplemental Information for Traditional Marine Foods" technical memo was presented to the Working Group in draft for a pre-read on April 18, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
1219.1	round 1	Metlakatla First Nation	9.5.2	Accidents or Malfunctions	Please indicate the way in which First Nations communities will be integrated into response planning.	As stated in Section 12.6 of the Application, 'Aurora LNG looks forward to continuing to consult with Aboriginal Groups about safety and emergency response strategies'. Aurora LNG is hopeful that such discussions will help identify meaningful ways in which Aboriginal Groups such as the Metlakatla First Nation may be integrated into Project-related response planning and preparedness.
1220.1	round 1	Metlakatla First Nation	9.7.3	Accidents or Malfunctions	Given the presence of SARA listed species and the potential for interactions with flare events, population effects may occur. A flare screen or other exclusion device should be added to project mitigation.	The assessment of an LNG Plant Malfunction on wildlife determined that potential residual effects on terrestrial wildlife (including SARA species) are not expected to have a population level effect and are predicted to be not significant. The mitigation measures that Aurora LNG have planned are intended to protect all terrestrial wildlife species, including those that are SARA listed. As such, Aurora LNG believes that no additional mitigation is warranted to protect SARA listed species from emergency flaring. Aurora LNG will continue to consult with Metlakatla First Nation on various aspects of the Project including the development of environmental management plans.
1221.1	round 1	Metlakatla First Nation	9	Accidents or Malfunctions	There is a general lack of clarity regarding which agencies will respond to an LNG incident on land and in the marine environment, and how these agencies will work with nearby (and potentially responding) First Nations such as Metlakatla. Though Metlakatla understands WCMRC and Coast Guard will often respond first to marine *oil* spills, what are the protocols for incidents with LNG escapement? Further development of emergency response planning between government agencies, First Nations, and the proponent is required.	As stated within Section 9.10.2 of the Application, "Since LNG evaporates quickly and does not leave a residue, a spill clean-up is not anticipated. If water freezes and results in damage to the environment, appropriate restoration programs will be deployed.' Emergency response service providers will be detailed within the Emergency Response Plan, to be finalized prior to operations. As per Section 12.6.1 of the Application, Aurora LNG will continue to consult with regulators, Aboriginal Groups, and interested stakeholders regarding safety and the development of the emergency response plan strategies.
1222.1	round 1	Metlakatla First Nation	10.2.1.2	Effects of the Environment on the Project	The application notes that vessel icing is an issue but preventative and response measure to manage this potential effect are not provided. Please indicate how vessel and berth icing and effects on weight, stability, seaworthiness, and berthing will be managed.	Potential structural icing on an LNG processing facility, marine terminal, or on LNG carriers or associated support vessels is addressed through facility design and by implementing a de-icing program where required during operations. The program would be developed during detailed design.
1223.1	round 1	Metlakatla First Nation	10.2.2.1	Effects of the Environment on the Project	The curve used to predict a 1;100-year flood is an historical record from the PRPA. It is generally recognized, in light of climate change, that the past is not a reliable predictor of the future and, in the case of rainfall events, a plus/minus 20% change is considered plausible. Please ensure that the facility design will accommodate a rainfall event equivalent to 1;100 value plus 20%. (165.6mm + 33.12 = 198.72mm) or provide a rationale for why this is not appropriate/necessary.	Climate change effects on precipitation during the life of the Project will be considered during final Project design. Section 10.2.2.1 of the Application acknowledges that this intensity-duration-frequency curve does not consider potential changes to rainfall patterns associated with climate change. As noted in Section 10.2.2.2 of the Application, a Stormwater Management Plan will be developed that will be designed to account for extreme weather events.
1224.1	round 1	Metlakatla First Nation	10.2.3.2	Effects of the Environment on the Project	Please indicate how the deck heights for the MOF and marine terminal platforms (9m and 12m respectively) were derived. If an extreme event at low tide plus storm surge generated an extreme water level of 8.06m (application p.10-8), how is a MOF deck height of 9 m sufficient to accommodate a similar storm at high tide accompanied by increased sea levels associated with climate change.	Aurora LNG notes that the wording in Section 10.2.3.1, p. 10-8 would benefit from additional clarification. The surge peaked at low tide; however, the peak total water level was attained six hours later (around high tide). As an erratum, Aurora LNG will revise the third from last sentence in the first paragraph on p. 10-8 to 'Abeysirigunawardena and Walker (2008) showed that an intense storm during the winter of 2003 generated a maximum surge of 73 cm at low tide, which produced an extreme water level of 8.06 m above Chart Datum six hours after low tide.' An errata document is being created that will capture this correction and it will be filed with the BC EAO.
1225.1	round 1	Metlakatla First Nation	10.2.6	Effects of the Environment on the Project	The Application has not considered tsunamis to pose a risk to the Project. Community members are nevertheless concerned by the damaging effect of or on project infrastructure by material put in motion by a tsunami.	Aurora LNG acknowledges Metlakatla First Nation's concerns regarding risks associated with tsunamis. The Application provides an assessment of the effect of tsunami on the proposed Project in Section 10.2.6. As stated in Section 10.2.6.4 'By adhering to the relevant codes and recommendations from the tsunami hazard assessment, the potential effects of tsunamis will be prevented, avoided, or reduced through design, construction and operational standards.'

1226.1	round 1	Metlakatla First Nation	11.3	CEAA 2012	Thank you for improving and updating table 11.3-3. We have identified a number of outstanding concerns with the table. Metlakatla believes that interactions for a number of the valued components will occur where they have been identified as having no interaction. For example under vegetation, a change in abundance may impact Aboriginal Socio-ec conditions; for visual quality, a reduction in visual quality may impact Aboriginal Health (people may not get out/use resources as much as a result of impact); and for infrastructure and services, a change in health care infrastructure and services may impact Aboriginal Health etc.	Change in Vegetation Abundance:Aurora LNG assumes that Metlakatla First Nation is asking that the change in abundance of vegetation species be incorporated into the assessment of effects on the environment on Socio-Economic Conditions because of the potential for a reduction in plant species that could be harvested for use by Metlakatla-owned or operated businesses. This effect has been considered in Section 11.3.8.5 (Changes to Aboriginal Socio-Economic Conditions as a Result of Changes to Harvested Foods as assessed in the Community Health VC, page 11-155). Aurora LNG acknowledges that this is an error in Table 11.3-3 and has corrected this in the errata document. If Metlakatla First Nation is asking for this interaction to be assessed in Section 11.3 because of the potential for effects on forestry (i.e., non-food harvest), this effect has been assessed in Section 6.4.5.2 under the assessment of effects for tenured land use and private property (see page-16.4-61 onward). Change in Visual Quality: The effects of a change in visual quality on people's use of the land and resources are assessed as part of the assessment of effects on Current Use. As described in Section 11.3.2.3 (page 11-29), Aurora LNG is of the opinion that there is an absence of a clear effect pathway from a change in visual quality to a change in Aboriginal Health. Change in Health Care Infrastructure: As per CEAA 2012 5(1)(c), the focus of the assessment is on effects to the environment on the various CEAA 5(1)(c) factors. Changes in health care infrastructure are not considered to be effects on the natural environment, but are rather social changes. The assessment of effects on health care infrastructure can be found in Section 6.3.5.5.
1227.1	round 1	Metlakatla First Nation	11.3.5.2	CEAA 2012	This section states that "unless available information indicates otherwise, resources harvested on or around Digby Island and in surrounding waters are not considered unique and can be harvested elsewhere within the LAA depending on harvesting protocols and availability of other locations". Metlakatla disagrees with this assumption. Digby Island is in close proximity to the community of Metlakatla and Prince Rupert and is some people's preferred location to gather resources. Nexen's assumption does not take into account the fact that harvesting resources elsewhere may have safety implications and cost implications (time, $). All conclusions associated with this assumption (including cumulative effects conclusions) need to be re-evaluated.	Please see the memo titled "Additional Information Regarding the CEAA 5(1)(c) and Part C Assessment Methods and the Consideration of Traditional Use Information in these Assessments" for further information and context related to the treatment of information provided by Aboriginal Groups, including information related to the reported use of the Project Development Area and the adjacent marine area, in Sections 11.3 and 12 of the Application. Aurora LNG believes that the assessment set out in the Application is fair and reasonable and that a re-assessment, as suggested in the comment, is neither warranted nor required.
1228.1	round 1	Metlakatla First Nation	Table 11.3-12	CEAA 2012	A key mitigation should include the development of a complaint mechanism for noise and vibration.	The following mitigation measures address this request: Mitigation measure 4.4.9: Nearby residents (i.e., within 1 km of activities) will be notified in advance of planned high disturbance noise-causing activities at the LNG facility. Mitigation measure 4.4.10: A process will be implemented to investigate all noise complaints in a timely manner Mitigation measure 4.4.13: A process will be implemented to address vibration complaints in a timely manner As outlined in Section 14.5 of the Application, the Noise Management Plan will describe requirements for notification of construction works to local residents, and a process outlining how noise complaints can be submitted and how they will be addressed. Aurora LNG requested specific feedback on proposed mitigation measures from Metlakatla First Nation during Technical Workshops #4 and #5. Aurora LNG is currently reviewing feedback received to date on mitigation measures and any revised or new mitigation measures proposed will be included as part of an updated Table 16-1 and 16-2 to be submitted to the EAO on Day 90.
1229.1	round 1	Metlakatla First Nation	11.3.6.3	CEAA 2012	For Aboriginal Socio-ec conditions, visual quality of harvesters and business owners/clients is impacted not only by carriers being docked, but by carriers transiting the shipping route. Visual quality assessments need to include the transiting vessels.	As discussed in Section 6.2.2.4 of the Application, the effects from shipping were not carried forward in the visual quality assessment because Project shipping will not result in a new visual element within the LAA (because the Prince Rupert Port is already regularly visited by large marine traffic), and based on the EAC Application results for the PNW LNG project (which is proposing to use similar sized ships, shipping frequency, and shipping route as for Aurora LNG) it was concluded that Project shipping will not introduce new visual elements or be visibly prominent from most viewpoints along the proposed shipping route.
1230.1	round 1	Metlakatla First Nation	11.3.7.3	CEAA 2012	General comment: Throughout this section for quantitative and qualitative changes in currently harvested species (terrestrial wildlife species, marine mammal, marine birds species etc), Nexen identifies that changes resulting from the project will be below environmental and regulatory thresholds and will not impact the 'viability of populations'. Without having a better understanding of what the thresholds actually are and what Nexen means by 'population viability', Metlakatla has concerns around their ability to continue to harvest such resources. Does "viable population" take into account that a certain amount of species are being/will be harvested? Please define the thresholds that are referred to and clarify what is meant by population viability.	Section 11.3.8.3 (Metlakatla First Nation) indicates that the analysis under the identified measurable parameters includes summaries of "information and findings related to the residual effects and VCs that have been deemed relevant to the assessment of Section 5(1)(c) Effects" (see pg. 11-123). Aurora LNG notes that the statements included under the "Quantitative and Qualitative Changes in Currently Harvested Species" measurable parameter referencing "environmental and regulatory thresholds" and "viability of the local or regional populations" for terrestrial wildlife and marine birds are information and findings related to the relevant VCs. As such, the relevant thresholds and the applicable definition for population viability are described in the associated VC. The marine mammals subsection in the "Quantitative and Qualitative Changes in Currently Harvested Species" section imports the findings of the Marine Mammals VC section of the Application (Section 4.10) and, consistent with the analysis in that section, refers to "long-term persistence" of species. Regarding "viability" as it relates to terrestrial wildlife and marine bird populations, the assessments of Wildlife Resources (Terrestrial) (Section 4.7) and Marine Birds (Section 4.11) define this as the long-term maintenance in abundance, richness/diversity, or distribution of relevant species through natural recruitment (i.e., species reproduction and immigration). Additional detail is provided in Sections 4.7.2.8 and 4.11.2.8, respectively (see pg. 4.7-17 and 4.11-14). In both contexts, the relevant VCs consider the long-term viability/persistence of individual species based on their current status within the LAA and RAA. This includes consideration of pressures on individual species, for instance, whether it is a species at risk or if it is used by Aboriginal Groups for traditional purposes.
1231.1	round 1	Metlakatla First Nation	Section 11 General	CEAA 2012	As stated in our screening comments, Metlakatla disagrees with the geographic extent that is used (LAA) in Section 11 for current use. Using the LAA as the geographic extent dilutes the impacts that will occur to the PDA for certain values. For example,wildlife resources/ hunting and terrestrial plants will be greatly impacted within the PDA but by using the LAA as the geographic extent, Aurora states that Meltakatla can go to other locations for these resources. This ignores the specific features of Digby Island that make harvesting there important and assumes these feautures are replicated throughout the territory. Metlakatla disagrees with the methodologies used in this chapter to characterize residual effects.	Aurora LNG is confident that the environmental assessment presented in the Application is fully compliant with all provincial and federal regulatory requirements. The LAA and residual effects characterization methods utilized for the assessment of Section 5(1)(c) Effects on current use were established in accordance with the Application Information Requirements and informed by pre-Application consultation completed by Aurora LNG. Such consultation included the pre-application workshop held on June 20 and 21, 2016 with Metlakatla First Nation, at which the proposed assessment methods and characterization criteria for socio-economic VCs and traditional use sections of the Application were discussed. Please also see the memo titled "Additional Information Regarding the CEAA 5(1)(c) and Part C Assessment Methods and the Consideration of Traditional Use Information in these Assessments", for further information and context related to the treatment of information provided by Aboriginal Groups, including information related to the reported use of the Project Development Area and the adjacent marine area , in Sections 11.3 and 12 of the Application.
1232.1	round 1	Metlakatla First Nation	11.3.7.3	CEAA 2012	Metlakatla disagrees with the summary of characterization of current use for hunting. Nexen identifies that given the wide distribution of other locations for hunting outside of the PDA, there is a moderate level of resilience. As mentioned in previous sections, there are proximity, safety, quality, quantity and rights issues that need to be taken into consideration and members can not realistically or easily "just go somehwere else" to access resources.	Aurora LNG is confident that the environmental assessment presented in the Application is fully compliant with all provincial and federal regulatory requirements. The methods utilized to characterize residual effects on hunting in the assessment of Section 5(1)(c) Effects were established in accordance with the Application Information Requirements and informed by pre-Application consultation completed by Aurora LNG. The specific characterizations for hunting presented in Section 11.3.8.3 (Assessment of CEAA 2012 5(1)(c) iii—Current Use of Lands and Resources for Traditional Purposes) were assessed based on the information contained in Section 11.3.8.2 (Existing Conditions for Metlakatla First Nation) and Section 5 (Metlakatla First Nation) of Appendix S.2 (Aboriginal Consultation) and the definitions identified in Section 11.3.2.5 (Residual Effects Description Criteria). Based on available information, the context for hunting by Metlakatla First Nation members was assessed as having a Moderate resilience (pg. 11-131), meaning that "[t]he effect will occur to a component that is able to accommodate some change" (see pg. 11-39). Please also see the memo titled "Additional Information Regarding the CEAA 5(1)(c) and Part C Assessment Methods and the Consideration of Traditional Use Information in these Assessments", for further information and context related to the treatment of information provided by Aboriginal Groups, including information related to the reported use of the Project Development Area and the adjacent marine area, in Sections 11.3 and 12 of the Application.
1233.1	round 1	Metlakatla First Nation	11.3.8.3	CEAA 2012	Metlakatla disagrees that once the combined magnitude, geographic extent, duration and context of the potential residual adverse effects described, that the overall effect is 'not significant'. Given the moderate magnitude, continuous frequency, irreversibility, permanent duration of impacts, and low resiliency, Metlakatla consideres these to be significant impacts.	Aurora LNG is confident that the environmental assessment presented in the Application is fully compliant with all provincial and federal regulatory requirements. Aurora LNG acknowledges that Metlakatla First Nation may have differing views regarding significance and the associated threshold as it relates to predicted residual effects on Current Use. In the context of the Application, significance was evaluated against the thresholds established in Section 11.3.2.7 (pg. 11-42). For Current Use, the significance threshold is triggered "if a residual effect on Current Use results in a condition where participation by Aboriginal people in a current use activityis no longer considered viable within existing conditions". Based on the information contained in Section 11.3.8.2 (Existing Conditions for Metlakatla First Nation) and Section 5 (Metlakatla First Nation) of Appendix S.2 (Aboriginal Consultation) and the analysis in Section 11.3.8.3 (Assessment of CEAA 2012 5(1)(c) iii—Current Use of Lands and Resources for Traditional Purposes), the Application concludes that Current Use of lands and resources by Metlakatla First Nation members will be able to continue with some modification and that Current Use of lands and resources for traditional practices by Metlakatla First Nation is expected to remain viable, and predicted effects of the Aurora LNG project are not anticipated to be significant (pg. 11-149).
1234.1	round 1	Metlakatla First Nation	11.3.8.4	CEAA 2012	Metlakatla identified a number of concerns in our comments with the acoustic environment assessment. Until those questions are answered to our satisfaction, there are remaining concerns related to the conclusions for magnitude and likelihood in the changes to aboriginal health as a result of changes to acoustic environment.	Aurora LNG acknowledges the concerns from Metlakatla First Nation regarding the acoustic environment assessment. The Metlakatla comments related to the acoustic environment are captured as comments 985.1 through 993.1 of this tracking table. Please refer to comments 985.1 to 993.1 for those responses.
1235.1	round 1	Metlakatla First Nation	11.3.8.5	CEAA 2012	Metlakatla is disappointed that no assessment took place for impacts to visual quality from key locations in the marine environment. Metlakatla members that work in the tourism industry could be impacted by the project as a result of visual quality changes and increases to industrial shipping. Tourists like to travel to and fish in pristine, wild environments. The addition of large industrial shipping operations takes away from the sensation of being in the wilderness and in a pristine environment. Please provide insight as to how this was incorporated into the assessment and how it may impact Metlakatla's socio-ec conditions.	Aurora LNG acknowledges Metlakatla First Nation's comment regarding the potential effect of changes to visual quality on certain enterprises of interest to Metlakatla First Nation, including tourism and fish guiding. Marine Viewpoints Aurora LNG received feedback from Aboriginal Groups in the Second Aboriginal Consultation Workshop (which took place March 16-17, 2016) regarding the proposed viewpoints to be used for the visual quality analysis. At that time, participants expressed the importance of including a viewpoint from the marine environment. As a result of this feedback, Aurora LNG included VP01 (see Fig. 6.2-4) in its Visual Quality assessment. This viewpoint was chosen over the proposed candidate viewpoint at Kinahan Island because it presented a more direct view of the Project components from the marine environment and therefore aligns with the conservative approach used to develop the Aurora LNG Application. Furthermore, following additional comments in the February 2017 Working Group meeting, and at the request of the BC EAO, Aurora LNG has undertaken further visual quality assessment from various other viewpoints. Please see the technical memo "Additional Visual Quality Renderings" that will be filed with the EAO. Use of a Pristine Environment Given the fact that the Project would operate within one of the more industrialized areas in the region, and that the shipping lane is currently used for similar large marine shipping activities, Aurora LNG is of the opinion that the areas likely to be affected by the Project are not currently pristine. As described in section 11.3-6 of the Application, Aurora LNG recognizes that Project effects on visual quality have the potential to affect Aboriginal owned tourism businesses by changing the experience of using the lands or waters (resulting in decreased demand or a relocation of associated practices to other, less affected, locations). As set out in section 11.3.8.5 of the Application, available information on Metlakatla First Nation economic enterprises (including tourism businesses) does not indicate that they would be affected by the predicted level of changes in visual quality - with vegetative and topographic screening and mitigation measures, the Project will not be directly visible from the communities of Dodge Cove and Crippen Cove, nor visible from Port Edward or to most residents of Prince Rupert. North of Digby Island, vegetation and topography are anticipated to screen Project components from views at Metlakatla residences. Some Project components may be visible from elevated locations within the Tsimpsean Peninsula. The Project will affect views from marine approaches to Prince Rupert Harbour, Mount Hays, and Mount Comblain, with the overall view being most noticeably changed from the priority viewpoint of Mount Hays. Project lighting will affect ambient light conditions within the PDA and will contribute to skyglow effects for the life of the Project. The Project will increase the proportion of industrialized landscape within the LAA, but this will not result in an overall change in visual character, which has already been affected by waterfront developments within the Port of Prince Rupert.

1236.1	round 1	Metlakatla First Nation	11.3.8.6	CEAA 2012	Metlakatla disagrees with a number of the findings in this section. We do not agree that the permanent and irreversible alteration of site contents and context is fully offset by data that will be gathered at the site. The archaeology sites have inherent value being left "as is", where people can visit them, learn about them in situ etc. Removing the site and collecting information does not fully offset the impact. Metlakatla therefore disagreed with the assessment that magnitude is "negligible". Metlakatla asserts that the magnitude will be greater than negligible and that this needs to be re-assessed. In addition to assessing loss of information about or alteration to site contents and context within the PDA, this impact should also be assessed within the RAA in order to provide the appropriate context. Please see Metlakatla's comments in the heritage section above relating to this issue. Finally, there are potentially more direct and indirect impacts to archaeological sites that occurs during the pre-construction, construction, and decommissioning phase than is captured in the EA. For example, adding excess material to the site can displace the water table, and potentially destroy preserved organic materials below the surface (example, wet site materials). These impacts haven't been assessed or considered. Please see comments in the Heritage resources chapter. These impacts need to be fully assessed in Chapter 7 and also in Chapter 11.	Aurora LNG acknowledges that heritage is an ongoing concern of Metlakatla First Nation, and welcomes the opportunity to discuss this matter further. Aurora LNG is confident that the correct approach to mitigating the loss of information about or alteration to site contents or contexts resulting from construction of the Project has been employed. Avoidance is recognized as the preferred option, and the majority of the archaeological sites with high significance within the PDA are situated within the proposed buffer (Figure 7-1 and Figure 7-2). If avoidance is not feasible, a program of systematic data recovery and/or archaeological monitoring will take place under a Section 12 alteration permit issued for HCA protected sites. Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Archaeological and Heritage Resources Management Plan. The success of the measures that are ultimately determined through this engagement is predicted to be high. Therefore, with the implementation of mitigation measures 7.1.1 to 7.1.3, residual effects are assessed to be not significant. Potential Project interactions with archaeological and heritage resources are only anticipated to occur during activities that result in tree removal or ground disturbance (including dredging) during the construction phase. The operation and decommissioning phases are not anticipated to result in additional tree removal or ground disturbance (including dredging) outside of the area affected during the construction phase, and therefore do not have potential to cause a measurable interaction with archaeological and heritage resources.
1237.1	round 1	Metlakatla First Nation	11.4.1	CEAA 2012	The AltaGas project should be included in this table and assessment- the project was approved prior to this application being submitted.	As outlined in section 3.7.1 of the AIR, the Project and Activities Inclusion list was finalized within three weeks of submitting the final AIR on November 23, 2015. The Environmental Evaluation for the AltaGas Ridley Island Propane Export Terminal was submitted well after this cutoff date, in December 2016. On January 3, 2017, AltaGas announced it would proceed with the Project as it had received its approval under section 67 of CEAA 2012. Given the timing for these activities, the AltaGas project was not considered in the cumulative effects assessment conducted in the Application.
1238.1	round 1	Metlakatla First Nation	11.4	CEAA 2012	As it currently stands impacts to Metlakatla will be diluted by lumping Aboriginal Groups together for the cumulative effects assessment in Chapter 11. MSS has maintained that this information be disagregated during the AIR comment periods and also during our workshop meeting with Nexen in October 2016. In their dAIR comment responses Nexen affirmed that they would disaggregate FN assessments as long as they were provided with community-specific data. Metlakatla has provided Nexen with the relevant data for them to conduct a CE assessment on Metlakatla First Nation interests. If the issue was that Nexen didn't have enough community specific information from other communities, CE should still be fully assessed for Metlakatla First Nation.	As described in Section 11.4 of the Application (pg. 11-380), Aurora LNG undertook a combined cumulative effects assessment for all of the Aboriginal Groups due to the incomplete nature of the information available within the respective RAAs for CEAA Section 5(1)(c) Effects for those past, present and future projects listed in Table 11.4-1 of the Application. In particular, Aurora LNG notes data deficiencies related to the extent and duration of Section 5(1)(c) Effects from past, present and reasonably foreseeable future projects in the RAAs, and usage relevant to possible interactions throughout the RAAs. This comment and Aurora LNG's response was discussed as part of Technical Workshop #5. Additional detail regarding Technical Workshop #5 will be provided in Aboriginal Consultation Report #3.
1239.1	round 1	Metlakatla First Nation	12.5.1.1	Aboriginal Consultation	Nexen indicates that Metlakatla will complete a final version of a "Metlakatla First Nation Report" and provide it to Nexen. MSS notes that the final report requires collaborative effort from both Nexen and MSS to identify specific impacts on Metlakatla Interests from the project. The report will be finalized as soon as possible following when all necessary information is made available and collaborative efforts are complete.	Aurora LNG looks forward to ongoing collaboration and consultation with Metlakatla First Nation. This includes consultation undertaken at Workshop #5 which was held on March 20-21, 2017. The workshop provided a meaningful opportunity to discuss Application findings related to the assessment of CEAA 2012 5(1)(c) effects and Metlakatla First Nation's Aboriginal Interests. In addition, it was an opportunity for Metlakatla First Nation to request any additional information needed to finalize the report.
1240.1	round 1	Metlakatla First Nation	12.5.5.3	Aboriginal Consultation	Harvesting of deer from Digby Island was excluded from the list of modern harvesting activities on Digby Island. Metlakatla members regularly acccess Digby Island for deer hunting. Impacts on deer and reduced access to Digby Island will adversely effect members' ability to harvest this resource.	The following statement is included in the summary of past use on page 12-104: "Aurora LNG understands that Metlakatla First Nation members historically hunted or trapped several species on Digby Island, including black bear, deer, ducks, geese, mink, and waterfowl." To avoid redundancy, Aurora LNG chose to include this statement in the summary of present use on page 12-105: "Aurora LNG assumes that, where possible, Metlakatla First Nation members continue to harvest all the species described in the past use section and in the same locations." Please note that this information forms the basis of the assessment of effects on harvesting-related rights (see Section 12.5.5.6, page 12-112 for a list of species harvested by Metlakatla First Nation within the PDA, including deer).
1241.1	round 1	Metlakatla First Nation	12.5.5.4 and General statement for all analysis of impacts to Metlakatla Interests	Aboriginal Consultation	In the final paragraph of this section, Nexen describes their approach to predicting the "degree that the exercise of the Aboriginal Interests may be adversely affected", taking into consideration, "the relative importance of the Project vicinity" and the "availability of other areas... where the meaningful exercise of the Aboriginal Interest could reasonably occur". Nexen's assumption that traditional practices associated with Digby Island can be transferred to another avaialable location is fundementally incorrect. Necessity or preference for a specific location for traditional use such as on or surrounding Digby Island relies on a number of factors including: ease/safety/cost/ability to access the site; knowledge and familiarity of specific locations; historical and current family/clan/tribe associations to specific locations; quality/quantity/unique attributes of resources available at the site; timing and seasonality; traditional right to access resources as per Tsimshian governance systems; competition for resrouces; etc. Furthermore, throughout Nexen's assessment, Nexen calculates that the PDA is only "xxx percent of Met territory". Such a statement is incredibly coarse and misleading. Notwithstanding the restrictions on Metlakatla people to "go elsewhere" for traditional practices, as discussed above, "elsewhere" would have to be a comparable ecological and geographic site with similar relative cultural significance to Digby Island (e.g. flat, nearshore island with mix forest and bog ecosystems, supporting similar species, within an easy boat or paddle from Prince Rupert and Melakatla Village and with a central role in Coast Tsimshian history), which the remaining percentage of Metlakatla territory is not. Given the above, Metlakatla requests that Nexen re-assesses the impact of the project on Metlakatla interests*without the assumption that Metlakalta practices at and surrounding Digby Island can be transferred to another location.*	Further information that provided context related to the assessment of the identified potential effects in the Application, including clarification regarding the assumptions utilized in the assessment, is provided in the technical memo entitled "Additional Information Regarding the CEAA 5(1)(c) and Part C Assessment Methods and the Consideration of Traditional Use Information in these Assessments" which will be filed with the BC EAO.
1242.1	round 1	Metlakatla First Nation	12.5.5.5 and all subsequent sections listing mitigations for impacts on Metlakatla Interests	Aboriginal Consultation	Mitigation measures listed by Nexen such as: ongoing consultation; progressing economic accommodation negotiations; provinding EA Capacity funding; and, following direction of government agencies, are not migitations. "Migitation Measures" are defined in the BC EAO Environmental Mitigation Policy (2014) as "a tangible conservation action taken to avoid, minimize, restore on sites, or offset impacts on environmental values and associated components, resulting from a project or activity. MSS requests that Nexen *re-evaluate impacts to Metlakatla interests applying only those mitigations that meet the definition above (additional migitations can be developed collaboratively). If no such mitigations are available, or do not completely mitigate for the impact, residual impacts must be clearly identified, characterized, and carried forward to conclusions and potential cumulative effects assessments.*	The definition quoted by Metlakatla First Nation focuses on environmental mitigation. While environmental effects are a key component of potential effects on Metlakatla First Nation Aboriginal Interests as assessed in Section 12.5.5, effects on Aboriginal Interests tend to benefit from different, and sometimes less measurable, mitigation measures than those used for environmental effects. For example, if the potential effect relates to Metlakatla First Nation's ability to make decisions related to their use of land or marine areas (see Sections 12.5.5.5, 12.5.5.8, and 12.5.5.9), then ongoing and meaningful consultation between Metlakatla First Nation and Aurora LNG can enable Metlakatla First Nation's to influence land and marine use decisions within the Project vicinity. Aurora LNG requested and received specific feedback on proposed mitigation measures from Metlakatla First Nation during Technical Workshops #4 and #5. Aurora LNG is currently reviewing feedback received to date on mitigation measures and any revised or new mitigation measures proposed will be included as part of an updated Table 16-1 and 16-2 to be submitted to the EAO on Day 90.
1243.1	round 1	Metlakatla First Nation	12.5.5.6 and all subsequent sections concluding on impacts on Metlakala interests.	Aboriginal Consultation	Given the flaws in logic assessing impacts to Metlakatla noted above in relation to section 12.5.5.5, this conclusion is unfounded. Assessing only impacts to the PDA in relation to the whole of Metlakatla territory; relying on mitigations that are not mitigations; and downplaying the relative importance of Digby Island result in a vast under-estimation of project impacts.	Aurora LNG believes that the assessment reasonably and fairly represents the importance of Digby Island to the exercise of Metlakatla First Nation Aboriginal Interests under the subheadings, especially taking into account the "Importance of the Project Vicinity" included in the assessment for each Aboriginal Interest. In addition, Aurora LNG requested and received specific feedback on proposed mitigation measures from Metlakatla First Nation during Technical Workshops #4 and #5. Aurora LNG is currently reviewing feedback received to date on mitigation measures and any revised or new mitigation measures proposed will be included as part of an updated Table 16-1 and 16-2 to be submitted to the EAO on Day 90. Please also see the memo titled "Additional Information Regarding the CEAA 5(1)(c) and Part C Assessment Methods and the Consideration of Traditional Use Information in these Assessments" for further information and context related to the treatment of information provided by Aboriginal Groups, including information related to the reported use of the Project Development Area and the adjacent marine area, in Sections 11.3 and 12 of the Application. This memo will be filed with the BC EAO.
1244.1	round 1	Metlakatla First Nation	12.5.5.6	Aboriginal Consultation	In this Section, Nexen lists findings for all VCs from Part B. Metlakatla has identified issues with each of the assessments of part B VCs. Before carrying forward the conclusions of Part B to Part C, Nexen must first resolve the identified issues and questions. Metlakatla recommends reassessing impacts to Metlakatla harvesting rights once the identified issues from Part B have been resolved as a result of application review.	Aurora LNG acknowledges that Metlakatla First Nation has issues with the assessment of part B VCs, however, the assessment set out in the Application was developed in accordance with the requirements of the AIR and informed by pre-application consultation with Metlakatla First Nation. Overall the assessment was reasonable. As a result, the re-assessment, as suggested, is neither warranted nor required.
1245.1	round 1	Metlakatla First Nation	12.5.5.6	Aboriginal Consultation	Nexen's assessment of loss of one hour of fishing time in 24hours as a result of an LNG vessel as "low to medium moderate" is underestimated. Most fishermen are not fishing 24 hrs/day, and most likely are in a specific location to catch a specific tide, a specific pulse of fish, or to fish at a particular time of day or during a particularly favourable weather window. Further, commercial fisherman may only be legally able to fish for very limited periods of time coinciding with openings. For example. salmon fishermen may be relying on fishing for only a few hours to provide a great amount of their annual income. Therefore, effects of losing an hour of fishing time could range from low impact to very high impact on a fisherperson.	See the "Effects of Lost Fishing Time" technical memo which will be filed with the BC EAO.
1246.1	round 1	Metlakatla First Nation	12.5.5.6	Aboriginal Consultation	Though areas of predicted air quality exceedances may not contain "human receptors" as defined by Nexen, they do contain "humans", including members of the Metlakatla Nation working on or near Fairview and Ridley Islands, as well as transiting the waters between Digby, Kaien and Ridley Islands. Further, changes in air quality will be experienced by Metlakatla members in the LAA--though they may not surpass provincial standards, the community has indicated any change of air quality is of potential major concern to members. Further consultation is required to conclude on the seriousness of effects on air quality changes for Metlakatla.	As identified by Metlakatla First Nation, the potential change in air quality has been incorporated into the assessment of potential effects on the experience of harvesting resources in Section 12.5.5.6, along with noise and visual quality effects. The Air Quality and Human Health assessments concluded that there will be no notable short-term (1 hr and 24 hr) or long-term (annual) effects on the health of people in Dodge Cove, Prince Rupert, Port Edward, Georgetown Mills, and Metlakatla village from exposure to airborne chemicals of potential concern, this conclusion is in regard to the general population, not just special receptors. As such, Aurora LNG does not anticipate that Metlakatla First Nation members using the marine environment in the Project Vicinity or working on or near Fairview Terminals or Ridley Island will experience a notable change in air quality as a result of the Project.
1247.1	round 1	Metlakatla First Nation	12.5.5.6 and other sections concluding the impacts to Metlakatla interests	Aboriginal Consultation	Though Metlakatla agrees that the relative importance of the project area must be considered when assessing the seriousness of impacts on Metlakatla harvesting (and other interests), Nexen's assessment of importance misses or underestimates key factors contributing to the importance of the Island to Metlakalta. The ease of safe access, historical significance, relatively pristine aesthetic experience, incremental loss of other locations in the harbour, variety of resources that can be harvested in one location, etc, all heighten the role of Digby Island and elevate its importance. Along with elminiting the "go elsewhere" assumption (as requested above), Nexen should re-assess the impacts on Metlakatla interests with a more accurate description of the relative importance of the Island to the Nation.	Aurora LNG appreciates this information from Metlakatla First Nation further describing the importance of Digby Island to Metlakatla First Nation. While the specific reasons identified in this comment have not been explicitly articulated to Aurora LNG prior to submission of the Application for review, Aurora LNG believes that the information that was included in Part C regarding particular importance of the Project Vicinity adequately represents Metlakatla First Nation's views. Specifically, the following statements, including direct quotes from Metlakatla First Nation's Project-specific study and other publicly available documents, were included throughout Part C:Metlakatla First Nation has described Digby Island as the "geo-political centre" of its traditional territoryMetlakatla First Nation has indicated that Tree Nob Group of islands is "critically important" for harvesting Metlakatla First Nation has stated that Digby Island's "importance cannot be overstated" Aurora LNG understands that the channel between Digby and Kaien and travelways to Tree Nob Group of islands are important and well-used by Metlakatla First Nation boaters. Please also see the memo titled "Additional Information Regarding the CEAA 5(1)(c) and Part C Assessment Methods and the Consideration of Traditional Use Information in these Assessments". Aurora LNG is confident that the environmental assessment presented in the Application is fully compliant with all provincial and federal regulatory requirements. As a result, the re-assessment, as suggested, is neither warranted nor required.

1248.1	round 1	Metlakatla First Nation	12.5.5.7	Aboriginal Consultation	Potential effect mechanisms: additional project effect mechanims exist, such as those precipitating from a loss of access to and quantity of traditionally harvested goods (leading to decrease in physical and mental health) and loss of knowledge of placenames/attributes/history/governance of Digby Island. Additional assessment should be done in conjunction wtih Metlakatla to understand and describe these potential effects, develop mitigations, and reach more rigorous conclusions.	Aurora LNG acknowledges the potential effect mechanisms described by Metlakatla First Nation, and believes they have been appropriately included in the Application. These topics are addressed in the assessment of effects on Metlakatla First Nation in the following sections of the Application:Loss of Access to Harvested Foods: Section 12.5.5.7, starting on page 12-128. Section 12.5.5.6, starting on page 12-118. Loss of Quantity of Harvested Foods: Section 12.5.5.7, page 12-126 acknowledges to importance of resource harvesting and points the reader to Section 12.5.5.6 to reduce redundancy. Effects on quantity of harvested resources are also assessed in Section 11.3.8.3. Loss of Knowledge of Placenames/Attributes/History of Digby Island: Section 12.5.5.7, starting on Page 12-129. Loss of Knowledge of Governance of Digby Island: Section 12.5.5.8, starting on page 12-136. In January 2017, Aurora LNG held Technical Workshop #4 to discuss the assessment of VCs set out in Part B of the Application. On March 20, 2017, Aurora LNG held Technical Workshop #5 with Metlakatla First Nation to further discuss the characterization of effects and significance conclusions outlined in the CEAA 2012 Section 5(1)(c) assessment, and the assessment of Project effects related to Aboriginal Interests in Part C. Technical Workshops #4 and #5 were also an opportunity to discuss feedback on mitigation measures, proposed management plans and follow-up programs. Throughout Technical Workshops #4 and #5, Aurora LNG documented Metlakatla First Nation opinions, concerns and feedback. Aurora LNG requested and received specific feedback on proposed mitigation measures from Metlakatla First Nation during Technical Workshops #4 and #5. Aurora LNG is currently reviewing feedback received to date on mitigation measures and any revised or new mitigation measures proposed will be included as part of an updated Table 16-1 and 16-2 to be submitted to the BC EAO on Day 90. Given the assessments listed above, Aurora LNG believes that the assessment set out in the Application is fair and reasonable. As a result, the re-assessment, as suggested, is neither warranted nor required.
1249.1	round 1	Metlakatla First Nation	12.5.5.7	Aboriginal Consultation	Though reference to the Heritage Act allows Nexen to conlude no cumulative effects on archaeological resources will result from this project, the effect of removing archaeological resources from the Prince Rupert harbour must be considered through the lens of the Metlakatla First Nation, not the provincial Archaeological Branch. For Metlakatla, the cumulative loss of significant archaeological resources in the territory, especially those that are accessible, intact, and in the vicinity of significant historical cultural locations in Prince Rupert Harbour is highly significant and requires substantial effort for avoidance, mitigation, and potential accommodation.Conclusions as to the significance of impacts to archaeology should be re-assessed to incorporate the Metlakatla perspective.	Aurora LNG acknowledges that Metlakatla First Nation may disagree with the finding that the Project will not result in cumulative effects on archaeological resources. Aurora LNG has worked closely with Metlakatla on archaeological matters to date and welcomes further discussion with Metlakatla First Nation during preparation of the Archaeological and Heritage Resources Management Plan.
1250.1	round 1	Metlakatla First Nation	12.5.5.7	Acoustic Environment	Further discussion is required with Metlakatla First Nation to characterize, describe and communicate potential noise effects for a fulsome understanding and accurate conclusion on the potential effects of noise from construction and operations of the project on Metlakatla members' daily activities.	During construction and operations noise levels during operations are not anticipated to exceed Health Canada or BC OGC noise guidelines and acoustic levels will meet established Health Canada guidelines. However, Aurora LNG acknowledges that noise levels will be above existing conditions sound levels, and will be perceptible to traditional users outside the PDA. Aurora LNG is committed to working with Metlakatla First Nation to continue developing a shared understanding of how potential Project effects may interact with the exercise of their Aboriginal Interests, and what mitigations may be available to help address those concerns
1251.1	round 1	Metlakatla First Nation	12.5.5.8	Aboriginal Consultation	Though important to recognize that this project may impact traditional governance, it is beyond the ability of Nexen, as well as the ability of MSS staff to be able to accurately describe and characterize impacts of the project on traditional governance systems. Further consultation and mitigation options must be explored with Metlakatla leadership.	Aurora LNG would look forward to receiving the views and opinions of Metlakatla leadership on how the Project may affect traditional governance.
1252.1	round 1	Metlakatla First Nation	14	Environmental and Operational Management Plans	The EMPs are deficient in detail per requirements in the AIR, which states that "The Application will provide a list and**comprehensive description** of the Environmental Management and Operational Plans for construction and operations of the proposed Project which will be refined during the Assessment of each VC." (bold underline added for emphasis). The Application, however, does not provide "comprehensive descriptions" of the EMPs. The brief descriptions largely identify information that is required for a "comprehensive description" without actually providing the description that the AIR demands. Further, as the Application states, "The EMPs describe the protection measures implemented onsite to avoid or reduce potential adverse effects." Since the EMPs are not provided - even in a preliminary form - we are therefore being asked to conclude on the significance of residual effects without the protection measures described in the EMPs. The brief descriptions and references to the list of relevant mitigation measures is not sufficient to determine adequacy for the purpose of this assessment. A key importance of an EMP is for reviewers to understand how the mitigation measures will be implemented and how they may collectively prevent significant harm to the sustainability of the VC. The EMP should also be very clear as how specific potential effects will be mitigated, including additional mitigation options and risk management procedures. The current descriptions don't explain how the EMPs relate to the results of the effects assessments (apart from simply listing related effects in a table). In the absence of comprehensive EMPs to review, the Working Group and decision makers are not able to determine whether the impacts are going to be reasonably addressed with what has been provided.	Section 14 of the Application provides a comprehensive list of proposed management plans to be developed as Project design details become available and the conditions of an approval are presented to the proponent. The proposed contents of these plans are substantively presented in the form of the many mitigation measures that have been developed for each VC and are summarized in Section 16. These mitigation measures, as well as design mitigation presented in the Project Overview, form the basis of the assessment of residual effects that is, in general, highly confident. Aurora LNG will engage with the appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the EMPs.
1253.1	round 1	Metlakatla First Nation	14	Environmental and Operational Management Plans	Please provide clarity as to when an appropriate level of detail will be provided and confirm that sufficient time be provided for the Working Group to review and comment before the assessment period ends.	Detailed management plans will be developed as Project design details evolve and according to conditions of a Project approval. Requirements regarding timing of these plans will be directed according to conditions of a Project approval and discussions with the applicable regulatory authorities. Aurora LNG will engage with the appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the EMPs.
1254.1	round 1	Metlakatla First Nation	15.2.1	Follow-up Programs and Compliance Reporting	A complete follow up program is not provided, as required by the AIR: "*The Application will provide a description of the proposed monitoring and follow-up programs, including the activities, objectives, and reporting,* ***in sufficient detail to reliably verify predicted effects (or absence of them) and to confirm both the assumptions and the effectiveness of mitigation***." (bold underline added for emphasis). The brief general description of the contents of the follow up program to be provided in the future is not sufficient for this assessment (per the AIR). Please provide a complete proposed follow up program for the heron rookery.	Aurora LNG is committing to maintaining setbacks to decrease the extent of sensory disturbance in the vicinity of active nesting sites for great blue heron and to reduce the potential for flushing during the nesting and rearing period. Aurora LNG acknowledges that Develop with Care recommends as a best management practice that excessive noises should not occur within 1,000 m of a great blue heron colony during the nesting window (BC MOE 2014). As per mitigation 4.7.4, high-disturbance Project-related activities (e.g., blasting, pile driving) will be avoided where practicable during the breeding window (i.e., January 15 through September 15) within 500 m of the great blue heron rookery at Dodge Cove. To address the uncertainty over the degree to which high disturbance activities occurring within 1,000 m of the heron rookery may result in disturbance displays by nesting herons (as per provincial guidelines), Aurora LNG is committing to monitoring for changes in breeding activity at the rookery if high disturbance activities for Project construction occur within 1,000 m of the rookery during the breeding window (January 15 to September 15 for great blue heron). Given the geography of the area and the fact that there is a ridge of land that visually separates the rookery from proposed road corridor it is unlikely that road construction activities will cause a change in breeding activity. Monitoring protocols will follow the Survey Protocol for Measurement of Nesting Productivity at Pacific Great Blue Heron Nesting Colonies (Vennesland and Norman 2006). Monitoring and adaptive approaches will be described in detail in the Wildlife Management Plan. Aurora LNG will engage with the appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding development of the Wildlife Management Plan. Survey Protocol for Measurement of Nesting Productivity at Pacific Great Blue Heron Nesting Colonies. The Heron Working Group.
1255.1	round 1	Metlakatla First Nation	15.2.2	Follow-up Programs and Compliance Reporting	A complete follow up program is not provided, as required by the AIR: "*The Application will provide a description of the proposed monitoring and follow-up programs, including the activities, objectives, and reporting,* ***in sufficient detail to reliably verify predicted effects (or absence of them) and to confirm both the assumptions and the effectiveness of mitigation***." (bold underline added for emphasis). The brief general description of the contents of the follow up program to be provided in the future is not sufficient for this assessment (per the AIR). Please provide a complete proposed follow up program for Acidification and Eutrophication.	The acidification and eutrophication follow-up and monitoring programs are expected to be developed on a regional level and the plan is to consult with Aboriginal Groups, MOE and other local industry to finalize those programs. It is expected that Aboriginal Groups will be involved in the implementation of those programs. Please see the "Additional Information about Eutrophication and Acidification in Freshwater" technical memo for additional details on future monitoring programs. This technical memo will be filed with the BC EAO.
1256.1	round 1	Metlakatla First Nation	15.2.3	Follow-up Programs and Compliance Reporting	A complete follow up program is not provided, as required by the AIR: "*The Application will provide a description of the proposed monitoring and follow-up programs, including the activities, objectives, and reporting,* ***in sufficient detail to reliably verify predicted effects (or absence of them) and to confirm both the assumptions and the effectiveness of mitigation***." (bold underline added for emphasis). The brief general description of the contents of the follow up program to be provided in the future is not sufficient for this assessment (per the AIR). Please provide a complete proposed follow up program for the Marine Sediment Deposition.	Aurora LNG is committed to developing and implementing a Marine Water Quality Monitoring Program to monitor turbidity and total suspended solids associated with dredging activities, to characterize water quality parameters in effluent discharges as per permitting requirements, and to monitor the implementation and effectiveness of mitigation measures. The plan will include water quality thresholds, monitoring frequency, and specific monitoring locations. This plan, as well as details specific to monitoring potential sediment deposition, will be developed in accordance with industry best management practices and standards, applicable regulations, and conditions of the Environmental Assessment Certificate and relevant permits. The plan will be developed in consultation with applicable regulators, Aboriginal Groups, and specific stakeholders.It is standard practice for these management plans to include (at least) the following information: background on the need for the program or planregulatory context consultation and engagementobjectivesmonitoring and field methodsreporting requirements In addition, Aurora LNG will implement an adaptive management framework as follows: Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended).
1257.1	round 1	Metlakatla First Nation	15.3	Follow-up Programs and Compliance Reporting	Complete monitoring programs are not provided, as required by the AIR: "*The Application will provide a description of the proposed monitoring and follow-up programs, including the activities, objectives, and reporting,* ***in sufficient detail to reliably verify predicted effects (or absence of them) and to confirm both the assumptions and the effectiveness of mitigation***." (bold underline added for emphasis). The brief general description of the contents of the monitoring programs to be provided in the future is not sufficient for this assessment. This is a deficiency per the AIR. Please provide complete proposed monitoring programs at a sufficient level of detail.	As outlined in Section 14.2 of the Application, each Environmental Management Plan (EMP) will include requirements for monitoring (e.g., compliance and/or effectiveness) and reporting. Aurora LNG will engage with the appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the EMPs. The implementation of EMPs will be overseen by environmental professionals to confirm compliance with monitoring and reporting requirements. EMPs, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended).
1258.1	round 1	Metlakatla First Nation	15.3	Follow-up Programs and Compliance Reporting	The six topics for monitoring programs (still to be provided) do not cover some components that should be expected to include compliance monitoring and reporting, such as noise, wildlife (marbled murrelet and bats), marine mammals, freshwater & marine fish habitat (not just monitoring of the offsetting plan), social values, and archaeology. All these components warranted EMPs to mitigate impacts, so some form of compliance monitoring and reporting should be expected. When complete monitoring programs are provided, they should include proposed monitoring related to all EMPs.	As outlined in Section 14.2 of the Application., each EMP will include requirements for monitoring (e.g., compliance and/or effectiveness) and reporting. Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the EMPs. The implementation of EMPs will be overseen by environmental professionals to confirm compliance with monitoring and reporting requirements.
1259.1	round 1	Kitsumkalum First Nation		General	It is Kitsumkalum's understanding that there has been no modeling of dredge for the water intake or outfall pipes? What is the justification of this?	Sediment transport modeling was not completed to predict sediment dispersal and deposition associated with trenching and burial activities during installation of the seawater intake and outfall pipes. Based on preliminary design and engineering, the intake and outfall pipes will be trenched and buried through the intertidal zone, and laid directly on the seafloor through the subtidal zone. However, no trenching and burial of the intake pipe (proposed at Casey Cove) is anticipated to be required. This is because the intake pipe is assumed to connect to a pump station constructed as part of the MOF, and the point of connection will be located within the subtidal zone, where the pipe will be laid directly on the seafloor. Based on the currently-proposed alignment of the outfall pipe, approximately 100 m of the 230 m long pipe will be buried through the intertidal zone, through areas composed primarily of cobble and gravel (i.e., not soft sediment). Based on the substrate type and the relatively low volume of material that will be disturbed during trenching activities (compared to the volume of material that will be disturbed during dredging activities), trenching and burial activities associated with the installation of the outfall pipe through the intertidal zone are not expected to generate elevated levels of TSS of magnitude or duration likely to result in residual adverse effects to marine fish health (see Section 4.9.5.5 for an assessment of potential health effects to marine fish associated with construction activities, including installation of seawater intake and outfall pipes). Therefore, sediment transport modeling was not completed. Furthermore, efforts will be made to conduct trenching and burial activities during low tide (i.e., in the dry); this will further reduce the amount of sediment likely to become suspended into the water column during trenching and burial activities.
1260.1	round 1	Kitsumkalum First Nation		General	The proponent seems to rely on permits, rather than commitments. Kitsumkalum expects the proponent to step up and exceed expectations, not continually aim to meet bare minimums. This is a recipe for failure.	As well as the applicable authorizations (including permits) listed in Table 1-23 of the Application, Aurora LNG is committed to numerous mitigation measures to manage potential effects of the Project, as summarized in Table 16-1 of the Application. Please see the "Revised Mitigation Measures Table" technical memo which categorizes these mitigation measures to indicate whether they are outside of permitting requirements (i.e., a legal requirement, industry standard/best management practice and/or Aurora LNG additional mitigation measure). The technical memo will be filed with the BC EAO.
1261.1	round 1	Kitsumkalum First Nation		General	It is our understanding that actual fish habitat restoration and offsets are only looked at as a number so far, and that no actual proposed areas have been brought forward. Off setting is particularly difficult in this region and project success is debatable. Rock reefs often impact mud habitats, artificial channels often need maintenance. Kitsumkalum is skeptical of the ability of the project to offset the 1000s of meters of habitat loss.	Aurora LNG acknowledges the comment and is committed to developing adequate, effective offsets that counterbalance residual serious harm to fish as per the Fisheries Act. As stated in the Conceptual Fish Habitat Offsetting Plan (Appendix V), the offsetting philosophy and ideas presented are intended to demonstrate Aurora's approach to identifying effective offsets and concrete ideas for counterbalancing harm. They provide a transparent starting point for constructive discussions about habitat offsetting, with the ultimate goal of developing widely endorsed, effective, appropriately located and well-designed offsets. Through collaborative engagement with regulatory agencies (primarily DFO) and consultation with Aboriginal Groups during the Fisheries Act authorization application process, Aurora LNG fully anticipates being able to find adequate and appropriate locations, and develop suitable designs, for effective offsets.

1262.1	round 1	Kitsumkalum First Nation		General	At working group meeting #4 it was discussed that emissions plume exceedances were modelled primarily outside of residential areas and "would only have potential to affect those who were working on Ridley Island, and likely for short duration" This is worrisome as although the duration and exposure may be limited at current build out, the island does have expansion plans. with workers potentially working in the plume regularly. We feel this is something that requires attention.	The locations where 24-hour PM10 were above the BC ambient air quality objectives were associated with the Fairview Terminal Phase I (for Base and Application Case) and Fairview Terminal Phase II (for the Cumulative Effects Assessment Case) and the Ridley Terminal, which is zoned as industrial use land and where there are no residences. At these locations, the concentration ratios for the Base Case (existing conditions) are already above 1.0. The concentration ratios for the Application Case illustrate that the Aurora LNG Project has a marginal influence on 24-hour PM10 concentrations at the Fairview and Ridley Terminals. The Aurora LNG Project is a minor contributor of PM10 at these industrial locations. 1-hour nitrogen dioxide concentrations are also above the BC ambient air quality objective during the Cumulative Effects Assessment Case at the Fairview Terminal (associated with Phase II of that project). It is noted that at these industrial sites, occupational exposure limits would apply to employees on-site, which is addressed by WorkSafeBC. While the BC Ambient Air Quality Objectives for 24-PM10 is 50 ug/m3, (for non-work related exposures) the WorkSafe BC 8-hour time-weighted average PM10 guideline is 3,000 ug/m3. For 1-hour nitrogen dioxide, the BC ambient air quality objective is 0.001 ppm or 188 ug/m3. However, the applicable WorkSafe BC exposure limit is a ceiling limit (i.e., the maximum concentration allowable at any time) and is 1 ppm or 1,880 ug/m3. The 24-hour PM10 and 1-hour NO2 concentration is expected to be well below the WorkSafe BC occupational exposure limits at the Fairview Terminal during both Phase I and Phase II of that project.
1263.1	round 1	Kitsumkalum First Nation		General	Environmental and socio-ec effects from the 400 man floating camp (proposed to house initial construction workers) have not been assessed. At minimum a technical memorandum assessing effects to VCs such as marine fish and fish habitat, marine use and navigable waters, and marine water quality should be prepared.	Please see the separate technical memo titled "Floating Camp Review" which will be filed with the EAO.
1264.1	round 1	Kitsumkalum First Nation		General	Generally there are many of the project components that have not been described with enough detail such that project effects are not clear. For example the site, containment and discharge to the environment (of salt and water) for terrestrial storage of marine sediments containing dioxin/furans is unknown; description of water temperature fluctuations associated with water tower cooling system discharge to the marine environment; description and quantities of intake and effluent from desalination plant; and, description and containment of soils overburden storage site (and water discharge quantities / quality). Without these descriptions it is difficult to agree with several of the characterizations of effects.	Details on the assessment of Project waste discharges and associated regulations, are provided in the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
1265.1	round 1	Kitsumkalum First Nation	AS3.3	Aboriginal Consultation	Table AS3-3 does not include all of the key concerns raised during the pre-application stage.	Table AS3-3 is a high-level summary of the key concerns raised by all members of the working group during the pre-Application stage of the environmental assessment related to all sections of the Application. The table was not intended to represent all concerns raised by Kitsumkalum First Nation. The full list of concerns raised by Kitsumkalum First Nation at the time of filing the Application is found in Table 8-1 of ACR #2 (see Appendix S.1). Table 12.3-4 of the Application includes Aurora LNG's understanding of key issues raised by Kitsumkalum First Nation during the pre-Application phase of the environmental assessment. This table was provided to Kitsumkalum First Nation for review in advance of a pre-submission workshop. In January 2017, Aurora LNG held Technical Workshop #4 to discuss the assessment of VCs set out in Part B of the Application. On April 4, 2017, Aurora LNG held Technical Workshop #5 with Kitsumkalum First Nation to further discuss thecharacterization of effects and significance conclusions outlined in the CEAA 2012 Section 5(1)(c) assessment, and the assessment of Project effects related to Aboriginal Interests in Part C. Technical Workshops #4 and #5 were also an opportunity to discuss feedback on mitigation measures, proposed management plans and follow-up programs. Throughout Technical Workshops #4 and #5, Aurora LNG documented Kitsumkalum First Nation opinions, concerns and feedback. Aurora LNG will be providing a draft of Aboriginal Consultation Report #3 (i.e. the interim consultation report) at day 90 of the 180 day Application-review period (as per the EAO's letter of December 14, 2016). As part of the draft Aboriginal Consultation Report #3, Aurora LNG will report on its understanding of the status of issues/concerns resolution withKitsumkalum First Nationfor the issues/concerns recorded during all phases of the EA (in table format), including those identified inAboriginal Consultation Report #2 and recorded as part of Technical Workshops #4 and #5.The final version of Aboriginal Consultation Report #3 will be submitted at day 120 of the 180 day Application-review period (as per the section 11 Order [as amended]).
1266.1	round 1	Kitsumkalum First Nation	Section 3, page 5	Air Quality	"Emissions of VOC's are not modelled as Canada and BC have not established objectives for total VOC's...are not considered further in this assessment." This statement is partially correct in that there are currently no ambient air quality objectives for specific VOCs like benzene in BC or nationally; however, it is quite common to model VOC's and in both national and provincial Environmental Assessments (EA's) to adopt suitable values from other representative jurisdictions. For example, the TransMountain Expansion Project which recently was approved by the NEB, and the Canadian and BC governments (EAC Certificate was issued) and TransMountain agreed to adopt ambient air quality objectives from regulators outside of BC. In addition, TransMountain agreed to comply with ambient objectives from Alberta for benzene, toluene, ethyl benzene and xylenes (BTEX), and H2S and mercaptans objectives and guidelines from Ontario. TransMountain incorporated these objectives into their engineering design process and dispersion modelling was conducted routinely to inform engineering design and site ambient air quality monitoring locations. In addition to adopting suitable ambient objectives and guidelines into the EA process, potential health effects from the Project and Cumulative Cases can be more rigourously examined in the Human Health Risk Assessment (HHRA). The natural gas or fuel gas being combusted by the compressor gas turbines (16), power generators (6), heaters (4), thermal oxidizers (4), flares (3) and camp site power generators (2) contains air toxics like BTEX and other contaminants and the combustion process will create other toxics like benzo (a) pyrene and formaldehyde. The Aurora project will consume a huge daily volume of feed gas estimated to be 104 million cubic meters per day. Section 1.2.7.2 (Natural Gas Pre-treatment and Liquids Extraction, page 1-37) of the EAC Application indicates that C5+ and BTEX compounds will be removed from the feed gas before the liquefaction process but will not remove any contaminants from the feed gas for use in the on-site stationary combustion equipment listed above. Section 3.2 of the AQ TDR identifies the major fugitive and incomplete combustion sources and primary VOC emitters for the Project. There are several speciated VOC calculation tools and emission factors available from respected regulators such as CARB, US EPA, USAF, TCEQ and others which Stantec have previously referenced in similar air quality assessments for other oil sands and upgrader projects. *Question: Will Aurora amend the air quality assessment to include: (1) predicted concentrations for all fugitive, combusted and non-combusted VOC, PAH and heavy metals in their assessment of Project effects and (2), include the same calculated emissions in combination with emission estimates from other proposed LNG projects in the RSA in the CALPUFF dispersion model for a Cumulative Case (as listed in Table 15 of the AQ TDR) to provide a more representative analysis of potential air quality/human health effects for the Application and CEA Cases?*	Refer to the technical memorandum, "Volatile Organic Compounds and Human Health Assessment" which will be filed with the BC EAO. The "Volatile Organic Compounds and Human Health Assessment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting. Other substances (e.g., PAHs, heavy metals) were not identified by regulators and stakeholders during the development of the Application Information Requirements as health concerns associated with air quality. While the TransMountain project may have included PAHs (as benzo-a-pyrene) and heavy metals in the Screening Level Human Health Risk Assessment, the risk quotients and incremental lifetime cancer risk associated with inhalation of heavy metals and benzo-a-pyrene were 3 to 8 orders of magnitude (i.e, 1,000 to 100,000,000 times) below the levels that would constitute a significant health risk in a highly populated and industrialized region (i.e., Burrard Inlet and Metro Vancouver) for which the air quality is already affected by industry. These values do not support the need to evaluate heavy metals in the air.
1267.1	round 1	Kitsumkalum First Nation	Section 4.3, page 13, Table 6	Air Quality	Multiple references to "with consideration given" to other monitoring data. It is not clear exactly how measured CAC data from multiple stations is used to calculate Baseline values. This should be clarified.	With respect to the baseline air quality, the phrase 'with consideration given' means that the stations referred to were studied to determine if their data differed meaningfully from the data used to determine baseline. The baseline is determined entirely on the primary station cited, with the other stations merely being reviewed for consistency.
1268.1	round 1	Kitsumkalum First Nation	Section 4.3, page 13, Table 7	Air Quality	Baseline values given in this table do not all agree with those given in Detailed Model Plan (Appendix 1) submitted to MOE. For example, PM2.5 24-hour and Annual values are less than specified in Detailed Model Plan Table 2.	In the intervening time period between approval of the Detailed Model Plan and completion of the assessment, better information on local air quality became available. Discussions with the Ministry of Environment resulted in three parameters having increased baseline values and two having reduced baseline values. These changes are small and did not result in any material changes to the modelling results or the assessment conclusions.
1269.1	round 1	Kitsumkalum First Nation	Section 7.4.2, page 43	Air Quality	End of second paragraph states "most effects to community receptors are attributed to future regional sources." As stated in the TDR, there are multiple future regional sources, and so it is not clear whether one of those sources or the Project itself is the largest contributor to effects on community receptors. All future regional sources are bunched into one group. We would like to know the relative importance of the Project relative to other individual projects.	The relative importance of the Project compared with other individual projects is described in detail in Section 7.4.2 of Appendix A (Air Quality TDR). The CEA Case Attribution section breaks down the contribution of the CEA case at eight locations by 1) the Base Case, 2) the Project Alone Case, and 3) Other Future Sources. Determining which future project is responsible at each receptor is a matter of reviewing the isopleth maps for the parameter in question and studying Table 15 (to determine which project was included in the modelling) and Figure 3 (to determine the included projects location). For example, studying Figure 5-49 shows the SO2 maxima for the CEA Case is at Fairview Terminal.
1270.1	round 1	Kitsumkalum First Nation	Many locations	Air Quality	No frequency of exceedance plots. Only one reference to FOE values on page 42 of TDR. Statement on page 49 that characterizes exceedances of PM10 and NO2 as "short term in duration, infrequent" are not backed up by actual published values. In Appendix 1 page 22 is states that "frequency counts of hourly exceedance will be reported". This is not done in the TDR. On page 4.2-37 of EA FOE for PM10 and NO2 are mentioned in the text for CEA case and Application case only. There needs to be a more explicit discussion of frequency of exceedance.	The dispersion modelling indicated that there are predicted exceedances of PM10 and NO2 adjacent to, and primarily attributable to emissions from, facilities other than the Aurora LNG Project. Frequency of exceedance plots for PM10 for Base Case, Application Case and CEA Case have been provided as Figures 1, 2, and 3 of the "Air Quality Figures (#1270.1)" technical memo. The maximum PM10 concentrations for the Base Case, Application Case and CEA Case (i.e. where exceedances are shown to occur) are predicted adjacent to the Prince Rupert Grain Terminal. The maximum frequency of exceedance for the Base Case, Application Case and CEA Case is 7.5%, 7.6% and 7.8% of the time, respectively. A frequency of exceedance plot for 1-hour NO2 for the CEA Case has been provided as Figure 4 of the "Air Quality Figures (#1270.1)" technical memo. The maximum NO2 concentration for the CEA Case (i.e. where exceedances are shown to occur) is predicted adjacent to the Fairview Terminal. The maximum frequency of exceedance for the CEA Case is 7.9% of the time (28.7 days where the daily hourly maximum exceeds the AQO of 188 ug/m3). The "Air Quality Figures (#1270.1)" technical memo will be filed with the BC EAO. The "Air Quality Figures (#1270.1)" technical memo was presented to the Working Group in draft for pre-read on April 17, 2017 under the title of "Air Quality Figures (#927)."
1271.1	round 1	Kitsumkalum First Nation	Many locations	Air Quality	The scale of the figures does not allow the reader to see isopleths close to the Project or close to CAC maxima. Would be helpful to see some zoomed in figures to see these areas more clearly.	The scale of the figures and the selected isopleth interval is chosen to balance the need for detail over a large area without cluttering the figure with unnecessary detail. There are 71 isopleth maps in the Air Quality Technical Data Report (Appendix A of the Application). If the Kitsumkalum Indian Band would like to provide a list of figures and specific geographic areas of interest, some revised maps with a larger scale can be provided.
1272.1	round 1	Kitsumkalum First Nation	Page 15, Table 5	Air Quality	This Table shows that precipitation values derived from WRF were low compared to normal precipitation. Appendix 3 Table 7-2 also shows that WRF precipitation is ~25-30% too low compared to actual precipitation over the modelled years. This will have effects on deposition rates and ambient concentrations. Why not use precipitation data from Prince Rupert Airport and convert daily values to hourly? What is the effect on calculated deposition rates that are used to assess acidification and eutrophication of using precipitation rates that are too low?	Table 7.2 shows that precipitation at Prince Rupert Airport and Prince Rupert Mont Circle are under-predicted by 25% and 30% respectively. Experience with like projects in a similar setting shows that this range of under/over prediction are common and expected. This information has no meaningful effect on the spatial pattern shown in Figure 7-9. The overall effect of this discrepancy on the effects assessment regarding acidic deposition is small. Prince Rupert Airport precipitation was not used as input to the CALMET model as the final approved Detailed Model Plan stated that precipitation from the WRF model would be used. The WRF precipitation data was determined to be representative and have the advantages of spatial variation and accounting for orographic effects (increased precipitation at high elevations).
1273.1	round 1	Kitsumkalum First Nation	Section 4.2, page 4.2-43	Air Quality	A commitment by the proponent is made to participate and contribute to regional ambient air quality monitoring programs. In our opinion it is very important to have ongoing continuous monitoring of CACs considering the modelling suggests that exceedances of PM10 and NO2 are likely. The details of this monitoring need to be established.	Details of Aurora LNG's participation in regional ambient air quality monitoring programs will be established prior to the commencement of operation of the Project. It is expected that the program will be consistent with any requirements that may be outlined in potential EAC conditions and in the process of obtaining a Permit under the Environmental Management Act, Waste Discharge Regulation.
1274.1	round 1	Kitsumkalum First Nation	Section 3, page 9	Air Quality	Fugitive dust from construction activities are considerable from the handling and processing of materials, but was determined negligible based on precipitation data and peat moss composition of the materials moved. More clarification should be given on the precipitation in the area and its contribution to eliminating fugitive dust emissions. There is a potential for dust events during periods of no precipitation especially during the summer. As most emission factors for fugitive dust are based on moisture content and silt content, these parameters should be determined to support the exclusion of fugitive dust during construction.	Measures are proposed to reduce, avoid, or mitigate coarse fugitive particulate emissions from construction. They are contained in Table 4.2-10 of part 4.2 of the Application (Mitigation Measures Proposed to Avoid or Reduce Air Emissions). Measures are proposed such as limiting vehicle speed, and dust suppression. Coarse particulate matter emissions are easily managed in this setting, and are generally not an issue. Consistent with the final approved Detailed Model Plant (Appendix 1, Air Quality - TDR: Appendix A of the Application), the assessment focuses instead on fine particulate matter (PM2.5) from combustion sources.
1275.1	round 1	Kitsumkalum First Nation	Section 3.1, page 9	Air Quality	The load factor was described as the ratio of actual engine fuel consumption to maximum rated output. It is unclear how the load factor for each equipment was calculated based on the engine power in horsepower (hp) and fuel consumption in litres per hour per unit (L/hr/unit).	The load factor for each engine was calculated based upon the ratio of actual engine power output to maximum rated engine output. The average engine power output was calculated based upon the fuel consumed, energy content of the fuel, and thermodynamic efficiency of a typical engine, assumed to be 35%. Load Factor = (average power output / maximum power output) Average power output of the engine was calculated as: Average Power Output (bhp) = (L/h of diesel) * (1 USG/3.785 L) * (137,000 BTU/USG of diesel) * (0.000393 bhp-h/BTU) * (thermodynamic efficiency of 0.35)
1276.1	round 1	Kitsumkalum First Nation	Section 3.1, pages 12, 13, 20	Air Quality	The emission factor for NOx is 2.6 g/hp-hr for all diesel equipment in Table 3-2 and Table 3-5 of the TAR. While there was no clear indication on the origin of the emission factor, NOx emission factors for equipment with power rating from 100 hp to 750 hp appears to be consistent with Table A4. in the US EPA publication "Exhaust and Crankcase Emission Factors for Nonroad Engine Modeling - Compression-Ignition, NR-009d" and accounting for the Transient Adjustment Factors (TAFs) provided in Table A5 of the same document. However, equipment with power rating less than 100 hp would have a higher emission factor based on Table A4. The emission factor for CO is either 3.7 g/hp-hr or 2.6 g/hp-hr for all diesel equipment. It is not clear how the CO emission factors were derived as they are not comparable to CO emission factors provided in Table A4 and TAFs provided in Table A5.	The emission factors that were used for estimating emissions from the construction equipment are obtained from the emission limits in The Off-Road Compression-Ignition Engine Emission Regulations (SOR/2011-261, SOR/2005-32). As more than 90% of diesel consumption (based upon total hp-hours) is associated with diesel equipment with engines larger than 100 hp, the emission calculations were simplified and only adopted emission standards for engines greater than 100 hp. Aurora LNG has not yet started detailed construction planning and the exact composition and engine size of the construction fleet has not yet been determined. Based upon the estimated construction period for the Project and the typical lifetime of heavy duty construction equipment, it is anticipated that the construction fleet would consist of primarily Tier 4 compliant construction vehicles (i.e. better than Tier 3 assumed for calculation purposes) but may also contain some Tier 3 or Tier 2 compliant engines for select specialized equipment. The actual emissions from the diesel construction equipment are anticipated to be less than the estimate presented in Appendix 2 of the Air Quality TDR (Appendix A of the Application).
1277.1	round 1	Kitsumkalum First Nation	Section 4.1, 30	Air Quality	Manufacturer performance data was used to estimate NOx emissions from compressor gas turbine drivers. Although the accuracy of the data maybe higher, there is a potential for underestimating NOx emissions as manufacturer data maybe based on optimal operation of equipment. Emission factors are recommended to provide a more conservative estimate of emissions.	The manufacturer performance data are in fact performance guarantees warranted by the various turbine manufactures. The manufacturer guarantees are a conservative representation of NOx emissions from Project gas turbines as actual emissions are typically less than the guaranteed upper limit. Project NOx emission estimates from the proposed gas turbines are conservative as they are based upon the adoption of manufacturer guarantees and the assumption that all turbines operate continuously at 100% of their maximum rated capacity.
1278.1	round 1	Kitsumkalum First Nation	Section 4.2.1, page 35	Air Quality	The estimated emissions in tonnes per day of PM10 is less than PM2.5 in Table 4-8. How is this possible?	In Table 4-8, PM10 is listed as 0.004 t/d, and PM2.5 is listed as 0.0044 t/d. In fact, all PM emitted by gas turbines is <2.5 um in diameter, and therefore PM2.5 is equal to PM10. The discrepancy is due to the PM10 emission number being rounded to three decimal places, and the PM2.5 being rounded to 4 decimal places.

1279.1	round 1	Kitsumkalum First Nation	Section 4.7, page 48	Air Quality	The text in section 4.7 indicated 206 Q-Flex LNG carriers will visit the terminal per year, which is contrary to 256 carrier visits indicated in Table 4-29. Clarification in which number was used in the calculation is required.	The correct number of Q-Flex LNG carriers that were assumed to visit the terminal per year is 256. The value of 206 noted in the text in section 4.7 of the Air Quality Technical Data Report is a typographic error. The calculations were correctly completed using 256 Q-Flex LNG carrier visits per year. An errata document is being prepared that will capture this correction and it will be filed with the BC EAO.
1280.1	round 1	Kitsumkalum First Nation	Section 4.7, page 49	Air Quality	The load factor was calculated based on actual speed and maximum speed rather than engine output. The calculation is likely not an accurate estimate of the vessels' load factor, and updating the calculation is recommended.	The required power output for the main engine of the vessel is a function of vessel speed. The calculated load factor for the main engine is correctly calculated as the ratio of actual speed to maximum speed to the power of 3. The equation is obtained from Section 2.5 (page 2-11) of ICF International (ICF) report titled "Current Methodologies in Preparing Mobile Source Port-Related Emission Inventories, Final Report. April 2009.". Revised calculations are not required.
1281.1	round 1	Kitsumkalum First Nation	Section 4.7, page 49	Air Quality	The emission factors of NOx, SO2 and PM2.5 were recommended by the BC MOE. Clarification and reference should be included for these emission factors.	During consultation with the BC MOE, Aurora LNG were advised of the MOE's preference that Aurora LNG adopt the same emission factors for LNG vessel emissions as used in the Prince Rupert Airshed Study (PRAS). The emission factors presented in Table 4-30 of Appendix 2 (Air Quality TDR) were selected based upon MOE recommendations to ensure consistency with the PRAS.
1282.1	round 1	Kitsumkalum First Nation	Section 2.4, page 3	Greenhouse Gases	Aurora LNG indicates that "inherent uncertainty in estimating emission rates from the Project…the emissions estimates are conservatively high to capture worst-case full build-out conditions." In Section 1.2, Proposed Project Description (page 1-3) ,the Project includes three LNG storage tanks and based on 4 production trains will produce 24 MTPA of LNG at full build-out. Although Aurora acknowledges that the Project's 4 trains may be built over two phases, Aurora is not asking for approval related to Phase 1 only, it is seeking approval for both Phases. As such, the suggestion that the GHG emissions estimate is conservatively high and represents worst-case, full build-out conditions is neither justified, nor supported. It represents a minimally reasonable approach. *Questions: Can Aurora describe why the GHG emission estimates for the two phases are conservatively high? Has Aurora committed to GHG emission intensity < 0.28 tCO2e/tCO2e LNG produced?*	The Project GHG emission estimates are conservative due to the assumed conditions that have been included in the worst-case, full build-out scenario. Conservative conditions include the following:Main gas supply is assumed to have a conservative 1.82% mol CO2 content. Other projects have used lower values for estimated C02 content. The entire facility power demand is expected to be produced onsite, including the power for the compressor gas turbines. It has been conservatively assumed that the Project will not consume electricity through BC Hydro Based on the current Project design, the GHG emission intensity has been conservatively estimated to be 0.28t CO2e/t LNG produced. This emission intensity is expected to be much lower once actual data is available during the operation phase of the Project. For further information, regarding how changes of mol CO2 % in the feed gas can affect the GHG emission intensity, please refer to the memo “Feed Gas Carbon Dioxide (CO2) content Impact on GHG Emissions for the Aurora LNG Application for an Environmental Assessment Certificate”, which will be filed with the BC EAO.
1283.1	round 1	Kitsumkalum First Nation	Section 4, page 5	Greenhouse Gases	As noted above, the suggestion that the GHG assessment is conservative based on go/no go decision with respect Phase 2 and market demand is irrelevant and not supported by the Project Application. This is not a conservative assumption - it is a minimally reasonable approach. *Question: Can Aurora describe why the GHG emission estimates for the two phases are conservatively high?*	The GHG assessment is not conservative based on proceeding with Phase 2 of the project. The Project GHG emission estimates are conservative due to the assumed conditions that have been included in the worst-case emissions, full build-out scenario. Conservative conditions include the following:Main gas supply is assumed to have a conservative 1.82% mol CO2 content. Other projects have used lower values for C02 content. The entire facility power demand is expected to be produced onsite, including the power for the compressor gas turbines. It has been conservatively assumed that the Project will not consume electricity through BC Hydro. This presents the worst case scenario for project emissions. For further information, regarding how changes of mol CO2 % in the feed gas can affect the GHG emission intensity, please refer to the memo “Feed Gas Carbon Dioxide (CO2) content Impact on GHG Emissions for the Aurora LNG Application for an Environmental Assessment Certificate”, which will be filed with the BC EAO.
1284.1	round 1	Kitsumkalum First Nation	Section 5, page 26	Greenhouse Gases	"For the purpose of adhering to a conservative approach, the following assumptions apply: During operations, terminal liquefaction capacity is assumed to be 94.5%, which means that the facility is operating on average about 345 days a year at maximum capacity. Power for the entire facility is conservatively assumed to be produced onsite, including the power for the compressor gas turbines. There is no electricity consumption through BC Hydro. Therefore, emission estimates are conservative as GHG emissions from power generation onsite are included in the assessment, compared to when lower GHG intensity grid power is imported from BC Hydro." Section 1.2.5.3 Power Supply of the Proposed Project Overview (page 1-29) indicates that a ~250 MW power generation facility will be installed onsite and the preliminary design indicates that it will be a combined cycle natural gas power plant. The power plant will operate 24/7/365 and the liquefaction trains will operate 345 out of 365 days at maximum capacity. The proponent again suggests that the GHG assessment is conservative and may be over-estimating GHG emissions but fails to acknowledge the Project description that forms the basis for the Application. These are not conservative assumptions - they appear to be based on a minimally reasonable approach. Q*uestion: Can Aurora describe why the GHG emission estimates for the two phases are conservatively high?*	The Project design includes GHG emissions from natural gas fired compressor turbine drives and power generation turbines. It has been assumed that all power requirements will be generated onsite and no electricity will be imported from the BC Hydro grid. Therefore, emission estimations are conservative in that GHGs will be released from power generation onsite instead of importing low GHG intensity grid power. As the facility design advances through detailed engineering, efficiencies and optimum equipment selections are expected to result in reduced overall project operation emissions.
1285.1	round 1	Kitsumkalum First Nation	Section 5.1, page 28	Greenhouse Gases	As noted above, the suggestion that the GHG assessment is conservative based on onsite power generation and not grid power reflects the preliminary design philosophy in the Application and would be mis-stated as an over-estimation of effects. Questions: Can Aurora describe why the GHG emission estimates for the power generation are conservatively high? Is Aurora committing to using grid power from BC Hydro, and if so, to what extent?	The Project design includes GHG emissions from both natural gas fired compressor turbine drives and power generation turbines. It has been conservatively assumed that all power requirements will be generated onsite and no electricity will be imported from the BC Hydro grid. Therefore, emission estimation in the Application are conservative (i.e., "worst case") in that GHGs will be released from power generation onsite instead of importing low GHG intensity grid power. As the facility design advances through detailed engineering, efficiencies and optimum equipment selections are expected to result in reduced overall project operation emissions. Discussions are still being held between Aurora LNG and BC Hydro to understand the extent in which the Project can be connected to the BC Hydro grid.
1286.1	round 1	Kitsumkalum First Nation	Section 6, page 39	Greenhouse Gases	As noted above, the suggestion that the GHG assessment is conservative yet reflects the preliminary design philosophy in the Application cannot be characterized as an over-estimation of effects. Aurora has not committed to emit fewer GHG emissions through FEED design so the GHG assessment represents a minimally acceptable and non-conservative approach. *Questions: Can Aurora describe why the GHG emission estimates for the two phases are conservatively high? Has Aurora committed to GHG emission intensity < 0.28 tCO2e/tCO2e LNG produced?*	The Project GHG emission estimates are conservative due to the assumed conditions that have been included in the worst-case, full build-out scenario. Conservative conditions include the following:Main gas supply is assumed to have a conservative 1.82% mol CO2 content. Other projects have used lower values for estimated C02 content. The entire facility power demand is expected to be produced onsite, including the power for the compressor gas turbines. It has been conservatively assumed that the Project will not consume electricity through BC Hydro As the facility design advances through detailed engineering, efficiencies and optimum equipment selections are expected to result in reduced overall project operation emissions. The use of a 1.82% mol CO2 content in the main gas supply is conservative as this represents the higher end of CO2 content expected by the Project. In comparison to other recently approved LNG projects in BC, this CO2 content is as much as 1% higher. This conservative assumption has been applied until such a date that agreements can be made with a transmission project which will act as the main gas supply to the Project. For further information, regarding how changes of mol CO2 % in the feed gas can affect the GHG emission intensity, please refer to the memo “Feed Gas Carbon Dioxide (CO2) content Impact on GHG Emissions for the Aurora LNG Application for an Environmental Assessment Certificate”, which will be filed with the BC EAO.
1287.1	round 1	Kitsumkalum First Nation	Section 4.3.2.4, page 4.3-5 and Section 4.3.2.8, page 4.3-10	Greenhouse Gases	"As stated in the CEA Agency (2003) document, GHG assessments cannot address the significance of a single project's potential effect on climate change, as the effect on climate change cannot be accurately quantified or measured. Although it is understood that there is a relationship between GHG emissions from anthropogenic sources over the past 100+ years and a changing climate as an effect thereof, effects on climate change cannot be addressed in this GHG assessment. The science of climate change has not advanced to the point where a clear cause and effect relationship can be established between Project specific releases and measurable changes to global climate." This CEAA document is out of date with respect to the advancement of our our knowledge of the the effects of humans on climate change. It is not uncommon in EA's in Canada to assess Project effects on climate change. For example, Sections 6.4 (Project Effects) and 8.2 (Cumulative Effects) Assessment of GHG's of the Air Quality and Greenhouse Gas technical Report for the TransMountain Pipeline Project included a a summary of the Projects effect on climate change. https://transmountain.s3.amazonaws.com/application14/V5C_TECH_REPS/0730.html. Aurora LNG should undertake a similar assessment to report the effects of the Project's GHG emissions (i.e., construction, operations and marine) and cumulative effects on climate change. *Question: What are the quantified effects of the Project on climate change and the cumulative effect of the proposed LNG plants in BC on climate change?*	In relation to guidance on how Canadian projects are to evaluate their potential impact on climate change, CEA Agency 2003 is still the most current guidance from the relevant regulatory authorities. As outlined in the approved AIR, the cumulative environmental effect related to GHGs is measured at the global level by international bodies such as the Intergovernmental Panel on Climate Change (IPCC) and is associated with global climate change. Thereby, the evaluation of cumulative effects of proposed LNG facilities in BC to global climate change is not within the scope of this assessment.
1288.1	round 1	Kitsumkalum First Nation	Section 4.3.2.5, page 4.3-7	Greenhouse Gases	Aurora LNG indicates that "inherent uncertainty in estimating emission rates from the Project…the emissions estimates are conservatively high to capture worst-case full build-out conditions." In Section 1.2, Proposed Project Description (page 1-3) ,the Project includes three LNG storage tanks and based on 4 production trains will produce 24 MTPA of LNG at full build-out. Although Aurora acknowledges that the Project's 4 trains may be built over two phases, Aurora is not asking for approval related to Phase 1 only, it is seeking approval for both Phases. As such, the suggestion that the GHG emissions estimate is conservatively high and represents worst-case, full build-out conditions is neither justified, nor supported. It represents a minimally reasonable approach. *Questions: Can Aurora describe why the GHG emission estimates for the two phases are conservatively high? Has Aurora committed to GHG emission intensity < 0.28 tCO2e/tCO2e LNG produced? In the event that Phase Two does not proceed, what are the total GHG emissions for Phase One and the GHG intensity?*	The Project GHG emission estimates are conservative due to the assumed conditions that have been included in the worst-case, full build-out scenario. Conservative conditions include the following:Main gas supply is assumed to have a conservative 1.82% mol CO2 content. Other projects have used lower values for estimated C02 content. The entire facility power demand is expected to be produced onsite, including the power for the compressor gas turbines. It has been conservatively assumed that the Project will not consume electricity through BC Hydro. Aurora LNG is continuing discussions with BC Hydro to determine if electrical options may become available. The current facility design is based on simple cycle gas turbine power generation which is the least efficient and most expensive to operate. As the facility design progresses through its engineering design, Aurora LNG will be looking for opportunities to improve facility efficiency and minimize energy waste. This is expected to include consideration of combined cycle gas turbines and waste heat recovery for use in other processes which would be expected to help lower the overall emissions including GHGs. Based on the current Project design, the GHG emission intensity has been conservatively estimated to be 0.28t CO2e/t LNG produced. This emission intensity is expected to be much lower once actual data is available during the operation phase of the Project. The current Project design includes the operations of the full build-out scenario. This method was approved in the AIR and meets the objective to evaluate the reasonable worst case scenario. For further information, regarding how changes of mol CO2 % in the feed gas can affect the GHG emission intensity, please refer to the memo “Feed Gas Carbon Dioxide (CO2) content Impact on GHG Emissions for the Aurora LNG Application for an Environmental Assessment Certificate”, which will be filed with the BC EAO.
1289.1	round 1	Kitsumkalum First Nation	Section 4.3.5.2, page 4.3-21	Greenhouse Gases	"The GHG Management Plan will also contain a Best Achievable Technology analysis." Table 28 on page 38 of the TDR indicates that 99% of the GHG emissions from operations will be discharged by stationary combustion sources and thermal oxidizers for acid gas. *Questions: Explain what is meant by 'Best Achievable Technology' analysis? Does Aurora mean Best Available Control Technology? What opportunities does Aurora currently understand are available to control GHG emissions and what level of reduction is Aurora committed to achieve?*	The GHG Management Plan will contain discussion that aligns with guidance from the BC Ministry of Environment on " Best Achievable Technology" (BC MOE 2015) and guidance from the Ministry of Natural Gas Development (MNGD) entitled "Best Available Techniques Economically Achievable (MNGD 2014). As the facility design advances through detailed engineering, efficiencies and optimum equipment selections are expected to result in reduced overall project operation emissions. Commitments cannot be made at this time, but these Best Achievable Technologies will be identified and discussed in the GHG Management Plan. British Columbia Ministry of Environment (BC MOE). 2015. Ministry of Environment FactSheet – Waste Discharges. Best Achievable Technology. Ministry of Natural Gas Development(MNGD). 2014. Best Available Techniques Economically Achievable Guideline.
1290.1	round 1	Kitsumkalum First Nation	Section 4.3.5.2, page 4.3-26	Greenhouse Gases	"Further, if future technology advancements in GHG emission reductions become available and are considered economically feasible, a reduced GHG intensity is expected." *Question: What reduced level of GHG emission intensity is Aurora committed to for Phases one and two?*	Commitments cannot be made at this time as to the level of reduction expected from future technology advancements. The statement quoted in this comment aligns with one of the intents of the BC Ministry of Natural Gas Developments (MNGD) guidance entitled "Best Available Techniques Economically Achievable" (MNGD 2014) and the Air Quality Mitigation #4.2.10 noted in the Application. Ministry of Natural Gas Development(MNGD). 2014. Best Available Techniques Economically Achievable Guideline.
1291.1	round 1	Kitsumkalum First Nation	Section 4.3.5.3, page 4.3-28	Greenhouse Gases	In Table 4.3-13, Aurora reports that the estimated GHG emissions for the Project will total 925,970 t CO2e which as avery large amount of emissions. In Table 4.3-15 on page 4.2-28, Aurora ranks these GHG construction emissions to be "Low" in terms of magnitude. *Question, what metric is Aurora comparing these construction GHG emissions to arrive at this determination? How does Aurora define the magnitude of Low, Medium and High GHG emissions in terms of values and what is the basis for these values?*	In the absence of provincial and federal GHG policy and legislation related to a quantitative definition of magnitude in environmental assessments, the construction GHG emissions were evaluated in the context of the provincial and national inventory reports (PIR and NIR, respectively). The Project, under the full build-out scenario, which includes four trains, will release approximately 925,970 tonnes of CO2e into the atmosphere over the entire construction period. Approximately 46% of the Project's GHG emissions are estimated to come from land clearing activities, 48% are from site preparation (fleet emissions) and on-shore construction, and 1% and 5% are from marine construction and vehicle traffic respectively. Construction emissions are not captured in the PIR and NIR. However, land clearing emissions are included. Land clearing makes up 46% (419,345 tonnes of CO2e) of the total construction emissions. Site preparation, which includes land clearing and decay, will take place over four years. Therefore, if assumed to be evenly distributed, emissions impacting the PIR and NIR would be approximately 104,836 tonnes of CO2e/year. Compared against the PIR and NIR totals, it is estimated that site preparation (land clearing and decay) activities would increase 2014 PIR and NIR totals by 0.17% and 0.01%, respectively. Therefore, the magnitude has been considered to be low. This assessment considers a low magnitude to be a measurable change from the existing conditions (i.e. increase 2014 PIR and NIR totals by 0.17% and 0.01%, respectively). However based on CEA Agency guidance (2003) and professional judgment the change is considered small in comparison to PIR and NIR totals.
1292.1	round 1	Kitsumkalum First Nation	Section 4.3.6, page 4.3-29	Greenhouse Gases	Aurora cites a report from Global Advisors that exporting BC LNG is expected to have an overall positive effect on global GHG levels as LNG fuel would displace coal and oil as fuel, which emit higher GHG's, Whereas, combustion of LNG may have this desirable outcome, it is not clear whether this statement is true if the LNG plant GHG operational emissions from cooling, compression and liquefaction, and acid gas incineration and power generation are accounted for. *Question: Confirm the global benefit of using BC LNG still exists if proper accounting of operational GHG emissions includes those related to producing the LNG at Aurora.*	The Global Advisors Report can't be directly connected with Aurora LNG as it was published before the submission of this Application. The Application limited its reference to the Global Advisors Report as it was only known that "if LNG exported from BC manages to reach a lower life cycle intensity than other fuel sources around the world, then exporting BC LNG could have an overall positive effect on global GHG levels." The Project's GHG intensity (0.28 t CO2e/t LNG produced) closely reflects the Global Advisors GHG intensity for BC "Clean" LNG with no carbon capture and storage (0.27 t CO2e/ t LNG produced). Conclusions of the Global Advisor Report "shows that 'clean' natural gas from BC could result in significantly reduced global GHG emissions depending on which scenario is achieved. " (Globe Advisors. 2014)

1293.1	round 1	Kitsumkalum First Nation	Section 4.3.7.1, page 4.3-29	Greenhouse Gases	Lost in the discussion is the fact that as AB is trying to reduce GHG emissions from the early retirement of its coal fired power plants, BC may potentially approve several LNG plants that create as much as or more GHG emissions that are being retired in AB. The outcome of this could be either no change in GHG emissions in AB and BC when Canadian commitments in international agreements were to reduce GHG emissions.	It is outside of the scope of this assessment to provide commentary on provincial and/or national policy or targets.
1294.1	round 1	Kitsumkalum First Nation	4.3, Table 4.3-3	Greenhouse Gases	Clarification is required to understand the value of the requested evaluation of upstream GHG emissions if it is in fact not to be incorporated into the assessment of Project GHG emissions.	Following receipt of the letter from ECCC to the BC EAO regarding the Project Upstream Greenhouse Gas Assessment (dated December 1, 2016), Aurora LNG and the BC EAO agreed on the delivery date of Feb 22, 2017 for the report. The Feb 22, 2017 delivery date was agreed to by the BC EAO to provide sufficient time for review of the material. The Aurora LNG Project Upstream Greenhouse Gas Assessment has been delivered to the BC EAO.
1295.1	round 1	Kitsumkalum First Nation	4.3	Greenhouse Gases	As it is clear that the Aurora LNG Project will not be in compliance with the provincial intensity benchmark of 0.16 tonnes of C02e/tonne of LNG, and may or may not reach within the intensity limits of 0.16-0.23 tonnes of C02e/tonne of LNG (for reduction in carbon tax levy), it is not clear how Nexen will offset the non-compliance. As with other VCs where offsetting is required these offsetting plans (even if preliminary) are presented in the assessment to understand how significant effects can be balanced. Although a Condition of the potential EAC will be the submission of a GHG Management Plan to the EAO (and other relevant agencies), again the contents of this plan are unknown and it is difficult to understand the true significance of the effects of GHG emissions. Suggest, at minimum, that GHG Management Plan include an GHG emissions offsetting plan and the development of these plans be a transparent process among all affected stakeholders.	Section 4.3.5.2 of the Application states "A GHG Management Plan will be prepared to identify the requirements of relevant GHG reporting legislation and will contain continuous assessment of monitoring and management requirements applicable to the mitigations listed in Table 4.3-12 (e.g., requirements of a fugitive emission survey program). The management plan will also contain a Best Achievable Technology analysis." Compliance with the provincial intensity benchmark of 0.16 tonnes of CO2e/tonne of LNG produced will be clarified in the annual reports submitted to the Climate Action Secretariat during the operation phase of the project. Each year, the project will be able to choose if it will purchasing credits, offsets or investing in a technology fund.
1296.1	round 1	Kitsumkalum First Nation	4.3 (page 4.3-12)	Greenhouse Gases	It is again a case of project splitting whereby the GHG intensity benchmark is based only on the "production emission" and does not include natural gas production or transmission of upstream of the facility. The Project will in fact not be a Project without the upstream and mid stream components. Although Nexen is following guidance from CEA and the Province (in their assessment methods), there is little hope for Canada or the Province to meet their Agreement targets (in the time frame) if we continue to ignore a holistic view of the LNG industry.	Following receipt of the letter from ECCC to the BC EAO regarding the Aurora LNG Project Upstream Greenhouse Gas Assessment dated December 1, 2016, Aurora LNG and the BC EAO agreed on the delivery date of Feb 22, 2017 for the report. The Aurora LNG Project Upstream Greenhouse Gas Assessment has been delivered to the BC EAO.
1297.1	round 1	Kitsumkalum First Nation	4.3 (Talbe 4.3-9)	Greenhouse Gases	As stated in the responses from the proponent to WG members associated with the screening review: "As indicated in the Application, it is not anticipated that waste management will interact with GHGs in a substantial manner. The primary basis for this conclusion is that Aurora LNG intends to avoid open burning of accumulated waste during all phases of the Project. Therefore, based on the avoidance and minimization of burning of accumulated waste, it is not anticipated that waste management contribute to GHGs in substantial manner. To reflect this commitment, the list of GHG mitigations has included a mitigation to "Minimize open burning of accumulated waste materials from the construction camp" (Mitigation 4.2.6) which will be managed through the Solid Waste Management Plan. This indicates that burning of waste during the construction phase may occur, but Aurora LNG plans to minimize this activity, where possible and safe to do so." Even with a timber salvage plan, how does Nexen propose to eliminate the wood waste from clearing of a 773 ha area (the PDA)? if not by burning?	The construction GHG inventory conservatively includes burning of biomass to account for debris, stumps, and unused portions of the salvaged timber. However, the Project intends to avoid the burning of biomass where practical and safe to do so.
1298.1	round 1	Kitsumkalum First Nation	4.3 (page 4.3-20	Greenhouse Gases	Kitsumkalum does not agree with the exclusion of LNG carrier emissions from the Project's operational total (emissions). The proponent could calculate the percentage of emissions attributable to their LNG carriers transiting, at minimum, from Triple island to the berth and assess this as part of the total project GHG emissions and operational intensity calculation.	Shipping activities are quantified and presented in Table 4.3-14 of Section 4.03 of the Application. These totals include emissions from LNG carriers (international) and domestic boats. In the GHG assessment, Project operation emissions are compared to PIR and NIR totals to determine the impact or percent contribution. However, the PIR and NIR totals do not include international shipping activities. Therefore, this assessment has excluded them in this comparison. Further, the GHG emission intensity presented in the Application does not include international shipping emissions as these would not be included in future compliance reporting obligations and would not be included in annual operation GHG intensity calculations.
1299.1	round 1	Kitsumkalum First Nation	4.3 (Table4.3-12	Greenhouse Gases	Kitsumkalum would like to participate in the development of the GHG Management Plan. As proposed in Table 4.3-12 many of the proposed mitigations that are to be a part of the GHG Management Plan are standard best practices, Kitsumkalum is looking for innovative and adaptive management strategies such that Nexen will be viewed as taking steps above and beyond industry standards to reduce their GHG footprint.	Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Greenhouse Gas Management Plan.
1300.1	round 1	Kitsumkalum First Nation	4.3	Greenhouse Gases	Kitsumkalum agrees with screening comments from WG members regarding the need to quantify the GHG emissions associated with Project decommissioning. Generally, and without FEED information, many of the emission rates / quantities associated with construction activities are but estimates. Estimates for decommissioning activities could be made.	The construction emission inventory was prepared based on Project estimates of equipment usage in conjunction with emission factors that apply to current mobile equipment. The decommissioning phase will be more than 30 years in the future. Therefore, not only are Project equipment estimates more difficult but emission factors for equipment that will operate at the time of decommissioning are currently unknown (i.e., current generation of equipment will be retired). Emissions calculations for the decommissioning phase are therefore not possible at this time. Given the nature of the decommissioning phase activities, it is expected that equipment usage will be for a shorter period of time and less intensive than the construction phase. However, future decommissioning requirements are unknown so this may be incorrect. Mobile equipment will likely consume fuel more efficiently and emissions may differ from current depending on technologies employed. These factors suggest that during the decommissioning phase of the Project, GHG emissions should be less than the construction phase.
1301.1	round 1	Kitsumkalum First Nation	4.3 (Table 4.3-15)	Greenhouse Gases	It is unclear how a Project Residual Effects on GHG Emissions can have a negligible magnitude from decommissioning and abandonment activities If GHG emissions have not be quantified for those effects.	Based on the assessment conclusion that construction emissions will have a "low" magnitude of GHG emissions and that decommissioning activity is expected to be a shorter period with less GHG emissions than the construction phase, it was qualitatively determined that decommissioning will have a negligible magnitude of GHG emissions. As identified in the Application, only land clearing emissions during the construction phase will impact the PIR and NIR emission totals. During the decommissioning phase, little-to-no land clearing is expected. Therefore, the decommissioning phase will have limited impact to the PIR and NIR emission totals.
1302.1	round 1	Kitsumkalum First Nation	4.3	Greenhouse Gases	Kitsumkalum would like to see commitment from the Proponent (and in the form of a Condition the potential EAC) to assess every five years the feasibility of using electricity for LNG production activities (and where feasible a move away from NG to electric drive power). This would also include a commitment to develop and build power drives such that they may be switched from NG driver to electric drive.	Aurora LNG acknowledges the intent of this comment. The Aurora LNG project is proposed in phases with two LNG trains planned for the first phase and subsequent phases based on market demand. If there are no power options available and the facility design is based on the current gas turbine scenario and the Project takes a final investment decision to move forward, it is very unlikely that Aurora LNG would consider retrofitting the constructed portions of the facility with e-LNG at a later date. Given the very high capital costs, very long lead order time, and the numerous linked aspects of changes in design involved and that all of the facility plans and operations procedures would be based on a defined set of hardware. However, it may be feasible to consider e-LNG for subsequent phases of the Project. This would need to be reviewed at that time based on the latest information available. The current Project design proposes the use of gas turbines for both LNG trains and onsite power generation. At this time, this is the only technically feasible option given the limitations of the BC Hydro grid to accommodate new industrial power demand. Aurora LNG is continuing discussions with BC Hydro and other potential power providers to determine if "e-LNG" is a feasible option. If Aurora LNG is able to secure sufficient reliable power for e-LNG in advance of detailed design, then this option will be reviewed in detail and may be considered a viable option at that time.
1303.1	round 1	Kitsumkalum First Nation	4.3 and 14.4	Greenhouse Gases	None of the proposed mitigation measure and to be part of the GHG Management Plan to lessen or manage GHG project effects will meaningfully reduce the Project GHG emissions intensity. Kitsumkalum is looking for substantial commitments from the proponent to reduce their intensity level (without the use of credits or offsets).	The Project will comply with the Greenhouse Gas Industrial Reporting and Control Act and will meet the GHG intensity benchmark through optimizing facility design and operation and if required through a combination of purchasing credits, offsets or investing in a technology fund. Discussions are underway with BC Hydro to understand the extent the Project could connect to the lower GHG intensive grid. These actions will reduce the overall GHG intensity of the Project.
1304.1	round 1	Kitsumkalum First Nation	4.4.1	Acoustic Environment	" noise is defined as unwanted sound and has the potential to affect the health and well-being of humans." What about fish, birds, animals, Bats etc. ? You mention a link between this section and different wildlife sections, but why then use this definition?	Noise effects on wildlife are considered in Section 4.7 of the Application (Wildlife Resources). Noise effects on marine mammals are considered in Section 4.10 of the Application (Marine Mammals). Noise effects on marine birds are considered in Section 4.11 of the Application (Marine Birds). The definition of noise in the Acoustic Environment (Section 4.4 of the Application) is in the context of assessing noise effects on humans.
1305.1	round 1	Kitsumkalum First Nation	4.4.2.1	Acoustic Environment	We have continually been fed the lines world class and world leading technology. And that LNG in BC will be a world leader. How do the thresh holds listed for noise and vibration compare to other world standards such as those in the E.U. ? If this project is to be world class, we expect the highest standards to be met! Please clarify how the project will be a world leader in this section and all sections!	The noise thresholds applied in the Application are based on the BC OGC noise guideline and Health Canada Noise Guidance. The Health Canada noise guidance is based on domestic and international scientific research pertaining to the human health impacts of noise. The noise thresholds are based on available information and knowledge acquired from Canadian and international sources. The vibration thresholds are based on a Canadian guideline (Environment Canada Environmental Code of Practice for Metal Mines) and municipal guideline (City of Toronto Construction Vibration Limit), which are considered the most applicable available guidance.
1306.1	round 1	Kitsumkalum First Nation	4.4.2.5	Acoustic Environment	Administrative boundaries lists jurisdictions but as mentioned in previous comment, world leading standards must be met.	The noise and vibration assessments are based on the most applicable Canadian guidance.
1307.1	round 1	Kitsumkalum First Nation	table 4.4.8	Acoustic Environment	The table says that flaring will not result in any change in noise level? Is this correct? I would imagine this would be quite noisy? And have a hard time believing that there is no noise associated with flaring. My BBQ makes noise and it burns significantly less fuel than a flaring event.	A normal operating flare has two noise mechanisms: combustion roar and gas jet noise. Combustion roar noise is typically in the lower frequency region of the audible frequency spectrum while gas jet noise occurs in the higher frequency spectrum. A flare with a stack tip design that results with low velocity and low level of turbulence will mix slowly with ambient air and burn relatively quietly. A flare with high velocity and high level of turbulence will burn much faster and emit higher combustion noise. The LNG facility will be designed and operated such that planned flaring will not result in any regulatory noise exceedances during normal operation. The flare will be designed to handle the emergency discharge/relief which is typically a high flow scenario, infrequent and of short duration. The emergency discharge can create some noise effects at nearby receptors but it is expected to be in compliance with the regulatory limits. There will be flaring events during the commissioning, start up and regular maintenance while the facility operation is optimized. Flaring events are controlled temporary, short term and intermittent.
1308.1	round 1	Kitsumkalum First Nation	4.4	Acoustic Environment	I am curious about many of the items listed as not contributing to increased sound levels. This seems counter intuitive. If one person whispers it is almost imperceptible but if 1000 people all whisper at the same time there becomes a very noticeable level of white noise. Is this accounted for and how?	The assessment indicates that there will be a measurable change in sound level at some receptor locations (Section 4.5.5.2 of the Application, Table 4.4-20, Table 4.4-21, Table 4.4-22). The assessment accounted for the cumulative effects of multiple noise emissions within a time period. Section 5.1.2 in the Acoustic Environment Technical Data Report (Appendix C of the Application) summarizes the noise emission sources during the construction and operation phase of the Project. Construction Year 1 and Year 5 were selected on the basis of highest construction equipment activities during marine based and land-based construction, respectively. During the operations phase, full build-out of the LNG processing facility was represented in the assessment. It includes the operations of all four LNG trains and the associated facilities (i.e., power plants, utilities, storage) to enable a conservative assessment.
1309.1	round 1	Kitsumkalum First Nation	table 4.4-9	Acoustic Environment	"High disturbance Project related activities (e.g. blasting and pile driving) will occur between the daytime hours of 7 a.m. and 10 p.m. Mitigation Mechanism: Reduce noise generating activities during the night time" I would suggest that the project re-consider these timelines. If not, I would like to volunteer the Nexen executives and proponents to live full time within earshot while a project conducts blasting and pile driving until 10PM. I can not imagine this for families with children and a reasonable bed time, elderly or other sensitive people.	Piling work will be required for foundation work during marine and land-based construction. Typical piling activities use impact type hammer equipment with sound power level in the order of 120 dBA. Vibratory pile hammers contain a system of counter-rotating weights, powered by hydraulic motors, and designed in such a way that horizontal vibrations cancel out, while vertical vibrations are transmitted into the pile. Vibratory hammer piling equipment is typically quieter than impact type hammer piling equipment. Drill or screw piling are a steel screw-in piling and ground anchoring system used for foundations. Screw piles are installed using various earth moving equipment fitted with rotary hydraulic attachments. In comparison to impact type hammer, drill piling and vibro-hammer piling are quieter options. The geo-technical conditions will determine the most suitable piling methods and, as outlined in mitigation measures 4.4.2 and 4.4.3, where conditions permit the quieter piling options will be used. As per mitigation measure 4.4.1, high disturbance project related activities (e.g., blasting, pile-driving, will occur between the daytime hours of 7 a.m. and 10 p.m.
1310.1	round 1	Kitsumkalum First Nation	Page 4.4-35	Acoustic Environment	"The assessment of compliance with the BC OGC Noise Guideline is performed for the operations phase only. BC OGC does not provide compliance criteria for construction noise assessment. Therefore, results from the construction phase scenarios are not compared to the noise thresholds from the Health Canada Noise Guidance." It is unfortunate that there are no compliance criteria during construction. Due to the long construction time though, some compliance criteria must be developed. The proximity to residences and extensive build time could potentially make living in the area during construction a disturbing undertaking. Once again, we expect the project to be world leading, so please illustrate to us how you plan to be world leading.	The Application contains a typo. The paragraph should be revised to ""The assessment of compliance with the BC OGC Noise Guideline is performed for the operations phase only. BC OGC does not provide compliance criteria for construction noise assessment. Therefore, results from the construction phase scenarios are not compared to the noise thresholds from the BC OGC Noise Guideline." An errata document is being created that captures these corrections and it will be filed with the BC EAO. Health Canada noise guidance does provide recommendations on noise criteria for construction activities. The Application compares the construction noise effect to the Health Canada guidance in Section 4.4.5.2 of the Application (Table 4.4-14 and Table 4.4-15).
1311.1	round 1	Kitsumkalum First Nation	page 4.4-37	Acoustic Environment	"An option to use a vibro-hammer pile or drill pile will be considered for the land-based piling operation where geotechnical conditions permit." this should read Vibro type installation should be used at all locations where possible.	Piling work will be required for foundation work during marine and land-based construction. Typical piling activities use impact type hammer equipment with sound power level in the order of 120 dBA. Vibratory pile hammers contain a system of counter-rotating weights, powered by hydraulic motors, and designed in such a way that horizontal vibrations cancel out, while vertical vibrations are transmitted into the pile. Vibratory hammer piling equipment is typically quieter than impact type hammer piling equipment. Drill or screw piling are a steel screw-in piling and ground anchoring system used for foundations. Screw piles are installed using various earth moving equipment fitted with rotary hydraulic attachments. In comparison to impact type hammer, drill piling and vibro-hammer piling are quieter options. The geo-technical conditions will determine the most suitable piling methods and, as outlined in mitigation measures 4.4.2 and 4.4.3, where conditions permit the quieter piling options will be used. As per mitigation measure 4.4.1, high noise effect activities such as pile driving will be undertaken during daytime hours.

1312.1	round 1	Kitsumkalum First Nation	Table 4.5-15	Water Quality	Prince Rupert airport is listed as not having cumulative effects on fresh water? De-icing, emissions, spills etc. Would all have impact. Is the above comment only because they do not share the same creeks and drainages? This may need to be considered as it would cumulatively affect the islands water.	The Prince Rupert airport will have environmental management plans in place to manage de-icing and spills. Project related effects to freshwater are evaluated due to LNG facility emissions of nitrogen and sulfur compounds, or due to project related water releases. For freshwater, cumulative effects of other regional industry or business is limited to the contribution of air emissions and related to deposition into water courses. Airplane emissions were accounted for in the air quality model under the cumulative emissions application (CEA) case by adding a background term to the model.
1313.1	round 1	Kitsumkalum First Nation	4.5	Water Quality	"The Freshwater Quality Assessment focuses on potential acidification and eutrophication effects related to air emissions from the proposed LNG facility." Why only air emissions? Water quality from the massive settling ponds that will need to be created during grubbing and clearing, potential to stir up legacy contaminants when grubbing, and other factors need to be addressed. Spills, waste management, and others may affect water quality	Potential effects of soil erosion on the freshwater ecosystem is assessed under Wastewater Management in the effect "Change in Fish Abundance or Relative Abundance" in the Freshwater Fish and Fish Habitat VC, Section 4.8.5.4. Runoff and discharges to marine water are assessed under Project Mechanisms for Change in the Physical or Chemical Composition of Marine Waters (Marine Water Quality VC, Section 4.5.15.3). It is noted in this section that "The soils storage area will be re-vegetated, where possible, and drainage patterns will be established to manage runoff to the marine environment." As noted in Mitigation 4.5.8 (Table 4.5.26, Section 4.5.15.3), the project will be designed to maintain discharges to the marine environment within regulations and guidelines for the protection of aquatic life so runoff from the soils storage area is not predicted to cause effects to the freshwater or marine ecosystems.
1314.1	round 1	Kitsumkalum First Nation	4.5	Water Quality	Report does not seem to include the extreme flashiness of creeks and systems caused by the extensive clearing of the site! The bogs, holding capacity and complexity will be removed. Streams and drainages will become extremely "flashy" resulting in high levels of erosion and water quality and quantity issues. not to mention potential habitat issues and loss.	Potential effects of soil erosion on the freshwater ecosystem is assessed under Wastewater Management in the effect "Change in Fish Abundance or Relative Abundance" in the Freshwater Fish and Fish Habitat VC, Section 4.8.5.4. Aurora LNG will limit disturbance to riparian areas, to the extent possible, and will not disturb watercourses or associated riparian areas outside of the PDA. Exclusion fencing will be installed where needed to delineate the areas to be protected. Erosion and Sediment Control facilities will capture diverted site run-off for settlement or testing prior to discharge into existing watercourses/marine environment. An environmental monitor will be onsite during all instream works to monitor for potential harm to fish (or fish habitat) and to evaluate or correct installed erosion control measures. The soils storage area will be re-vegetated, where possible, and drainage patterns will be established to manage runoff. The systems put in place to mitigate sediment and erosion control will account for potential high flow events. Project activities that result in a change or loss of fish habitat will be mitigated through the fisheries habitat offset plan, as required under the Fisheries Act.
1315.1	round 1	Kitsumkalum First Nation	4.5.2.7	Water Quality	Likelihood of residual effects. Wording of Low - freshwater quality can largely be avoided or mitigated these should read will largely be avoided and mitigated. Similar issues for med and high.	Edits to the Application are not possible during the Application Review stage. As these suggested revisions are largely editorial in nature, this comment is noted.
1316.1	round 1	Kitsumkalum First Nation	4.5.3.2	Water Quality	water chemistry was taken for hardness nutrients…… but were pollutants such as LEPH's PAHs etc. looked at as potential background. Or are we to assume that **any future levels found are caused by some form of project impact?**	Full chemical datasets are provided in Appendix E Surface Freshwater Technical Data Report of the Application. Parameters include total and dissolved metals, nutrients, organic carbon, and physical parameters. PAHs and LEPH's were not measured as part of the freshwater assessment as there is expected to be no input of these contaminants. The future monitoring programs are anticipated to include a more detailed baseline collection program and these additional parameters may be considered during that time.
1317.1	round 1	Kitsumkalum First Nation	4.5.3.2	Water Quality	wouldn't the leading cause of acidity be organic matter and not geological and soil characteristics? Soil characteristics is misleading and while it includes the decomposing organic material, it does not solely refer to the organics. Nor is the actual cause discussed. It seems to be only speculated. It should be determined why and how before approving a project that could potentially shift a number of ecosystems!	Section 4.5.3.2 provides an overview of current conditions for freshwater systems. The pH in lakes and streams can vary due to influence from numerous factors including surficial geology, sediments and soils, rainfall, and historical pollution sources. Regions with high precipitation often have dilute waters with acidic to circum-neutral pH.
1318.1	round 1	Kitsumkalum First Nation	4.5.3.2	Water Quality	13 out of 39 lakes are high, moderate or sensitive to acid inputs. This is 33%! This seems to be downplayed a fair bit throughout the rest of the document. This was also brought up at the working group.	Section 4.5.3.2 of the Application provides an overview of current conditions for freshwater systems. Lakes with a natural acid neutralizing capacity less than 50 µeq/L are considered acid-sensitive due to limited acid buffering capacity. Lakes located in areas of high precipitation, such as those found in coastal British Columbia (BC), have rainwater-diluted ion chemistry, leading to low buffering capacity and alkalinity, and are therefore considered acid sensitive.
1319.1	round 1	Kitsumkalum First Nation	Table 4.5.6	Water Quality	Waste management was not included as a potential change in physical composition of surface water. If rain water typically falls over an acidic forest floor, then seeps through soil, vegetation, organic matter and wetlands prior to reaching streams and tributaries prior to flowing out to the ocean, and now Nexen is proposing to remove all the vegetation on a large site and that water will likely flow over hard surfaces and be deposited directly to creeks, and ocean. I would disagree. there will be some changes to local water qualities and changes to the chemistry of those watercourses. both in flow volumes and in chemical composition. the flashiness, reduced flows (due to less reserve) etc. is not addressed here.	The potential effects of soil erosion on the freshwater ecosystem is assessed under Wastewater Management in the effect "Change in Fish Abundance or Relative Abundance" in the Freshwater Fish and Fish Habitat VC, Section 4.8.5.4 of the Application. Runoff and discharges to marine water are assessed under Project Mechanisms for Change in the Physical or Chemical Composition of Marine Waters (Marine Water Quality VC, Section 4.5.15.3 of the Application). It is noted in this section that "The soils storage area will be re-vegetated, where possible, and drainage patterns will be established to manage runoff to the marine environment." As noted in Mitigation 4.5.8 (Table 4.5.26, Section 4.5.15.3 of the Application), the Project will be designed to maintain discharges to the marine environment within regulations and guidelines for the protection of aquatic life. Runoff from the soils storage area is therefore not expected to cause effects to the freshwater or marine ecosystem.
1320.1	round 1	Kitsumkalum First Nation	4.5.5	Water Quality	Why is water quality in relation to waste management, not included in water quality? This does not seem to make sense	The assessment of potential Project effects on freshwater quality focused on effects of acidification and eutrophication, as inputs from effluent discharges to freshwater are not planned. Potential effects of soil erosion on the freshwater ecosystem are assessed under Wastewater Management in the effect "Change in Fish Abundance or Relative Abundance" in the Freshwater Fish and Fish Habitat VC, Section 4.8.5.4 of the Application. Runoff and discharges to marine water are assessed under Project Mechanisms for Change in the Physical or Chemical Composition of Marine Waters (Marine Water Quality VC, Section 4.5.15.3 of the Application). It is noted in this section that "The soils storage area will be re-vegetated, where possible, and drainage patterns will be established to manage runoff to the marine environment." As noted in Mitigation 4.5.8 (Table 4.5.26, Section 4.5.15.3 of the Application), the Project will be designed to maintain discharges to the marine environment within regulations and guidelines for the protection of aquatic life. Runoff from the soils storage area is therefore not expected to cause effects to the freshwater or marine ecosystem.
1321.1	round 1	Kitsumkalum First Nation	Table 4.5-15	Water Quality	Prince Rupert airport is listed as not having cumulative effects on fresh water? De-icing, emissions, spills etc. Would all have impact.	The Prince Rupert airport will have environmental management plans in place to manage de-icing and spills. Project related effects to freshwater are evaluated due to LNG facility emissions of nitrogen and sulfur compounds, or due to project related water releases. For freshwater, cumulative effects of other regional industry or business is limited to the contribution of air emissions and related to deposition into watercourses. Airplane emissions were accounted for in the air quality model under the cumulative emissions application (CEA) case by adding a background term to the model.
1322.1	round 1	Kitsumkalum First Nation	Table 4.5-11	Water Quality	Mitigation number 4.2.3 Use of busses where feasible. These should be powered by LNG then to further help reduce emissions. A commitment should be made.	In Table 4.2-10, measures are proposed to mitigate emissions by using buses, where feasible (4.3.3). They are contained in Section 4.2 of the Application (Mitigation Measures Proposed to Avoid or Reduce Air Emissions). Specific measures such as the use of LNG as fuel will be evaluated at the construction procurement stage based on the availability of LNG fuel, LNG buses, and other factors.
1323.1	round 1	Kitsumkalum First Nation	Table 4.5-11	Water Quality	mitigation 4.2.5 burning of biomass should read: must use air curtain burners to avoid excessive ash and emissions. There are several local operations that provide this service.	Measures are proposed to reduce, avoid, or mitigate emissions from the burning of biomass. They are contained in Table 4.2-10 of part 4.2 of the Application (Mitigation Measures Proposed to Avoid or Reduce Air Emissions). Measures are proposed such as salvaging timber, avoiding biomass burning, and reducing or postponing biomass burning consistent with the Open Burning Smoke Control Regulation (BC Reg. 145/93 and BC Reg. 41/2016 amendments). Air curtain burners are an effective technology and will be considered during the FEED process as part of the land clearing procurement process.
1324.1	round 1	Kitsumkalum First Nation	page 4.5-27	Water Quality	Wording like "only three lakes are predicted to have exceedances" shows the leading nature of the report. This is not objective scientific writing. It is like saying we only destroyed one town. One is not acceptable especially if it is your town. Call the facts as they are. three lakes are predicted to have exceedances and let the data speak for its self. There are many other leading comments through out the document. this is pulled forward in section 4.5.37 as "no critical load exceedances were predicted for 87% ...." but conversely that means 13% will have exceedances. These are supposed to be Impact studies, **not Non impact studies.**	Edits to the Application are not possible during the Application Review stage. All data was presented in appendices and tables within the Water Quality Technical Data Report (Appendix E of the Application) with the intent of providing transparent and scientifically based results.
1325.1	round 1	Kitsumkalum First Nation	4.5.6.3	Water Quality	"there is medium likelihood of a residual cumulative effect for eutrophication" and "Adverse effects may be difficult to avoid" If this was said about impacts to the Nexen CEO's backyard or where his/her kids play and areas they use for recreation, would they think this was an ok project to go ahead?	The likelihood scale (low, medium, high) is used to indicate the probability that emissions will interact with aquatic systems. Since it will be hard to avoid facility air emissions being deposited into aquatic systems and this will occur to some extent, it was rated as medium. For eutrophication, Dodge Cove Reservoir (LAK11) had a predicted exceedance to nutrient nitrogen loading limits and Lake 05 is modeled to exceed lower bound nutrient nitrogen limits. The modeling used several conservative assumptions for air quality, water quality, and soil quality. As a result, predicted or modeled exceedances are not an indication that effects will occur in these lakes, but that they may occur.
1326.1	round 1	Kitsumkalum First Nation	4.5.9	Water Quality	Follow up programs, Kitsumkalum requires the results and data from all follow up programs. Not through public links that must be searched regularly, but we require to be updated and informed as new material is added to these reports.	The water quality follow-up and monitoring programs are expected to be developed on a regional level and the plan is to consult with Aboriginal Groups, MOE and other local industry to finalize those programs. It is expected that Aboriginal Groups will be involved in the implementation of those programs. Please see the "Additional Information about Eutrophication and Acidification in Freshwater" technical memo for additional details on future monitoring programs. This technical memo will be filed with the BC EAO.
1327.1	round 1	Kitsumkalum First Nation	4.5.13.1	Water Quality	the "detailed sediment sampling program ran from Jan 15- feb 3 2016". To be clear this is one field shift, to collect all your "detailed" data. Was this enough sampling to fully characterize and be statistically significant?	A detailed sediment sampling program was carried out at the three proposed dredge footprints (Berth 1, Berth 2 and the MOF). A total of 192 samples were collected to characterize physical parameters, metals, PAHs, PCBs, and PCDD/Fs in marine sediment. This included 28 surface samples (0-0.07 m depth), 102 large interval core samples (0-1.5 m depth, divided into 0.5 m intervals), and 62 small interval core samples (0-1.0 m depth, divided into 0.2 m intervals). Sediment samples were collected over two field programs; a 5 day field program (December 15 to 19, 2014) and a 16 day field program (January 15 to February 3, 2016). The field program design was reviewed and approved by Environment and Climate Change Canada (ECCC) prior to sampling. The sampling programs also met ECCC disposal at sea evaluation criteria for number of samples required based on dredge volume. The field programs yielded a comprehensive and statistically robust dataset.
1328.1	round 1	Kitsumkalum First Nation	page 4.5-52	Water Quality	marine sediment screening results are present but I do not see reference to the results or data.	Table 4.5-22 on page 4.5-52 of the Application, which lists marine sediment screening criteria and guidelines, forms part of the methods section for collection of baseline data. The sediment results, with discussion of screening, are presented in Section 4.5.13.3 of the Application.
1329.1	round 1	Kitsumkalum First Nation	4.5.13.3	Water Quality	"dredge areas is generally good" once again, subjective language. Dredge materials passed or failed CCME guidelines. XX percent of the samples were found to exceed.... should be the wording. We do not trust wording like generally good. It infers that some are bad. Especially when Kitsumkalum was not permitted on field studies. Your wording in the conclusion is more appropriate, that the chemistry met the BC regulations.....	The text "sediment quality in the proposed dredge areas is generally good", is an overview statement to provide general context for the reader on sediment conditions. Table 4.5-24, which follows this text, provides a detail breakdown of screening results by parameter.
1330.1	round 1	Kitsumkalum First Nation	4.5.15.3	Water Quality	TSS run-off entering the marine environment. This will likely be a large amount (locally) as the project is proposing to grub and strip a enormous area of wet boggy land. Extreme sediment and erosion control methods must be employed to avoid impacts from TSS.	Potential effects of soil erosion on the freshwater ecosystem is assessed under Wastewater Management in the effect "Change in Fish Abundance or Relative Abundance" in the Freshwater Fish and Fish Habitat VC, Section 4.8.5.4 of the Application. Aurora LNG will reduce disturbance to riparian areas, to the extent possible, and will not disturb watercourses and riparian areas outside the PDA. Exclusion fencing will be installed where needed to delineate the protected areas. Erosion and Sediment Control facilities will capture diverted site run-off to manage discharge into existing watercourses/marine environment. An environmental monitor will be onsite during all instream works to monitor for potential harm to fish and to evaluate and manage erosion control measures. The soils storage area will be re-vegetated, where possible, and drainage patterns will be established to manage runoff to the marine environment. The systems in place to mitigate sediment and erosion control will account for high flow events.
1331.1	round 1	Kitsumkalum First Nation	4.5.15.3	Water Quality	"Loss of sediment from dredge equipment is estimated at 3% of the total volume dredged" On quick calculation that is approximately 15,792 cubic meters. I am not a dredge expert but that seems like a lot of TSS depending on particle size and suspension times! The section then goes on to say disposal of the 562,000 cubic meters of dredge "may" affect water quality. It is hard to believe anything other than it will affect water quality at least on the short term!	In the final paragraph of Section 4.5.15.3 of the Application, it is noted that "During disposal of the dredged sediment at sea, there would be elevated TSS levels in the water column following each disposal event". Dredgate disposal is therefore acknowledged as a project mechanism for change in water quality. This effect is characterized in detail, with the support of sediment plume modelling, in Characterization of Residual Effects component of Section 4.5.13.3 of the Application.
1332.1	round 1	Kitsumkalum First Nation	page 4.5-62	Water Quality	The operations section: Projects keep touting "best available technology" We expect this to apply to all aspects of the project and would like the following outlined more concisely: What kind of wastewater treatment is proposed? Is deep discharge the best available technology? Really? By seeing that desalination is part of the plan, is a closed loop system now out of the question. It was my understanding that best practices did not include changing ocean temperatures and that most facilities were trying to do away with the old flush through systems.	Aurora LNG has acknowledged and committed to adhere to wastewater regulatory requirements prior to discharging to the marine environment. There are various wastewater treatment technologies available that Aurora LNG will assess prior to selecting the treatment technology for the Project. During operations, water will be recirculated /recycled throughout the facility, where feasible. This includes process water and water in the cooling system. Water is lost from the closed loop system through evaporation. Therefore, "makeup water" is required to replenish or "top up" the water supply for the process units. Makeup water is also required to dilute and flush the system for mineral concentrations that increase due to the water evaporation. It is expected that approximately 50% of the process water will evaporate. The desalination plant is not a closed loop system. The desalinated sea water will supply potable water, demineralized water, power plant cooling water, utility water and firewater for the facility. Included in this is the makeup process water that will be required throughout operations. Please also see the "Discharges to the Marine Environment" technical memo, which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
1333.1	round 1	Kitsumkalum First Nation	page 4.5-63	Water Quality	Storm water run off will require large settling ponds and monitoring to ensure water quality, buffering and slow release. It is not as simple as "discharging into vegetated areas and natural drainages."	Stormwater discharges from the facility site will be captured and managed. The discharges will meet applicable guidelines, regulations and permit requirements before discharge to the marine environment. Complete plans for stormwater management will be produced during detailed Project design. Please see the "Discharges to the Marine Environment" technical memo, which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
1334.1	round 1	Kitsumkalum First Nation	page 4.5-64	Water Quality	Soils storage area: we have major concerns over this. How it will be managed and the shear volume of moss, bog and organic debris that will be piled to drain. Major systems and management plans are required to even consider this. I have personally seen first hand how awful spoil areas can be if not managed correctly.	The soils storage area(s) will be designed by appropriately qualified engineers, and constructed by experienced contractors. Drainage from the storage area(s) will be managed to meet applicable regulations, guidelines and permit requirements. Please see the "Discharges to the Marine Environment" technical memo, which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
1335.1	round 1	Kitsumkalum First Nation	Table 4.5-26	Water Quality	4.5.1 needs to read, minimum 30 meter buffer. Discussion of wind firmness, assessment for longevity of buffers, etc. it is not as simple as just leave a buffer and walk away. There needs to be assurances that the buffer will be able to withstand the storm events that are so common in the area.	As part of the delineation of the riparian zones during pre-construction works, vegetation stability and windthrow assessments will be completed. Riparian areas are regulated under the Riparian Areas Regulation (RAR) which is a provincial legislation to protect riparian areas during residential, commercial, and industrial development. Best management practices will also follow those outlined in Ministry of Environment guidance documents including Environmental Best Management Practices for Urban and Rural Land Development: Aquatic and Riparian Ecosystems, and Standards and Best Practices for Instream Works.

1336.1	round 1	Kitsumkalum First Nation	Table 4.5-27	Water Quality	4.5.2 needs to include operations, not just construction.	This comment is unclear. Table 4.5-27 shows model inputs for sediment dispersion and deposition predictions.
1337.1	round 1	Kitsumkalum First Nation	page 4.5-78	Water Quality	Deep outfall pipes and non recycled cooling water does not sound like best available technology.	Aurora LNG has acknowledged and committed to adhere to wastewater regulatory requirements prior to discharging to the marine environment. There are various wastewater treatment technologies available that Aurora LNG will assess prior to selecting the treatment technology for the Project. During operations water will be recirculated /recycled throughout the facility, where feasible. This includes process water and water in the cooling system. Water is lost from the closed loop system through evaporation therefore "makeup water" is required to replenish or "top up" the water supply for the process units. Makeup water is also required to dilute and flush the system water mineral concentrations that increase due to the water evaporation. It is expected that approximately 50% of the water will evaporate. The desalination plant does not exclude a closed loop system. Desalinated sea water will supply potable water, demineralized water, power plant cooling water, utility water and firewater for the facility. Included in this is the makeup water that will be required throughout operations. Please also see the "Discharges to the Marine Environment" technical memo, which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
1338.1	round 1	Kitsumkalum First Nation	Table 4.5-29	Water Quality	WCC is not included in the cumulative effects of water quality. Why?	The assessment concluded that there is no potential for spatial overlap between marine water quality effects from the Aurora LNG Project and the proposed WCC LNG development. Project interactions with the marine environment were considered, to determine potential for spatial overlap. Aurora LNG and WCC LNG will, if constructed, discharge waste water to the marine environment. Wastewater discharges will be subject to permit restrictions, limiting the quality and quantity of waste, the discharge rate, and the size of the waste discharge initial dilution zone. WCC LNG may also require dredging, which will be subject to the same mitigation measures used for Aurora LNG (e.g. silt curtains), to limit sediment dispersion. Considering the wastewater regulatory restrictions, mitigation measures for dredging, and the distance of over 9 km between the two projects, no potential for spatial overlap was identified.
1339.1	round 1	Kitsumkalum First Nation	Figure 4.5-12	Water Quality	Cumulatively there is a lot of dredge! Depending on project schedules there is huge potential for adverse effects to marine life due to WQ issues. Although as stated there is low likelihood of spatial overlap of TSS plumes, the cumulative effects to Marine life may be large. If multiple dredge programs occur simultaneously, the area of refuge for marine life will become limited. the overall suspension of contaminants becomes much more substantive and impact to local food harvest becomes dangerous. Therefore it is hard to understand the determination that the likelihood of residual cumulative effects as low. this needs to be re-visited.	Individual dredging programs will result in increased TSS in the surrounding water. However, without spatial overlap, simultaneous programs will not act cumulatively to further increase TSS, and associated contaminant concentrations in water. Potential cumulative effects of dredging and disposal at sea on marine fish health are assessed in Section 4.9.6.6 of the Marine Fish and Fish Habitat VC. The assessment considered the possibility that construction schedules of future proposed projects may overlap temporally with that of Aurora LNG, and the potential residual cumulative effects on marine fish health are characterized accordingly. In the event that construction schedules do overlap, a relatively larger area of the RAA would be affected by elevated TSS concentrations. However, potential cumulative effects would be limited to the Prince Rupert area, where most of the projects are proposed, and at the Brown Passage disposal at sea site. Vast areas of marine habitat within the RAA would be unaffected by elevated TSS concentrations; therefore, suitable habitats are not expected to be limited for marine species that avoid localized areas of elevated TSS.
1340.1	round 1	Kitsumkalum First Nation	4.5.17.2	Water Quality	see comment above. Just because spatial overlap is likely minimal, does not address cumulative impact to the environment.	Individual dredging programs will result in increased TSS in the surrounding water. However, without spatial overlap, simultaneous programs will not act cumulatively to further increase TSS, and associated contaminant concentrations in water. Potential cumulative effects of dredging and disposal at sea on marine fish health are assessed in Section 4.9.6.6 of the Marine Fish and Fish Habitat VC. The assessment considered the possibility that construction schedules of future proposed projects may overlap temporally with that of Aurora LNG, and the potential residual cumulative effects on marine fish health are characterized accordingly. In the event that construction schedules do overlap, a relatively larger area of the RAA would be affected by elevated TSS concentrations. However, potential cumulative effects would be limited to the Prince Rupert area, where most of the projects are proposed, and at the Brown Passage disposal at sea site. Vast areas of marine habitat within the RAA would be unaffected by elevated TSS concentrations; therefore, suitable habitats are not expected to be limited for marine species that avoid localized areas of elevated TSS.
1341.1	round 1	Kitsumkalum First Nation	Section 4.5.13.1	Water Quality	The Canadian Council of Ministers of the Environment (CCME) has not established interim sediment quality guidelines (ISQGs) and probable effects levels (PELs) for Total PAHs in sediments; however, ISQGs and PELs are available for 18 individual PAHs. These benchmarks should be used in Table 4.5-22 and carried forward to the effects assessment.	In the Marine Sediment and Water Quality Technical Report (Appendix F of the Application), sediment data were screened against the CCME guidelines for individual PAHs. Of the 192 samples tested, all were below the Disposal at Sea total PAH screening criterion, and only four samples had individual PAH concentrations above CCME ISQG. Given the limited number of individual PAH exceedences, the total PAH criterion, which encompasses 16 high priority PAHs was considered more appropriate for the effects assessment.
1342.1	round 1	Kitsumkalum First Nation	Section 4.5.13.1	Water Quality	The CCME has not established ISQGs and PELs for Total PAHs in sediments; however, other sources of "threshold effects" and "probable effects" type benchmarks have been developed for use in risk and/or impact assessments. For example, MacDonald *et al.* (1996) provides threshold effects levels (TELs) and probable effects levels (PELs) of 1.684 and 16.77 mg/kg dry weight, respectively. These benchmarks should be considered for use in the effects assessment. MacDonald, D.D., R.S. Carr, F.D. Calder, E.R. Long, C.G. Ingersoll. 1996. Development and evaluation of sediment quality guidelines for Florida coastal waters. Ecotoxicology. 5: 253-278.	The Disposal at Sea total PAH screening criterion encompasses 16 individual PAHs considered relevant to environmental effects in the marine environment. Therefore this criterion was considered the most appropriate for total PAH screening in the effects assessment.
1343.1	round 1	Kitsumkalum First Nation	Appendix F (5.3)	Water Quality	It is stated that concentrations of arsenic and copper were routinely above ISQGs, but at naturally occurring concentrations for the area. This statement should be verified by comparing to the distribution of concentrations in reference areas within the RAA.	The assessment of dredge material focused on sediment sampling within the dredge footprint and followed the Disposal at Sea evaluation criteria for characterizing sediments. Elevated arsenic and copper levels in soils of the Skeena Region are documented in the Ministry of Environment Protocol 4: Determining Background Soil Quality. These documented levels are similar to those found in sediment from the assessment area. Elevated levels of copper and arsenic were found at all depths sampled, (down to 15 m below seabed), indicating that these metal concentrations predate industrial activity.
1344.1	round 1	Kitsumkalum First Nation	4.5.15	Water Quality	Residual effects of re-deposition on benthic invertebrates during and post- dredging activities have not been included in the effects assessment. This information needs to be provided.	The potential for marine fish and invertebrates to be crushed or buried by marine sediment during dredging activities is assessed under the 'change in mortality risk' effect (Section 4.9.5.4 of the Application). The potential for health effects to marine fish and invertebrates due to exposure to elevated TSS concentrations during dredging activities is assessed under the 'change in health' effect (Section 4.9.5.5 of the Application).
1345.1	round 1	Kitsumkalum First Nation	4.5.15.3	Water Quality	Limited information on the proposed mitigation for the sanitary wastewater effluent management during construction and operations is provided in the application. Specifically, no details on the expected capacity or treatment level of the wastewater facility are provided. More detailed information is required to conclude that no residual effects will occur.	As stated in Section 4.5.15.3 of the Application (Characterization of Residual Effects – Waste Management), waste water outfall designs and locations will comply with federal and provincial legislation designed to protect water quality. Sanitary wastewater will meet effluent permit requirements, including dechlorination of any chlorinated wastewater. Mitigation 4.5.8, Table 4.5-26 also states that waste discharges to the marine environment will comply with the Fisheries Act, Canadian Environmental Protection Act, Canada Shipping Act 2001, and the BC Environmental Management Act (Waste Discharge Regulation). Specific details on waste volumes and contaminant concentrations are not yet available and will be determined during Front End Engineering Design. However, Aurora LNG is legally obliged to abide by all waste discharge regulations, designed to protect the marine environment. Environmental effects from waste discharge are therefore predicted to be not significant. Further details on project waste discharges and associated regulations, are provided in the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
1346.1	round 1	Kitsumkalum First Nation	4.5.15.3	Water Quality	Limited information on the proposed mitigation for the desalination wastewater effluent management during operations is provided in the application. Specifically, no details (or predictions) on the volumes of wastewater generated nor the feasibility of meeting water quality guidelines (WQGs) are provided. More detailed information is required to conclude that no residual effects will occur.	Desalination waste water will meet CCME and BC regulatory water quality guidelines (WQG) outside of the initial dilution zone. These guidelines allow a maximum temperature change of $\pm 1^0$C from ambient at any time, location, or depth and a maximum rate of change $<0.5^0$C per hour. The CCME interim WQG for salinity limits the change of salinity to 10% from background conditions for a given time and depth. The residual chlorine concentration at the edge of the initial dilution zone, will be below the CCME WQG (0.5 µg/L). The exact size of the initial dilution zone is not yet known, and will be determined through modelling in the permitting phase. However, under the Fisheries Act, waste discharges within and outside the initial dilution zone, cannot be acutely toxic to fish. The effect of desalination waste discharge was assessed based on adherence to legally-binding legislation, designed to protect aquatic life. Further details on project waste discharges and associated regulations, are provided in the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
1347.1	round 1	Kitsumkalum First Nation	Section 4.5.15.3	Water Quality	Limited information on the proposed mitigation for the cooling water effluent management during operations is provided in the application. Specifically, no details (or predictions) on the volumes of wastewater generated nor the feasibility of meeting WQGs for temperature are provided. More detailed information is required to conclude that no residual effects will occur.	Cooling water discharge will meet CCME and BC regulatory water quality guidelines for temperature, outside of the initial dilution zone. These guidelines allow a maximum change of $\pm 1^0$C from ambient at any time, location, or depth and a maximum rate of change $<0.5^0$C per hour. The exact size of the initial dilution zone is not yet known, and will be determined through modelling in the permitting phase. However,under the Fisheries Act, waste discharges within and outside the initial dilution zone, cannot be acutely toxic to fish. The effect of cooling water discharge was assessed based on adherence to legally-binding legislation, designed to protect aquatic life. Further details on project waste discharges and associated regulations, are provided in the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
1348.1	round 1	Kitsumkalum First Nation	Table 4.5-26	Water Quality	Mitigation measure 4.5.5 is to use silt curtains, "where practicable, to reduce the spatial extent of suspended sediments in the water column during dredging activities." The description of how the silt curtains will be implemented is very brief. The use of silt curtains for mitigating the effects of elevated TSS on marine water quality should be described in more detail. In addition, there appears to be a contradiction between the statements in Table 4.5-26 that "there is a moderate likelihood of success with this mitigation measure" and "this mitigation measure is effective in the short-term." If success is only moderately likely than the mitigation measure will not always be effective.	The manner in which silt curtains are employed is dependent on numerous factors, including water depth, currents, tides, wave height, wind direction and speed, and the nature of the work conducted within the curtains. As such, specific details on silt curtain use cannot be provided until these factors are established on a site-specific basis. Silt curtains will be used, where practicable, to isolate the work site from the surrounding marine environment, during dredging. Strong currents, high winds and waves, and frequency of marine traffic into/out of the work site may prevent placement of silt curtains, and or limit their effectiveness. Fluctuating water depth due to tidal patterns may also alter the area over which silt curtains can be employed. Use of silt curtains was classed as having a moderate likelihood of success due to the limiting factors listed above. The classification of "effective in the short-term" refers to the duration over which the measure is employed, and not the likelihood of success. The modelling of TSS plumes does not incorporate the use of silt curtains.
1349.1	round 1	Kitsumkalum First Nation	Table 4.5-26<	Water Quality	Mitigation of TSS dispersion during infrastructure (i.e., non-dredging) construction is not discussed in the table of mitigation measures proposed to avoid or reduce change in physical or chemical composition of marine waters. An assessment of mitigation during infrastructure construction needs to be added to this list.	In Section 4.5.15.3 of the Application, under Characterization of Residual Effects - General Construction Activities, it is stated that "The volume of sediment disturbed by marine construction will be much lower than for dredging, and mitigation measures (e.g., silt curtains) will be used where practical to limit sediment dispersion"
1350.1	round 1	Kitsumkalum First Nation	4.6 Table 4.6-10	Vegetation and Wetland Resources	Mitigation 4.6.1 - "Pre- construction rare plant surveys will be conducted in the PDA, near known locations of rare plants" How is this a mitigation to avoid or reduce change in the Abundance of Plant species of Interest when it is known and assumed that all vegetation within the PDA will be removed? The rationale for selection of this mitigation measure states that it will increase the confidence in the location and extent of the occurrence of rare plants? we questions the reasoning behind this because confirming that rare plants exist and then clearing them away so that construction can occur is not mitigation for reducing or avoiding a plant species of interest. It's simply identifying where something is so that it can be documented and subsequently destroyed.	A pre-construction survey is required to reconfirm the full extent of each known occurrence as a precursor to plant relocation, which is the subsequent pre-construction mitigation measure. If additional plants are detected at the time of the pre-construction survey, contingency measures would be implemented such as relocation or collection of seed or propagules of those newly identified plants to reestablish populations off-site, or to augment existing off-site populations.
1351.1	round 1	Kitsumkalum First Nation	4.6 Table 4.6-10	Vegetation and Wetland Resources	Mitigation 4.6.3 -"The red-listed non vascular plant, Sphagnum majus and blue listed non-vascular plant, Sphagnum centrale will be translocated from the known locations within the PDA" - Kitsumkalum sees translocation of this species of moss as a poor mitigation measure. The likelihood of failure is too great to suggest this as a viable mitigation. What evidence does Aurora LNG have that this mitigation is viable? and what kind of monitoring measures is Aurora LNG prepared to put forth to monitor the success or failure of this measure?	The BC Conservation Data Centre's Guidelines for Translocation of Plant Species at Risk (Maslovat 2009) notes that, "in some cases, translocations may be the only viable option. For example, translocation can be a useful tool to mitigate threats to plants in development areas where no other option is feasible." Avoidance is not feasible for Sphagnum centrale and Sphagnum majus because they are located within the PDA. If the Project proceeds, the risks of attempting translocation are limited because the populations would otherwise be lost as a result of clearing within the PDA. Aurora LNG considers this a potentially-viable mitigation measure considering the successful research trials and methods of peatland restoration and moss propagation that have been developed in conjunction with the horticultural/agricultural sector and oil & gas sectors in North America and Europe. Examples of research institutes with publications that address the restoration of Sphagnum spp. include, but are not limited to the following: Peatland Ecology Research Group at the University of Laval, http://www.gret-perg.ulaval.ca/ See: Quinty, F. and L. Rochefort, 2003. Peatland Restoration Guide, second edition. Canadian Sphagnum Peat Moss Association and New Brunswick Department of Natural Resources and Energy. Québec, Québec. Peatland Restoration program at the Northern Alberta Institute of Technology http://www.nait.ca/70709.htm See: Sobze, J., M. Gauthier and R. Thomas 2012. Peatland Restoration – Harvest and Transfer of Donor Material. Technical Note. Available at: http://www.nait.ca/docs/1_Donor_Site_Harvesting_and_Moss_Transfer.pdf Aurora LNG will monitor the performance (survival, establishment, and growth) of the translocated populations during the growing season according to the Guidelines for Translocation of Plant Species at Risk (Maslovat 2009) . Translocation results will be made available to the BC Conservation Data Centre in order to increase collective knowledge of the species.
1352.1	round 1	Kitsumkalum First Nation	4.6 Table 4.6-10	Vegetation and Wetland Resources	Mitigation 4.6.6 - "An invasive Plant Management Plan will be implemented - The Weed Control Act and Regulations prohibit the spread of noxious weeds on highways and prohibits…" Kitsumkalum does not consider this a "mitigation" this is a baseline and bare minimum practice. Aurora LNG has to do this because it is the law. It should therefore not be considered mitigation bit rather a requirement of development. Mitigation should include what is above and beyond requirements.	This comment cites the rationale for the mitigation measure, not the mitigation itself: The mitigation is to develop and implement an Invasive Species Management Plan.

1353.1	round 1	Kitsumkalum First Nation	4.6	Vegetation and Wetland Resources	In the Summary section under "Likelihood of Residual Effects For Change in Abundance of Plant Species of Interest" it is stated that "the translocation (of plant species of interest) will be successful". This is in direct relation to Sphagnum majus and Sphagnum centrale. Kitsumkalum disagrees with this conclusion. There is no evidence presented in the document that supports this statement.	The full statement in the Summary Section says, "There is a medium likelihood that residual effects to plant species of interest will occur and that the translocation will be successful. Although Sphagnum majus and Sphagnum centrale are known to be present within the PDA and disturbance cannot be avoided, their translocation to outside the PDA is expected to be successful in mitigating the effect. Potentially suitable habitat (i.e., bogs) is present within the terrestrial LAA, which will increase the likelihood of successful translocation (Maslovat 2009)." Section 4.6.2.7 defines Medium likelihood as " Medium—Adverse interactions between the Project and vegetation and wetland resources may be difficult to avoid or mitigate, and adverse residual effects are likely". So while the translocation mitigation is expected to be successful, the medium likelihood rating accounts for some uncertainty. The assumption is that if the species can be relocated to a suitable habitat (which is known to exist) then it is reasonable to assume it will be successful.
1354.1	round 1	Kitsumkalum First Nation	Table 4.6.11	Vegetation and Wetland Resources	Mitigation 4.6.10 - This is monitoring not mitigation. It is stated that soils will be monitored and adaptive management will be provided if necessary. What does this mean? What adaptive management? If vegetation and soils are effected from NO2 and SO2 atmospheric concentrations and soil acidification or soil eutrophication occur to levels that are unacceptable what actual mitigation measure outside of "monitoring" will occur?	Monitoring the predicted areas of exceedance (for acidification or eutrophication) to determine whether any adverse effects are detectable is the first step to determine whether any additional mitigation is required.The following factors are uncertain:whether potential effects will be observable and measurable,the timeframe within which effects from this mechanism could be detectable,the degree to which they could occur, andthe rate of change observed in soils and/or ecological communities. Therefore, monitoring is required before further mitigation measures are evaluated and applied. It is expected the monitoring effort will be regionally focused to encompass all of the potential airshed contributors and coordinated through the BC Ministry of Environment. In establishing that regional monitoring effort, it is assumed that the Ministry will determine the monitoring criteria and outline a suite of potential mitigation measures to address expected outcomes based on the monitoring results.Aurora LNG's framework for adaptive management is as follows: Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended). Precise adaptive management measures cannot be defined ahead of time without knowing what the issue(s) are.
1355.1	round 1	Kitsumkalum First Nation	Table 4.6.11	Vegetation and Wetland Resources	Mitigation 4.2.8 - "An Air Quality Management Plan" is cited as a mitigation measure. It is Kitsumkalum' view that Management Plans are not mitigation measures but rather a Management Plan would list mitigation measures within it. Therefore what exactly is the mitigation measure in this case? is it the "Project Specific Program" to reduce air emissions? if so, what is the "Project Specific Program" exactly? How will it reduce Air Emissions? Those would be the mitigations measures....Please be specific about what exactly the mitigation measure is going to be.	See table 4.2-10 of the Application for specific mitigation measures that would be included in the Air Quality Management Plan. The intent of listing mitigation measure 4.2.8 in this vegetation and wetlands section is to acknowledge that mitigation measures within the Air Quality Management Plan would contribute to reducing effects (due to emissions) on vegetation.
1356.1	round 1	Kitsumkalum First Nation	4.6	Vegetation and Wetland Resources	Under the heading "Characterization of Residual Effects for Change in Abundance or Condition of Ecological Communities of Interest" The conclusion is made that the implementation of the mitigation measures in table 4.6-10 will reduce potential edge effects to "negligible magnitude". Kitsumkalum would like to see the detailed reasoning behind this conclusion. How did Aurora LNG come to this conclusion?	The reasoning behind the conclusion of negligible magnitude is based on first identifying the potential mechanisms that could affect ecological communities at the edges of the PDA, and then identifying a feasible mitigation measure for each potential effect-mechanism.Examples of effect mechanisms that were considered include the following: creation of additional edge by windthrow; deposition/aggradation due to erosion processes; or, changes in soil moisture levels due to stormwater flows. Examples of corresponding mitigation measures include the following: windthrow management (windfirming treatments) of remaining stands; application of erosion and sediment control measures; and maintaining pre-existing surface hydrology patterns While there may be some changes to soil moisture, soil temperature, air temperature, or light levels within communities located at the edge of the PDA, given the feasible mitigation/management measures identified in Tables 4.6-10 and 4.6-11 of the Application, any remaining changes to abiotic factors are not anticipated to result in measurable effects to ecological communities of interest due to edge effects. The characterization of residual effects is thus predicted to be negligible (see Table 4.6-5 of the Application for the definition of negligible in this context).
1357.1	round 1	Kitsumkalum First Nation	4.6	Vegetation and Wetland Resources	It is stated that the residual loss of old-growth forest is low in magnitude. If the old growth forest that the project will be effecting is considered in terms of the PDA (10%), the residual loss of old-growth forest is high and long term. The Characterization of Residual Effects does not consider the PDA. It gives thresholds in consideration of the entire RAA which produces a skewed conclusion of what is actually going to happen on the ground. In our view this is unacceptable. If the project is going to cut down 100% of the old growth forest within the PDA, regardless of what populations are present in the RAA or LAA, this will have a high residual effect that is long term in duration. This is of particular interest to traditional users in that the "go elsewhere to get your resources" argument does not hold well with. If people wanted to use the resources on the PDA they will no longer be able to because it will be gone. Therefore the residual effect of the loss of this resource, within that geographical extent, is high and long term. The assessment of residual effects, in this particular case, is flawed.	The government of BC has developed the approved Great Bear Rainforest Order (GBRO), which establishes explicit retention targets for old growth forest within the landscape units that this Project intersects. The GBRO is based on a regional ecosystem management approach, which means natural resources such as old growth forests are managed on a regional scale, such as the landscape units identified in the GBRO. These landscape units are considerably larger than the PDA, or LAA. The Application aligns with the ecosystem management approach in effect within the region, and uses the retention targets contained in the GBRO to guide characterization of the magnitude of Project effects (See table 4.6-5 in the Application re: old growth magnitude criteria relative to the GBRO thresholds for the relevant landscape units.) The GBRO represents an approved Ministerial Order which allows for up to 40% loss of old growth forest from the specified landscape units which correspond to the Project's RAA. The loss of old growth forest due to the Aurora LNG Project is far below such allowable thresholds set for other (timber harvest) industries within the region. Effects on the changes in consumptive and non-consumptive land and resource use for traditional purposes are presented in Section 11.3 and 11.4 of the Application, and include assessment on vegetation gathering. Effects on First Nation harvesting-related Aboriginal interest are presented in Part C, Section 12 of the Application. Together these sections address the site-specific loss of vegetation resources for traditional use within the PDA. See also the technical memo titled, Additional Information Regarding the CEAA 5(1)(C) and Part C Assessment Methodologies and the Consideration of Traditional Use Information in these Assessments" prepared by Aurora LNG in response to comments pertaining to concerns about access and availability of traditional use species. This technical memo will be filed with the BC EAO.
1358.1	round 1	Kitsumkalum First Nation	Table 4.6.13	Vegetation and Wetland Resources	Mitigation No. 4.6.15 - a Wetland Monitoring Program is not a mitigation; it is a Monitoring Program. What exact mitigations are Aurora LNG proposing? If the monitoring program finds that the wetland functions have not been adequately replaced or met, what actual mitigations is Aurora planning on?	Mitigation measure 4.6.15 specifically refers to monitoring the performance of restored, enhanced, or created wetlands that are established according to the Project's approved Wetland Compensation Plan. This monitoring is intended to determine whether or not the compensatory habitat is functioning as intended. In the event that restored, enhanced, or created wetland habitat is determined, through monitoring, to be not functioning as intended, then adaptive management would be applied. Aurora LNG's framework for adaptive management is as follows: Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended). Precise adaptive management measures cannot be defined ahead of time without knowing what the issue(s) regarding function is, but potential examples could include such management measures as: adjustment to wetland hydrology through grading or channel design; replanting with more-suitable plant species; controlling herbivory; or removing invasive plant species. The precise measures would depend on the stressors and/or monitoring plan results.
1359.1	round 1	Kitsumkalum First Nation	Table 4.6-14	Vegetation and Wetland Resources	How are Operations not applicable to the residual effects on the change in Abundance of Plant Species of Interest and Wetland Function in the PDA, TLAA, VALAA and/or RAA .	During operations, no plant species of interest or wetlands will remain in the PDA; they will have been removed during construction. During operation of the Project, no residual effects on plant species of interest or wetland functions are anticipated in the remaining study boundaries, thus the use of N/A in the residual effects summary table. Effects on wetlands due to acidification/eutrophication are addressed under changes to condition of ecological communities of interest, for which there are residual effects during the operations phase; these are characterized in Table 4.6-14 of the Application.
1360.1	round 1	Kitsumkalum First Nation	Section 4.6	Vegetation and Wetland Resources	"Old-growth forests are relatively undisturbed and common in the RAA; they are considered resilient because they can recover from perturbation, albeit taking over 200 years to develop". The last part of this statement is key to concerns Kitsumkalum has when reading that the old growth forest loss that will occur is expected to be low in magnitude. The time it takes to re-establish vegetation populations to existing levels should be considered when evaluating residual effects.	The duration of an effect is one attribute that is used to characterize residual effects, while magnitude is another attribute. See Table 4.6-5 of the Application for definitions of each characterization. All characterizations in Table 4.6-5 are considered for each measurable parameter that contribute to each residual effect. The duration of effects on old growth forest are considered long-term, but of low magnitude according to the definitions of each term provided in Table 4.6-5.
1361.1	round 1	Kitsumkalum First Nation	Section 4.6.6.5	Vegetation and Wetland Resources	Under Cumulative Effects Mitigation it is stated that it is expected that future projects will be held to the same standards as past and present projects, including compensation required for ecologically important wetlands and offsetting. This is not adequate mitigation. Specific mitigations are needed in order for this project to go forward in relation to all of the other projects and development which have occurred or will possibly occur within the RAA.	Please see Table 4.6-13 of the Application for the full suite of mitigation measures intended to avoid, limit, and/or offset the loss of wetland functions for this Project. These Project-specific mitigation measures will also directly reduce potential for cumulative interactions.
1362.1	round 1	Kitsumkalum First Nation	Section 4.6.7.1	Vegetation and Wetland Resources	Kitsumkalum strongly disagrees with the conclusion that the project residual effects to vegetation and wetland resource will not be significant based on the reasoning that plant species of interest are viable within the RAA and traditional use plants are abundant elsewhere. The "can be found elsewhere" reasoning is not acceptable. It is our opinion that the vegetation and wetland resources within the PDA will be significantly altered because the project will destroy them. The fact that they can be found elsewhere in the RAA is irrelevant to us when considering what will be lost within the boundaries of the PDA. Although something may be present elsewhere, does not reflect if someone has access to it elsewhere, knows where it is, or is allowed to access it elsewhere due to territories and house groups.	Effects on the changes in consumptive and non-consumptive land and resource use for traditional purposes are presented in Section 11.3 and 11.4, of the Application and include assessment of vegetation gathering. Effects on First Nations harvesting-related Aboriginal interest are presented in Part C, Section 12 of the Application. Together these sections address the site-specific loss of vegetation resources for traditional use within the PDA. Please also see the technical memo titled, "Additional Information Regarding the CEAA 5(1)(C) and Part C Assessment Methodologies and the Consideration of Traditional Use Information in these Assessments" prepared by Aurora LNG in response to comments pertaining to concerns about access and availability of traditional use species. This technical memo will be filed with the BC EAO.
1363.1	round 1	Kitsumkalum First Nation	4.11	Water Quality	Kitsumkalum is has considerable concern to the potential for severe impacts to the disturbance of Great Blue Heron habitat in Delusion Bay estuary. The Riparian buffer between the habitat and the flares is considered insufficient. Operations and construction have the potential to exclude or seriously reduce the success of overwintering, breeding and juvenile survival of this blue listed species of special concern.	Aurora LNG considered placement options of the flare system within the PDA to reduce potential interaction with environmental valued components and to limit the amount of light dispersal (Table 1-26). Maintenance and emergency gas flaring is not expected to occur during normal operating procedures but only occasionally during emergency and upset conditions and during controlled events such as startup, shutdown, venting and purging (see Section 1.2.5.1 of the Application). As the flare stack is located approximately 3 km from the heron rookery in Dodge Cove, interaction with nesting birds is expected to be negligible. Mitigations for great blue heron presented in the Application focus on measures to protect herons during breeding, the most sensitive timing period. The setback distances defined in mitigation measures 4.7.4, 4.7.6, and 4.7.18 are intended to reduce disturbance at active nests sites as well as surrounding habitat use for fledging and foraging. The marine riparian disturbance buffer of 30 m will be applied during all phases of the Project and is expected to further reduce potential for disturbance of herons foraging in Delusion Bay during Project operation.
1364.1	round 1	Kitsumkalum First Nation	4.11	Marine Wildlife - Marine Birds	Kitsumkalum considers the entire Delusion Bay Estuary to be rare, sensitive and critical habitat to a myriad of Marine species. The Marine Riparian zone is considered insufficient in width and the location of the flaring structures will cause unacceptable disturbance or avoidance of this otherwise productive habitat.	Section 1.2.5.1 of the Application describes the proposed flare system design. Aurora LNG considered placement options of the flare system within the PDA to reduce potential interaction with environmental valued components and to limit the amount of light dispersal (Table 1-26). As per mitigation 4.7.20, maintenance flaring events will be scheduled during daylight hours to the extent practicable to further reduce attraction by birds and bats to flare system infrastructure during nocturnal migration or foraging. Additionally, the marine riparian disturbance buffer of 30 m will be applied during all phases of the Project to retain shoreline habitats and limit noise and light dispersal, and is expected to further reduce potential for disturbance marine species using shoreline and nearshore habitats in Delusion Bay.
1365.1	round 1	Kitsumkalum First Nation	4.7	Wildlife Resources (Terrestrial)	Kitsumkalum considers the Marine riparian management zone associated with Delusion Bay to be too narrow to provide a sufficient buffer between construction and operations. The inherent richness of the estuary and edge effect are favoured habitat for many species. The conceptual layout of project components at full build-out (figure no. 1-2) does not provide a depiction of a realistic concept to support terrestrial wildlife species. Species such as Western screech owl and Little brown Myotis are expected to favour these habitats . The project does not depict a concept that considers natural breaks in terrain or an effort to protect or maximize cover.	Habitats surrounding Delusion Bay were rated as having high or moderate suitability for western screech-owl and little brown myotis under existing conditions, however Delusion Bay was rated as Nil suitability for both species to support breeding activity (Section 4.7.3.2 of the Application). The assessment for change in habitat identifies that the change in area of preferred habitat (i.e., high or moderate suitability) from clearing within the PDA will results in a 17% change from existing conditions for western screech-owl and little brown myotis (Table 4.7-13) with indirect effects extending beyond the PDA boundaries (Table 4.7-14). As described in Section 4.7.5.2, the assessment of change in habitat was considered conservative because it assumed that all vegetation will be removed from within the PDA. Collectively, the riparian reserve zones, management areas, and marine riparian disturbance buffer will result in the retention of mature and old forested habitat; these areas are not predicted to continue to serve as preferred habitat for either species during operations (e.g., Figure 4.7-10 and Figure 4.7-11), but will reduce noise and light disturbance effects to adjacent habitats, including Delusion Bay. The riparian buffers also maintain connectivity between forested and wetland communities northwest of the PDA and Delusion Bay. These corridors will facilitate access to upland and intertidal habitats for species that rely on them for breeding, roosting, foraging, and staging activities.
1366.1	round 1	Kitsumkalum First Nation	4.8	Freshwater Fish and Fish Habitat	In table 4.8-13 the proponent describes the area of fish habitat to be lost in the PDA to be 10,857 m². This would require an off-setting replacement at 2x which is 21,714 m² of similar fish habitat. Kitsumkalum has considerable doubt that this can be achieved in the region and an even lesser degree of confidence that said off-setting will be successful.	Offsetting for serious harm in the marine and freshwater environments will be considered collectively by Aurora LNG. This is because the freshwater habitats affected by the Project will affect anadromouos fish species (e.g., pink and coho salmon) that use freshwater and estuarine habitats for spawning and rearing. While efforts will be made to maximize the amount of freshwater habitat created or enhanced to offset the loss of fish habitat in watercourses within the PDA (i.e., "like-for-like" habitat replacement such as those on Digby Island presented in the Conceptual Fish Habitat Offsetting Plan [Appendix V]), the overall objective of the offset plan will be to maximize fish productivity for CRA fish species affected by the Project. Thus, where opportunities exist to create, restore, or enhance habitats used by juvenile salmon in estuarine or marine environments, particularly where options in the estuarine or marine environments have lower risks, uncertainties, or time lags than options in the freshwater environment, these projects will be included in the detailed offset plan with the objective of providing a net gain in production in the regional fishery. Through collaborative engagement with regulatory agencies (primarily DFO) and consultation with Aboriginal Groups during the Fisheries Act authorization application process, Aurora LNG fully anticipates being able to find adequate and appropriate locations, and develop suitable designs, for effective offsets.
1367.1	round 1	Kitsumkalum First Nation	4.8	Freshwater Fish and Fish Habitat	Further to table 4.8-13, the riparian habitat to be lost is 218,830 m², replacement at 2x would be 437,664 m². Kitsumkalum considers this to be near impossible to duplicate or offset this unique island wetland complex. In addition, to apply a minimum DFO standard 15 m riparian zone is unacceptable. The complex moss -forest environment acts as a buffer to provide a moderated slow release of the ~ 3 meter annual rainfall received by his maritime island. It would be more appropriate to apply a minimum 30 meter riparian management zone on either side of the streams and inter-tidal zones of the Delusion Bay Estuary. It may be important to reserve more fore-shore habitat to prepare for the future rise in sea-levels, this may be as much as 2 meters during the life of the project. This needs to be world leading not minimum legal requirement setting.	Potential effects of the Project on fish and fish habitat, including riparian habitat, that result in serious harm to fish will be offset as per the requirements of the Fisheries Act and associated permitting. Replacement of 218,830 m2 of riparian habitat at a 2:1 ratio is not likely possible in the LAA; however, riparian areas next to watercourses that no longer exist do not provide services to the watercourses that have been removed (e.g. shade, leaf litter, insect input) and will not be accounted for in the fina offsetting calculations. Riparian area measurements have been applied as per the Riparian Management Area Guidebook (Ministry of Forests, 1995). Aurora LNG has provided a conservative protection of a minimum of 15 m riparian reserve zone (RRZ) on all streams, including non-fish bearing, where MFLNRO guidelines do not specify an RRZ. Offset riparian habitat will be a component of the detailed habitat offset plan developed for the project. The area of riparian habitat offsets proposed will be proportionate to that which will provide full riparian function to instream freshwater habitat and marine habitat designed to offset the predicted loss in fisheries productivity resulting from the project. Discussion on the foreshore habitat is addressed in the Marine Fish and Fish Habitat section (4.09) of the Application.
1368.1	round 1	Kitsumkalum First Nation	4.8	Freshwater Fish and Fish Habitat	Kitsumkalum considers the potential for serious and irreversible harm to the watershed of Delusion Bay and the valuable contribution to the productivity of this small Estuary to the function of the greater Skeena River estuary.	Aurora LNG acknowledges that Kitsumkalum First Nation considers Delusion Bay a valuable contributor to the function of the greater Skeena River estuary. Aurora LNG believes that the annual contribution of fish from the watercourses within the PDA to the CRA fishery of the Skeena River estuary is negligible in comparison to the annual contribution other tributary watersheds and the mainstem habitats make to the Skeena River estuary. This is because the majority of streams within the PDA on Digby Island are short (<500 m), small (S3 or S4), with non-fish-bearing reaches above impassable barriers, and water quality that is less than optimal for salmonids (i.e., low pH). Therefore, Aurora LNG believes that effects of the Project on watercourses within the PDA are likely to have a negligible effect on annual production of the CRA fishery in the Skeena River estuaryAurora LNG will, through collaborative engagement with regulatory agencies (primarily DFO) and consultation with Aboriginal Groups during the Fisheries Act authorization application process, provide habitat creation, enhancement, or restoration to offset the CRA fish production lost due to habitat losses caused by the Project.

1369.1	round 1	Kitsumkalum First Nation	4.8	Freshwater Fish and Fish Habitat	Kitsumkalum considers the freshwater invertebrate productivity to be essential to sustain fish health and productivity. A baseline invertebrate inventory for the streams affected in the PDA would be appropriate to provide an indicator for stream health. This should be initiated pre- construction and for reasonable increments throughout the project operations up to and including de-commissioning.	Aurora LNG acknowledges that freshwater invertebrate production is essential to fish health and productivity. However, Aurora LNG believes that it is not necessary to collect baseline invertebrate data or monitoring invertebrates in streams throughout the life of the Project. This is because Aurora LNG has committed to mitigation measures that avoid, eliminate, or reduce potential effects to CRA fish species e.g. salmon and charr, as a result of changes in water quality, stream flow, and sedimentation. By doing so, Aurora LNG believes that these mitigation measures will equally protect freshwater invertebrates and their habitat. Additionally, changes in water quality that would cause a change in the abundance, distribution, or species composition of freshwater invertebrates are not anticipated. Aurora LNG will engage with appropriate regulatory agencies and Aboriginal Groups identified in Schedule B of the Section 11 Order(as amended) to develop the environmental effects monitoring plans required for freshwater and marine environments.
1370.1	round 1	Kitsumkalum First Nation	4.8	Freshwater Fish and Fish Habitat	Kitsumkalum is concerned about the potential for harm to the Delusion Bay estuary habitat. We would suggest that a baseline condition assessment be initiated and monitored over the life of the project to assess the productivity and condition of this transition zone between fresh and salt water.	Aurora LNG acknowledges that Kitsumkalum is concerned about the potential for harm to Delusion Bay estuary habitat. However, changes in water quality and stream flow that would cause a change in the productive capacity of the Delusion Bay estuary are not anticipated due to retained marine riparian buffer and because all discharged water will meet regulatory requirements. As such, Aurora LNG does not believe a baseline condition assessment needs to be initiated in Delusion Bay. During construction and operation specific water quality parameters (e.g., total suspended solids, total nitrogen) will be recorded to support permitting.
1371.1	round 1	Kitsumkalum First Nation	4.8 p. 4.8-53	Freshwater Fish and Fish Habitat	In Additional Mitigation measures: to transport salvaged fish outside the PDA is unacceptable. The final paragraph about surface water quality changes is vague and lacks a level of description to provide assurance that fish and fish health will be protected. It is well known that clear-cut, clearing and grubbing produce a flashy hydrological response in a watershed. Kitsumkalum is very concerned that an industrial disturbance this close to critical fish and fish habitat will cause serious and permanent damage to the fresh water and estuary environment. Settlement ponds, ditching and filter fabric systems will require careful design and engineering to mimic the natural buffering of this coastal ecosystem.	Aurora LNG will transport and release fish salvaged from affected watercourses within the PDA to the nearest watercourses with similar water quality (e.g., temperature and salinity) and habitat (e.g., pools for rearing). However, transport and release of fish to watercourses outside of the PDA may be required if similar water quality and habitats are not present. The selection of potential release areas will be determined in advance of any fish salvage conducted with consideration of the water quality and habitat conditions as well as the distance and access that may affect the time required to hold fish in tanks or tubs before release. Riparian buffers (15 m minimum on both sides of the streams) will be left adjacent to all watercourses remaining within the PDA after construction and impact to the upstream watershed will be minimized, where possible. These measures will reduce the potential effect of sediment reaching the streams and the estuary, and minimize the reduction in freshwater run-off reaching the estuary; no change in any water quality parameter is expected to occur. Aurora LNG agrees that careful planning will be required in developing a detailed water management plan and erosion and sediment control measures. FEED will provide input to the Marine and Freshwater Resources Management Plan and Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of this plan.
1372.1	round 1	Kitsumkalum First Nation	4.8 table 4.8-15	Freshwater Fish and Fish Habitat	Kitsumkalum finds this description to be inadequate for such a critical piece. Include " and excessive grease" behind leaks in the opening sentence. Remove**" where possible"** with respect to fueling construction vehicles. We require more information for the proponents fuel management safety systems such as: Spill response capacity must be adequate to contain/ control all volumes of hydrocarbons on site. Spill capacity must be adequate to contain/ control Spills to the ditches, ponds and silt fences for site water management systems. All machinery will be supplied with spill kits and additional spill containers will be onsite at strategic locations. All crew members will be trained and understand spill response equipment and their use. We would expect to see a detailed description of spill capacity for all Marine operations including fuel storage and adequate containment for these storage stations.	Aurora LNG acknowledges the wording suggestions and have revised Mitigation No. 4.8.10 as follows: All construction equipment onsite will be kept clean, free of leaks, excess oil, and grease. Refuelling or servicing of construction equipment will take place at least 30 m away from any watercourse or waterbody; exceptions may be made for large or immobile construction equipment in which case drip trays or bermed areas will be utilized so that any spillage will not enter the waterbody. An errata document is being compiled that captures these corrections and it will be filed with the BC EAO. The mitigation has been revised to clarify the intent of the "where possible" wording as relocation of such equipment for fueling purposes may cause more environmental disturbance. Measures related to the use of fuels and machinery on site will be included inthe Marine and Freshwater Resources Management Plan. The plan will address spill containment capacity, number, type, and size of on site spill kits, and training for all personnel on site. All site personnel will review, understand, and follow all of the management plans while working on site. Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Marine and Freshwater Resources Management Plan.
1373.1	round 1	Kitsumkalum First Nation	4.9.5.1	Marine Wildlife - Marine Birds	The Marine Fish and Fish Habitat VC was reviewed alongside the Marine Water Quality VC in order to understand whether effects related to exposure to TSS were addressed. Section 4.9.5.1 lists the assumptions underlying the effects assessment. To assess effects related to TSS exposure, factors including dredge volume, disposal volume, and dredge rate were used to predict concentrations and spatial extent of TSS exposure. However, assumptions around exposure duration were not explicitly stated here and need to be provided.	The amount of time TSS levels are anticipated to exceed guidelines for the protection of aquatic life associated with dredging and disposal at sea activities was included in the model as part of the sediment dispersion modeling exercises. As described in Appendix G (Technical Data Report - Aurora LNG: MOF and Terminal Dredge Modelling), elevated TSS levels are expected to persist in Casey Cove for the duration of dredging activities (dredging in Casey Cove is anticipated to run for approximately 20 hours per day for approximately 48 days), with levels returning quickly to baseline conditions upon cessation of dredging activities. At South Digby Island, elevated TSS levels are expected to persist for the duration of dredging activities (dredging is anticipated to occur for ten hours per day for approximately 13 days at Berth 1 North, 17 days at Berth 1 South, and 11 days at Berth 2), with levels returning quickly to baseline conditions upon cessation of dredging activities. As described in Appendix H (Technical Data Report - Aurora LNG: Disposal at Sea Modelling), elevated TSS levels are expected to persist at Brown Passage during and immediately following each disposal event, with levels returning to baseline conditions relatively faster in shallower waters than in deeper waters. Disposal of dredged materials from the MOF is anticipated to require 124 disposal events (once every 8 hours, for approximately 41 days); disposal of dredged materials from Berth 1 North is anticipated to require 18 disposal events (once every 16 hours, for approximately 11 days); disposal of dredged materials from Berth 1 South is anticipated to require 23 disposal events (once every 16 hours, for approximately 15 days); disposal of dredged materials from Berth 2 is anticipated to require 15 disposal events (once every 16 hours for approximately 9 days). Dredging and disposal at sea activities will be limited to the DFO least risk timing window (November 30 to February 15) and will take place over two years. The amount of time marine fish may be exposed to elevated levels of TSS during dredging and disposal at sea activities was considered in the assessment of potential changes in marine fish health (Section 4.9.5.5 of the Marine Fish and Fish Habitat VC). In addition to the duration of dredging and disposal at sea activities themselves, and associated TSS levels, other factors such as species, life stage, and the behaviour of the individual may also influence exposure duration. For example, some species (such as pelagic fish), may choose to move away from or avoid areas of elevated TSS (Kjelland et al. 2015), resulting in relatively short-duration exposure. Other species (such as demersal fish, species with lower motility, or sessile invertebrates) may remain near the dredge or disposal areas, resulting in exposure to elevated TSS for relatively longer duration (up to a maximum of approximately 2.5 months, the length of the DFO least risk timing window). Reference: Kjelland, M.E., Woodley, C.M., Swannack, T.M. and D.L. Smith. 2015. A review of the potential effects of suspended sediments on fishes: potential dredging-related physiological, behavioral, and transgenerational implications. Environment Systems and Decisions, 35(3): 334-350.
1374.1	round 1	Kitsumkalum First Nation	4.9.5.5	Marine Wildlife - Marine Birds	The Marine Fish and Fish Habitat VC was reviewed alongside the Marine Water Quality VC in order to understand whether effects related to exposure to TSS were addressed. While estimates of exposure concentrations are stated in section 4.9.5.5, the application is less clear on exposure durations. Newcombe and Jensen (1996) provide a means for estimating severity of effects for estuarine fish (models 4 and 5) based on exposure concentration and exposure duration. These models could be used to estimate the likelihood and degree of residual effects to fish health. Newcombe, C. P. and J. O. Jensen. 1996. Channel suspended sediments and fisheries: a synthesis for quantitative assessment of risk and impact. North American Journal of Fisheries Management 16(4):693-727.	Duration of effect was considered in the Application. Specifically, duration is one of the metrics by which every residual effect is characterized (please see Table 4.5-5). Aurora LNG considered adopting quantitative thresholds for some of these metrics, including duration. Ultimately, however, the thresholds used were adopted because they can be applied consistently to all four potential effects and across different mechanisms within the same potential effect. In contrast, quantitative thresholds - such as the Newcombe and Jenson (1996) approach, are highly context specific. There are several reasons why the model predictions in the reference cited in the comment are not appropriate to an EA context and in particular for those in the Skeena estuary. First, Newcombe and Jensen (1996) (N&J) highlight the great variability among species, and importance of life-stages and particle size. They base their meta-analysis on studies that were (1) species-focused, (2) typically from highly controlled laboratory studies, and (3) "adequately documented". They implicitly assume information is available on several variables that are required to apply their linear models. That is, the N-J approach is of most use in data-rich, species-specific applications, where fish are exposed to steady elevations of TSS, non-stop, for a prolonged duration. In the context of an EA, where many species, life-stages and biophysical scenarios are involved, information on key variables is lacking, and (in this case) TSS plumes are highly variable over time and space, the approach is far less viable or practicable. Indeed, N-J recognize that the response of fish in wild populations exposed to episodic pulses of elevated TSS (as would be the case here) may not fit with their model predictions since, for example, wild fish are likely to actively avoid TSS plumes.
1375.1	round 1	Kitsumkalum First Nation	Table 4.9-2	Marine Fish and Fish Habitat	There is no reference to potential effects of "Ballast Water" on marine habitat, fish, and invertebrate species in the subtidal, tidal, and beach zones. In addition to the initial listing of species that have been reported to be introduced to the BC coast by ballast water releases, there should be a ballast water management and release monitoring approach. The Proponent needs to state whether the International Maritime Organizations (IMO's) "International Convention for the Control of Ship's Ballast Water and Sediments"[1] will be adhered to. As outlined in these guidelines all ships that are exchanging ballast water must: 1. Exchange water outside the Canadian EEZ (200 Nautical Miles offshore or if not possible due to storm at an absolute minimum of 50 Nautical Miles offshore), ballast water treatment and a ballast water exchange monitoring plan; 2. Carry a ballast water record book; 3. Possess a ballast water management certificate.	As per Mitigation Measure No. 4.5.7 (Section 4.5.15.3, Table 4.5-26 of the Water Quality VC), vessels transiting to and from the Aurora LNG marine terminal will adhere to the Vessel Pollution and Dangerous Chemicals Regulations and the Ballast Water Control and Management Regulations under the Canada Shipping Act (2001). The Ballast Water Control and Management Regulations are aimed at avoiding the introduction of invasive species to local waters, and outline a number of mandatory ballast water management procedures related to ballast water management plans, ballast water exchange and treatment, reporting requirements, compliance and enforcement, and research. Therefore, no adverse effect on marine water quality as a result of ballast water discharge is expected. Subsequently, no adverse effects to marine fish and fish habitat are expected.
1376.1	round 1	Kitsumkalum First Nation	Table 4.9-3	Marine Fish and Fish Habitat	Under the "Potential Project Effects" column, there is no mention of one of the greatest and likely dangers for fish and fish habitat of this project, the accidental release of larger amounts of bunker oil as well as the continuous release of smaller amounts of oil and exposure to antifouling paint as part of normal operations. These effects, and their effect mechanism, measurable parameters and rationale for measurable parameters should be listed here even if they have also been listed elsewhere in the Application.	The potential effects of accidents or malfunctions are assessed in the Section 9 of the Application, separately from those associated with Project construction and routine operations in order to avoid repetition. Section 9.8 considers On-shore Hazardous Spill, while Section 9.9 considers Vessel Grounding or Collision, which includes consideration of the potential release of hazardous materials to the marine environment. The proposed Project and associated marine transportation does not include the 'continuous release of smaller amounts of oil'. Any release of oil or other hazardous material would be considered an accident or malfunction, not a routine operations activity.
1377.1	round 1	Kitsumkalum First Nation	4.9.2.5	Marine Fish and Fish Habitat	It is uncertain whether the spatial boundaries are also based on oil dispersion models taking currents and wind into consideration in case of a bunker oil spill. Clarification is necessary.	Spatial boundaries for the Marine Fish and Fish Habitat VC were developed to assess potential effects resulting from Project construction, routine operations, and decommissioning, and reflect the areas within which such effects could be measurable. A bunker fuel spill is considered an unlikely event and would constitute an accident or malfunction. It is standard EA methodology to consider potential effects of accidents and malfunctions separately from other Project-related effects. For a discussion of the potential effects of bunker fuel spill on marine fish and fish habitat, please see Section 9.9 of the Application.
1378.1	round 1	Kitsumkalum First Nation	Table 4.9-5	Marine Fish and Fish Habitat	Within the "Magnitude" row and under the "Quantitative Measure…" column we recommend quantifying statements in the following way: For "Low", we suggest quoting how much change from existing conditions is needed to define change. As an often accepted value we are suggesting a 20% change from existing conditions for all measurable parameters such as water quality parameters.	Aurora LNG appreciates the suggestion to adopt specific thresholds for the magnitude levels, and this approach was given serious consideration during the refinement of these criteria. Ultimately, there were two main reasons why a qualitative approach was adopted: The degree of deviation from baseline conditions required to meet the different levels ('negligible', 'low', 'moderate', 'high') would likely vary depending on the specific effect and underlying mechanism. It is unlikely that adequate detail could be always obtained on each mechanism and for each potential effect to defensibly specify a % deviation from baseline conditions. In summary, Aurora LNG felt that a qualitative approach was ultimately more appropriate and defensible than having quantitative thresholds for each magnitude level.
1379.1	round 1	Kitsumkalum First Nation	4.9.2.8	Marine Fish and Fish Habitat	Significance of an effect should not be bounded by temporal or population level limits as is done here. A significant effect can occur over short periods of time and affect less than the whole population of a fish species. In addition, significant effects can occur for other species groups and should not be limited to "a marine fish population". Please change this entire paragraph.	Aurora LNG acknowledges that defining a significance threshold for an ecological Valued Component (VC) is subjective, as it depends on what characteristics of the VC are considered of value to an individual or organization. For the Marine Fish and Fish Habitat VC, Aurora LNG took an ecological function approach, whereby an exceedance of the significance threshold (i.e., local extirpation of a population) could result in a significant effect on the function of the marine ecosystem. The definition also allowed adequate flexibility to be generalizable to all four marine fish and fish habitat potential effects. Effects manifesting over a short period of time, or on a scale that does not affect the whole population, were captured as part of the broader characterization of residual effects, based on the metrics defined in Table 4.9-5. Finally, the term 'fish' is used as per the Fisheries Act definition, which does include marine species beyond the taxonomic group of finfish. Please see page 4.9-1 (second paragraph) of the Application for this definition of 'fish'.
1380.1	round 1	Kitsumkalum First Nation	4.9.3.1	Marine Fish and Fish Habitat	In the listing of different modelling studies provided, there is no current and wind dispersion model for large scale and accidental bunker oil releases and for operational and likely frequent releases of bunker oil, and other mechanical fluids as well as ballast water from the tankers. Please provide such a model.	The potential effects of an accidental release of bunker fuel on marine water quality and marine fish and fish habitat are discussed in Section 9.9 of the Application. The assessments in Sections 4.5 (Water Quality VC) and 4.9 (Marine Fish and Fish Habitat VC) focus on potential effects of Project construction, routine operations and decommissioning. It is standard EA practice to consider the effects of accidents and malfunctions separately from other Project-related effects. Aurora LNGdisagrees with the statement that there will be "likely frequent releases of bunker oil, and other mechanical fluids...".Vessels calling on the Aurora LNG marine terminal will comply with all relevant federal and international regulations (e.g., Vessel Pollution and Dangerous Chemical Regulations of the Canada Shipping Act, 2001) that have been established to minimize the potential for releases of hazardous materials. For a discussion on preventative measures and response measures that would be implemented in the unlikely event of an accidental spill, please see Section 9.9.2. Aurora LNG is of the opinion that undertaking current and wind modelling of large scale and or accidental bunker oil releases is not required to characterize potential Project interactions between released oil and marine fish and fish habitat. Oil trajectory modelling following an unlikely release incident would use real-time meteorological and oceanographic data to more accurately predict the movement of oil, and guide response activities at that time. The release of ballast water is regulated by Transport Canada through the Ballast Water Control and Management Regulations of the Canada Shipping Act (2001). The regulations are aimed at avoiding the introduction of invasive species to local waters, and outline mandatory management procedures for ballast water management, exchange and treatment, reporting requirements, compliance and enforcement, and research. Further discussion is provided in Table 4.5-17 and in the Water Quality VC (Section 4.5.15.3, Operations). Vessels transiting to the Aurora LNG marine terminal will comply with Transport Canada regulations, as per Mitigation 4.5.7 (Section 4.5.15.3, Table 4.5-26 of the Water Quality VC).
1381.1	round 1	Kitsumkalum First Nation	4.9.3.2	Marine Fish and Fish Habitat	For all of the locations the observations appear to be purely based on presence and absence without any attempt to determine densities by species or species groups. Please explain how Aurora LNG plans to measure changes in species densities or relative species composition in the intertidal and subtidal zone based on presence-absence based surveys? Please also provide a summary table for all surveyed locations for the intertidal and subtidal species composition and densities.	Detailed methods and results of Project-specific field surveys are provided in Appendix L. Estimated relative abundance of species and species groups is presented using density where appropriate (e.g., quadrat-based observations during intertidal surveys, numbers per area seined) and other metrics where more suitable (e.g., number per length of ROV transect or number per time of tangle net set). Summary tables of intertidal data are presented in Appendix 1 of Appendix L, summary tables of subtidal data are presented in Appendix 2 of Appendix L, and summary tables of marine fish data (sampled in both the intertidal and subtidal) are presented in Appendix 6 of Appendix L. The characterization of species composition and relative abundance in Appendix L was used to inform the assessment of Project-related effects that could result in changes to species composition or relative abundance. Assessment of potential change in habitat is in Section 4.9.5.2, assessment of change in behaviour is in 4.9.5.3, assessment of change in mortality risk is in Section 4.9.5.4, and assessment of change in health is in Section 4.9.5.5.

1382.1	round 1	Kitsumkalum First Nation	Figures 4.9-3, 4.9-4 and 4.9-5	Marine Fish and Fish Habitat	Please explain why the areas that are going to be dredged as part of the construction of marine infrastructure are by colour-coding (dark blue) characterized as “altered” and not as “lost” or as “permanently altered”. At least those areas have to be characterized as temporarily lost until the composition and density of all species is similar to pre-project metrics.	Figures 4.9-3 to 4.9-5 show alteration and loss of marine substrate and vegetation as a result of Project construction. The area affected by dredging is captured by three colours: light pink (indicating a change from intertidal to [lower elevation] intertidal), dark pink (indicating a change from intertidal to subtidal), and blue (indicating a change from subtidal to [deeper] subtidal). These changes are classified as 'alterations' since the substrate will remain available for use by marine species (including CRA species) after dredging has been completed, but will be different in their nature. Other changes, in which the substrate is completely removed from the marine environment, are classified as "lost". The figures do not further depict between alterations that are considered temporary or permanent; this distinction is covered in the text itself. A permanent alteration is determined based on DFO's definition -- i.e., that the change is of a duration that could impair the ability of a CRA species to complete one or more life processes. Habitat changes caused by dredging (or any other mechanism), that fulfilled this definition were included in the area estimates of permanent alteration, and will be offset. The lag time during which marine communities recover to their climax state (resulting in a productivity deficit) are (and will continue to be) accounted for in estimates of offsetting requirements through an appropriate offset ratio.
1383.1	round 1	Kitsumkalum First Nation	Figure 4.9-7b	Marine Fish and Fish Habitat	The figure shows only one dredging location at the jetty site while Figure 4.9-3 shows another dredging location south of Tuck Island that would be exposed to higher current speeds and therefore sediment disturbed by dredging would likely be deposited at higher distances from the dredging location shown for the one dredging site close to Digby Island. Please add the second dredging site and related sedimentation patterns to Figure 4.9-7b.	The purpose of Figure 4.9-6 and Figure 4.9-7 (in the Marine Fish and Fish Habitat VC) was to demonstrate that sediment deposition associated with dredging activities is expected to occur predominantly in areas that experience natural sedimentation (as opposed to accretion). The LNG Jetty - Berth 1 North and the Pile-and-Deck MOF option were chosen as two examples to visually display this phenomenon. At the LNG Jetty – Berth 2, areas of predicted sediment deposition (displayed in Figure 10-6 of Appendix G [Technical Memorandum - Aurora LNG: MOF and Terminal Dredge Modelling]) are also expected to occur predominantly in areas that experience natural sedimentation (displayed in Figure 64a of Appendix M [Hydrodynamic Modelling of Changes in Sediment Erosion and Accretion due to Project Infrastructure]).
1384.1	round 1	Kitsumkalum First Nation	4.9.5.2	Marine Fish and Fish Habitat	The loss of eelgrass is not expressed in the big picture of percentage loss of eelgrass within the Prince Rupert Harbour area. The categorization of the loss of eelgrass as “moderate in magnitude” can only be made once the total historical versus current extent of eelgrass occurrence in the Prince Rupert Harbour area has been assessed. Please add an assessment of total area of historical and current eelgrass in the harbour area to this report and then base the assessment of magnitude of effect on the bigger picture.	It is standard Environmental Assessment methodology to assess and characterize project-related effects in relation to current (i.e., existing baseline) conditions. Management and restoration decisions for eelgrass, which consider a broad spatial and temporal scope, are the responsibility of regulatory agencies (such as Environment and Climate Change Canada, Fisheries and Oceans Canada, the Government of BC's Ministry of Environment and Ministry of Forest, Lands and Natural Resource Operations) and local environmental groups. Wherever possible and practicable, Aurora LNG will adopt restoration or offsetting goals to complement the objectives of these efforts. However, Aurora LNG believes that baseline conditions should be based on current -- not historical -- conditions. Please note that cumulative effects (which consider past, present and reasonably foreseeable projects) are considered in Section 4.9.6 of the Application.
1385.1	round 1	Kitsumkalum First Nation	4.9.5.2	Marine Fish and Fish Habitat	The characterization of dredging and marine construction as “low to moderate” is in our opinion inappropriate based on the Proponent’s own classification scheme and the Fisheries Act: The Act does not define harm as “harm to fish populations” but harm to “CRA fish” in Section 35(1) of the Fisheries Act and prohibits any work, undertaking or activity that results in serious harm to fish that are part of a CRA fishery, or to fish that support such a fishery. Serious harm to fish is defined as “the death of fish or any permanent alteration to, or destruction of, fish habitat of a spatial scale, duration, or intensity that fish can no longer rely upon such habitats for use as spawning grounds, or as nursery, rearing or food supply areas, or as a migration corridor, or any other area in order to carry out one or more of their life processes.” Therefore, harm especially to eelgrass beds clearly falls under this classification and therefore the effects of dredging and construction should be re-classified as a significant adverse effect.	Aurora LNG is of the opinion that the characterization of residual changes to marine fish habitat (under the 'change in habitat effect', Section 4.9.5.2) is fair. The magnitude of residual changes in marine fish habitat associated with dredging and marine construction activities (including infilling, pile driving, and the installation of intake and outfall pipes) is characterized as being low (i.e., measurable, but below regulatory guidelines [i.e., serious harm to fish under the Fisheries Act] and does not affect the long-term persistence of any marine fish population) to moderate (i.e., measurable, above regulatory guidelines [i.e., serious harm to fish under the Fisheries Act], but does not affect the long-term persistence of any marine fish population). The characterization of 'low magnitude' accounts for residual effects such as those associated with sediment deposition during dredging activities, which are not expected to limit or diminish the ability of CRA fishery species to complete one or more life processes; therefore, residual serious harm to fish is not anticipated. The characterization of 'moderate magnitude' accounts for residual effects such as those associated with the loss of habitat during dredging activities (e.g., eelgrass), which are expected to constitute serious harm to fish and will require offsetting. With the successful implementation of mitigation measures identified in Table 4.9-11, including the development and successful implementation of a habitat offsetting plan, residual changes in marine fish habitat from dredging and marine construction activities are not expected to threaten the long-term persistence of a marine fish population. Therefore, residual effects are considered not significant.
1386.1	round 1	Kitsumkalum First Nation	4.9.5.2	Marine Fish and Fish Habitat	Where are accidental and large volume or operational and small volume oil spill effects considered under Marine Fish and Habitat? It is not sufficient to provide this information Under Accidents and Malfunctions; please also assess it here and in the context of damage to CRA fish and their habitat.	It is standard Environmental Assessment practice to consider the effects of accidents and malfunctions separately from other Project-related effects (i.e., effects of construction, routine operations, and decommissioning). Potential effects of an accidental oil release on marine fish and fish habitat are assessed in Section 9.9 of the Accidents and Malfunctions VC chapter.
1387.1	round 1	Kitsumkalum First Nation	Table 4.9-18	Marine Fish and Fish Habitat	Under the row labelled 4.9.14, the Proponent mentions that an Environmental Monitor will be onsite during pile driving and blasting. Please state whether an Environmental Monitor will be on site for all other construction activities as well and whether local First Nations have been asked to fill the Environmental Monitor position.	Aurora LNG will retain the services of an onsite environmental monitor throughout the construction phase of the Project. It is anticipated the environmental monitor will need to be a "qualified professional", with demonstrated experience and knowledge of environmental monitoring. As outlined in mitigation 5.2.5, Aurora LNG is committed to working with training and education facilities, Aboriginal Groups, and local communities to increase opportunities to obtain training required for Project participation. Aurora LNG welcomes further discussions with Kitsumkalum First Nation regarding training and education opportunities.
1388.1	round 1	Kitsumkalum First Nation	4.9.5.4	Marine Fish and Fish Habitat	Eelpouts (Zoarcidae spp.) are described as “more motile…fish” . We disagree with this characterization in this context since eelpouts have the tendency to seek shelter or even burry deeper when disturbed (experience of author: Dr. Elmar Plate) and thus are unlikely to avoid mortality during dredging.	Aurora LNG acknowledges that the mention of eelpout as a fish likely to flee the area in response to dredging was not appropriate. An errata document is being compiled that captures this correction and it will be filed with the BC EAO. The assessment of change in mortality risk described in Section 4.9.5.4 will not be affected by the removal of eelpout from the list on Page 4.9-87.
1389.1	round 1	Kitsumkalum First Nation	4.9.5.5	Marine Fish and Fish Habitat	Is a contingency plan for water release in place? Please state the trigger concentrations for water treatment in a table and show how the trigger concentrations are monitored for all COPCs.	Waste water discharges are subject to a range of permitting and regulatory oversight, dependent on the source and nature of the discharge. Details on Project waste discharges and associated regulations, are provided in the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
1390.1	round 1	Kitsumkalum First Nation	Table 4.9-21	Marine Fish and Fish Habitat	This table, as does the whole “Marine Fish and Habitat” chapter, leaves out all effects of accidental and large volume oil spills and operational and small volume oil spills. Wherever else in this Application they are mentioned, please also assess them here and in the context of damage to CRA fish and their habitat.	It is standard Environmental Assessment practice to consider the effects of accidents and malfunctions separately from other Project-related effects (i.e., effects of construction, routine operations, and decommissioning). Potential effects of an accidental oil release on marine fish and fish habitat are assessed in Section 9.9 of the Accidents or Malfunctions VC chapter.
1391.1	round 1	Kitsumkalum First Nation	Table 4.9-22	Marine Fish and Fish Habitat	Please explain why only one of the many past projects has led to change in mortality risk and none have led to changes in health? Just like the proposed Aurora LNG Project, all past projects have led and continue to lead to changes in mortality risk and health of marine fish and fish habitat.	Aurora LNG can not speak for the assessments completed by other projects. The purpose of Table 4.9-22 in the Marine Fish and Fish Habitat VC (Section 4.9) is to identify other past, present, and reasonably foreseeable future projects and physical activities that may interact cumulatively (from a marine fish and fish habitat perspective) with the proposed Aurora LNG Project. A description of each project and physical activity that was considered in the cumulative effects assessment is included in Table 3-4 of the Assessment Methods (Section 3.0 of the Application). Table 4.9-22 identifies past projects and physical activities that have resulted in lasting effects to marine fish habitat, or that continue to adversely affect fish through changes in mortality risk, behavior, or health. For a past project or physical activity to interact cumulatively with the Aurora LNG Project itself (and receive a check mark in Table 4.9-22), the following needs to be satisfied: i) the past project continues to adversely affect marine fish and fish habitats (e.g., the project continues to result in the injury or mortality of marine fish), and ii) these adverse effects are likely to interact cumulatively with the proposed Aurora LNG Project (e.g., adverse effects of the past project or physical activity overlap on a spatial or temporal scale with the proposed Aurora LNG Project, or affect a population within the Marine Fish and Fish Habitat RAA, such that the effects are expected to interact cumulatively). Section 3.7 of the Assessment Methods Chapter provides additional details on the methods for assessing cumulative effects.
1392.1	round 1	Kitsumkalum First Nation	4.9.6.6	Marine Fish and Fish Habitat	In this paragraph, planned projects and their metrics of permanent CRA fish habitat alterations are listed as a start of a meaningful cumulative impact assessment. In addition to these numbers expressed in lost or permanently altered area, we need the same metrics for all existing projects in Prince Rupert Harbour to assess “real” cumulative impacts. Please provide these numbers and delineate all past and planned future loss or permanent alterations of ACR fish and fish habitat in table format and as a GIS layer on a map. As it stands, the cumulative impact assessment does not provide any overview/assessment of cumulative impact in this area. As part of this assessment, please also provide an estimate of suggested total development limits in this area to protect its ecological function.	Please note that for a cumulative effects assessment, "residual" effects are considered from Aurora LNG's Project and other past, present and reasonably foreseeable projects likely to interact cumulatively. Residual effects constitute any remaining effect after the implementation of mitigations - including habitat offsetting, which is not considered in the rationale underpinning this comment. Aurora LNG is committed to fulfilling their legal obligation to develop adequate, effective offsetting to counterbalance serious harm to fish caused by the loss or permanent alteration of habitat. Further, Aurora LNG assumes that other projects will also adhere to their legal requirement to offset any serious harm to fish they cause, since failure to do so would contravene the Fisheries Act and trigger serious consequences. As such, residual effects of the Aurora LNG Project and other potentially interacting projects as a result of areas lost or permanently altered are not expected to interact cumulatively in a manner that could cause adverse effects to the productivity or sustainability of CRA species. Finally, since a consideration of the residual effect of Project should include habitat offsetting, it is not necessary, appropriate (or, indeed, possible) to map areas lost or permanently altered for all past, present or reasonably foreseeable future projects.
1393.1	round 1	Kitsumkalum First Nation	Appendix G, 4.1 (top panel) and Table 4-2	Marine Fish and Fish Habitat	The measured peaks of the horizontal current speeds appear to be consistently underestimated by the modelled results for all higher current speeds. Please adjust and re-calibrate the model based on empirical data. For the 16.7 m depth, the observed maximum values are more than twice the modeled values.	As discussed in Section 4.3 of Appendix G of the Application) re-calibration of the model is not considered necessary. There are a few very large speed values in the observed data, which are attributed to buoy motion. A moored buoy is often susceptible to spikes in the current data due to pitch and roll of the sensor by wave action and these are considered noise. Readings at Tuck Buoy gave a maximum current speed of up to 40.2 cms-1 at 16.7 m depth, which is unrealistic values for near the seabed. The company that collected and supplied the ADCP data (Ausenco) confirmed there were some discrepancies in data quality and the uncertainties are larger than desired for the purpose of comparison to model output. However, the data indicate that the model is performing well in this region, following the trends in the observed data. There are a number of instances at each depth where the model slightly over-predicts the currents.
1394.1	round 1	Kitsumkalum First Nation	Appendix G. 12.1	Marine Fish and Fish Habitat	In this paragraph it is stated that “Values exceeding 5 mg/L can extend as a narrow plume northwards to a maximum distance of 700 m, with width remaining within 300 m.” We may have missed it but this result did not appear to have been reported in Section 4.9 Fish and Fish Habitat. If missed, please add this statement to Section 4.9 and interpret its results in the light of significance of effect.	A detailed description of the spatial and temporal extent of predicted TSS sediment plumes associated with dredging activities at the MOF and the LNG Jetty is included in Appendix G (Technical Memorandum - Aurora LNG: MOF and Terminal Dredge Modelling). This information was considered in the assessment of potential effects to marine fish health associated with exposure to elevated levels of TSS (under the 'change in health' effect, Section 4.9.5.5 of the Marine Fish and Fish Habitat VC).
1395.1	round 1	Kitsumkalum First Nation	Appendix V, Conceptual Fish Habitat Offsetting Plan, Table 16, Table 17	Fish Habitat Offsetting Plan	The rationale that only “hard” habitats have to be offset would only apply if the “soft” habitats would not provide for CRA fish species. This is not true based on the Proponent’s own baseline studies that found CRA fish species in the “hard” and the “soft” bottomed habitats especially considering that “fish” in the Fisheries Act are defined as “parts of fish, shellfish, crustaceans, marine animals and any parts of shellfish, crustaceans or marine animals, and the eggs, sperm, spawn, larvae, spat and juvenile stages of fish, shellfish, crustaceans and marine animals;”. We therefore think that by applying the Fisheries Act provisions correctly to ACR” fish” rather than “whole fish populations” and including the non-fish ACR species a total minimum of 172,124 m2 of area has to be entered into the habitat offsetting account for change in marine substrate resulting from dredging, infilling, and installation of seawater system pipes. Based on the same rationale, an additional minimum of 19,883 m2 (MOF–pile-and-deck-option) or 78,675 m2 (MOF-concrete caisson option) have to be added to the offsetting account due to marine substrate loss.	The distinction between "hard" and "soft" substrates is not based on whether or not they "provide for" CRA species. Rather, the distinction is based on whether or not a change to, or removal of, such habitat has the potential to cause residual serious harm to fish - i.e., that it could impair the ability of a CRA species to complete one or more life process. As per Page 47 of the Conceptual Fish Habitat Offsetting Plan (Appendix V), "The potential for residual serious harm to fish resulting from a change in intertidal or subtidal substrates depends on the comparative value of the initial and final conditions". For this reason, the different types of changes are identified (i.e., soft to hard, hard to soft, change in height or shape of soft substrate, change in height or shape of hard substrate - Page 47; loss of hard substrate, loss of soft substrate - Page 48), and consideration is given to the potential for residual serious harm from each change. For details on this distinction, please see Pages 47 48 of the Conceptual Fish Habitat Offsetting Plan (Appendix V).
1396.1	round 1	Kitsumkalum First Nation	4.9	Marine Fish and Fish Habitat	"unidentified larval fish (a grouping that could possibly include eulachon, as well as other Osmerids)." Nexen should confirm identity as utilization of project area by eulachon is important information to Kitsumkalum as this species is a key food source.	It was not possible to distinguish between larval eulachon and other osmerids captured in beach seines during the marine fish surveys; these individuals in their larval stage can only be distinguished through DNA analysis. However, the absence of confirmation of larval eulachon was not used to infer absence of eulachon from the LAA. Information collected during the Project-specific marine fish surveys were complemented by information collected from publicly available literature (including TEK), and both types of sources were used to characterize existing conditions for marine fish (including eulachon) and fish habitat in areas potentially affected by the Project. See Appendix L (Marine Fish and Fish Habitat TDR) for more details.
1397.1	round 1	Kitsumkalum First Nation	4.9 (page 4.9-26)	Marine Fish and Fish Habitat	Nexen is missing information provided by Kitsumkalum regarding TU and current use of the Project LAA.	Aurora LNG acknowledges that Kitsumkalum First Nation did provide TU and current use of the Project LAA information. This information was incorporated into Section 6.5 (Marine Use and Navigable Waters), Section 11.3.10 (Assessment of Section 5(1)(c) Effects - Kitsumkalum First Nation) and Section 12.5.7 (Aboriginal Interests - Kitsumkalum First Nation) of the Application. The information is also included in Section 7 of the Aboriginal Consultation TDR (Appendix S.2).
1398.1	round 1	Kitsumkalum First Nation	4.9 (page 4.9-27)	Marine Fish and Fish Habitat	Potential project interaction is missing. Project component "Waste management" and potential effect "change in habitat". Cooling tower discharge has the potential to affect fish habitat, and those discharges from de-salination plant, and waste from floating camp etc.	Potential effects to fish and fish habitat resulting from waste discharges to the marine environment are assessed in the Marine Fish and Fish Habitat assessment under Project Mechanisms for Change in Health, Section 4.9.5 of the Application. This section details the mechanisms for change in fish health due to waste discharges during construction, operation, and decommissioning. The assessment identifies waste discharges during construction and operations, including power generation cooling water and treated sanitary wastewater (which may include chlorine content). Mitigation 4.5.8 in Table 4.9-20 covers waste discharges to the marine environment. Potential residual effects are assessed in the Characterization of Residual Effects for Change in Fish Health, under Construction – Waste Management, and Operations – Waste Management. The fish and fish habitat assessment did not assess waste discharge characteristics (e.g. temperature, chlorine concentration) individually. Instead, the potential for all waste discharges to affect fish health was assessed. Waste discharges, regardless of make up, are managed in the same manner; permit conditions limit the quality and quantity of the waste discharged and impose monitoring requirements. Aurora LNG is legally-obliged to abide by permit conditions, which are designed to protect marine life. Therefore, waste discharge effects to fish and fish habitat were considered not significant. The assessment of potential effects to fish and fish habitat resulting from waste discharges is supported by information from the Marine Water Quality assessment (Section 4.5.11 of the Application). A significant residual adverse environmental effect on marine water quality is one that is predicted to result in a change in sediment or water quality that would result in a health risk to a local population of marine biota. The marine water quality assessment therefore covers changes in water quality that may significantly affect fish and fish habitat. Table 4.5-19 in the Marine Water Quality section lists Project-related wastewater inputs to the marine environment as a project effect mechanism, and potential effects of this mechanism are assessed in Section 4.5.15. Mitigations 4.5.8 and 4.8.9 in Table 4.5-26 cover waste discharges to the marine environment. Potential residual effects to marine water quality related to waste management are characterized in the Characterization of Residual Effects component of Section 4.5.15.3. Further details on project waste discharges and associated regulations, are provided in the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.

1399.1	round 1	Kitsumkalum First Nation	4.9 (page 4.9-28)	Marine Fish and Fish Habitat	Kitsumkalum would like to see a follow-up study to confirm the predictions that there will be no measurable effect to marine water quality / marine resources from localized marine water acidification or eutrophication. And to confirm there will be no changes to water quality (and thus marine / estuarine vegetation from changes to TSS (especially in Delusion Bay)	Marine water acidification and eutrophication is not expected to occur due to the high buffering capacity of marine waters. Therefore, no adverse effects on marine water quality and marine fish and fish habitat are expected from acidification and eutrophication. However, it is anticipated that a selection of freshwater lakes and streams (which may include streams that flow into Delusion Bay) will be monitored to verify the prediction of no adverse effects on water quality due to acidification and eutrophication. These acidification and eutrophication monitoring programs are expected to be regionally focused and developed in consultation with MOE, Aboriginal Groups, and industry partners. Regarding TSS-driven effects on marine vegetation, all site discharges into the marine environment, including discharges into Delusion Bay (e.g., from the soils storage area), will comply with relevant regulations and permitting requirements, and therefore no adverse effects to marine vegetation in Delusion Bay are expected from these discharges. Adherence with these regulations is a legislated requirement of all proponents, including Aurora LNG, and failure to adhere to them can have serious ramifications. Aurora LNG is committed to developing and implementing a Marine Water Quality Monitoring Program, which will include monitoring turbidity and confirming the effectiveness of mitigation measures. The plan will include water quality thresholds, monitoring frequency, and specific monitoring locations. The content of the plan will be developed in accordance with industry best management practices and standards, applicable regulations, and conditions of the Environmental Assessment Certificate and relevant permits. For further details, please see the "Discharges to the Marine Environment" technical memo, which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
1400.1	round 1	Kitsumkalum First Nation	4.9 (Appendix M)	Marine Fish and Fish Habitat	The hydrodynamic modeling (of erosion and accretion) did not incorporate vessels at berth as a modelled scenario. Suggest this should be included to assess the potential changes to fish habitat. Characterization of effects is not complete.	Since vessels are not expected to be berthed continuously, and do not constitute part of the Project infrastructure, they are not expected to have any prolonged, consistent or meaningful impact on sediment erosion and accretion rates. As such, Aurora LNG does not believe that incorporation of vessels into hydrodynamic modelling of Project infrastructure is necessary. Nevertheless, the potential effects of Project vessels on marine fish and fish habitat are considered throughout Section 4.9, and potential effects on marine water quality are considered in Section 4.5.
1401.1	round 1	Kitsumkalum First Nation	4.9 (Appendix M)	Marine Fish and Fish Habitat	include follow-up modelling of hydrodynamic with FEED to quantify changes to fish habitat, and include monitoring program to ensure effects are as predicted in EA.	Aurora LNG is confident that potential changes to marine fish habitat due to sediment deposition and accretion have been adequately characterized (Appendix M of the Application), and that the resultant effects have been adequately assessed (Section 4.9, Marine Fish and Fish Habitat). Aurora LNG has committed to a Marine Sediment Deposition Monitoring Program to monitor potential sediment accumulation in the vicinity of Charles Point if the concrete caisson MOF option is constructed (see Section 15.2.3 of the Application). The details of this monitoring program will be developed in accordance with industry best management practices and standards, applicable regulations, and conditions of the Environmental Assessment Certificate and relevant permits.
1402.1	round 1	Kitsumkalum First Nation	4.9 (Table 4.9-13)	Marine Fish and Fish Habitat	What is the difference between "habitat permanently altered" and "habitat lost"?	"Permanently altered" means that the habitat has changed from one type to another for a duration that could impair the ability of a species to complete one or more life process. "Habitat lost" indicates that the marine habitat is completely removed and no longer available for use by fish, such as when it is raised above the high tide level through infilling.
1403.1	round 1	Kitsumkalum First Nation	4.9 (Table 4.9-13)	Marine Fish and Fish Habitat	There is no characterization of the fish habitat at Brown Passage, yet there are project effects at that location. With in the EA project effects at Brown Passage appear to be limited to affects to fish (and not also to fish habitat). There are known sponge reefs within the potential range of sediment deposition effects. See PNW LNG "Brown Passage Subtidal Survey, October 22, 2014"	Please see the technical memo titled "Brown Passage: Characterization of Existing Conditions and Potential Effects associated with Disposal at Sea"which will be filed with the BC EAO.
1404.1	round 1	Kitsumkalum First Nation	4.9 (page 4.9-63)	Marine Fish and Fish Habitat	It is stated that construction activities (e.g. dredging) will occur 20 hours a day at the MOF). This is outside the window BMP from the BC OGC for noise management (near residential Dodge Cove) Clarification is required.	The construction phase noise assessment includes noise effect from dredging activities for a daily duration up to 20 hours. The BC OGC noise guideline recommends construction activity during the daytime period (7:00 to 22:00); however, the guideline does not set specific noise limits for construction activity. Noise effect from dredging activities during the nighttime period is predicted to be in compliance with the thresholds recommended by the Health Canada noise guidance. Please see the "Sleep Disturbance and Speech Interference" technical memo for a discussion on potential sleep disturbance. The technical memo assessed the potential sleep disturbance noise effect due to construction activities. The results indicate that construction noise effect at all receptors is below the noise threshold with the exception of receptor R2 (Dodge Cove). Additional mitigation measures are required during the construction phase to reduce the predicted noise effect to below the sleep disturbance threshold of 45 dBA. The additional mitigation measures are presented in the technical memo. The technical memo will be filed with the BC EAO. The "Sleep Disturbance and Speech Interference" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
1405.1	round 1	Kitsumkalum First Nation	4.9 (Table 4.9-20)	Marine Fish and Fish Habitat	Mitigation 4.5.3 and 4.5.8 is not sufficient to ensure water quality objectives for the protection of aquatic life. Should include "when exceedance are discovered outside the area predicted to have exceedances then shut down of construction activities will occur until a reduction in TSS occurs (and new mitigations implemented to ensure exceedances outside the predicted area of exceedances do not occur). " Monitoring of TSS/turbidity and temperature should also be included as mitigation to water quality via regular monitoring of waste water discharge (both construction and operations, e.g. cooling tower effluent [temperature at outfall] and over burden storage area discharge [TSS / turbidity], especially during rain events])	The on-site environmental monitor will work with the dredging contractor to identify and implement site-specific mitigation measures, if water quality exceedences are detected. Waste discharges to the marine environment will be subject to effluent and receiving environment monitoring. The spatial scale, frequency, and required parameters for monitoring will be defined in waste discharge permits issued for the Project. Further details on Project waste discharges and associated regulations, are provided in the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
1406.1	round 1	Kitsumkalum First Nation	4.9 (page 4.9-102)	Marine Fish and Fish Habitat	There is a disconnect between the daily duration of dredging activities (20hrs/day for 48 days at MOF) and the requirement for Noise Management (from the OGC 7am - 10pm). Only the noise of blasts and pile driving were modelling in the Acoustic Assessment, but realistically dredging activity will also cause noise (therefore should be modelled) and is proposed to happen outside the OGC window. Please clarify effects due to noise from dredging activity.	Noise effect during dredging activity is included in the assessment. The dredging activity noise emissions are summarized in Table 5-2, Section 5.1.2.1 of the Acoustic Environment Technical Data Report of the Application. The noise model indicates that the Project related construction activities (including dredging) will meet the Health Canada noise guidance thresholds.
1407.1	round 1	Kitsumkalum First Nation	4.9	Marine Fish and Fish Habitat	There is no sense of the magnitude of change in temperature in the receiving environment (marine)at the cooling tower discharge. In order to understand potential effects this needs to be characterized (and not left to permitting).	Cooling tower blowdown water will meet CCME and BC water quality guidelines for temperature, outside of the initial dilution zone. These guidelines allow a maximum change of $\pm 1^{0}$C from ambient at any time, location, or depth and a maximum rate of change <0.5^{0}C per hour. The exact size of the mixing zone is not yet known, and will be determined through modelling in the permitting phase. Waste discharges within and outside the mixing zone, cannot be acutely toxic to fish (per the Fisheries Act)The effect of cooling tower blowdown waste discharge was assessed based on adherence to legally-binding legislation, designed to protect aquatic life (see Section 4.5.15.3). With a commitment to meet the water quality guideline of maximum change of $\pm 1^{0}$C beyond the mixing zone, the effect was characterized as not significant (low in magnitude, within the LAA, continuous, and long-term in duration). Further details on Project waste discharges and associated regulations, are provided in the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
1408.1	round 1	Kitsumkalum First Nation	4.9	Marine Fish and Fish Habitat	Kitsumkalum disagrees with the characterization of residual effects to marine fish habitat given that there is no characterization of utilization of habitats by fish (to support an understanding of productivity for offsetting); that there is a significant amount of fish habitat to offset and the conceptual fish offsetting plan presented in the Application is not sufficient in detail, alternatives, or consideration of other project which may required offsetting "space" ; and that many of the suggested mitigation measures do not go the step further to include a stoppage of work if 'issues"/exceedances arise or include sufficient commitment to monitoring to confirm effects predictions are correct to justify the conclusions (of residual effects to marine fish and fish habitat).	Aurora LNG has characterized the utilization of habitats by fish to support an understanding of productivity for offsetting. Extensive field studies were undertaken to characterize habitats that would be affected by the Project, and the species that use these habitats. The results of these studies, presented in Marine Fish and Fish Habitat TDR (Appendix L), guided the development of the proposed offsetting measures. Aurora LNG is committed to fulfilling their legal obligation to develop adequate, effective offsets that counter-balance residual serious harm to fish. This commitment will be accomplished by following DFO's guidance on offsetting. This guidance involves understanding habitat productivity through the concepts of species utilization of, and dependence upon, habitats, broken down by species and life stage. It also involves setting specific success criteria, that are subsequently used as benchmark indicators that the offsets have fulfilled their productivity objectives and, as such, have counterbalanced Project-driven serious harm. As stated in the Conceptual Fish Habitat Offsetting Plan, the offsetting philosophy and ideas presented were intended to be concepts that demonstrate Aurora LNG's approach to identifying effective offsets and concrete ideas for counterbalancing harm. They provide a transparent starting point for constructive discussions about habitat offsetting with the ultimate goal of developing widely endorsed, low-risk, effective, appropriately located and well designed offsets. Offset projects and the corresponding "space" required for those projects will be identified through field surveys and in consultation with regulatory agencies (primarily DFO) and Aboriginal Groups. Final designs, amounts, locations, success criteria and monitoring requirements will ultimately be approved by DFO in the Fisheries Act Authorization permit. Construction of the offsets will be monitored to ensure adherence to the proposed mitigation measures and regulatory requirements and to evaluate the effectiveness of the proposed mitigation measures. Where relevant, threshold values (e.g. CCME water quality guidelines) will be used during monitoring and exceedances will trigger construction action, such as temporary cessation of activity (stop work), or slowing of activity. Details of these adaptive measures will be included in the forthcoming Marine and Freshwater Resources Management Plan. Additionally, the final fish habitat offsetting plan, that will from part of the Request for Authorization application to DFO, will include details on offset monitoring, with specific objectives focused on assessing the effectiveness of habitat offsetting.
1409.1	round 1	Kitsumkalum First Nation	4.9 (Table 4.9-22)	Marine Fish and Fish Habitat	Alta Gas Propane facility is not listed in the projects interaction list for cumulative effects on Marine Fish and Fish Habitat	As outlined in section 3.7.1 of the AIR, the Project and Activities Inclusion list was finalized within three weeks of submitting the final AIR on November 23, 2015. The Environmental Evaluation for the AltaGas Ridley Island Propane Export Terminal was submitted well after this cutoff, in December 2016. On January 3, 2017, AltaGas announced it would proceed with the Project as it had received its approval under section 67 of CEAA 2012. Given the timing for these activities, the AltaGas project was not considered in the cumulative effects assessment conducted in the Application.
1410.1	round 1	Kitsumkalum First Nation	4.9.6.3	Marine Fish and Fish Habitat	Kitsumkalum does not agree with the characterization of cumulative effects to marine fish and fish habitat given that the CFHOP does not ensure that the total area of habitat destruction can be offset (the proponent cannot ensure that there is enough area in the RAA to complete the offset requirements)	Aurora LNG is committed to fulfilling their legal obligation to develop adequate, effective offsets that counterbalance residual serious harm to fish. This commitment will be accomplished by following DFO's guidance on offsetting. This guidance involves following DFO's preference for in-kind over out-of-kind offsetting and for projects in the local area. It also involves setting specific success criteria, that are subsequently used as benchmark indicators that the offsets have fulfilled their productivity objectives and, as such, have counterbalanced Project-driven serious harm. Through collaborative engagement with DFO, and consultation associated with the Fisheries Act authorization application process, Aurora LNG fully anticipates being able to find adequate and appropriate locations, and develop suitable designs, for effective offsets. Additionally, all other proponents are legally bound to offset serious harm to fish caused by their projects. Aurora LNG assumes that other proponents will fulfill this obligation, since not doing so would violate the Fisheries Act and have severe consequences for those proponents. Consequently, Aurora LNG stands by the characterization of cumulative effects to marine fish and fish habitat.
1411.1	round 1	Kitsumkalum First Nation	4.9.9	Marine Fish and Fish Habitat	Follow-up and monitoring to ensure effects to marine fish habitat are as predicted should include monitoring around the berth dredging area (and not just at Charles Point).	Aurora LNG is committed to implementing follow-up programs when there is a conclusion of potential residual adverse effect and either a low prediction confidence in that conclusion or uncertainty in a specific component of the assessment, In these cases, a follow-up program will be used to verify the accuracy of predictions. Criteria for proposed inclusion of a follow-up program are consistent with the Considerations for Developing a Follow-up Program outlined in the Operational Policy Statement Follow-up Programs under the Canadian Environmental Assessment Act (Government of Canada, 2011). Aurora LNG has committed to a number of follow-up programs specific to marine fish and fish habitat and marine water quality (see Section 15, Summary of Follow-up Programs and Compliance Reporting), including a Sediment Deposition Monitoring Program. This program will focus on monitoring sediment deposition within a localized area near Charles Point. This program has been put forward because of the potential for sediment deposition in this area to result in serious harm to fish (as defined under the Fisheries Act). As described in Section 4.9.5.2 of the Marine Fish and Fish Habitat VC, the results of hydrodynamic modeling suggest that up to 4-5 cm/year are predicted to be deposited in this area (see Figure 69 (c) of Appendix M [Hydrodynamic Modeling of Changes in Sediment Erosion and Accretion due to Project Infrastructure]), where substrates are composed primarily of a mix of cobble and boulder (see Section 5.1 and Section 2 of Appendix L, Marine Fish and Fish Habitat TDR). As a result, the deposition of sediment in this area could result in serious harm to fish, and additional offsetting would need to be discussed with DFO. However, sediment deposition in this area is only anticipated to occur if the Concrete Caisson MOF is selected for construction, and therefore the program will not proceed if the Pile-and- Deck MOF option is selected. Based on the results of sediment transport modelling (Appendix M), sediment deposition and accretion in other areas (i.e., areas away from Charles Point) are predicted to occur predominately over sediment habitats and changes are expected to be localized and gradual (see Figure 64 (c) and Figure 65 (c) of Appendix M). As such, any changes are not expected to affect the ability of marine species to complete their life processes, and serious harm to fish is not anticipated. For this reason, no monitoring is proposed for areas outside of Charles Point.
1412.1	round 1	Kitsumkalum First Nation	Appendix H	Marine Fish and Fish Habitat	Although Aurora LNG completed sediment transport and deposition modeling for Brown Passage (as a disposal site), there is no characterization of the habitat or fish presence and as such the characterization of effects to marine fish and fish habitat is not complete. There are multiple benthic and demersal fish species utilizing the area and there are cloud and glass sponge within the deposition zone (in previous DAS zone) (See Brown Passage Subtidal Survey, PNW LNG, Stantec, October 22, 2014) and destruction of these habitat forming species and effects to fish are not fully characterized in the Application.	Potential effects of the disposal of dredgeate on fish habitat at the Brown Passage disposal at sea site are assessed in Section 4.9.5.2 of the Marine Fish and Fish Habitat VC (see page 4.9-52). This assessment considered effects to deep-water soft sediment habitats; however, it did not consider potential effects to glass sponges (Hexactinellida), which are known to occur in this area. For a discussion and characterization of potential effects to glass sponges, Please see the technical memo titled "Brown Passage: Characterization of Existing Conditions and Potential Effects associated with Disposal at Sea"which will be filed with the BC EAO. The potential for injury or mortality of marine fish and invertebrates due to disposal of dredgeate at Brown Passage are assessed in Section 4.9.5.4 of the Marine Fish and Fish Habitat VC (see pages 4.9-87 to 4.9-88). Finally, the potential effects to marine fish health from exposure to elevated TSS concentrations during disposal at sea are assessed in Section 4.9.5.5 (see pages 4.9-103 to 4.9-104).
1413.1	round 1	Kitsumkalum First Nation	Appendix V	Fish Habitat Offsetting Plan	When a "no significance" determination for residual effects and cumulative effects to fish and fish habitat (both freshwater and marine) is presented, but this determination hinges on the ability to offset "serious harm" it is difficult to agree with this characterization given the Conceptual Fish Habitat Offsetting Plan presented in the Application. There is little confidence that the Proponent can in fact find enough area within the RAA to offset the habitat losses presented in the Application (both freshwater and marine) nor that the two main areas / zones being considered for offsetting designs (Casey Cove and Delusion Bay) are areas where there are potential effects from the project (which may affect the offsets) can support effective offsets.	Aurora LNG is committed to fulfilling their legal obligation to develop adequate, effective offsets that counterbalance residual serious harm to fish. This commitment will be accomplished by following DFO's guidance on offsetting. This guidance involves following DFO's preference for in-kind over out-of-kind offsetting and for projects in the local area. It also involves setting specific success criteria, that are subsequently used as benchmark indicators that the offsets have fulfilled their productivity objectives and, as such, have counterbalanced Project-driven serious harm. Through collaborative engagement with regulatory agencies (primarily DFO) and consultation with Aboriginal Groups during the Fisheries Act authorization application process, Aurora LNG fully anticipates being able to find adequate and appropriate locations, and develop suitable designs, for effective offsets.

1414.1	round 1	Kitsumkalum First Nation	Appendix V (Figure 8) and 4.9	Fish Habitat Offsetting Plan	It is not clear why percent cover (for eelgrass) was not characterized for Delusion Bay. Kitsumkalum does not think that effects from air emissions from operational activities and from discharge from the overburden storage (and potential discharge from the site storing of the 0.5m layer of marine sediments....where the site is currently unknown) are adequately characterized or mitigated to ensure no effects to Delusion Bay (marine and freshwater fish habitat, and marine and freshwater riparian habitat). Percent cover and extent of all riparian and marine vegetation should be characterized in Delusion Bay such that a monitoring program (developed in consultation with regulatory authorities and Schedule B and C First Nations) could become part of the EAC Conditions (as it should) to ensure the effects are as predicted.	Eelgrass beds in Delusion Bay were delineated during a dedicated eelgrass survey conducted from July 31 to August 6, 2015. Survey methods are described in Section 5.4.2 of the Marine Fish and Fish Habitat TDR (Appendix L), and the results for Delusion Bay are presented in Section 5.4.3.4. The following text is taken from Pages 69 and 70: "Delusion Bay harboured a continuous, dense eelgrass bed along the southwestern edge at its mouth but, moving northward was filled with extensive, and short-canopied (~15 to 20 cm canopy height) eelgrass patches. Both sparse (Photo 47) and dense (up to 100% cover) patches (Photo 48) extended nearly a kilometre northward, within brackish zones along the edges of the main freshwater outflow, to the head of Delusion Bay (see Figure 36 and Figure 37). Beaked widgeongrass was observed (but not delineated) in the stream centre, as well as along high intertidal fringes along the length of Delusion Bay. A very small patch of Scouler's surfgrass was located on a rocky outcrop in the middle of the bay (see Figure 36, Photo 49 and Photo 50). Because of the extensive coverage of eelgrass in Delusion Bay (see Figure 36 and Figure 37), and limited low tide timing available for sampling, the decision was made to focus on comprehensive delineation of beds and patches; no quadrat-based estimates of percent cover, shoot density, or canopy height were taken in this area." Marine riparian vegetation in Delusion Bay was characterized during an intertidal survey conducted from July 31 to August 3, 2015. Survey methods are described in Section 5.1.2 of the Marine Fish and Fish Habitat TDR (Appendix L), and results for Delusion Bay are presented in Section 5.1.3.4. Based on current Project design plans, the soil storage area will be located to the west of Delusion Bay and will not overlap with the marine riparian habitat zone (defined as a 10 m buffer [horizontal distance] from the high water mark) or any salt marsh vegetation or eelgrass. The soil storage area will be confined within a berm, and contact water will be managed and tested before being directed into Delusion Bay. Water discharged from this area will comply with relevant permit requirements. As such, no adverse effects on marine vegetation (e.g., salt marsh and eelgrass) or associated fish and invertebrates are anticipated.
1415.1	round 1	Kitsumkalum First Nation	4.10.2.4	Marine Wildlife - Marine Mammals	The Application notes that "The term 'qualitative' was added to qualify likelihood under the measurable parameter for change in mortality risk to better reflect the style of assessment (i.e., a qualitative assessment of mortality risk was undertaken; no quantitative assessment of vessel strike likelihood was performed)." There is no explanation as to why the risk of ship strikes was not evaluated quantitatively or why a comprehensive collision risk assessment was not done.	As strike risk increases in higher density traffic areas, the likelihood of residual cumulative effects for change in mortality risk to marine mammals is considered high. In the event of an accidental vessel strike, effects on the marine mammal involved are assumed to be permanent and irreversible, and would be of heightened concern for SARA-listed species. Based on current marine mammal population sizes and trends for species known to occur in the RAA, changes in mortality risk are considered unlikely to affect population viability, and as noted in the Application, are therefore expected to be not significant. Quantitative vessel strike analysis typically has a high level of uncertainty due to significant challenges associated with predicting the level of behavioural response for specific marine mammal species and limited data available on species-specific strike rates. As a result, and as noted in the IR, a qualitative analysis was completed, with a moderate level of prediction confidence. This approach is consistent with the approach taken for the recently approved Pacific NorthWest (PNW) LNG project, that will occur in the same region of BC. The analysis conducted for Transmountain Pipeline Expansion Project provided estimates of potential vessel-whale encounter risk. This analysis did not extend to vessel-whale strike risk due to limited data available on species-specific responses (e.g., whether the animal dives or turns) to vessel approach. Aurora LNG maintains that residual effects to marine mammals from an increased potential for ship strikes have been adequately characterized and are expected to be not significant.
1416.1	round 1	Kitsumkalum First Nation	4.10.2.8	Marine Wildlife - Marine Mammals	It is stated that "This section describes the threshold for potential effect, beyond which a residual effect is considered significant". Although the Proponent used measurable parameters (see Table 4.10-2) to assess potential effects of the Project, no specific thresholds (e.g., km2 exposed or % population exposed to specific sound levels) are provided in this section. Instead, it is stated that "A significant adverse residual effect is defined as one that threatens the long-term persistence of a marine mammal species or local population in the RAA'. Thus, the effects assessment appears to take a more qualitative rather than a quantitative approach.	For the marine mammals assessment, a significant adverse residual effect was defined as one that threatens the long-term persistence of a marine mammal species or local population in the RAA. As outlined in Section 4.10.2.8 of the Application, the significance thresholds represent the limits of an acceptable change in a measurable parameter or state of the VC, based on applicable legislation, regulatory guidance documents or other management standards. Where thresholds are not set by legislation, guidance documents or standards (as in this case), a threshold has been developed based on scientific literature and professional judgment.
1417.1	round 1	Kitsumkalum First Nation	4.10.3; 4.10.5; Appendix N	Marine Wildlife - Marine Mammals	There is not enough baseline information to characterize the seasonal distribution and relative abundance of various marine mammal species within the LAA. Although adequate data were available to determine abundance for two species (humpback whale and harbour porpoise), density estimates for other marine mammal species would contribute more to the understanding of the use by various species of the LAA and would have been pertinent in assessing potential effects of the Project on marine mammals. The data are therefore not adequate to support a quantitative impact assessment where the potential for mortality or injury is a realistic outcome of an accident or malfunction or to quantitatively assess the effects of Project activities on changes in health or behaviour.	The assessment of change in health, change in behaviour, and change in mortality risk for marine mammals relies on not only the results of the Aurora LNG marine mammal surveys and subsequent analysis and results, but baseline information that includes a literature review, the results of marine mammal surveys for other proposed projects, and information collected by the BC Cetacean Sightings Network. These sources provide information on the seasonal distribution and abundance for marine mammals present within the LAA and RAA. A quantitative vessel strike analysis typically has a high level of uncertainty due to significant challenges associated with predicting the level of behavioural response for specific marine mammal species and limited data available on species-specific strike rates. As a result a qualitative analysis for change in mortality risk was completed, with a moderate level of prediction confidence. Aurora LNG maintains that residual effects to marine mammals from an increased potential for ship strikes have been adequately characterized and are expected to be not significant.
1418.1	round 1	Kitsumkalum First Nation	4.10.5.1	Marine Wildlife - Marine Mammals	The statement "Pile driving was modelled in deep water sites where sound typically propagates furthest" is not necessarily true. Propagation in shallow water is highly complicated and sound may travel further under certain conditions than in deep water. In fact, Appendix P, Table 1 notes that modeling for pile driving was done for water depths <23 m, so the statement is confusing.	To clarify the intent of the statement: Out of the potential locations where Project-related pile driving activitiesare anticipated, acoustic modelling sites were selected based on areas of relatively deeper water. As noted, the extent of underwater noise is dependent on many factors (e.g., water temperature and depth) and all acoustic modelling included the geoacoustic properties of the sites, depth and temperature. As part of the Marine and Freshwater Resources Management Plan, developed through engagement with applicable regulatory agencies and Aboriginal Groups, field verification will be undertaken at multiple locations to confirm predicted extents of underwater noise levels over the full range of predicted values for in-water blasting and impact pile driving.
1419.1	round 1	Kitsumkalum First Nation	4.10.5.4	Marine Wildlife - Marine Mammals	A comprehensive collision risk assessment should have been conducted for large cetacean species in the LAA and for various types of project-related vessels. The collision risk assessment should be based on transit routes, vessel speeds, ability of vessels and marine mammals to take effective evasive action to avoid collisions, and accurate estimation of the distribution of species' relative densities. All collision risk assessments should have been presented as part of the Application and appropriately documented with uncertainties and limitations of the analyses clearly stated so that collision risk to marine mammals during all seasons is well understood. If the collision risk assessment indicates a non-zero probability of collision with any large cetacean species in the LAA, then further work would be required to determine what the likely annual incident of collisions would be and if they may detrimentally affect population viability (e.g., species listed under SARA). In addition, results of the collision risk assessment would need to be evaluated in light of adding to or modifying necessary mitigation measures. Of particular concern is the potential population level effect of mortality from ship strikes on the Northern Resident killer whale due to this population's low abundance (Williams and O'Hara 2009). It is difficult to assess the actual potential impacts of vessel collisions to marine mammals in the LAA based on the information provided in the Application, particularly due to the inadequate baseline information regarding seasonal distribution and relative abundance in the LAA, and the lack of detail regarding mitigation measures to prevent ship strikes with marine mammals.	As strike risk increases in higher density traffic areas, the likelihood of residual cumulative effects for change in mortality risk to marine mammals is considered high. In the event of an accidental vessel strike, effects on the marine mammal involved are assumed to be permanent and irreversible, and would be of heightened concern for SARA-listed species. Based on current marine mammal population sizes and trends for species known to occur in the RAA, changes in mortality risk are considered unlikely to affect population viability, and as noted in the Application, are therefore expected to be not significant. Quantitative vessel strike analysis typically has a high level of uncertainty due to significant challenges associated with predicting the level of behavioural response for specific marine mammal species and limited data available on species-specific strike rates. As a result, and as noted in the IR, a qualitative analysis was completed, with a moderate level of prediction confidence. This approach is consistent with the approach taken for the recently approved Pacific NorthWest (PNW) LNG project, that will occur in the same region of BC. The analysis conducted for Transmountain Pipeline Expansion Project provided estimates of potential vessel-whale encounter risk. This analysis did not extend to vessel-whale strike risk due to limited data available on species-specific responses (e.g., whether the animal dives or turns) to vessel approach. Aurora LNG maintains that residual effects to marine mammals from an increased potential for ship strikes have been adequately characterized and are expected to be not significant.
1420.1	round 1	Kitsumkalum First Nation	4.10.5.4	Marine Wildlife - Marine Mammals	Measures to be taken by a vessel to avoid a marine mammal collision have only been specified in vague terms (see Table 4.10-10), and there is not any assessment of the effectiveness of these measures on actually avoiding a collision with transiting marine mammals or an aggregation of feeding marine mammals. No analysis has been presented in the Application regarding stoppage time and stopping distance for a vessel to avoid a marine mammal collision or to determine if this is even possible given a reasonable detection range of a marine mammal from a vessel. There is also no analysis of the feasibility of making route adjustments to avoid a marine mammal.	Project-related vessels will proceed at a safe speed and respect any regionally-defined or PRPA-specific speed profiles that are applicable at the time of operations, subject to navigational safety. The intent of the educational material proposed in Table 4.10-10 is to raise awareness of potential marine mammal presence in the area. Decisions regarding the need for, and feasibility of, undertaking measures such as route or speed alterations upon sighting and approach of a marine mammal(s) rest entirely with the shipmaster and pilot after taking into account navigational and human safety. Educational materials will also detail the reporting protocols in the event of an accidental strike. The Technical Review Process of Marine Terminal Systems and Transshipment Sites (TERMPOL) process, conducted by Transport Canada, will address vessel speeds and routing, in consideration of mariner safety, environmental effects and feedback through engagement with PRPA, DFO, Aboriginal Groups, and others. Aurora LNG is willing to collaborate in regional programs planned and developed by government and in conjunction with other proponents, regarding regional management of effects of vessel strikes on marine mammals in the RAA.
1421.1	round 1	Kitsumkalum First Nation	4.10.5.4	Marine Wildlife - Marine Mammals	According to the Application, "….ship strikes are more likely to occur when ships are over 80 m in length and travelling at 14 kts or faster (Laist et al. 2001; Panigada et al. 2006). Potential for change in mortality risk is therefore considered greatest during transit operations (relative to other Project phases and vessel types)…". Nonetheless, the Application states that LNG carriers may travel at speeds of up to 16 kts; no vessel speed restrictions have been proposed. The Application only states that "Project-related vessels will proceed at a safe speed", but "safe speed" is not defined. To reduce the risk of ship strikes which have been assessed to be of moderate magnitude and medium likelihood during operations, LNG carriers should not travel >14 kts within the RAA.	The Technical Review Process of Marine Terminal Systems and Transshipment Sites (TERMPOL), conducted by Transport Canada, will address vessel speeds and routing, in consideration of mariner safety, environmental effects, and feedback through engagement with PRPA, DFO, Aboriginal Groups, and others. Aurora LNG is willing to collaborate in regional programs planned and developed by government and in conjunction with other proponents, regarding regional management of effects of vessel strikes on marine mammals in the RAA.
1422.1	round 1	Kitsumkalum First Nation	4.10.5.4	Marine Wildlife - Marine Mammals	The mitigation measures for reducing ship strike are outlined as "Aurora LNG will develop educational material that will be distributed to Project-related vessel operators, tug operators, and pilots to inform them of the species of marine mammals in the area, their conservation status, the risk of ship strikes and what mariners can do to help reduce those risks (e.g., reporting the sightings to other mariners, reducing speeds). Educational material will also detail reporting protocols in the event of an accidental strike." However, the Proponent then goes on to say that "Education does not guarantee that vessel operators will take heed of the information provided." Further information is required to gauge the adequacy of this mitigation measure. For example, the level of effort used to detect marine mammals, equipment used to enhance detection, protocols for translating sightings into mitigation action by the ship's captain, data recording, analysis, and reporting-out on the results of monitoring and the efficacy of protocols for avoiding marine mammal collisions.	Project-related vessels will proceed at a safe speed and respect any regionally-defined or PRPA-specific speed profiles that are applicable at the time of operations, subject to navigational safety. The intent of the educational material proposed in Table 4.10-10 is to raise awareness of potential marine mammal presence in the area. Decisions regarding the need for, and feasibility of, undertaking measures such as route or speed alterations upon sighting and approach of a marine mammal(s) rest entirely with the shipmaster and pilot after taking into account navigational and human safety. Educational materials will also detail the reporting protocols in the event of an accidental strike. The Technical Review Process of Marine Terminal Systems and Transshipment Sites (TERMPOL) process, conducted by Transport Canada, will address vessel speeds and routing, in consideration of mariner safety, environmental effects and feedback through engagement with PRPA, DFO, Aboriginal Groups, and others. Aurora LNG is willing to collaborate in regional programs planned and developed by government and in conjunction with other proponents, regarding regional management of effects of vessel strikes on marine mammals in the RAA.
1423.1	round 1	Kitsumkalum First Nation	4.10.9	Marine Wildlife - Marine Mammals	The Proponent should consider a follow-up program to monitor underwater noise effects on marine mammals as a result of increased shipping as the magnitude of the residual effects are deemed to be moderate and the likelihood is deemed to be high. In addition, follow-up monitoring for harbour porpoise should occur, as the Application found a Significant effect on the change in behaviour of harbour porpoise. Monitoring would help discern what the actual changes in behaviour are and to what extent they are Significant.	Aurora LNG will engage with the appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Marine and Freshwater Resources Management Plan. This plan will describe best management practices and mitigation measures that will be implemented during construction and operation of the LNG facility to avoid or reduce potential adverse effects of Project activities on marine mammals. The plan will include details on the following: Prior to the start of marine construction, acoustic modelling of in-water blasting will be done to verify assumptions and predictions made in this assessment and refine mitigation measures, as necessary.Field verification will be undertaken at multiple locations to confirm predicted extents of underwater noise levels over the full range of predicted values for in-water blasting and impact pile driving.A marine mammal monitoring program will be developed and implemented to enforce an exclusion zone during in-water impact pile driving and around the in-water blasting area.Aurora LNG is willing to collaborate in regional programs planned and developed by government and in conjunction with other proponents, regarding regional management of effects of underwater noise and vessel strikes on marine mammals in the RAA.
1424.1	round 1	Kitsumkalum First Nation	Appendix N: 3.1.3.1	Marine Wildlife - Marine Mammals	The Appendix notes that "There have been a few rare sightings of California sea lions (*Zalophus californianus*), and northern elephant seals (*Mirounga angustirostris*) (Ford 2014). This statement is not supported by the reference. According to Ford (2014), northern elephant seals are not considered rare in northern BC; there is not enough information for this claim for the RAA. In fact, Ford (2014) report a winter haul-out for California sea lions within the RAA near Digby Island. Thus, the statement is incorrect and this species should have been included in the Application in Table 4.10-5 under 4.10.3.2.	As noted in Appendix N of the Application, Table 7 presents the 12 marine mammal species (or ecotypes) that are considered to regularly occur in the RAA. The Application further notes that many species of marine mammal are migratory and/or wide-ranging, and the inclusion of a marine mammal in Table 4.10-5 is meant to qualitatively reflect the standard distribution of these species. Specific occurrence of a particular species within the RAA at any given time fluctuates, and is therefore uncertain. As explained in the footnotes to Table 4.10-5, other species, not included in this table, may also be infrequently sighted within the RAA. As noted in the IR, Ford (2014) identifies a California sea lion winter haulout near Digby Island. However, he recognizes that this species is predominantly observed in the Strait of Georgia and along the west coast of Vancouver Island, and is only observed near Haida Gwaii and on the central mainland coast in some years. Ford (2014) also reports that breeding occurs off southern California and Baja California, Mexico and only males are expected to migrate through BC waters in the fall and spring. As a result, it is not anticipated that California sea lions will occur regularly within the RAA. Ford (2014) does not show elephant seal sightings within the RAA and reports they may occur along the northern BC coast. Sightings of elephant seals are typically of individual animals. Although it is possible they may be observed within the RAA, it is anticipated sightings would be infrequent.
1425.1	round 1	Kitsumkalum First Nation	Appendix N: 3.1.3.1	Marine Wildlife - Marine Mammals	Northern fur seals (*Callorhinus ursinus*) are not mentioned in the Application but it is possible that they could occur in the RAA.	Many species of marine mammal are migratory and/or wide-ranging, and the inclusion of a marine mammal in Table 4.10-5 (of the Application) is meant to qualitatively reflect the standard distribution of these species. Specific occurrence of a particular species within the RAA at any given time fluctuates, and is therefore uncertain. Other species, not included in Table 4.10-5 , may also be infrequently sighted within the RAA. Northern fur seals are more typically observed over the continental shelf (Ford 2014) than within the RAA.
1426.1	round 1	Kitsumkalum First Nation	Appendix N: 4.4.1	Marine Wildlife - Marine Mammals	It is reported that "Humpback whale sighting numbers were the lowest in the spring and early-summer survey periods." No attempt is made to explain why the survey found lower numbers of humpbacks during the summer than the rest of the year. It is noted that PNW also found lower numbers during summer. However, these findings are in contrast to Ford (2014) that humpbacks are most numerous from April through November. Additionally, according to Appendix O, the number of detection days in 2014 with humpback whale calls peaked from mid-July to late October.	Ford (2014) reports that humpback whales are observed year-round in BC waters, and as noted in the IR, are most abundant in BC waters from April to November. Substantial changes in humpback whale distribution and abundance within the feeding season and inter-annually are also noted (Ford 2014). The Aurora marine mammal surveys covered the RAA (Chatham Sound) and as a result, only provide information on marine mammal presence within the RAA. As the data collected are not reflective of humpback whale abundance "in BC waters", humpback whale sighting information does not contradict Ford (2014). Ford et al. 2010 reported that winter sightings of humpback whales, observed during surveys conducted by DFO, were noted to occur particularly in Chatham Sound and off northern Haida Gwaii. As noted in Appendix O, acoustic data were collected between July and October/November 2014, not during the winter months. It should also be noted that an absence of marine mammal calls does not reflect an absence of the species. Ford, J.K.B., Abernethy, R.M., Phillips, A.V., Calambokidis, J., Ellis, G.M., and Nichol, L.M. 2010. Distribution and relative abundance of cetaceans in western Canadian waters from ship surveys, 2002-2008. Can. Tech. Rep. Fish. Aquat. Sci. 2913: v + 51 p.
1427.1	round 1	Kitsumkalum First Nation	Appendix O: 1.2	Marine Wildlife - Marine Mammals	No explanation is provided as to why acoustic monitoring was not done year-round – monitoring only took place during July to October/November 2014.	While the data collected during the acoustic monitoring program (Appendix O) was analyzed for marine mammal vocalizations, detection of marine mammals was not the primary objective of this program. The primary objective of the acoustic monitoring program was to document the baseline noise conditions near the proposed Project site so as to provide a statistical noise distribution of the pre-Project development conditions. The timing and duration of the program were therefore developed primarily in consideration of the desire to characterize the existing ambient sound levels and existing vessel traffic, both of which are adequately captured in the selected 3.5 month period that spans periods of lower and higher expected vessel traffic in the region.
1428.1	round 1	Kitsumkalum First Nation	Appendix O: 3.3	Marine Wildlife - Marine Mammals	The acoustic data were not analyzed for minke whale or Steller sea lion vocalizations, but no explanation is given as to why. Also, no explanation is provided why the acoustic monitoring was not done year-round – monitoring only took place during July to October/November 2014.	While the data collected during the acoustic monitoring program (Appendix O) was analyzed for marine mammal vocalizations, detection of marine mammals was not the primary objective of this program. The primary objective of the acoustic monitoring program was to document the baseline noise conditions near the proposed Project site so as to provide a statistical noise distribution of the pre-Project development conditions. The timing and duration of the program were therefore developed primarily in consideration of the desire to characterize the existing ambient sound levels and existing vessel traffic, both of which are adequately captured in the selected 3.5 month period that spans periods of lower and higher expected vessel traffic in the region.

1429.1	round 1	Kitsumkalum First Nation	4.1 (Appendix P)	Marine Wildlife - Marine Mammals	It is unclear how the proponent will be able to monitor for harbour porpoise the area at the limit of behavioural thresholds (160 dB 1uPa) given the distance of esonified area (above threshold), especially at the berth area during construction activities. Even if activities are conducted during daylight hours any sea state above Beaufort 2 will make it very difficult to observe harbour porpoise on the water at any distance, and given their general lack of vocalization hydro acoustic monitoring is also less affective. residual effects are characterized as significant, but as we know this does not halt the approval of a project EA certificate so how are we to ensure this listed species population is to remain sustainable in the region?	The mitigation measures proposed are consistent with recovery strategies and action plans, where such documents exist. The suite of mitigation measures proposed are expected to be effective at achieving their primary objectives (i.e., to reduce potential for changes in health and behaviour during in-water blasting; to reduce potential for changes in health and behaviour during impact pile driving; and to reduce potential changes in marine mammal mortality risk from increased risk of vessel strikes). A meeting was held with DFO on April 25, 2017 to discuss the Application and proposed mitigation measures to reduce the potential residual effects on marine mammals as a result of construction activities. Aurora LNG will explore further mitigation measures (e.g., double bubble curtain, hydrosound dampener) to reduce the extent of underwater noise that exceeds the NOAA interim behavioural threshold for impulsive noise (160 dB re 1 µPa SPLrms) as a result of impact pile driving. As noted in the Application, impact pile driving will occur during daylight hours, and an underwater noise field verification program will be conducted to verify predicted sound pressure levels and the size of the exclusion zone.As part of the Marine and Freshwater Resources Management Plan a monitoring program will be developed and implemented to enforce and effectively monitor the applicable exclusion zone during in-water impact pile driving. Aurora LNG would welcome specific feedback regarding the proposed mitigation measures, including suggested revisions to the currently proposed mitigation measures, from Kitsumkalum First Nation.
1430.1	round 1	Kitsumkalum First Nation	4.11.3, Appendix Q	Marine Wildlife - Marine Birds	The Application, including the assessment of potential environmental effects on marine birds and the Marine Bird Technical Data Report (Appendix Q) does not provide a level of detail on marine bird population trends, threats, and Aboriginal reliance on the species group that is required to support the environmental assessment of a development project of this nature in the North Coast of British Columbia. The technical data report only provides a high-level overview of the marine bird ecology in the RAA and is deficient in the following areas: • The Proponent followed standardized protocols for the collection of marine bird data, but only report on species occurrence data. • The report authors make inferences between these data and species abundance and richness, without the support of statistical analysis and/or population models on relative abundance and/or densities. • The technical data report does not present information on the population status (e.g., stable, increasing, decreasing) of marine birds that occur in the LAA and RAA. • Specific data and information of the seasonal abundance (density or total number) of marine birds in the LAA and RAA is not provided. • An indication of habitat quality (either in a sense within the LAA/RAA or compared to other regions that are used to fulfill those same life-history requirements) for various life functions or marine bird species in the LAA and RAA is not provided.	Aurora LNG acknowledges this comment. Appendix Q of the Application provided a summary of the seasonal presence, abundance, richness, and distribution of marine birds from stationary shoreline count and vessel-based survey data completed for the Project. These were placed into context with presence, abundance, and richness information provided for other projects within the RAA. Please refer to Tables 1-2, and 1-3 for a detailed summary of the total number of marine birds observed during Project field studies. The technical data report (Appendix Q of the Application) specifically characterizes abundance (i.e., the total number of individuals observed), relative frequency of species detection (i.e., the percentage of total observations), and species richness (i.e. the number of species observed). For vessel-based surveys, the average number of species and individual birds per transect is also reported with a measure of error (i.e., standard deviation) to facilitate seasonal comparison of marine bird presence within the RAA. Characterization of residual effects to marine birds can be reasonably determined through the existing evaluation of Project specific and regional data in combination with information available in scientific literature and professional judgement and experience. To support the assessment of effects to marine birds, the current status of marine birds potentially occurring within the LAA and RAA was considered. The status of species of management concern was described in Table 2 of Appendix Q and Table 4.11-7 of the Application, and represents species that have shown either declining populations or trends in recovery but are currently not considered secure. Marine birds not listed in these tables are considered not at risk (i.e., have stable or increasing populations). A summary of traditional use of marine birds is provided in Section 4.11.3.2 of the Application. Aurora LNG was limited in drawing comparisons in marine bird habitat associations and their relative importance, with other regional datasets due to the methods used to collect or present those data (i.e., site specific habitat information was not collected or not presented). However, information on seasonal abundance, richness, and distribution of marine birds is still considered in combination with life history information on species and species groups, to provide context on the relative importance of marine habitats within the LAA for breeding, foraging, roosting, and staging activities compared to those available in the region.
1431.1	round 1	Kitsumkalum First Nation	4.11.2.4	Marine Wildlife - Marine Birds	The evaluation of potential effects is based primarily on a qualitative assessment. For the assessment of the change in marine bird habitat, the Proponent states that this was based on a quantitative measure, but this measure only documents the areal extent of the marine habitat that will be lost or altered by the construction of the project facilities. This effect does not account for the value that this habitat provides for the various life requisites of marine birds.	Section 4.11.5.2 of the Application provides a combined quantitative and qualitative discussion of the direct change in habitat for marine birds as a result of Project activities and infrastructure as well as indirect change resulting from sensory disturbance. A description of the habitats, the species (or species groups) expected to be affected by change in those habitats, and their value to support foraging, staging, roosting, or breeding activities is described in 'Project Mechanisms for Change in Habitat' therein. A more detailed discussion of species presence and use of habitats within the PDA and LAA is found in Appendix Q and summarized in Section 4.11.3.
1432.1	round 1	Kitsumkalum First Nation	4.11.5.2	Marine Wildlife - Marine Birds	While the Proponent has quantified the amount of habitat impacted, the Application makes weak inferences regarding the importance of this habitat to marine birds. Habitat associations are not specifically addressed in the Project-specific field surveys.	Marine habitat associations for individual species, or species groups, are described in detail in Appendix Q. Species observed to be associated with nearshore marine habitats within the LAA during Project field studies are described in Sections 4.1.3 and 4.2.3 of Appendix Q. Section 4.2.3 of Appendix Q provides additional information on species observations and associations on farshore marine habitats. Tables 2-1 and Table 3-1 of Appendix Q provide a break down of detection for individual species, across habitat types sampled during Project field studies. Species' habitat associations were used in Section 4.11.5.2 to characterize effects of change in habitat from construction and operation of marine infrastructure (e.g., foraging and roosting opportunities).
1433.1	round 1	Kitsumkalum First Nation	4.11.5.2	Marine Wildlife - Marine Birds	The Proponent stated that results from the Project-specific field surveys showed that marine bird abundance was highest at the mouth of Delusion Bay, which is directly adjacent to the project development area (footprint), but it has not characterized the importance of the habitat in Delusion Bay for marine birds. The Proponent also makes inferences that the results of the field studies are consistent with existing regional data, with specific regard to marine bird abundance, and not habitat associations. While sources are identified in the literature review section of the Marine Bird Technical Data Report (Table 1 in Appendix Q), the specific references that describe known marine bird abundance in the area are not cited.	Section 4.11.3 of the Application provides a description of the findings, indicating that bird abundance and richness was generally similar across points (with exceptions to stations reporting higher numbers of individuals and species described therein). Table 2-1 of Appendix Q of the Application provides a summary of individual species reported at each shoreline stationary count. Compared to other locations, counts completed in Delusion Bay (i.e., MBDI09 and MBDI10) recorded fewer individual birds and species but nonetheless indicate that habitats at those locations support use by shorebirds, ducks, grebes, loons, gulls, corvids, and eagles (for example). Aurora LNG was limited in drawing comparisons in marine bird habitat associations with other regional datasets due to the methods in which some of those regional records were collected and presented in publicly-available reports (i.e., not all include site-specific information to draw habitat associations). However, information on seasonal abundance, richness, and distribution is still valuable in combination with life history information on species and species groups, to provide context on the importance of marine habitats within the LAA relative to those available in the region. Table 1-1 of Appendix Q of the Application provided a detailed summary of historical marine bird occurrence records within the RAA by species and dataset. Citations for each data source were provided as footnotes to the table and correspond to citations provided in Section 6 of Appendix Q (Literature Review).
1434.1	round 1	Kitsumkalum First Nation	4.11.5.2	Marine Wildlife - Marine Birds	On page 4.11-27, it is stated that "Given that most marine birds present in the LAA and RAA have secure populations (no reference provided) and have access to other suitable marine habitats, marine birds are expected to demonstrate a moderate degree of resilience to change in habitat availability as a result of the Project." In making this determination, the Proponent has not provided evidence that "most marine bird populations" are secure, nor has it provided information to describe suitable marine bird habitats in the region.	Section 4.11.3 and Appendix Q of the Application outline the methods and findings for characterizing existing conditions for marine birds. Both parts of the Application considered whether marine birds had secure populations by providing a review of their conservation status. Species of management concern include species known to, or with potential to, occur within the RAA that are considered of interest from a conservation perspective (i.e., federal or provincial species or subspecies at risk). Information on species of management concern, including occurrence records, species accounts, management plans, or other guidance documents, was compiled from the BC CDC (BC CDC 2017) and the Species at Risk Public Registry (Environment Canada 2016) and are referenced in the Application. The remaining marine bird species are considered to have secure federal or provincial conservation status (i.e., are designated Not at Risk or on the BC Yellow List). Marine habitat associations for individual species, or species groups, are described in detail in Appendix Q of the Application. Species observed to be associated with nearshore marine habitats within the LAA during Project field studies are described i Sections 4.1.3 and 4.2.3 of Appendix Q. Section 4.2.3 ofAppendix Q provides additional information on species observations and associations on farshore marine habitats. Tables 2-1 and Table 3-1 of Appendix Q provide a break down of detections for individual species, across habitat types sampled during Project field studies. Information on species presence, richness, abundance, and distribution was used to inform the assessment and characterization of potential Project effects. 1435.1	round 1	Kitsumkalum First Nation	4.11.5.2	Marine Wildlife - Marine Birds	The Proponent states that the primary mitigation for the loss and alteration of marine bird habitats is the Conceptual Fish Habitat Offsetting Plan that is aimed to offset the loss of marine communities and species. As its name implies, this plan is conceptual and will need approval by Fisheries and Oceans Canada. Regardless, the Application has not provided a comparison of the habitat the Proponent proposes to construct to the types and quantities of habitat that will be lost or altered.	The conceptual fish habitat offsetting plan provides information on the types and quantities of habitats expected to be destroyed or altered that would ultimately lead to serious harm to fish (Section 9, Appendix V). The type, quantity, and location of habitat affected is explicitly considered in the design of habitat offsetting along with the ecological roles of those habitats, within that specific environmental context. This includes the ecological value those habitats have for supporting marine bird life history requirements (e.g., foraging). Offsets will be designed to counterbalance resulting serious harm to fish, in keeping with DFO's guidelines (DFO 2013). Key aspects of DFO's guidelines include a principle of offsetting Project impacts by selecting in-kind offsets over out-of-kind offsets where appropriate (see Section 10.4 and 10.5 of Appendix V). In accordance with DFO's guidance (DFO 2013), in-kind offsets are intended to replace the same quantity and quality of habitat that is being destroyed or altered as a result of the Project. The conceptual plan provides preliminary concepts for the types of offsets that Aurora LNG anticipates creating and the methodology used to design offsets and calculate offsetting quantities. Reference: Fisheries and Oceans Canada (DFO). 2013. Fisheries Productivity Investment Policy: A Proponent's Guide to Offsetting. Available at: http://www.dfo-mpo.gc.ca/pnw-ppe/offsetting-guidecompensation/index-eng.html. Accessed: March 2017.
1436.1	round 1	Kitsumkalum First Nation	4.11.5.2	Marine Wildlife - Marine Birds	The Proponent makes the over simplistic assumption that marine birds will use this new habitat without providing any evidence to support this case. In this regard, no discussion was provided to quantify the abundance of marine birds in the habitat that will be lost or the expected timeframe (e.g., short-term or long-term) for both creating this habitat and ensuring that it becomes a functional habitat for marine birds.	Marine bird shoreline stationary counts were located in areas of the LAA adjacent to proposed Project infrastructure (e.g., the MOF, marine terminal, trestle and berths) to characterize seasonal abundance, richness, habitat associations. A detailed summary was provided in Appendix Q of the Application. The conceptual fish habitat offsetting plan provides information on the types and quantities of marine habitats expected to be destroyed or altered as a result of Project activities and infrastructure (Section 9, Appendix V of the Application). The type, quantity, and location of habitat affected is explicitly considered in the design of habitat offsetting along with the ecological roles of those habitats, within that specific environmental context. Offsets will be designed in keeping with DFO's guidelines by selecting in-kind offsets over out-of-kind offsets where appropriate (see Section 10.4 and 10.5 of Appendix V; DFO 2013). In-kind offsets are intended to replace the same quantity and quality of habitat that is being destroyed or altered as a result of the Project. In turn, in-kind offsets will provide replacement habitat for fish communities as a mechanism to counterbalance serious harm to fisheries affected by the Project. Because in-kind offsets will be developed to replace the quantity, quality, and function of fish habitat removed or altered by the Project, they are expected to provide similar compensatory marine bird habitat (inclusive of habitat types and the marine prey species they support). Once built, the effectiveness of the offsets will be monitored to confirm they are performing as designed.
1437.1	round 1	Kitsumkalum First Nation	4.11.5.3	Marine Wildlife - Marine Birds	The Proponent has stated it will increase employee awareness regarding the potential for mortality and/or injury to marine birds caused by lit infrastructure and that some staff will be provided information on how to handle and release birds that are grounded. These measures are typically more challenging to implement unless standards are in place and key staff (e.g., environmental monitors) are specifically trained to take on the responsibility for dealing with birds that are found on site. It is also challenging to ensure that all project staff are reporting occurrences of marine birds. However, the chances of this can be improved when strong policies are in place and enforced by the company.	Aurora LNG is committed to monitoring potential effects of the Project on bird and bat mortality, and promoting an environment of awareness and compliance among Project personnel. To facilitate compliance with Project mitigation measures, educational materials provided to employees and contractors will include information on procedures for documenting and reporting bird injury or mortality, and handling and release of stranded birds. The on-site Environmental Monitor or Monitors will be responsible for providing access to educational materials, training and advising staff, maintaining an accurate record of injury and mortality events, and communicating this record to applicable regulatory authorities at a prescribed interval. Complete details will be outlined in the Wildlife Management Plan.
1438.1	round 1	Kitsumkalum First Nation	4.11.5.4	Marine Wildlife - Marine Birds	The Proponent provided an overly simplified conclusion that marine birds observed near the marine terminal and MOF have been observed to use shoreline or nearshore habitats throughout the LAA and are expected to move to other similarly suitable habitats present in the LAA or RAA during Project construction. The Proponent provides no details as to why or when marine birds are using habitats throughout the LAA and RAA. There can be an energetic cost associated with marine bird avoidance of Project activities, or displacement from preferred habitats, but the Proponent has not provide a measurement or details on these energetic costs in the effects assessment.	A discussion of marine bird abundance, richness, and seasonal distribution, and use (e.g., foraging, staging, roosting) is found in several locations in the Application, including Appendix Q, Section 4.11.3, and Section 4.11.5.2. The determination that marine birds observed using habitats near the marine terminal and MOF have been observed to use shoreline and nearshore habitats throughout the LAA and are expected to move to similarly suitable habitats is supported by Project and regional data, literature, and professional judgement from prior experience. These materials provide information on the overall distribution and use of habitats within the LAA. Section 4.11.5.4 provides reference to supporting information in Appendix Q. The energetic cost associated with marine bird avoidance or displacement due to Project activities was assessed in Section 4.11.5.4. As indicated therein with reference to supporting literature, behavioural responses are known to be species-specific. Although flushing distances have been measured for some species under specific conditions (e.g., marbled murrelet response to high-speed recreational vessel traffic), the energetic expenditures associated with those movements are not widely available, nor are they easily placed into appropriate context with the nature of Project-specific disturbance effects. In absence of detailed information, a qualitative approach was used to evaluate change in behaviour (including the energetic cost of avoidance or displacement). See Sections 4.11.5.1 and 4.11.5.4 for further details.
1439.1	round 1	Kitsumkalum First Nation	Table 6.6-2	Community Health	While the Summary of Key Information and Concerns that influenced the Scope of the Assessment included "Vulnerable Populations" and "Changes in social environments (e.g. increased crime, drug activity, homelessness)" the measureable parameters in Table 6.6-2 excludes housing affordability, increased homelessness and for those parameters that were identified, are proposed to be qualitative. Surveys can be conducted to provide quantitative information similar to the surveys conducted by Kitsumkalum in 2016 and it is therefore recommended survey monitoring be implemented for Kitsumkalum as the project develops to assess how well people are coping with the boom and bust and implement adaptive management measures if needed.	Baseline information provided in Section 6.3.3 of the Application was informed through the review of publicly available information as well as through key informant interviews conducted in the LAA and RAA. Section 13.5 provides consideration of concerns and issues not addressed in Part B of the Application. In particular, Section 13.5.3 addresses private property values and Section 13.5.4 addresses cost of living. With respect to monitoring, mitigation 6.3.1 (Social Management Plan) integrates an adaptive management framework and will be used to monitor the effectiveness of mitigation measures proposed in Section 6.3 of the Application. Aurora LNG's framework for adaptive management is as follows: the social management plan, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plan will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plan will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended).
1440.1	round 1	Kitsumkalum First Nation	5.1	Economic Conditions	Terrace and Kitsumkalum IR1 are not identified as being economically affected by the project. This is incorrect since people from all over the region will be drawn to the jobs offered by Aurora LNG and there is therefore the potential to affect the viability of businesses who currently rely on workers. In addition, because the region will be impacted from many of the VCs and specifically KKN, the expectation is that benefits in terms of employment and contracting will be made available to those living in the region not only in the LAA.	The LAA, which encompasses communities that have the greatest potential to experience adverse economic Project effects was established within the AIR. With respect to potential changes in labour supply and demand and potential changes in commercial businesses affected by Project spending, the LAA encompasses Prince Rupert and nearby communities (see Table 5.2-3 of the Application). Aurora LNG acknowledges that some workers may be drawn from outside of the LAA (i.e. from the RAA). In Section 5.2, baseline information for both LAA communities, as well as the RAA in total is provided. Where applicable, the analysis of effects is also extended to the RAA - see "Characterization of Residual Effects for Change in Labour Supply and Demand" on pp 5.2-61 - 5.2-66, and "Characterization of Residual Effects for Change in Activities for Commercial Businesses Affected by Project Spending" on pp. 5.2-71 to 5.2-75. As indicated in Table 5.2-41, project residual effects on economic conditions are anticipated to extend to the RAA. Project benefits, including employment and business opportunities are estimated on the basis of RAA communities.
1441.1	round 1	Kitsumkalum First Nation	Table 5.2-2	Economic Conditions	Please define local e.g. have lived in Prince Rupert for three years, have an address, etc.?. Labour will come from Terrace as well since the drive is only 1.5 hrs. and many KKN members have relatives in Prince Rupert.	In the context of the Table 5.2-2 in the Application, the adjective "local" means labour from within the LAA. However, it is anticipated that the Project will also hire labour from Terrace, and other RAA communities, as well as from communities elsewhere in BC.

1442.1	round 1	Kitsumkalum First Nation	Table 5.2-3	Economic Conditions	According to the Investment Ready Community Profile created by the City of Terrace (2015), Terrace is the service hub of the northwest region, with 46% of employment working in the service sector, compared to 37% regionally (City of Terrace, 2015). These means many services and supplies will be sourced from Terrace in addition to labour however Terrace is not included within the LAA economic boundary even though the "LAA encompasses the communities that are most likely to be called upon to provide labour, goods, and services required for the Project construction and operations".	The LAA, which encompasses communities that have the greatest potential to experience adverse economic Project effects was established within the AIR. With respect to potential changes in labour supply and demand and potential changes in commercial businesses affected by Project spending, the LAA encompasses Prince Rupert and nearby communities (see Table 5.2-3 of the Application). Aurora LNG acknowledges that some workers may be drawn from outside of the LAA (i.e. from the RAA). In Section 5.2, baseline information for both LAA communities, as well as the RAA in total is provided. Where applicable, the analysis of effects is also extended to the RAA - see "Characterization of Residual Effects for Change in Labour Supply and Demand" on pp 5.2-61 - 5.2-66, and "Characterization of Residual Effects for Change in Activities for Commercial Businesses Affected by Project Spending" on pp. 5.2-71 to 5.2-75. As indicated in Table 5.2-41, project residual effects on economic conditions are anticipated to extend to the RAA. Project benefits, including employment and business opportunities are estimated on the basis of RAA communities.
1443.1	round 1	Kitsumkalum First Nation	Section 5.2.2.8	Economic Conditions	Significance Thresholds for Residual Effects. The definition does not provide a threshold, i.e. distinguishable is not defined - what is distinguishable? How much (quantity or quality) of a change in economic condition does there need to be so that one can say it is distinguishable? One business closing its doors because it can't keep employees - is that distinguishable?	Absent any well established quantitative thresholds for determining a "significant economic effect", Aurora LNG is using an "expression of condition" approach to qualitatively define a threshold. "Distinguishable" in the context of the economic significance threshold definition, means distinct from current conditions or trends. In other words, the condition can be reasonably attributed to the Aurora LNG project rather than due to other economic factors, such as seasonal variations or structural changes affecting the economy (including such factors as in-migration, out-migration, closure and opening of other businesses and projects). It is difficult to apply a numerical threshold to socio-economic effects that would be representative and reasonably accepted. For some, no amount of adverse economic change is acceptable, regardless of whether the local economy as a whole may benefit. Therefore, we are using a definition that allows us to first characterize the predicted effects post mitigation, and based on this characterization determine if the above significance threshold has been "passed". If it is clearly evident that there wil be material un-mitigable residual adverse economic effects attributable to the Project, then it could reasonably be considered significant. However, this conclusion will need to be made with appropriate consideration of the local economic context. For example, businesses may be both positively affected (through increased commercial activity) and adversely affected (through higher labour costs) by the presence of the Project.
1444.1	round 1	Kitsumkalum First Nation	Page 5.2-37	Economic Conditions	Kitsumkalum education and training section. All references to the survey data collected in 2016 is incorrect - Kitsumkalum 2016 is the correct reference. Crossroads did not conduct the survey or report on the information as identified in the Kitsumkalum and Crossroads 2016 report .	It is not stated in the section on Kitsumkalum First Nation, Education and Training on page 5.2-36 of the Application that Crossroads conducted the survey, but rather that a survey was conducted. The report Kitsumkalum Traditional Use Study and Socio-economic Impact Assessment, Aurora Liquefied Natural Gas Project identifies that it was prepared by both Kitsumkalum First Nation and Crossroads Cultural Resource Management Ltd., and a full citation to this effect is provided on page 5.2-36, as well as in the references at the end of Section 5.2 of the Application. The use of "Crossroads 2016" as a short-hand for the full citation - as indicated on page 5.2-36 - was not intended to imply sole authorship by Crossroads. To avoid potential misinterpretation of this shorthand citation an errata will be be provided to clarify that "Crossroads 2016" means "Kitsumkalum and Crossroads 2016." An errata document is being created that will capture these corrections and it will be filed with the BC EAO.
1445.1	round 1	Kitsumkalum First Nation	Section 5.2.5.1	Economic Conditions	Analytical Assessment Techniques. Terrace and Kitsumkalum IR1 have been excluded from this assessment in the change in labour supply and demand despite the recognition the region will be economically affected by the project.	Section 5.2.5.1 assesses residual effects change in labour supply and demand at the LAA spatial level. The LAA, which encompasses communities that have the greatest potential to experience adverse economic Project effects was established within the AIR. With respect to potential changes in labour supply and demand, the LAA encompasses Prince Rupert and nearby communities (see Table 5.2-3 of the Application). Aurora LNG acknowledges that some workers may be drawn from outside of the LAA (i.e. from the RAA). In Section 5.2, baseline information for both LAA communities, as well as the RAA in total is provided. Where applicable, the analysis of effects is also extended to the RAA - see "Characterization of Residual Effects for Change in Labour Supply and Demand" on pp 5.2-61 - 5.2-66. As indicated in Table 5.2-41, project residual effects on economic conditions are anticipated to extend to the RAA.
1446.1	round 1	Kitsumkalum First Nation	Table 5.2-34	Economic Conditions	Developing work packages that consider capacity of local and regional businesses and facilitating local content is helpful to assist local and regional people in benefiting from the development, however, these benefits are short term during construction only. Effectiveness timing therefore should be characterized as short term rather than short and long term. Beyond construction there is no evidence to show these benefits will last since unless there is another LNG project being constructed the work will be significantly reduced.	While the nature and magnitude of opportunities will differ, depending on Project phase, Aurora LNG intends to apply this mitigation across all Project phases. Table 5.2-39 provides an estimate of annual procurement from suppliers in Northwest British Columbia during the operations phase.
1447.1	round 1	Kitsumkalum First Nation	Table 5.2-34	Economic Conditions	No mitigation has been developed to address the transition to the bust from the boom. In addition, the boom-bust effects need to be incorporated in to the social effects section 6 as the literature shows many boom-bust effects as discussed in Kitsumkalum's comments on Infrastructure and Services Section of this EA.	The transition from construction to the operations phase of the project will result in changes in economic opportunities associated with the Project. This is discussed under the heading "Transition from Construction to Operation" on pp. 5.2-61 and pp. 5.2-62 of the Application. Because of the large amount of labour needed to construct the project, relative to the size of the local labour pool, the majority of construction workers will be recruited from outside of northwest BC. On an annualized basis, it is estimated that the Project will result in 395 direct, indirect, and induced jobs within the RAA (see Table 5.2-35). By comparison, the Project is expected to generate 795 direct, indirect, and inducedjobs within the RAA during operations (Table 5.2-36), of which it is expected that many will be filled by local residents. Because employment opportunities for local residents are predicted to be similar (or greater) during operations phase, the "boom-bust" model is not anticipated for the Project. Skills and qualifications required for many of the operations positions will differ from those needed during construction, and therefore an emphasis on training and education will enable those individuals seeking construction and/or operational positions to prepare for such work. Aurora LNG will support training initiatives for local and Aboriginal communities across construction and operations phases, as described in Mitigation 5.2.5.
1448.1	round 1	Kitsumkalum First Nation	Section 5.2.5.1	Economic Conditions	Direct Employment. Why is there a discussion on RAA and then it switches to LAA? Throughout this economic Section 5 there are several inconsistencies in data and predictions being discussed wit LAA and RAA.	The LAA, which encompasses communities that have the greatest potential to experience adverse economic Project effects was established within the AIR. With respect to potential changes in labour supply and demand and potential changes in commercial businesses affected by Project spending, the LAA encompasses Prince Rupert and nearby communities (see Table 5.2-3 of the Application). Aurora LNG acknowledges that some workers may be drawn from outside of the LAA (i.e. from the RAA). In Section 5.2, baseline information for both LAA communities, as well as the RAA in total is provided. Where applicable, the analysis of effects is also extended to the RAA - see "Characterization of Residual Effects for Change in Labour Supply and Demand" on pp 5.2-61 - 5.2-66, and "Characterization of Residual Effects for Change in Activities for Commercial Businesses Affected by Project Spending" on pp. 5.2-71 to 5.2-75. As indicated in Table 5.2-41, project residual effects on economic conditions are anticipated to extend to the RAA. Project benefits, including employment and business opportunities are estimated on the basis of RAA communities.
1449.1	round 1	Kitsumkalum First Nation	Section 5.2.5.1	Economic Conditions	Direct Employment. Kitsumkalum would like to know what the requirements are to qualify for trades jobs. For example, can an Apprentice access employment or does someone need to have a Red Seal Certificate? Does a trades person need a minimum number of years of experience?	Aurora LNG will initiate its detailed design process following a Project approval from both BC and CEAA. Aurora LNG expects to determine its required skill sets and trades for both construction and operations during the detailed design process. At this time, it is expected that apprentices will be able to access Project employment and every effort will be made to ensure that individuals that are mid-way through their apprenticeship would have the opportunity to complete it with the Project. Apprentices that have completed their training and become certified journey persons would have access to employment. Journey persons that have the Red Seal endorsement on their provincial or territorial certificates of Qualification and Apprenticeship would have access to employment. Aurora LNG will continue to consult with Aboriginal Groups and local communities on employment opportunities as the Project progresses.
1450.1	round 1	Kitsumkalum First Nation	Section 5.2.5.1	Economic Conditions	Indirect and Induced Employment. The numbers of indirect and induced annual jobs during construction seem to be very low given the capital cost of the project is $23B even though LNG projects are capital intensive. More detailed information is needed to show how these numbers are developed. Why is the calculated direct jobs based on the availability of LAA people only? Estimating the number of jobs created by the development is extremely important when predicting population increases. Kitsumkalum would like more information on indirect and induced employment.	The magnitude of direct, indirect, and induced employment jobs was estimated using the following method: 1. Direct employment was based on an estimated 5% of the Project's 5,000 person construction workforce hired locally. 2. Indirect and induced employment were based on the construction employment multipliers for Prince Rupert contained within tables 3.1 and 3.3 of the document: British Columbia Local Area Economic Dependencies: 2006 (Horne 2009). To add conservatism to the analysis, the results of calculations were rounded up, and in the case of induced economic effects, it was assumed that the "no safety net" scenario applies (which results in a higher degree of induced effect than otherwise). Aurora LNG acknowledges that there is only a moderate degree of precision in these estimates. First, it is not known precisely how many local and regional residents will be employed during construction. Factors influencing this include the size of the available construction labour force and/or the willingness of individuals to take up Project construction positions. The local area multipliers from Horne (2009) likely only provide a rough approximation of indirect and induced effects because of differences between constructing the Aurora LNG plant and generally smaller construction projects upon which the multipliers are based. For example, with Aurora LNG most materials and components will be brought to the construction site from suppliers outside of the LAA, and the labour force will be required to live in the construction camp on Digby Island while on shift. For the above mentioned reasons, the direct, indirect, and induced employment estimates should be considered indicative rather than precise. The assessment of effects on employment focuses on effects on LAA communities for reasons discussed in response to Comment #1440.1 and Comment #1441.1. Because the LAA has a smaller labour force than the RAA, assuming that effects on employment will occur mainly in the LAA provides an element of conservatism in the assessment. In reality, Aurora LNG anticipates that individuals from other communities in the RAA, as well as elsewhere in BC would participate in Project construction.
1451.1	round 1	Kitsumkalum First Nation	Page 5.2-63	Economic Conditions	Tonts et al (2012) concludes the socioeconomic wellbeing and experience of resource communities varies based on regional characteristics, the type of resource and the community. Resource dependence is not the only factor - the type of commodity is important - Tonts et al explains that a community with gold is less stable than one with iron as gold mines can experience volatility whereas iron production is more stable. LNG is short term - we know there will be a closure at the end of construction - 5 to 8 yrs. Community remoteness, population size, percentage of indigenous peoples, unemployment rates and level of education all are factors that determine if a community is resilient to resource developments that include boom-bust dynamics. The authors also recognize the issue is complex and their study only looked at the time period when the 33 communities studied were in a boom phase. The information cited from the Tonts et al (2012) appears to be incorrect.	The provided reference to Tonts (2012) is incorrect. The correct citation is to the following report by Matthew Tonts: Tonts, Matthew. May 2010. Labour Market Dynamics in Resource Dependent Regions: An Examination of Western Australia. Geographic Research, 48(2), pp. 148-165. The correct citation will be included in an errata document that is being developed and will be filed with the BC EAO.
1452.1	round 1	Kitsumkalum First Nation	Section 5.2.5.1	Economic Conditions	Summary. Early on in this section it is stated the construction phase benefits will last 10 yrs. however in the Summary it is stated the short term construction phase is known and people will be able to transition to operations as the area is moderately resilient. Given the significant amount of literature on boom-bust dynamics, the resource curse, and the negative impacts to indigenous people in general worldwide, it is unclear how the lack of appropriate mitigation provided in this EA overall to ensure participation of regional indigenous people in the project so they can receive benefits and not be negatively effected as well as provide mitigation from the construction to the operations phase will most certainly result in vulnerable people being worse off as a result of the project. Kitsumkalum recommends additional mitigation measures be proposed to maximize socioeconomic benefits and minimize socioeconomic effects.	Aurora LNG maintains that the mitigation measures identified to support local and Aboriginal economic participation in the Project are appropriate. These include: Mitigation 5.2.1 - Inform local residents and Aboriginal Groups of job and procurement opportunities during all Project phases. Develop work packages that consider the capacity and capabilities of local and regional businesses. Mitigation 5.2.5 - Identify potential shortages of workers with specific skill requirements, and work with training and education facilities, Aboriginal Groups, and local communities to increase opportunities for Aboriginal and local community members to obtain training required for Project participation. Further, Aurora LNG has identified numerous mitigation measures for addressing adverse effects on infrastructure and services, land and resource use, marine navigation and use, visual quality, and community health. In addition, it is expected that the social management plan (Mitigation 6.3.1) will include an adaptive management framework. Aurora LNG's framework for adaptive management is as follows: management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended). Because there will be substantial local employment opportunities during Project operations as well as Project construction, Aurora LNG maintains that the Project can avoid a "boom and bust" phenomena.
1453.1	round 1	Kitsumkalum First Nation	general	Economic Conditions	Operations Direct Employment. What are the skills needed to operate the facility and where will the workers come from - what percentage will be from other parts of B.C., Canada and Internationally?	There are numerous jobs associated with an operating LNG plant, broadly divided into four employment areas: management, administration and other, operations, and technical services/other. Examples of LNG plant positions include: LNG technicians, pipeline operations technicians, gas control system operator, terminal operator, power engineer, power generation technician, process engineer, process control engineer, health and safety technician, maintenance coordinator, maintenance technicians, controller, human relations, plant manager. Each position requires specific skills, expertise, and experience. The majority of positions will require skills associated with plant operations and maintenance. Aurora LNG estimates that approximately 90% of its workforce will be Canadian residents, and the balance will be foreign and work on a FIFO basis. It is Aurora LNG's objective to operate the plant "locally" meaning that the majority of its operations staff will live near the plant. It is expected that the proportion of local residents working at the facility will grow over time, as "home grown" expertise in LNG plant operations is developed.
1454.1	round 1	Kitsumkalum First Nation	general	Economic Conditions	Indirect and Induced Employment during Operations. How were the indirect and induced job multipliers derived? Operations is 25 yrs. - why is there a closed camp for operations? Why would people not move to the area if they have an operations job?	The magnitude of indirect and induced employment jobs was estimated based on the estimated number of jobs for Canadian residents (540 out of 600 in total), multiplied by Prince Rupert employment ratios for Misc. Manufacturing contained in tables C.2.1, C.2.2, and C.2.3 of the document: British Columbia Local Area Economic Dependencies: 2006 (Horne 2009). Aurora LNG anticipates maintaining an operations work camp because at least during the early years of operations it is expected that a proportion of the operations work-force will be from outside of the RAA, and will work on a FIFO basis. The expectation is that over time most operations positions will be filled either by people that are residents of local communities or will have moved into the area to take up employment. However, the work camp will still be maintained to house crews for periodic maintenance turnarounds.
1455.1	round 1	Kitsumkalum First Nation	Section 5.2.5.1	Economic Conditions	Likelihood of Residual Effects. Change in labour supply and demand is identified as having moderate to high likelihood of adverse effects during decommissioning, however the construction workforce will peak at 5000 + indirect + induced jobs which will reduce to 600 at operations. The end of the construction phase will likely have more adverse effects than the loss of 600 jobs + indirect + induced. In addition, no specific mitigation has been provided to address these adverse effects.	Only a small proportion of the construction workforce is predicted to be hired locally (estimated at 5% of the peak workforce requirements of 5000). Because it is predicted that there will be more locally based labour associated with operations than with construction (compare tables 5.2-36 and 5.2-35) the transition from construction to operations is predicted to have only low to moderate effects overall.
1456.1	round 1	Kitsumkalum First Nation	Section 5.2.5.2	Economic Conditions	Page 5.2-68. The comment re operations spending by LNG workers conflicts with a previous statement that identifies the majority of operations workers coming from outside the region and to be housed in a closed camp.	The last paragraph on page 5.2-70 notes that "the majority of the workforce will be hired from outside the region" and refers to the construction workforce. Aurora LNG intends that the majority of the operations workforce will be comprised of individuals either hired from local communities or persons who have moved into the region with the Project. For both construction and operations phases, it is Aurora LNG's goal to maximize local/regional hiring.

1457.1	round 1	Kitsumkalum First Nation	Section 5.2.5.2	Economic Conditions	Residual effects Commercial Businesses Construction. There could be a stronger commitment to work with local and regional businesses so they can benefit during construction and transition to operations. There is a commitment to develop work packages specific to local and regional companies, however, how engagement with local and regional businesses will be carried out is not mentioned. How will the proponent manage its EPCM contractor and the subcontractors to ensure local content is included and facilitate long term benefits from the development?	Aurora LNG will initiate its detailed design process following a Project approval from both BC and CEAA. Aurora LNG expects to determine its required skill sets and trades during that process. As noted in mitigation 5.2.5, Aurora LNG will identify potential shortages of workers with the identified skill requirements, and work with training and education facilities, Aboriginal Groups, and local communities to increase opportunities for Aboriginal and local community members to obtain training required for Project participation. As noted in mitigation 5.2.2, Aurora LNG will provide information to employment agencies and economic development organizations to help them plan for increased demand for construction labour . As noted in mitigation 5.2.1, Aurora LNG will inform local residents and Aboriginal Groups of job and procurement opportunities during all Project phases. Aurora LNG will develop work packages that consider the capacity and capabilities of local and regional businesses. It is expected that notice of these opportunities may be through a combination of employment agencies, trade union offices, local, regional, and national newspapers, and the Aurora LNG website. Regarding EPCM contractors, it is expected that Aurora LNG will include specific local hiring criteria in the EPCM contract documents. The contractual criteria would also have requirements for the EPCM contractor to report back on extent of local hiring. The exact details will be developed during the Project design process.
1458.1	round 1	Kitsumkalum First Nation	Section 5.2.5.2	Economic Conditions	Again this section switches between opportunities offered to LAA and both LAA and RAA. For example transportation and logistics opportunities appears to be restricted to the LAA. Kitsumkalum have a rail line through their IR and would very much like to have the opportunity to provide transportation and logistics services for the development. Kitsumkalum will be impacted by the development and should have access to contracting and employment at all phases of the development. The EA is ambiguous in terms of what will be offered to who since Kitsumkalum are classified as within the RAA.	The LAA, which encompasses communities that have the greatest potential to experience adverse economic Project effects was established within the AIR. With respect to potential changes in labour supply and demand and potential changes in commercial businesses affected by Project spending, the LAA encompasses Prince Rupert and nearby communities (see Table 5.2-3 of the Application). Aurora LNG acknowledges that some workers may be drawn from outside of the LAA (i.e. from the RAA). In Section 5.2, baseline information for both LAA communities, as well as the RAA in total is provided. Where applicable, the analysis of effects is also extended to the RAA - see "Characterization of Residual Effects for Change in Labour Supply and Demand" on pp 5.2-61 - 5.2-66, and "Characterization of Residual Effects for Change in Activities for Commercial Businesses Affected by Project Spending" on pp. 5.2-71 to 5.2-75. As indicated in Table 5.2-41, project residual effects on economic conditions are anticipated to extend to the RAA. Project benefits, including employment and business opportunities are estimated on the basis of RAA communities. Information included in the assessment of economic effects is not intended to imply any restriction by Aurora LNG or its contractors in regards to where or with whom they will procure goods or services, or hire labour.
1459.1	round 1	Kitsumkalum First Nation	Table 5.2-38	Economic Conditions	Please add two other columns to this table - sourced outside NWBC but within B.C., sourced outside NWBC in Canada, and sourced internationally. It is unclear why so many goods and services are not sourced in B.C. or Canada. One example is camp services. - only 50% from NWBC?	See Section 1, Table 1-4 of the Application for an overview breakdown of spending in BC, Canada, and Internationally, and Table 1-5 for an itemized breakdown of spending within Canada. Aurora LNG anticipates that 70% of capital spending will occur overseas because the LNG plant will be pre-fabricated at overseas facilities and then shipped as modular units to the Project site on Digby Island for assembly. Aurora LNG estimates that there will be nearly $8.4 billion in purchasing from Canadian suppliers, including $3.3 billion in purchasing from B.C. suppliers. With respect to the camp, the estimate provided in Table 5.2-38 is inclusive of capital and operating costs. Aurora LNG anticipates that it will work with an existing large industrial camp provider to design and supply the camp, and Aurora LNG expects that large portions of the camp will be modular components that could be constructed at locations either inside or outside of BC depending on the supplier commercial arrangements.
1460.1	round 1	Kitsumkalum First Nation	Section 5.2.5.3	Economic Conditions	An important addition to Assumption 3 is many people rely on traditional foods to supplement their food purchases and for First Nations these foods are also important for good health.	Aurora LNG acknowledges this assumption, and will include it as an erratum. An errata document is being created that will capture these corrections and it will be filed with the BC EAO.
1461.1	round 1	Kitsumkalum First Nation	Section 5.2.5.4	Economic Conditions	Regional Cumulative Effects for change in labour supply and demand. If multiple projects were constructed it is likely they would be staggered. According to a Mining Australia 2013 article (https://www.australianmining.com.au/oil-gas/what-it-takes-to-build-70-billion-worth-of-lng-plants-bechtel-construction-facts/) Bechtel was able to employ 4500 of 10,000 required construction workers from the Gladstone area for the 3 projects constructed on Curtis Island from 2010 to 2014. These projects had modules imported similar to what is proposed for LNG projects in Prince Rupert, however Aurora LNG is estimating only 5% of the workforce will come from the region - please explain. In addition, the article notes that the company is helping businesses who held contracts during construction to transition to post LNG construction phase.	The Gladstone region has a much larger population than does the LAA or RAA, which accounts for much of this difference. As of 2015, the Gladstone population was 67,465 (source: http://www.qgso.qld.gov.au/products/reports/gladstone-region-pop-report/gladstone-region-pop-report-2016.pdf) , This compares to the 2011 LAA population of 14,396 and RAA population of 32,906. From 2002 to 2015 Gladstone's population has been growing at an average annual rate of about 3.2%, with the majority of growth attributed to in-migration. This growth coincided with the construction of numerous industrial and infrastructure projects including aluminum processing, civil and port works, coal export facilities, as well as LNG plants. Therefore, it is likely that the Gladstone region has a high proportion of residents who are working in the heavy industrial construction sector, thus providing a large labour pool for Bechtel to draw on. There is no recent history of large industrial construction occurring in the LAA or RAA that has resulted in permanent in-migration of construction workers (the Rio Tinto Kitimat modernization project, the largest recent industrial construction project that occurred in NWBC was built mainly with FIFO labour). The estimate that 5% of Aurora LNG's peak construction workforce will be hired from persons within the LAA (i.e. 250 persons) considers the size of the labour pool for construction-related occupations as well as estimated labour availability - based on the unemployment rate. The actual number of local/regional area residents directly employed on Project construction may be more or less than 250, depending on their availability, appropriate skills/experience, and interest.
1462.1	round 1	Kitsumkalum First Nation	Section 5.2.5.4	Economic Conditions	Summary of Economic Effects. Aurora LNG should develop a Local Content Plan that would outline how it will work with its contractor, subcontractors and local/regional businesses to ensure local content is maximized and also commit to assisting businesses who have contracts to transition beyond construction. The Local Content Plan should also outline how Aurora LNG will assist Kitsumkalum members on and off reserve living in the region to participate in employment and training opportunities.	Aurora LNG maintains that mitigation measures identified in Section 5.2 are sufficient to facilitate economic participation in the Project by Aboriginal and local community members and businesses.
1463.1	round 1	Kitsumkalum First Nation	Section 5.2.9	Economic Conditions	Follow-up and Monitoring. No follow-up programs are proposed and there is therefore no way to determine if mitigation has been effective. A Local Content Plan should include monitoring of the participation of the people and businesses living in the LAA and RAA to verify the contracting and employment benefits have been provided and people are not worse off as a result of the project.	Aurora LNG maintains that mitigation measures identified in Section 5.2 are sufficient to facilitate economic participation in the Project by Aboriginal and local community members and businesses.
1464.1	round 1	Kitsumkalum First Nation	14	Environmental and Operational Management Plans	Section 14.2 Social Management Plan. This plan does not address any of the major socioeconomic issues associated with the boom-bust dynamics (other than some issues associated with camp workers and health services) that will originate from the Project. In addition Kitsumkalum request socioeconomic effects to on-reserve infrastructure and services be added to the SMP, as increased cost of housing will cause overcrowding on reserve unless mitigated. Without a more comprehensive SMP, Kitsumkalum members will inevitably be worse off as a result of the project. Kitsumkalum recognizes Aurora LNG cannot be held responsible for all socioeconomic issues within the region, however the project will impact people and more effort is needed by Nexen to mitigate these effects. Two additional plans to the SMP would be useful: Training and Employment plan; and Construction to Operations Transition plan. These plans would enhance benefits and mitigate for negative effects associated with many of the social issues not currently included in the plans.	The Social Management Plan (mitigation 6.3.1) does not include specific mitigation to address changes in Kitsumkalum on-reserve infrastructure and services. Mitigation measures identified in Table 6.3.10 are expected to effectively manage Project-related effects on accommodation. As such, the likelihood that in-migration, resulting from Project-related changes in accommodations, to Kitsumkalum will increase demand for on-reserve infrastructure and services or directly result in overcrowding is reduced. In the cumulative case, Aurora LNG understands that effects on accommodations from several simultaneous projects could result in increased in-migration to Kitsumkalum resulting in increased demand for on-reserve infrastructure and services and the potential of overcrowding. To aid in mitigating residual cumulative effect, as noted throughout Section 6.3.6, Aurora LNG will participate in government-led initiatives to address these effects. To increase local benefits (e.g., employment and procurement) Aurora LNG will:Mitigation 5.2.1 - Inform local residents and Aboriginal Groups of job and procurement opportunities during all Project phases. Develop work packages that consider the capacity and capabilities of local and regional businesses.Mitigation 5.2.2 - Provide information to employment agencies and economic development organizations to help them plan for increased demand for construction labour.Mitigation 5.2.5 - Identify potential shortages of workers with specific skill requirements, and work with training and education facilities, Aboriginal Groups, and local communities to increase opportunities for Aboriginal and local community members to obtain training required for Project participation.A specific construction-to-operations transition plan is not proposed. However, as noted in Section 5.2.5.1 (subsection 'Transition from Construction to Operations'), while a loss of direct employment from construction to operations is expected, there is potential that some appropriately skilled construction workers could transition into operation-based employment (recognizing that differing skillsets and education are associated with operations). Where workers are unable to transition from construction into operations, adverse effects could occur as result of decreased employment; however, the relatively short-term nature of Project construction is known and will be anticipated by workers who are employed by the Project. In addition, labour income, skills and experience gained while employed with the Project will further offset adverse effects. In the case of gained skills and experience, these benefits of employment could improve qualifications for employment on other future projects. As noted above, mitigation measures targeted at increasing local benefits (e.g., employment and procurement) could also further offset these effects.
1465.1	round 1	Kitsumkalum First Nation	6.2.2.8	Visual Quality	Kitsumkalum has concerns regarding the threshold for significance. 1) Why use the Partial Retention VQC as the threshold as opposed to Retention or Modification VQCs? No justification is provided. 2) Why is the presence of VQ planning objectives among local authorities a criterion for significance? Would this not imply that the visual quality VC could have just been scoped out of the EA altogether if no planning objectives were present? Furthermore, it assumes that if no planning objectives were present, then visual quality is of no concern to any other groups who had input into the plans, which is almost certainly not the case. It also assumes that there are no groups external to the local planning process that are concerned about visual quality, which not true given the Kitselas' and Kitsumkalum's interests in the area.	The significance threshold used in the assessment of effects on visual quality incorporates a number of elements. These are: - The post-development EVC exceeds Partial Retention. - The average existing EVC was either Preservation, Retention or Partial Retention - The viewpoints from which the change is viewed are of moderate to high importance - Visual quality is documented as an important planning objective for government authorities in the LAA. These thresholds incorporate both quantitative and qualitative elements. The first two elements relate to existing visual condition (EVC) in the post-development and baseline conditions. EVC is a measure of the degree of visual disturbance that is present. This element indicates that if the project is causing the EVC to exceed partial retention (i.e. over 7% disturbance) in an area for which disturbance is less than 7% then this could result in a significant effect. A higher threshold for potential significant effect was not used because then even with substantial project-induced change to visual quality the effect would not be significant. The third element relates to importance. While there is a degree of subjectivity in quantifying "importance", the criteria considered include the number, type, and intensity of receptors that may be affected, including residences, scenic highways, tourist locations, and recreational areas. The fourth element, planning context, recognizes that the assessment of visual quality should not be based on measurable criteria only, but should incorporate the extent to which government agencies (local, regional, provincial) seek to protect visual quality as a policy objective. This element allows for the possibility that significance determination can be made even in situations where change in visual quality based on measured elements (e.g. EVC) does not warrant it. Conversely, if protection of visual quality in an area is not considered an important policy objective by relevant government and regulatory authorities then this is also relevant when making a significance determination.
1466.1	round 1	Kitsumkalum First Nation	6.2.5	Visual Quality	The justifications to exclude the shipping route from the assessment are not convincing. First, while the Project's LNG tankers will not add a "new visual element" to the view scape, they are expected to triple the current shipping traffic through the PRPA, which is significant. If it is not considered significant, it should be explained why that is the case. Second, the Pacific Northwest LNG EA concluded that the effects of the project were not significant on the basis that there were no planning objectives specific to visual quality in any local development plans. As indicated in the previous comment, Kitsumkalum does not agree that this is an appropriate criteria to evaluate significance. Additionally, the Pacific Northwest LNG EA indicated that along with the terminal, the LNG tankers created a residual effect that triggered a cumulative effects assessment. No comparable CEA would be possible if shipping is scoped out of the assessment. Given the large increase in shipping traffic the Project will bring, a cumulative effects assessment including shipping seems warranted. We therefore requests that an assessment of shipping on visual quality be included.	As discussed in Section 6.2.2.4 of the Application, the effects from shipping were not carried forward in the visual quality assessment because Project shipping will not result in a new visual element within the LAA (because the Prince Rupert Port is already regularly visited by large marine traffic), and based on the EAC Application results for the PNW LNG project (which is proposing to use similar sized ships, shipping frequency, and shipping route as for Aurora LNG) it was concluded that Project shipping will not introduce new visual elements or be visibly prominent from most viewpoints along the proposed shipping route.
1467.1	round 1	Kitsumkalum First Nation	6.2.3\6.2.5	Visual Quality	There seems to be a disconnect with respect to the assessment methodology and the determination of significance. The assessment goes to great lengths to describe the current and post-development EVC for each VSU affected by the project, but the final determination of significance is based only on the average change in EVC over the entire LAA. It is clear from table 6.2-14 that each of the three VSUs located on Digby Island will undergo significant changes to EVC, yet that is not considered at all in the significance determination. Given that the bulk of the analysis in the assessment is specific to the VSUs, the potential changes to EVC in those VSUs should be included as a criteria in the determination of significance.	The assessment considers the change to visual quality within the LAA, not change specifically from the assessed viewpoints. The four viewpoints that were analysed show potential effects from a number of different locations, including several locations located close to the facility. These viewpoints could be expected to be affected more than those located further away within the LAA. The assessment weighted the potential effects on the assessed viewpoints, but also considered the likely change to visual quality within the LAA overall. This balance is evident in Table 6.2-14 of the Application, which presents change in EVC both to individual visual sensitivity units, as well as to the overall view from each viewpoint.
1468.1	round 1	Kitsumkalum First Nation	6.2.5.2	Visual Quality	Table 6.2-14 indicates that the % Alteration for the Project Condition for the overall view of VP01 is 1.9%, but the EVC is listed as Retention, when it should be Partial Retention. The same goes for VLI 292 for VP02. Additionally, the Existing Condition EVC for VLI 280 should be Partial Retention.	In Section 6.2.5.2, Table 6.2-14, Page 6.2-39, the EVC of the Overall View for VP01 in the Project Condition should be changed to “Partial Retention” from “Retention.” In the same table the EVC for VP02, VLI 292 should be changed to “Partial Retention” to “Retention.” As well, the EVC for VPO2, VLI 280 should be changed to “Partial Retention” from “Retention.” An errata document is being created that will capture this correction and it will be filed with the BC EAO.

1469.1	round 1	Kitsumkalum First Nation	6.2.3.2	Visual Quality	No information is presented on night time viewers of the landscape and/or night sky in order to establish context on any assessment of lighting effects. For example, Metlakatla, Port Ed, Dodge cove, potentially lie within the light dome for a project of this size, where the view of the night sky would be affected. Are there any beaches or camp sites where the views of the night sky could be affected? Additional information is needed to assess the lighting effects. Cumulatively, lighting on the project can have major impacts to visual quality in the area not to mention the wildlife etc.	It is acknowledged in Section 6.2.10 of the Application that the Project will contribute to skyglow in the Prince Rupert area. Depending on atmospheric conditions, the sky glow created by a combination of Prince Rupert, nearby industrial facilities, as well as the Project may be discernable from a considerable distance. However, the magnitude of sky glow generated from the Prince Rupert area at receptor locations located more than a few km away is likely limited by the relatively small size of the lit urban and industrial areas. Through the use of shielded and directional lighting fixtures (mitigations 4.7.9 and 6.2.1) the Project's contributions to sky glow will be minimized. Other lighting effects (glare and light spill) are more relevant to receptor locations within a direct line of sight to Project lighting. As discussed in Section 6.2.5.2 of the Application, the only residential receptors within a direct line of site of the Project are in Prince Rupert. There is a possibility that the Project will be visible from one campground - the Prince Rupert R.V. Campground, though topographical and/or vegetation screening are expected to limit the line of view towards the Project from this location. If the Project is visible from this location, it is anticipated that the change in visual quality will be similar to that for VP03 (Prince Rupert Residences), in that the Project will result in a small incremental change in a view already heavily modified by industrial development along the Prince Rupert waterfront.
1470.1	round 1	Kitsumkalum First Nation	6.2.3.2	Visual Quality	The selection of viewpoints did not include any considerations for use as light receptors. Of the four viewpoints selected, only VP03 was suitable as a light receptor, as it was the only one that people would actually visit at night. Additional receptors for the light assessment could have been identified that were appropriate for use in an assessment of lighting effects and were safe to access at night. We request that at least one additional view point as a light receptor be considered.	Other viewpoints were considered in the assessment of lighting effects, including potential receptor locations in Port Edward. However, because Port Edward does not have a direct view towards the Project, lighting effects were not assessed. Similarly, most streets in Prince Rupert run SW to NE, with most homes and commercial buildings oriented SE to NW (i.e. either looking back towards Mount Hays or looking across the harbour towards the Tsimshian Peninsula). Because the Project is located SE of Prince Rupert, and because of topographical shielding, it will not be visible to the majority of Prince Rupert residences. For this reason, VP03 was selected for assessing lighting effects, because it is the closest residential area within a direct line of site of the Project, and thus has the highest potential to experience adverse effects. Please see the technical memo "Additional Visual Quality Renderings" that will be filed with the EAO for additional viewpoints.
1471.1	round 1	Kitsumkalum First Nation	6.2.5.1	Visual Quality	The justification for the qualitative assessment of ambient light is based on the distance of VP03 from the Project, but no mention is made of the effect of sky glow, which could very well be apparent at that distance, especially under more rural conditions. A discussion of sky glow in the context of nighttime use of the surrounding landscape should be included in the justification of a qualitative assessment.	It is acknowledged in Section 6.2.10 of the Application that the Project will contribute to skyglow in the Prince Rupert area. Depending on atmospheric conditions, the sky glow created by a combination of Prince Rupert, nearby industrial facilities, as well as the Project may be discernable from a considerable distance. However, the magnitude of sky glow generated from the Prince Rupert area at receptor locations located more than a few km away is likely limited by the relatively small size of the lit urban and industrial areas. Through the use of shielded and directional lighting fixtures (mitigations 4.7.9 and 6.2.1) the Project's contributions to sky glow will be minimized. Other lighting effects (glare and light spill) are more relevant to receptor locations within a direct line of sight to Project lighting. As discussed in Section 6.2.5.2 of the Application, the only residential receptors within a direct line of site of the Project are in Prince Rupert. There is a possibility that the Project will be visible from one campground - the Prince Rupert R.V. Campground, though topographical and/or vegetation screening are expected to limit the line of view towards the Project from this location. If the Project is visible from this location, it is anticipated that the change in visual quality will be similar to that for VP03 (Prince Rupert Residences), in that the Project will result in a small incremental change in a view already heavily modified by industrial development along the Prince Rupert waterfront.
1472.1	round 1	Kitsumkalum First Nation	6.2.7.1	Visual Quality	It is not described anywhere how the average post-development EVC of the LAA was calculated, nor how that relates to Table 6.2-14, despite both items being critical to the assessment. Please include an explicit methodology regarding the calculation of average post-development EVC over the LAA.	The average post development EVC change resulting from the Project considered the change in views from assessed viewpoints, as well as potential visibility of the Project based on the viewshed analysis. The viewshed analysis shows that the Project will not be visible from most areas within the LAA (see Figure 6.2-5), and thus will not contribute to a change in visual quality for most of the LAA. Those areas where the Project is visible is represented by the four assessed viewpoints. Of the four viewpoints assessed, only VP02 (Mt. Hays) is expected to have an overall change in EVC that exceeds partial retention, and is attributable to the Project. For these reasons, it is concluded that the average post development EVC change in the LAA resulting from the Project will not exceed 7% (i.e. partial retention).
1473.1	round 1	Kitsumkalum First Nation	Table 6.3-3	Infrastructure and Services	General Comment Baseline. It appears as though direct and indirect potential impacts to infrastructure and services has not been identified for Terrace or Kitsumkalum IR1. We know based on the last boom with up to 3000 workers at Rio Tinto Alcan in Kitimat, housing will be affected by such a large development like Aurora LNG in other nearby communities. Terrace is the major business centre of the north and indirect effects will occur from the influx of people who will work or contract to the Project. In addition, if the Hwy and the Hospital will be affected, how will the people utilizing these services who live in Terrace and Kitsumkalum IR1 not be affected?	The spatial boundaries for the Infrastructure and Services VC align with those defined in the AIR, and includes Terrace and Kitsumkalum IR1. Table 6.3-3 indicates that the Northwest Regional Airport Terrace Kitimate (YXT) and Mills Memorial Hospital (Terrace) are part of the local assessment area (LAA) and the Terrace Census Agglomeration Area (including the City of Terrace) and Kitsumkaylum 1 IR (Kitstumkalum First Nation) are part of the regional assessment area (RAA). As characterized in Section 6.3.6 of the Application, residual cumulative effects on infrastructure and services would apply to all residents of the RAA accessing affecting infrastructure and services. With respect to this comment,this includes transportation infrastructure and services and health care infrastructure and services within the RAA accessed by Kitsumkalum members and residents of Terrace. Similarly, persons who live outside the RAA but access infrastructure and services within the RAA would also be affected. Cumulative effect characterizations for the RAA are summarized in Table 6.3-29. Residual cumulative effects on change in transportation infrastructure and services with the Project are characterized as high in magnitude, to extend to the RAA, are continuous, long-term in duration, reversible and occur within a moderately resilient socio-economic context. Residual cumulative effects on change in health care infrastructure and services are characterized as high in magnitude, to extend to the RAA, are continuous, long-term in duration, reversible and occur within socio-economic context that has low resiliency to change.
1474.1	round 1	Kitsumkalum First Nation	Section 6.3.3.2	Infrastructure and Services	General Comment Baseline. Although 2011 Statistics Canada data is the latest data available for population of Terrace and Prince Rupert, some discussion is needed about the most recent boom in Terrace from the Rio Tinto Alcan project and the increased cost of housing.	Baseline information depicting recent changes in housing demand within the RAA is reflected in Section 6.3.3.2 subsection 'Home Construction, Sales and Pricing'. Under this heading, baseline information from 2004 through 2014 regarding issued residential building permits and the value of building permits is provided. Baseline information shows a dramatic increase in 2014 with respect to both the number of issued residential building permits (indicating a sharp increase in demand) as well as a dramatic increase in the value of issued residential building permits (indicating an increase in the value of homes being built).
1475.1	round 1	Kitsumkalum First Nation	Section 6.3.3.2	Infrastructure and Services	General Comments Baseline. Several Kitsumkalum Members live in Prince Rupert, therefore, the Prince Rupert School District provides services to off reserve Kitsumkalum First Nation members as well. This applies to all infrastructure and services in Prince Rupert as Kitsumkalum Members live in Prince Rupert.	Aurora LNG understands that numerous Kitsumkalum members live within the LAA, including Prince Rupert, and that Project effects on infrastructure and services within the LAA could affect these members. It is also understood that effects on LAA infrastructure and services would be realized by members who live outside the LAA but also access these services.
1476.1	round 1	Kitsumkalum First Nation	Section 6.3.3.2	Infrastructure and Services	Hospital and healthcare registrations for current demand - great baseline - how will we know if mitigation is not working during monitoring - an increase in demand by 10%, 20%? What is the threshold or trigger?	Through the Social Management Plan (mitigation 6.3.1), changes in baseline conditions will be monitored through identified indicators to determine the effectiveness of proposed mitigation measures. Means to monitor the effectiveness of mitigation measures will be determined through engagement with potentially affected service providers, in this case Northern Health, during development of the Social Management Plan. In addition, Aurora will implement an adaptive management framework as follows for the plan: the plan, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plan will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plan will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended).
1477.1	round 1	Kitsumkalum First Nation	Section 6.3.3.2	Infrastructure and Services	It is unclear why impacts to aboriginal healthcare does not include Terrace and other aboriginal peoples who live in Prince Rupert with similar issues to those quoted by Metlakatla. The literature is abundant with respect to the overall lower health status of aboriginal peoples in Canada. Kitsumkalum has several members who live in Prince Rupert.	The spatial boundaries for the Infrastructure and Services VC align with those defined in the AIR, and includes Terrace and Kitsumkalum IR1. Table 6.3-3 indicates that the Northwest Regional Airport Terrace Kitimate (YXT) and Mills Memorial Hospital (Terrace) are part of the local assessment area (LAA) and the Terrace Census Agglomeration Area (including the City of Terrace) and Kitsumkaylum 1 IR (Kitstumkalum First Nation) are part of the regional assessment area (RAA). Aurora LNG understands that many Kitsumkalum members live in Prince Rupert. As characterized in Section 6.3.5.5, adverse residual effects on health care infrastructure and services would apply to all residents of the LAA accessing affected infrastructure and Services. This includes Aboriginal persons living in Prince Rupert including Kitsumkalum members. Similarly, persons who live outside the LAA but access infrastructure and services within the LAA would also be affected. Residual effect characterizations for change in health care infrastructure and services within the LAA are summarized in Table 6.3-27 of the Application.
1478.1	round 1	Kitsumkalum First Nation	Section 6.3.3.2	Infrastructure and Services	Housing and Accommodation. This section acknowledges housing as a concern, especially for aboriginal people but is missing a lot of baseline housing information for Terrace. Several studies have been completed - housing needs assessments - however they have not been reviewed or included in the baseline summary.	Additional baseline information regarding accommodations within the RAA is provided in the "Supplemental Baseline Information for Infrastructure and Services" technical memo including whether supplemental information affects conclusions provided in Section 6.3 of the Application. The technical memo will be filed with the BC EAO.
1479.1	round 1	Kitsumkalum First Nation	Section 6.3.3.2	Infrastructure and Services	Housing and Accommodation. Kitsumkalum provided data showing 34% cannot afford accommodation on reserve, while 56% cannot off reserve. Why is this data not provided as baseline?	While information specific to housing, as provided in the 2016 Report 'Kitsumkalum Traditional Use Study and Socio-economic Impact Assessment' (the Report), is referenced in Section 6.3.3.2 (subsection 'Housing andAccommodations'), information provided in Table 9 of the Report is not included.This information is provided below. Respondents to Kitsumkalum's 2006 questionnaire (Q2) show that over one-third of on-reserve respondents cannot afford on-reserve accommodation while more than half (56%) of off-reserve respondents cannot afford off reserve accommodation (see the below table). The percentage of on-reserve respondents reporting that they cannot afford accommodations is greater than that of the aggregate sample. An opposite trend is identified off-reserve. With respect to living conditions, a greater percentage of on-reserve respondents indicate poor housing conditions (41%) that off-reserve respondents (37%) with similar trends in inadequate space (30% vs. 24%). In both cases, the percent of on- and off-reserve respondents with at least one child reporting poor housing conditions and inadequate space is greater than that reported by the aggregate sample. Indicator On Reserve - IR 1 (%)Off Reserve (%)Total respondents Respondents with at least 1 child Total respondents Respondents with at least 1 child Cannot afford accommodation34465650Poor housing condition41463740Inadequate space30472433Source: Adopted form Kitsumkalum First Nation 2016 Information provided above helps strengthen Aurora LNG's understanding of the Kitsumkalum socio-economic environment but the details do not change the conclusions reached through Aurora LNG's conservative approach. The characterization of residual adverse effects (see Section 6.3.5.3) and residual cumulative effects (see Section 6.3.6.4) on accommodations remain unchanged. Reference: Kitsumkalum First Nation. 2016. Kitsumkalum Traditional Use Study and Socioeconomic Impact Assessment – Aurora Liquefied Natural Gas Project. Prepared for Nexen Energy ULC.
1480.1	round 1	Kitsumkalum First Nation	Section 6.3.3.2	Infrastructure and Services	Housing and Accommodation. Although the baseline shows owners pay a higher shelter to income ratio we disagree owners would be more vulnerable to housing costs. It depends on when they purchased their house and unless they have a variable interest rate mortgage have a fixed monthly payment. Owners are subjected to higher property taxes. Renters are subjected to increases in rent from market forces. Both groups are equally vulnerable and FNs are more vulnerable due to their education, employment and economic status being lower than the non aboriginal population. At a meeting between Kitsumkalum and Nexen we raised the issue that socioeconomic impacts, especially regarding housing and access to healthcare need to be separated out for Kitsumkalum (or Aboriginal Peoples in general) from the rest of the population due to the increased vulnerability and greater impacts. It was to be placed in Other Matters of Concern however it is not and instead refers back to the general VC impact assessment. It is unclear how Nexen has addressed this concern either by identifying the impact or mitigating for it.	As noted and recognized through baseline information presented in Section 6.3.3.2 of the Application (subsection 'Housing and Accommodations'), data indicate that Aboriginal persons are more vulnerable to changes in the cost of accommodations as the shelter-cost-to-income ratios among Aboriginal persons is higher than that of the aggregate population. As accurately noted in the comment, additional socio-economic considerations make Aboriginal persons more vulnerable to changes in accommodations. While Section 6.3 of the Application does not disaggregate residual effects on accommodations and health care infrastructure and services on the basis of Aboriginal vs. non-Aboriginal persons, residual effects as characterized in Section 6.3.5 and 6.3.6 would be experienced by any person accessing accommodations or health care infrastructure and services within the LAA and RAA respectively. With respect to residual effects, Aurora LNG is confident that the suite of mitigation measures provided in Section 6.3 will effectively manage Project-related effects on accommodations and health care infrastructure and services. With respect to residual cumulative effects, Aurora LNG will participate in provincial and/or regional led initiatives to address cumulative adverse effects on infrastructure and services. With reference to the October 25, 2016 meeting, the view that disaggregated characterizations be provided in 'Other Matters of Concern' in Part C is captured in Table 12.9-1 where it is noted that "Aurora LNG has not incorporated an additional socio-economic assessment in Part C because it believes that these effects have been adequately addressed in other sections of the Application.
1481.1	round 1	Kitsumkalum First Nation	Section 6.3.3.2	Infrastructure and Services	Housing and Accommodation. Non-market housing information for Terrace is missing.	Additional information on non-market housing within the RAA is provided in the "Supplemental Baseline Information for Infrastructure and Services" technical memo. A discussion as to whether supplemental information affects conclusions presented in Section 6.3 is also provided. The technical memo will be filed with the BC EAO.
1482.1	round 1	Kitsumkalum First Nation	Section 6.3.3.2	Infrastructure and Services	Page 6.3-45 second paragraph second sentence seems out of place as it is a general statement re units available to aboriginal peoples in Prince Rupert. Kitsumkalum members live in both Prince Rupert and Terrace and both locations are likely to be impacted by increased housing costs.	The identified sentence "there are approximately 170 social housing units in Prince Rupert for low-income tenants of Aboriginal descent" should be removed. An errata document is being created that will capture this correction and it will be filed with the BC EAO.
1483.1	round 1	Kitsumkalum First Nation	Section 6.3.3.2	Infrastructure and Services	Housing and Accommodation. More information should be provided on the 168 bed construction camp Horizon north is pursuing - is this for the Aurora LNG Project? It is also unclear who the camps will be constructed for on Digby Island or the two at Port Edward (4,000 workers each). What projects would these camps be constructed for?	Referenced documents used to describe accommodation camps proposed for the LAA, as provided in section 6.3.3.2, do not include additional detail regarding the purpose of these camps, with the exception of PNW LNG where it is stated that accommodation camps near Port Edward will be used (references provided below). None of these accommodation camps are associated with the Aurora LNG Project. Section 6.3.3.2 does not list project-specific accommodation camps such as that associated with BG LNG. 1484.1	round 1	Kitsumkalum First Nation	Section 6.3.5.1	Infrastructure and Services	Analytical Techniques Impact Assessment. Terrace and Kitsumkalum IR1 are not considered in the impact assessment. Terrace is the service center of the northwest. Any large development will impact infrastructure and services and will impact those who are most vulnerable such as aboriginal peoples living on and off reserve. Kitsumkalum members live in both Prince Rupert and Terrace and can migrate between both Cities. The absence of assessing potential effects on Infrastructure and Services in the Terrace area is a significant gap in this environmental assessment.	The spatial boundaries for the Infrastructure and Services assessment align with those defined in the AIR, and include Terrace and Kitsumkalum IR1. Table 6.3-3 of the Application indicates that the Northwest Regional Airport Terrace Kitimate (YXT) and Mills Memorial Hospital (Terrace) are part of the local assessment area (LAA) and the Terrace Census Agglomeration Area (including the City of Terrace) and Kitsumkaylum 1 IR (Kitstumkalum First Nation) are part of the regional assessment area (RAA). Aurora LNG understands that many Kitsumkalum members live in Prince Rupert. As characterized in Section 6.3.5 of the Application, adverse residual effects on infrastructure and services would apply to all residents of the LAA accessing affected infrastructure and Services. Similarly, persons who live outside the LAA but access infrastructure and services within the LAA would also be affected. Residual effect characterizations for the LAA are summarized in Table 6.3-27 of the Application.

1485.1	round 1	Kitsumkalum First Nation	Section 6.3.5.1	Infrastructure and Services	Analytical Techniques Impact Assessment. Assumptions seems to be missing for the spin-off construction jobs from the 5000 peak workers phase 1. Who will provide camp services, catering, subcontracting, etc.- how many people? Usually the factor is 2.5, i.e. 2.5(5,000) = 12,500 people needed during peak construction. This is double the population of Prince Rupert. KKN would like to see a review of the Gladstone projects where 3 LNG facilities were built and the increase in population rather than a calculation built on assumptions that may be missing important aspects of the population estimates.	Assumptions provided in Section 6.3.5.1 relate to direct employment effects. Indirect and induced employment and population effects are assessed in Section 5.2 and 6.3.5.2 respectively. Population effects are estimated using a combination of modeling (discussed below). Case study analysis was not used to assess population change. Economic Modelling Statistics Canada's Inter-provincial Input/output Model was used to estimate direct, indirect and induced employment effects during construction (see Sections 1.4 and 5.2.5). Results of this modeling were used in conjunction with LAA and RAA baseline characteristics and Statistics Canada Economic Multipliers to derive indirect and induced employment effects within the RAA. Indirect and induced employment accounts for the forms of employment highlighted by Kitsumkalum. Using these methods direct peak construction employment was estimated at 5,000 persons. Presented in Table 5.2-35, indirect and induced employment was estimated at an additional 145 annual jobs within the RAA (note, additional employment is estimated to occur outside the RAA). Using direct workforce estimates developed by Aurora LNG for operations (a direct peak workforce of 200 persons), indirect and induced employment for the RAA (using the same methods as used for construction) were estimated. Presented in Table 5.2-36, indirect and induced employment was estimated at an additional 195 annual jobs within the RAA (note, additional employment is estimated to occur outside the RAA). Population Modelling Results of economic modelling and analysis completed in Section 5.2 were carried forward as inputs that informed population modelling completed in Section 6.3. Population modelling completed in Section 6.3 accounted for direct, indirect and induced in-migration resulting from Project employment and adjusted for household characteristics (i.e., baseline data for the LAA and RAA was used to adjusted for the in-migration of spouses and dependents). Replacement effects (i.e., additional in-migration in response to increased employment for vacated positions resulting from workers leaving current positions to seek employment with the Project) were also accounted for through population modelling. The resulting output (see Section 6.3.52) provides an estimate of population change, over that estimated in the base case by BC Stats, and is considered conservative (i.e., overstated).
1486.1	round 1	Kitsumkalum First Nation	Section 6.3.5.1	Infrastructure and Services	Analytical Technical Impact Assessment. Please define local. This definition would be useful for the entire EA as it is mentioned in various sections.	In general, 'local' refers to the local assessment area (LAA) and is defined in the AIR and in Table 6.3-3 as follows: "Includes communities within the mainland portion of the Skeena-Queen Charlotte Regional District (SQCRD) including: City of Prince Rupert, District Municipality of Port Edward, Dodge Cove Improvement District, Crippen Cove, other communities within the SQCRD Electoral Areas (SQCRDA) A and C, Lax Kw'alaams IR 1 (Lax Kw'alaams Band), S1/2 Tsimpsean Indian Reserve 2 (Metlakatla First Nation), Dolphin Island 1 (Gitxaala Nation). Highway 16 up to and including the Northwest Regional Airport Terrace Kitimat (YXT) and Mills Memorial Hospital (Terrace) are also included." Exceptions: Local is also used in the term 'Local Health Area' which is an administrative boundary defined by the BC Ministry of Health. This does not perfectly align with the description of the LAA. In Section 6.3.3.2 'Hospital and Health Care Capacity' local and non-local demand refers to patient registrations with addresses inside or outside a given hospital's catchment area. 'Local roads' refer to municipal roads References to 'local' as taken from cited references. Local would refer to the description provided in the referenced material. In most cases, this use of 'local' is qualified when used in the context of the assessment.
1487.1	round 1	Kitsumkalum First Nation	Section 6.3.5.1	Infrastructure and Services	Project Mechanisms For Community Infrastructure and Services. The presence of a camp is not likely to mitigate effects to housing costs as demonstrated by several resource development projects throughout the world (e.g., Gladstone, Australia). Please provide at least one example of the presence of a camp mitigating these effects with a similar scenario to Aurora LNG to show there will be minimal effect to housing cost from the project in both Prince Rupert and Terrace. Effects to Kitsumkalum IR1 will occur if housing costs increase in both these Cities.	Section 13.5 of the Application provides additional consideration of issues and concerns not addressed in Part B of the Application. This includes private property value (section 13.5.3) and cost of living (section 13.5.4). Drawing on case-study analysis, these sections present scenarios that show positive effects and scenarios that show adverse effects of industrial development on private property values and cost of living. Each section concludes with a determination of the status of the issue or concern. Case-study analysis of the use of accommodation camps as a effective means of mitigating adverse effects on accommodations was not completed; however; as noted in Section 6.3 of the Application, the use of accommodation camps to address Project effects on commercial accommodations is a well-established management measure to reduce adverse effects on nearby communities (see IFC 2012). International Finance Corporation [IFC]. IFC Performance Standards on Environmental and Social Responsibility. 2012. Available at: https://www.ifc.org/wps/wcm/connect/c8f524004a73daeca09afdf998895a12/IFC_Performance_Standards.pdf?MOD=AJPERES. Accessed: January 2016.
1488.1	round 1	Kitsumkalum First Nation	Section 6.3.5.1	Infrastructure and Services	Project Mechanisms For Community Infrastructure and Services. Please define local.	In general, 'local' refers to the local assessment area (LAA) and is defined in the AIR and in Table 6.3-3 as follows: "Includes communities within the mainland portion of the Skeena-Queen Charlotte Regional District (SQCRD) including: City of Prince Rupert, District Municipality of Port Edward, Dodge Cove Improvement District, Crippen Cove, other communities within the SQCRD Electoral Areas (SQCRDA) A and C, Lax Kw'alaams IR 1 (Lax Kw'alaams Band), S1/2 Tsimpsean Indian Reserve 2 (Metlakatla First Nation), Dolphin Island 1 (Gitxaala Nation). Highway 16 up to and including the Northwest Regional Airport Terrace Kitimat (YXT) and Mills Memorial Hospital (Terrace) are also included." Exceptions: Local is also used in the term 'Local Health Area' which is an administrative boundary defined by the BC Ministry of Health. This does not perfectly align with the description of the LAA. In Section 6.3.3.2 'Hospital and Health Care Capacity' local and non-local demand refers to patient registrations with addresses inside or outside a given hospital's catchment area. 'Local roads' refer to municipal roads References to 'local' as taken from cited references. Local would refer to the description provided in the referenced material. In most cases, this use of 'local' is qualified when used in the context of the assessment.
1489.1	round 1	Kitsumkalum First Nation	Section 6.3.5.1	Infrastructure and Services	Project Mechanisms for Community Infrastructure and Services. The transition from the construction phase (5 to 8 yrs.) to operations has been missed. This transition will result in declining housing costs and increased vacancies. The relatively small number of operations people will likely not result in increased pressure on housing given the need to accommodate during the construction phase. There will be a boom-bust dynamic as a result of the construction and operations phases of this development. This has not been discussed. Please refer to the literature on this topic when justifying the identification of potential impacts from the influx of people whether it be migrants or FIFO. The transition from construction phase to operations is discussed in the economics section however no mitigation is proposed to minimize these effects other than providing information and working with other groups.	The assessment of change in accommodations takes into consideration the existing supply of housing within the LAA and RAA and qualifies this with information regarding predicted new builds (e.g., accommodation camps, lands available for development). While it is acknowledged that a surge of in-migrating workers followed by a sudden decline could result in an oversupply of accommodations, this scenario is not considered in Section 6.3 of the Application. Rather, the assessment of change in accommodations (Sections 6.3.5.3 and 6.3.6.4) assumes (from economic modelling completed in Section 5.2) that roughly 95% of the peak construction workforce will be employed on a fly-in/fly-out (FIFO) basis, 3% comprised of current residents of the LAA and RAA and 2% from in-migrating workers (see Section 6.3.5.1). From this, approximately 100 in-migrating workers are anticipated at peak construction. During operations approximately 20% of the peak workforce will be comprised of FIFO workers, 12% current residents and 68% in-migrating workers (see Section 6.3.5.1). An estimate of 408 in-migrating workers are anticipated during operations. Estimates of direct employment suggest that demand from housing will increase from construction to operations and consequently an oversupply of housing is not anticipated. Similarly, indirect and induced employment is anticipated to increase form construction to operations. Assuming a percentage of these workers in-migrate to the LAA and RAA demand for housing will increase from construction to operations. From Section 5.2.5.1 it is noted that a loss of direct employment from construction to operations is expected. However, there does exist potential for some appropriately skilled construction workers to transition into operation-based employment (recognizing that required skill-sets are largely different between construction and operations). Section 5.2.5.1 also notes that while adverse effects could occur as a result of decreased construction employment, the relatively short-term nature of Project construction is known and will be anticipated by workers who are employed by the Project. It is further suggested that labour income, skills and experience gained while employed with the Project will further offset adverse effects and that in the case of gained skills and experience, these benefits of employment could improve qualifications for employment on other future projects. In addition, through mitigation 6.6.1 (Employee Assistance Program), employees will be provided with access to financial planning and similar counselling services. These services can be accessed by workers to help prepare them for this transition. Through these measures and an understanding of the work schedule, the magnitude of adverse effects on community health and wellness following the transition from construction to operations is anticipated to be reduced.
1490.1	round 1	Kitsumkalum First Nation	Section 6.3.5.1	Infrastructure and Services	Closed camp - good mitigation, however how will this be monitored/enforced? Will this encourage people to live in the community rather than camp?	The worker camp will be a closed-access camp, meaning that Project employees will be expected to remain onsite for the duration of their work shifts. Failure to adhere to the camp policies will result in worker termination. In addition, on-site security services (mitigation 6.3.9) will also control access on and off site. The closed-access camp and Project-specific transportation to/from the airport and the camp will likely dissuade fly-in/fly-out construction workers from in-migrating to LAA and RAA communities. However, as assessed throughout Section 6 (Social Environment), regardless of camp or project housing policies it is anticipated that direct, indirect and induced employment during construction and operations will result in measurable levels of in-migration (workers and their families) to the LAA and RAA (see Section 6.3.5.2).
1491.1	round 1	Kitsumkalum First Nation	Table 6.3.-21	Infrastructure and Services	The Social Management Plan in KKN's view is not rigorous as it does not provide enough detail on how monitoring and adaptive management will occur. Also, many of the proponents have excluded on reserve effects. For KKN it appears Aurora LNG has excluded effects to housing costs and access to healthcare in this EA and therefore impacts to the Nation will also be excluded from the SMP. This is a major concern for KKN.	Additional information on the Social Management Plan (mitigation 6.3.1) is included in Section 14.12 of the Application. As currently proposed, the plan includes consideration of Project-related effects on accommodations and health care infrastructure and services (which are assessed in Section 6.3). Detailed information beyond commitments to embed an adaptive management approach into the Social Management Plan is not provided in the Application. Rather, details of the Social Management Plan will be developed through engagement with regulators, Aboriginal Groups and interested stakeholders. Aurora LNG's framework for adaptive management is as follows: the social management plan, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plan will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended).
1492.1	round 1	Kitsumkalum First Nation	Table 6.3.-21	Infrastructure and Services	Item 6.3.4 of the Table. Engagement with government, FNs and the public is good however FNs need resources to monitor and engage. Also, the engagement of other large developers is necessary to manage boom-bust effects.	Aurora LNG understands capacity constraints could limit the ability of First Nations to engage and participate in monitor of Project effects. Aurora LNG hopes to better understand these constraints so that Project-measures can be implemented such that engagement with Aurora LNG does not further constrain available capacity. While Aurora LNG cannot guarantee that other proponents of projects within the RAA will engage collaboratively with Aurora LNG, as noted throughout Section 6.3.6 Aurora LNG will participate in government-led regional initiatives with respect to cumulative effects on community infrastructure and services.
1493.1	round 1	Kitsumkalum First Nation	Table 6.3.-21	Infrastructure and Services	While the construction camp will reduce impacts to infrastructure and services it will not minimize them to a level that will not effect people living in the region because of the sheer size of the project and the number of people coming to the area for the construction phase. This is amplified if other projects move forward at the same time.	Despite Project design to use on-site accommodations, enforce a 'closed-access camp' policy and to implement numerous mitigation measures (see Tables 6.3-21, 6.3-22, 6.3-23, and 6.3-26), Aurora LNG acknowledges that effects on infrastructure and services are likely to still occur. These residual effects are assessed in Section 6.3.5 of the Application. The Project's contribution to cumulative residual effects and cumulative residual effects with the Project are assessed in Section 6.3.6.
1494.1	round 1	Kitsumkalum First Nation	Table 6.3.-21	Infrastructure and Services	Is the Project adhering to IFC Performance Standards? KKN agree these Standards should be used since currently there is insufficient information in the EA to address effects to indigenous populations or vulnerable peoples.	Section 6.3 of the Application does not state that the Project is adhering to International Finance Corporation (IFC) Performance Standards on Environmental and Social Responsibility; rather, IFC standards were reviewed and informed the development of the following mitigation measures: 6.3.5, 6.3.6, 6.3.10. The reference 'IFC 2009' is incorrectly cited in Table 6.3-21 and Table 6.3-22, and is not included in Section 6.3.11 (References). The reference should be cited as 'IFC 2012' in Table 6.3-21 and Table 6.3-22 with the below citation included in Section 6.3.11. An errata document is being created that will capture these corrections and it will be filed with the BC EAO. International Finance Corporation [IFC]. IFC Performance Standards on Environmental and Social Responsibility. 2012. Available at: https://www.ifc.org/wps/wcm/connect/c8f524004a73daeca09afdf998895a12/IFC_Performance_Standards.pdf?MOD=AJPERES. Accessed: January 2016.
1495.1	round 1	Kitsumkalum First Nation	Section 6.3.5.1	Infrastructure and Services	Characterization of the impacts to infrastructure and services does not include indirect workers and total influx of people and therefore is underestimated. Please explain.	Population modelling to support the assessment of change in community infrastructure and services included predicted effects on direct, indirect and induced population increases in both the LAA and RAA (see Section 6.3.5.2 and 6.3.6.4 of the Application). Modeling included consideration of workers and their families. Modeled population effects inform the effect mechanism 'population change' which is a fundamental consideration in the assessment of change in accommodations, change in transportation infrastructure and services and change in health care infrastructure and services. Adverse effect characterizations for each residual effect assessment in Section 6.3 consider population effects with residual effects characterized accordingly. Characterizations of residual effects are therefore not understated.
1496.1	round 1	Kitsumkalum First Nation	Section 6.3.5.1	Infrastructure and Services	Page 6.3-62. Although caseloads for police re crime is lower in the LAA than BC , increased crime is associated with boomtowns and one can expect increased crime in the RAA from the effects of this development. It is important to monitor and adaptively manage for this potential effect	Aurora LNG acknowledges that residual adverse effects and residual cumulative effects on crime could occur within the LAA and RAA. Increased demand on police services within the LAA and RAA are discussed in Sections 6.3.5.2 and 6.3.6.3 respectively. Project-effects on the social determinant of health 'social environments', including consideration of changes in crime, are assessed for the LAA and RAA in Sections 6.6.5.3 and 6.6.6.3 respectively. Through the Social Management Plan (mitigation 6.3.1), Project-effects on police services will be monitored and adaptively managed. See Section 14.12 for additional information on the Social Management Plan.
1497.1	round 1	Kitsumkalum First Nation	Section 6.3.5.1	Infrastructure and Services	Page 6.3-62. The literature on boomtown effects show the transition from resource developments where there is a large influx of people followed by massive layoffs result in a potential for depression and other health issues (Alberta Oil sands suicide rate increased in first six months of 2015 by 30%). Aurora LNG needs to mitigate these effects by helping people prepare for the transition.	The relationship between employment and income and community health and wellness is identified in Table 6.6-2 and discussed throughout Section 6.6.5.3 as an effect mechanism. In particular, linkages between 'employment and income' and stress and anxiety and health status are identified. Informing the effect mechanism 'employment and income', as used in the assessment of change in community health and wellness, is the assessment of change in labour supply and demand (see Section 5.2.5.1). Section 5.2 is referenced, where applicable, in Section 6.6.5.3. From Section 5.2.5.1 it is noted that a loss of direct employment from construction to operations is expected. However, there does exist potential for some appropriately skilled construction workers to transition into operation-based employment (recognizing that required skill-sets are largely different between construction and operations). Section 5.2.5.1 also notes that while adverse effects could occur as a result of decreased construction employment, the relatively short-term nature of Project construction is known and will be anticipated by workers who are employed by the Project. It is further suggested that labour income, skills and experience gained while employed with the Project will further offset adverse effects and that in the case of gained skills and experience, these benefits of employment could improve qualifications for employment on other future projects. In addition, through mitigation 6.6.1 (Employee Assistance Program), employees will be provided with access to financial planning and similar counselling services. These services can be accessed by workers to help prepare them for this transition. Through these measures and an understanding of the work schedule, the magnitude of adverse effects on community health and wellness following the transition from construction to operations is anticipated to be reduced.

1498.1	round 1	Kitsumkalum First Nation	Section 6.3.5.3	Infrastructure and Services	As mentioned in previous comments, changes to accommodation will occur both in the LAA and the RAA as demonstrated by the literature. This effect has been completely missed.	Effects on accommodations are assessed throughout Section 6.3 of the Application. Section 6.3.5.3 'Characterization of Change in Accommodations' assesses adverse residual effects on accommodations within the LAA while Section 6.3.6.4 'Cumulative Effects Assessment for Change in Accommodations' assesses adverse cumulative effects on accommodations within the RAA. Stated in section 6.3.7.1 of the Application, adverse residual effects on accommodations within the LAA are not significant; however, in Section 6.3.7.2 adverse cumulative effects with the Project are significant.
1499.1	round 1	Kitsumkalum First Nation	Table 6,3-22	Infrastructure and Services	Engagement with aboriginal groups and a management plan will likely not be effective mitigation. There needs to be a plan to mitigate for the increase in homelessness during construction of these large developments which involves the provincial, federal, municipal governments, First Nations, and anti-poverty organizations. The project will cause these effects and should spearhead the assembly of such a group, i.e. advocate to the government the need to manage these effects as they occur. To comply with the International Finance Commission Performance Standards people should not be worse off as a result of project development.	Aurora LNG is confident that through Project design (i.e., a closed-access accommodation camp), logistics plans (e.g., that non-local workers will be transported to their home communities following the completion of their shifts), and mitigation measures proposed in table 6.3-22, commitments to ongoing engagement (mitigation 6.3.4, 6.3.11), and through development and implementation of the Social Management Plan (mitigation 6.3.1) adverse effects on accommodations will be reduced. With respect to cumulative residual effects within the RAA, Aurora LNG will participate in government-led regional initiatives with respect to cumulative effects on community infrastructure and services, including accommodations. It is expected that other projects that require regulatory approval will be subject to similar mitigation through the environmental assessment and permitting processes. Adherence to International Finance Corporation (IFC) Performance Standards on Environmental and Social Responsibility is not a requirement of the AIR.
1500.1	round 1	Kitsumkalum First Nation	Section 6.3.5.3	Infrastructure and Services	Page 6.3-68. The prediction of housing includes the potential for new housing to be built in addition to other mitigation measures that are likely to be ineffective given the large influx of people. The construction of new houses will result in a greater surplus of housing during the bust - the end of the construction phase and will reduce housing costs affecting those who purchased their houses during the construction phase and becoming unemployed. Aurora LNG needs to provide assistance to people so they are aware of these effects and help them transition from the boom to the bust. This is best accomplished as a cooperative between Aurora LNG, other major construction project proponents, governments, FNs and representatives of the public	The assessment of change in accommodations takes into consideration the existing supply of housing within the LAA and RAA and qualifies this with information regarding predicted new builds (e.g., accommodation camps, lands available for development). While it is acknowledged that a surge of in-migrating workers followed by a sudden decline could result in an oversupply of accommodations, this scenario is not considered in Section 6.3 of the Application. Rather, the assessment of change in accommodations (Sections 6.3.5.3 and 6.3.6.4) assumes (from economic modelling completed in Section 5.2) that roughly 95% of the peak construction workforce will be employed on a fly-in/fly-out (FIFO) basis, 3% comprised of current residents of the LAA and RAA and 2% from in-migrating workers (see Section 6.3.5.1). From this, approximately 100 in-migrating workers are anticipated at peak construction. During operations approximately 20% of the peak workforce will be comprised of FIFO workers, 12% current residents and 68% in-migrating workers (see Section 6.3.5.1). An estimate of 408 in-migrating workers are anticipated during operations. Estimates of direct employment suggest that demand from housing will increase from construction to operations and consequently an oversupply of housing is not anticipated. Similarly, indirect and induced employment is anticipated to increase form construction to operations. Assuming a percentage of these workers in-migrate to the LAA and RAA demand for housing will increase from construction to operations. From Section 5.2.5.1 it is noted that a loss of direct employment from construction to operations is expected. However, there does exist potential for some appropriately skilled construction workers to transition into operation-based employment (recognizing that required skill-sets are largely different between construction and operations). Section 5.2.5.1 also notes that while adverse effects could occur as a result of decreased construction employment, the relatively short-term nature of Project construction is known and will be anticipated by workers who are employed by the Project. It is further suggested that labour income, skills and experience gained while employed with the Project will further offset adverse effects and that in the case of gained skills and experience, these benefits of employment could improve qualifications for employment on other future projects. In addition, through mitigation 6.6.1 (Employee Assistance Program), employees will be provided with access to financial planning and similar counselling services. These services can be accessed by workers to help prepare them for this transition. Through these measures and an understanding of the work schedule, the magnitude of adverse effects on community health and wellness following the transition from construction to operations is anticipated to be reduced.
1501.1	round 1	Kitsumkalum First Nation	Section 6.3.5.4	Infrastructure and Services	Transport networks impacts. There is also a potential for an increase in vehicular accidents within the RAA given the route from the Northwest Regional Airport to Prince Rupert will be used by the Project	Section 6.3.6.5 includes consideration of cumulative effects on transportation infrastructure and services, including that related to roads and traffic (Highway 16 is specifically mentioned), within the RAA. However, due to numerous data gaps (i.e., vehicle traffic associated with all Projects and physical activities considered in the cumulative case [see Table 6.3-28]) a quantitative assessment of vehicular accidents is not provided. Rather, the potential for vehicular accidents is understood to increase in relation to increased traffic volumes. Residual cumulative effects on transportation infrastructure and services, which is understood to encompass potential motor vehicle accidents, is characterized as being high in magnitude, to occur throughout the RAA, are continuous and long-term in duration, reversible and occur within a moderately resilient socio-economic context (see Table 6.3-29 for a summary of residual cumulative effect characterizations). It is anticipated that if Aurora LNG determines that substantive Project-related traffic will start to utilize the Northwest Regional Airport (and associated Highway 16 to Prince Rupert) that a Project shuttle service will be considered to mitigate the potential increase in vehicle traffic (and potential accidents). This will be looked at in more detail in development of the Project Traffic Management Plan. Additional consideration of motor vehicle collisions is provided in Section 9.4 (Accidents and Malfunctions, subsection Motor Vehicle Collisions).
1502.1	round 1	Kitsumkalum First Nation	Section 6.3.5.4	Infrastructure and Services	Camp Policies - closed camp etc. is it legal to prevent people from leaving camp and terminate their employment if they do? Or if they use their own vehicle rather than the company transport?	Noted in Section 6.6.5.3 subsection 'Mitigation for Change in Community Health and Wellness' and similar sections of subsequent effects (as well as other social VCs), "the worker camp will be a closed-access camp, meaning that Project employees will be encouraged to remain onsite (See Section 1.2 Proposed Project Description). Failure to adhere to the camp policies will result in worker termination". As the owner of the work site including the camp, Aurora LNG will impose the appropriate management requirements for camp and transportation to align with the Social Management Plan and its mitigation measures.
1503.1	round 1	Kitsumkalum First Nation	Section 6.3.5.5	Infrastructure and Services	Health services impacts will extend to the RAA, in Terrace and will result in greater difficulty in accessing health services as has been documented in the literature - please refer to impacts documented in Fort McMurray and Gladstone. These impacts need to be monitored and adaptively managed collaboratively within the RAA.	As noted in Section 6.3.6.6 of the Application, it has been recognized that the baseline demand for health care infrastructure and services in the RAA is frequently not met and hospitals will not be able to accommodate additional demands created by a larger population without an increase in level of service. In particular, the availability of physicians in the RAA is lower than the provincial average and even a relatively small increase in demand could affect the quality of health care delivery in the area. With respect to Project residual effects on health care infrastructure and services within the LAA (which includes the Mills Memorial Hospital), through the Social Management Plan (mitigation 6.3.1) changes in demand will be monitored and mitigation measures adaptively managed to meet changing conditions. With respect to cumulative residual effects within the RAA, Aurora LNG will participate in government-led regional initiatives with respect to cumulative effects on community infrastructure and services, including health care infrastructure and services. It is expected that other projects that require regulatory approval will be subject to similar mitigation through the environmental assessment and permitting processes.
1504.1	round 1	Kitsumkalum First Nation	Table 6.3-27	Infrastructure and Services	All geographic extent effects are limited to the LAA, however all effects will extend beyond the RAA for the construction phase and the transition from construction to operations. This is a serious oversight in this summary of effects.	The LAA boundaries represent the spatial extent to which Project-related activities, change in population and employment and income could contribute to a direct, predictable and measurable adverse change in potential effects identified in Table 6.3-2 of the Application. The RAA boundaries capture an area that established context for the determination of significance of Project specific effects as well as encompasses the spatial extent where cumulative effects are most likely to occur. As discussed in Section 6.3.5 and summarized in Table 6.3-27, it is predicted that residual effects from the Project are limited to the LAA; however, cumulative residual effects are predicted to extend to the RAA (assessed in Section 6.3.6 and summarized in Table 6.3-29). Effects are predicted to extend into the RAA in the cumulative case as multiple LNG projects, pipelines, and other industrial developments proposed to be constructed in the RAA between 2015 and 2025 may result in rapid increase in in-migrating and temporary populations as non-local workers move into the communities. As such, the Project is predicted to have adverse residual effects on change in community infrastructure and services, accommodations, transportation infrastructure and services and health care infrastructure and services within the LAA but to contribute to cumulative residual effects within the RAA. Assessment methods established in Section 3 of the Application, in accordance with Section 3 of the AIR, do not require characterization of effects beyond the RAA.
1505.1	round 1	Kitsumkalum First Nation	Figure 6.3-16	Infrastructure and Services	RAA Populations estimates (note the axis label is incorrect). The assumptions to arrive at this increase in population from all the developments moving forward is grossly underestimated as only the direct jobs were used in the project alone population estimates methodology. The total influx of people from all the projects moving ahead at the same time must include direct and indirect jobs related to the developments and their families. It is more accurate to use other real examples of where projects have moved forward at the same time and what the population increase was and how effective their mitigation was. There are several scientific papers from Australia where multiple developments - mining and LNG - have resulted in population increases and cumulative social effects.	The mislabeling of the Y axis in Table 6.3-16 is acknowledged. The Y axis is incorrectly labeled as "LAA population" as opposed to "RAA population". An errata document is being created that will capture these corrections and it will be filed with the BC EAO. The commenter has incorrectly interpreted assessment methods and population modelling results. Discussed in Section 6.3.5.21, population modelling includes estimates of direct, indirect and induced population effects. Inclusive of these estimates are associated replacement effects (i.e., in-migrating workers filling vacated roles by current residents seeking employment with the Project) as well as effects associated with in-migrating spouses and dependents. Overall Project-related population effects are illustrated in Figure 6.3-14. With respect to Figure 6.3-16, Project-related changes in population (as noted above) are added to estimates of direct, indirect and induced population change associated with the Projects listed in Table 6.3-28. Therefore, Figure 6.3-16 also depicts estimates of direct, indirect, and induced (including replacement and family effects) population change. Regarding case-study analysis, Section 13.5 draws on numerous comparable case studies to that of the Project and provides a discussion of effects of population change on 'quality of life/community identity', 'social cohesion', 'private property values', and 'cost of living'.
1506.1	round 1	Kitsumkalum First Nation	Section 6.3.6.3	Infrastructure and Services	Cumulative Effects. This section in addition to all other sections in 6.3 acknowledges effects will extend to RAA, however mitigation is only proposed for LAA. This means those effects extending into RAA will not be mitigated or adaptively managed. This is a major concern for KKN.	Mitigation measures identified in Section 6.3.5 are proposed to avoid or reduce Project residual effects within the LAA and the Project's contribution to cumulative effects within the RAA. In addition to mitigation measures proposed in Section 6.3.5, Aurora LNG will also participate in government-led regional initiatives with respect to cumulative effects on community infrastructure and services at the regional level. (see Section 6.3.6).
1507.1	round 1	Kitsumkalum First Nation	Section 6.3.6.3	Infrastructure and Services	Cumulative Effects. The reason the effects are being assessed for cumulative effects is because post mitigation there are residual effects. Therefore the contribution to cumulative effects remain and must also be mitigated.	Mitigation identified in Tables 6.3-21, 6.3-22, 6.3-23 and 6.3-26 of the Application are predicted to reduce the Project's contribution to cumulative effects on change in community infrastructure and service. Given that cumulative effects may occur as a result of interactions with physical activities outside the control of the proponent, collaborative initiatives may be required among those responsible for other projects or physical activities as well as other third parties, including participation in government-led regional initiatives, may be required to reduce these cumulative effects.
1508.1	round 1	Kitsumkalum First Nation	Section 6.3.6.3	Infrastructure and Services	KKN are not satisfied with the mitigation proposed by PNW for social effects; comments provided to PNW are similar to comments provided here for Aurora LNG project.	Aurora LNG is confident that the suite of mitigation measures proposed as part of the Social Management Plan will effectively manage the predicted adverse residual effects on infrastructure and services.
1509.1	round 1	Kitsumkalum First Nation	Section 6.3.6.3	Infrastructure and Services	Page 6.3-89 last paragraph. Please clarify. On the one hand it is stated municipalities will be limited in terms of revenues realized from the project while on the other hand it is stated the economic development benefits will be long term. Unless there is concerted effort to diversify the economy before the end of construction the benefits will not last and the municipalities without revenues will be unable to improve their infrastructure or services in any of the phases, especially during operations.	The closing paragraph on page 6.3-89 of the Application refers to long term benefits to community infrastructure and services in the RAA associated with the Project and reasonably foreseeable major projects in or near the RAA that were selected to interact cumulatively with the Project (Section 6.3.6.1). Collectively, through tax revenue, service fees and other income sources generated by other projects and indirect and induced population effects associated with the Project, economic development is anticipated within the RAA, leading to long term beneficial effects on community infrastructure and services in the RAA. As discussed in Section 14.12, the Social Management Plan will be developed with regulators, Aboriginal Groups and concerned stakeholders. with the objective to outline mitigation measures to reduce or avoid Project-related economic and social effects.
1510.1	round 1	Kitsumkalum First Nation	Section 6.3.6.4	Infrastructure and Services	Cumulative Effects Mitigation for Accommodation. While Aurora LNG commits to participating in government led initiatives to manage cumulative effects, KKN would like to see LNG proponents advocate for such an initiative to ensure their contribution to cumulative effects are addressed. In addition, KKN suggest Aurora LNG commit to sharing and participating in monitoring programs to assess for effects over time.	Through the implementation of mitigation measures identified in Table 6.3-22, the Social Management Plan (mitigation 6.3.1) and in consideration of Project design (use of an on-site closed-access accommodation camp), the Project's contribution to cumulative effects is expected to be reduced. As noted in Section 6.3.64, since future projects requiring regulatory approval through the environmental assessment and permitting processes will be subject to similar mitigation requirements/expectations as that proposed by Aurora LNG, the contribution to cumulative effects within the RAA associated with these projects are also expected to be reduced. However, in recognition that cumulative effects could still occur, Aurora LNG has committed to participating in government-led regional initiatives with respect to cumulative effects on infrastructure and services, including accommodations. It is ultimately a government responsibility to coordinate such regional initiatives among a variety of proponents according to public policy.
1511.1	round 1	Kitsumkalum First Nation	Section 6.3.6.4	Infrastructure and Services	Residual cumulative effects. Temporary effects to housing costs needs to be defined and put into context. If several projects proceed temporary may mean 10 yrs. or more. For people who will be at risk of losing their home due to increased property taxes or increased rents a few months to one year of this increased cost will result in the need to relocate outside the region or become homeless. Terrace has seen homelessness double in two years due to the increased cost of housing (see Terrace and District Community Services homeless count), where 74% were aboriginal.	It is anticipated that Project-related population increase in the RAA will have an adverse effect on housing availability and affordability over the short term (residual effect restricted to the duration of the construction or decommissioning period or less; see Table 6.3-4 for residual effects characterization criteria). Over time, the housing market is expected to return to a supply/demand balance as housing and accommodations are influenced by market pressures. However, because of the increased population and level of economic activity, accommodation costs will likely be higher than at present. Therefore, as per Table 6.3-29, residual cumulative effects on infrastructure and service are predicted to be long term (residual effect extends through the operations phase). Cumulative effects on accommodations are determined to be significant (see Section 6.3.7.2).
1512.1	round 1	Kitsumkalum First Nation	Section 6.3.6.6	Infrastructure and Services	Health Services Cumulative Effects. While Aurora LNG commits to participating in government led initiatives to manage cumulative effects, KKN would like to see LNG proponents advocate for such an initiative to ensure their contribution to cumulative effects are addressed. In addition, KKN suggest Aurora LNG commit to sharing and participating in monitoring programs to assess for effects over time.	Through the implementation of mitigation measures identified in Table 6.3-26, the Social Management Plan (mitigation 6.3.1) and in consideration of Project design (use of an on-site closed-access accommodation camp with an on-site medical facility), the Project's contribution to cumulative effects is expected to be reduced. As noted in Section 6.3.6.6, since future projects requiring regulatory approval through the environmental assessment and permitting processes will be subject to similar mitigation requirements/expectations as that proposed by Aurora LNG, the contribution to cumulative effects within the RAA associated with these projects are also expected to be reduced. However, in recognition that cumulative effects could still occur, Aurora LNG has committed to participating in government-led regional initiatives with respect to cumulative effects on infrastructure and services, including health care infrastructure and services. It is ultimately a government responsibility to coordinate such regional initiatives among a variety of proponents according to public policy.
1513.1	round 1	Kitsumkalum First Nation	Section 6.3.7.1	Infrastructure and Services	Significance of Residual Project Effects. While economic benefits consider indirect effects in terms of tax revenue and other inputs to the economy, social effects are noted here to only address direct effects. Please explain why when indirect effects originate from project activities. Indirect effects due to the additional influx of people to support the project development are often greater in magnitude than the direct project effects and must be included in the overall assessment. In addition the RAA has not been characterized as being affected by the project because of the constraint of assessing the direct effects only.	Sections 5.2 (Economic Conditions), 6.3 (Infrastructure and Services) and 6.6 (Community Health) of the Application consider direct, indirect and induced population effects in the assessment of residual and cumulative residual effects. Population effects were modeled for the LAA and RAA using employment estimates provided in Section 5.2 (i.e., direct, indirect and induced employment) and modeled against baseline and forecasted population estimates from BCStats (see Section 6.3.3.2 subsection 'Population'). Workforce estimates were supplemented with estimates of population change related to replacement in-migration and family structures. Population estimates for the LAA and RAA are presented in Sections 6.3.5.2 and 6.3.6.4 respectively. Significance determinations provided in Section 6.3.7 for Project residual effects and cumulative residual effects account for direct, indirect and induced population change.

1514.1	round 1	Kitsumkalum First Nation	Section 6.3.7.2	Infrastructure and Services	Significance of Residual Cumulative Effects. As mentioned in previous comments the significance of cumulative effects is underestimated as it does not account for the indirect effects, i.e. the additional influx of people to support the development of the project.	Population modelling to support the assessment of change in community infrastructure and services included predicted effects on direct, indirect and induced population increases in both the LAA and RAA (see Section 6.3.5.2 and 6.3.6.4). Modeling included consideration of workers and their families. Modeled population effects inform the effect mechanism 'population change' which is a fundamental consideration in the assessment of change in accommodations, change in transportation infrastructure and services and change in health care infrastructure and services. Adverse effect characterizations for each residual effect assessment in Section 6.3 consider population effects with residual effects characterized accordingly. Similarly, significance definitions account for population change and therefore are not understated.
1515.1	round 1	Kitsumkalum First Nation	9 / page 6.4-86	Land and Resource Use	Under the hunting section, the proponent has seemingly missed the points that have now been brought forward made on several occasions. The first point is that there will likely be "no hunting zones" that are much larger than the project footprint. No firearm discharge areas will likely be 500m from the fence line of the project, substantially reducing hunting area on the island. The second is that the hunting pressures that will increase drastically in the region in general (not just wildlife management area 6-14). If this project proceeds, the local population will substantially grow. That population will want to hunt and fish the area, thus putting substantial pressure on the resources. We have experienced this with the BC-Hydro NTL powerline. and the Rio Tinto Expansion. Although camp workers were not allowed to have firearms and fishing rods in the camps, they would stay in the region on days off to hunt and fish. The project did not have the longevity that Aurora will and even still there was a notable decrease in wildlife populations. This point still does not seem to make it into the document. There is not much for mitigation that can seemingly be done, however it WILL be an environmental and social impact! this is glossed over on page 6.4-87. Perhaps wildlife improvement funds could be part of the mitigations?	No Hunting Zones Project residual effects assessed in Section 6.4.5.3 of the Application are characterized as extending into the LAA (the entirety of Digby Island; this area is inclusive of the PDA). As such, potential areas within the LAA beyond the PDA boundary that may be subject to additional setbacks from Project infrastructure, with respect to the discharge of firearms and bows, is accounted for in the assessment and accurately characterized. Hunting Pressures Non-Local Workers Most of the non-resident construction labour force will work on a fly-in/fly-out (FIFO) basis and will be accommodated at the Project's closed-access camp (meaning that workers will be expected to stay at the camp for the duration of their shift unless they must leave for work-related purposes). Combined with logistics planning that will require workers to be transported from the Project site to their community of hire following the completion of shifts and mitigation measures restricting the storage of hunting and fishing gear on-site (mitigation 4.8.11) and from engaging in recreational and commercial fishing on Digby Island, increases in hunting and fishing demand from FIFO construction workers are expected to be negligible. When present in local communities, adverse effects on hunting and fishing (i.e., increased pressure from Project-workers) from non-local workers will be further minimized through the Worker Code of Conduct and worker orientation (mitigation 6.3.3) which will communicate expectations for respectful conduct (e.g., expectations regarding engagement in hunting and fishing activities). In addition, Aurora LNG will develop and implement a Community Engagement Plan (mitigation 6.3.4) to facilitate ongoing and meaningful community engagement including monitoring, recording, and will provide a framework from which to address community complaints and concerns (mitigation 6.4.3 - community Process). In-migrating Workers It is assumed that a small proportion of the overall Project labour force may choose to relocate to the LAA. In-migrating workers have the potential to increase competition for resources within the LAA and RAA. To address potential concerns related to increased pressure on hunting and fishing due to Project-related population change, Aurora LNG will develop and implement a Community Engagement Plan (mitigation 6.3.4) to facilitate ongoing and meaningful community engagement including monitoring, recording, and will provide a framework from which to address community complaints and concerns (mitigation 6.4.3 - community Process). Wildlife Improvement Funds Mitigation measures proposed in Section 4 (Environmental Effects) of the Application such as the Wetland Compensation Plan (mitigation 4.6.12), Wildlife Management Plan (mitigation 4.7.16), Environmental Management Plan (mitigation 4.7.21), and Fish Habitat Offsetting Plan will avoid, reduce, or offset predicted adverse effects on wildlife. Additional mitigation beyond that provided in the Application (see Section 16 for a summary) is not currently proposed.
1516.1	round 1	Kitsumkalum First Nation	6.4.3.3	Land and Resource Use	Page 6.4-13 "Part 2 of the GBR LUO sets out objectives for the North Coast Area, within which the RAA is located. Objectives include the protection of Aboriginal features, important aquatic habitats, rare plants and important wildlife habitat. Within the RAA, there are three important areas identified in the Order; including grizzly bear habitat, important fisheries watersheds, and cedar stewardship areas (Government of BC 2016a)." Although the proponent has gone through Archaeology branch for working in and around heritage sites, Kitsumkalum has not been allowed by the proponent to be on site while studies and works surrounding our aboriginal, traditional features have been undertaken. and the fact that the midden and archaeological sites are not mentioned here seems odd and suspect.	Aboriginal Heritage Features (including shell middens) are objectives under the Great Bear Rainforest LUO and are present in the RAA. An errata document is being created that will capture this clarification and it will be filed with the BC EAO. Please refer to the "Aurora LNG's Approach to Consultation with Aboriginal Groups" technical memo for information regarding the field programs conducted for the project. This memo will be filed with the BC EAO. Aurora LNG endeavoured to identify and create opportunities where it could involve Aboriginal Groups in field work. As part of this process, Aurora LNG has prioritized the involvement of those Aboriginal Groups located in closest proximity to the location of the Project on the basis that these Aboriginal Groups have a higher likelihood of being effected by any potential effects associated with the Project. Due to logistical and operational limitations associated with field operations, Aurora LNG has had to limit participation by Aboriginal Groups further removed from the location of the Project including Kitsumkalum First Nation.
1517.1	round 1	Kitsumkalum First Nation	Page 6.4-14	Land and Resource Use	Refers to a private lot owned by Aurora LNG Joint Venture Partners. Who is the JV partner? Is this the IGBC referred to on 6.4-24? What does IGBC stand for? and where is the parcel of land?	Aurora LNG Joint Venture Partners include Nexen and INPEX Gas British Columbia Ltd. (IGBC). As shown on Figure 6.4-6, the noted private lot is located along Casey Cove near Charles Point.
1518.1	round 1	Kitsumkalum First Nation	Table 6.4-16	Land and Resource Use	4.2.5 should use air curtain burners for open burning on site. They reduce emissions, ash and fire escapement risk.	As discussed in Section 4.2.5 of the Application, the Project will avoid burning of biomass and accumulated waste material from the construction camp or postpone burning to meteorologically-suitable days. This mitigation measure reflects industry standards and regulatory requirements for open burning (Open Burning Smoke Control Regulation), and has been proven to be an effective measure to reduce open burning air emissions and to reduce effects on local air quality. Aurora LNG acknowledges that Air Curtain burners can be suitable for specific situations and will consider the use of Air Curtain burners during the FEED process and during the land clearing procurement process.
1519.1	round 1	Kitsumkalum First Nation	6.5.4.2	Marine Use and Navigable Waters	The Application determined that wake waves generated by LNG carriers and escort tugs are not likely to cause adverse effects on Aboriginal and commercial marine harvest. This was determined based upon a report produced for LNG Canada that predicted that wake generated by LNG carriers and escort tugs travelling at 12 knots will be less than 0.4 m high (at the source vessel), which is within the size range of naturally occurring waves in the region. They provide an example that wave height in Douglas Channel experiences a maximum height was 3.4 m with an averaged 0.14 m. The Application then screens out vessel wake in the assessment because it is expected that mariners and shoreline harvesters will be accustomed to dealing with project-related wake waves. While the magnitude vessel wake waves maybe well within the range of normal wave conditions, the predicted wave conditions are not provided for Chatham Sound.	Environment Canada and Fisheries and Oceans Canada monitor 17 buoys that record weather data. However, none of the buoys are located in Chatham Sound. Of these buoys, two were used in Section 6.5.4.2 to represent the potential range of wave heights experienced in the Project area. The South Hecate Strait buoyis located in relatively deep water (approximately 228 m) in an exposed area with high fetch, where Hecate Strait meets Queen Charlotte Sound. The mean monthly average wave height recorded at this buoy is 1.8 m, while the historical maximum is 13.7 m. The Nanakwa Shoal buoy, in Douglas Channel, is located in relatively shallow water (approximately 22 m) in a confined area with less potential for east-west fetch. Mean monthly average wave height at this buoy is 0.14 m and the historical maximum is 3.4 m. Specific wave height information for Chatham Sound is not available through the buoy monitoring system noted above. However, the weather buoy in South Hecate Strait is relatively more exposed than Chatham Sound, while the Douglas Channel buoy is in a much more confined location. The exposure and fetch of Chatham Sound are less than the area of the South Hecate Strait buoy, yet greater than the Douglas Channel buoy location. It is therefore reasonable to assume that average wave height experienced in Chatham Sound will fall somewhere between that seen at South Hecate Strait and that seen in Douglas Channel. The assessment in Section 6.5.4.2 states that a wave height range of 0.14 m and 1.8 m is assumed to be the average natural wave height typically observed in the Project area.
1520.1	round 1	Kitsumkalum First Nation	6.5.4.2	Marine Use and Navigable Waters	The assessment does not consider wave frequency or timing. Increased wave frequency could increase the likelihood of shoreline and intertidal erosion, thus impacting habitat for intertidal species (i.e., harvested invertebrates and algal species). Where the timing of waves and intertidal harvesting overlap, vessel wake can have a detrimental disturbance effect on harvesting practices as harvesters must accommodate for vessel wake. In addition, there has been no tanker wave study and wake wash impact assessment conducted in the Application. A more sophisticated analysis (magnitude, frequency, timing) is required to reduce uncertainties in the assessment, and provide a more rigorous framework for comparison with both the ambient storm wave climate and the wake associated with shipping traffic. Therefore, it is premature to conclude that there will be no adverse effects on shoreline/intertidal habitats and intertidal harvesting, much less to conclude that there is no pathway for effects to occur as was done in the Application.	Potential changes to marine fish habitat resulting from vessel wake generated by Project-related vessels are discussed under the 'change in habitat' effect (Section 4.9.5.2, Marine Fish and Fish Habitat). Based on the results of the assessment, wake effects resulting from vessels associated with the Project are not expected to adversely affect marine fish habitat. Therefore, wake effects were not considered further within the Marine Fish and Fish Habitat assessment. If it is conservatively assumed that intertidal harvesters working on shore are using both low tide periods in a day (this is unlikely, as the two low tides in a day are not often the same tidal height and, therefore, one is more suitable for harvesting than the other), and harvesting can be undertaken for two hours during each low tide (i.e., one hour on each side of each low), then approximately 17% (4/24 hours) of each day is available for intertidal harvesting. The potential for intertidal harvesters to interact with Project-related shipping effects is temporally restricted on a daily basis. For approximately 83% of each day, wake from Project-related shipping will not interact with intertidal harvesters Section 6.5.4.2 of the Application describes that the mean monthly average natural wave height in the area is assumed to be between 0.14 m and 1.8 m. The potential maximum wave height (immediately adjacent to the source vessel) of 0.4 m, produced by LNG carriers and escort vessels at 12 knots, is within the range of the mean monthly average wave height in the Project area. The modeled wake height of LNG carriers (and other vessel types) indicates that wake-related waves attenuate as they travel further from the source vessel (Oceanic Consulting Corporation 2014). This means that the actual wave height when it reaches the shoreline is lower than the wake height at the source vessel, and well within the natural wave height range currently experienced by shoreline harvesters. Additional large vessel traffic may alter the frequency of vessel generated wake but this is not expected to measurably change the wave activity in the area. Moreover, Project-related vessels will travel along the existing and established shipping route currently used by larger marine traffic (e.g., container ships, cargo ships, breakbulk ships, ferries) to enter and exit Prince Rupert harbour. The predicted wake-related wave height 300 m from the centreline of travel of a large, loaded LNG carrier traveling 12 knots (and that modeled for 14 knots) is similar to those predicted for ore carriers, cruise ships, and BC Ferries vessels (Oceanic Consulting Corporation 2014), all of which call at the Port of Prince Rupert. Project-related wake effects are not expected to differ from the variable wave heights and conditions already experienced by shoreline harvesters, relating to natural weather patterns and large vessel traffic. Reference: Oceanic Consulting Corporation. 2014. Kitimat Ship Wake Study. Prepared for: LNG Canada Development Inc.
1521.1	round 1	Kitsumkalum First Nation	6.5.2.1	Marine Use and Navigable Waters	The environmental and economic consequences of species invasions are well known in the US and Canada. However, the Application does not discuss any potential for the introduction of invasive species into the LAA and RAA. The Application does mention that the Canadian Shipping Act and the associated Ballast Water Control and Management Regulations (BWCMR) exist, but there was no formal assessment. The regulations require tankers to exchange ballast at least 50 nautical miles west of Haida Gwaii or Vancouver Island. These areas are quite far offshore so unless there is noncompliance with the regulations, this measure should reduce the likelihood of introduction of invasive species. However, the BWCMR only require a 95% exchange rate of ballast so that 100% elimination of the potential for the introduction of exotics is not required nor mentioned in the Application. In addition, the effectiveness of mid-ocean ballast exchange depends entirely on compliance and the method of ballast treatment. Pui Gwun Lo (2009) pointed out several caveats regarding the effectiveness of mid-ocean ballast exchange. Hull fouling is another means for invasive species to be introduced into the LAA and RAA. Hull fouling involves organisms such as barnacles or mussels attaching themselves to ship hulls and either encountering structures in a new port or releasing larvae into the water. Therefore, invasive species should have been discussed and assessed in the Application.	Sections 6.5.2.1 and 6.5.6.4 of the Application identify the legislation and regulations pertaining to the control and management of ballast water. As per Mitigation Measure No. 4.5.7 (Section 4.5.15.3, Table 4.5-26, of the Water Quality assessment), vessels transiting to and from the Aurora LNG marine terminal will adhere to the Vessel Pollution and Dangerous Chemicals Regulations and the Ballast Water Control and Management Regulations under the Canada Shipping Act (2001). The Ballast Water Control and Management Regulations are aimed at avoiding the introduction of invasive species to local waters, and outline a number of mandatory ballast water management procedures related to ballast water management plans, ballast water exchange and treatment, reporting requirements, compliance and enforcement, and research. Project-related international shipping will be required to adhere to these regulations. The Prince Rupert Port Authority (PRPA) is a standing member of the Green Marine Program, which encourages international ship owners to implement anti-fouling measures to reduce the risk of aquatic invasive species introductions from hull-attached organisms. The PRPA also monitors the potential establishment of invasive species as part of the Plate Watch program. To date, no aquatic invasive species have been documented in the Prince Rupert harbour as part of this program. Because the above identified mandatory management procedures for preventing the introduction of aquatic invasive species are well established and effective, a separate assessment of invasive species is not warranted.
1522.1	round 1	Kitsumkalum First Nation	6.5	Marine Use and Navigable Waters	Assessing only what is known as the "Primary Route" from Triple Island through Chatham Sound is inappropriate, regardless of the "frequency of use". All in/out bound shipping routes have the potential to be used by the Aurora LNG project ships and should be assess as so. Kitsumkalum disagrees that the effects of the two secondary routes is the same as for the primary (e.g. effects to the breeding colonies of birds at Lucy Island).	The assessment of Marine Use and Navigable Waters was done using the primary shipping route. This choice was conservative because it represents the route that most shipping traffic is expected to use and therefore has the greatest potential for adverse effects to marine navigation and fisheries. As described in Section 6.5.2, while alternative shipping routes exist, LNG carriers should only deviate from the prescribed route under unusual circumstances (e.g., such as under the direction of the LNG carrier captain or marine pilot to avoid a collision or other emergency). As a result, the assessment focused on the primary shipping route.
1523.1	round 1	Kitsumkalum First Nation	6.5 (Figure 6.5-2)	Marine Use and Navigable Waters	how was the "small vessel route" (especially on the west side of the channel) rationalized? What is the characterization of "small vessel"? It is our understanding that proponent had very little in the way of small vessel traffic information (baseline) ("While no reliable marine data were available to quantify these vessel movements in a systematically and spatially relevant way, common boating routes and other relevant marine features (e.g., marine parks and marinas) are discussed in Recreation and Tourism (see Section 6.5.3.2)"; therefore, clarity is needed to understand the effects to "small vessel" traffic (which would generally represent Aboriginal travel marine use). Characterization of residual effects is currently inappropriate with out this assessment.	See the "Small Craft Assessment" technical memo which will be filed with the BC EAO.
1524.1	round 1	Kitsumkalum First Nation	6.5	Marine Use and Navigable Waters	The summary of key concerns associated with the assessment of Marine Use and Navigable Waters (and within the potential effects) does not assess the effects to marine use (and Aboriginal rights) from perceived changes to marine safety.	The key concerns used to help develop the assessment of Marine Use and Navigable Waters were devised through engagement with Aboriginal Groups, as described in Section 6.5.2.2. Table 6.5-2 describes the key concerns scoped into the assessment as a result of this consultation; Table 6.5-13 and Table 6.5-14 outline the mitigation measures proposed to address Project-related impacts to marine use. The assessment of effects on Kitsumkalum First Nation's harvesting-related Aboriginal Interests (Section 12.5.7.6), cultural wellbeing (Section 12.5.7.7), use of trails and travelways (Section 12.5.7.11), and current use of lands and resources for traditional purposes (Section 11.3.10.3) found that marine safety and access to traditional use sites will be maintained with the implementation of mitigation measures. As described in Section 6.5.3.3 of the Application, Aurora LNG will develop a Marine Activities Plan (Mitigation 6.5.2) to describe how the Project's marine activities will be managed to avoid or reduce effects on current marine users and other stakeholders. Aurora LNG will engage with regulatory agencies, Aboriginal Groups, marine users, and other interested stakeholders in the development of this plan. Additional input to the planning process will result from the safe-shipping workshops and the recommendations from the TERMPOL study.

1525.1	round 1	Kitsumkalum First Nation	6.5 (Table 6.5-5)	Marine Use and Navigable Waters	In order to characterize "magnitude" of effects to marine use and navigable waters there must be some threshold established (especially since the measurable parameters are quantitative in nature), a "measurable change" is not sufficient to appropriately characterize residual effects.. These thresholds should be decided in consultation with regulatory agencies and affected Aboriginal groups.	The thresholds used for the characterization of significant adverse effects on Marine Use and Navigable Waters were developed because there were no established or existing federal, provincial, municipal, or industryquantitative benchmarks for Marine Use and Navigable Waters. The threshold was not quantitative but was based on knowledge of the baseline conditions for Marine Use and Navigable Waters, the potential Project effects, and concerns identified by stakeholders. The threshold provides a reasonable cut off point above which the potential Project effects are predicted to become significant. A determination of significant residual effects for Marine Use and Navigable Waters is one where the proposed Project activities are not compatible with established marine use plans or policies, or where the Project will create a change or disruption that widely restricts or degrades present marine uses to a point where the activities cannot continue at current levels and for which this change cannot be mitigated (see Section 6.5.2.8). Key elements of this threshold are explained further:"Not compatible" indicates that the Project completely eliminates the option to practice a marine activity."change or disruption that widely restricts or degrades present marine use" indicates that the potential Project effect has a large geographical extent or severely reduces the ability to practice a marine activity relative to the existing conditions."Cannot continue at current levels and for which this cannot be mitigated" indicates that the current marine practices cannot continue even with mitigation. The assessment used extensive data, including: literature, government reports, other Environmental Assessment Applications from similar projects in the regions, and Traditional Use and Knowledge studies (however, issues specific to Aboriginal Groups were assessed in Part C of the Application). Data were obtained from Fisheries and Oceans Canada (DFO), the Pacific Pilotage Authority (PPA), the British Columbia Marine Conservation Analysis (BCMCA) online database (see Section 6.5.3 for more information on the information sources, and the technical memo: "Effects of Lost Fishing Time" for further assessment of marine fisheries). This technical memo will be filed with the BC EAO. The assessment made conservative assumptions to improve prediction confidence. Discussions of the assumptions made and prediction confidence are provided in Sections 6.5.5.1 and 6.5.8, respectively. Overall, Aurora LNG is confident in their understanding of the baseline conditions, the assumptions made, and the conclusion of no significant adverse effects on Marine Use and Navigable Waters.
1526.1	round 1	Kitsumkalum First Nation	6.5	Marine Use and Navigable Waters	A commitment to develop a Marine Activities Management Plan is insufficient. Management plans must be presented in sufficient detail at this stage to provide a comprehensive sense of mitigations and commitments. These elements need to be in place to inform the assessment process.	As described in Section 6.5.3.3 of the Application (and further detailed in Section 14.11), Aurora LNG will develop a Marine Activities Plan (Mitigation 6.5.2) to describe how the Project's marine activities will be managed to avoid or reduce effects on current marine users and other stakeholders. Aurora LNG proposes to develop this plan in consultation with regulatory agencies, Aboriginal Groups, marine users, and other interested stakeholders. The safe-shipping workshops, TERMPOL study, and participation on the Prince Rupert Port Authorities' Marine Construction and Coordination Committee are expected to lead to recommendations regarding such issues as ship design/operation, terminal design, navigational routes, risks and accident avoidance, and pollution prevention). Additional information on the nature of the Marine Activities Plan will be shared as the plan is developed. The level of detail provided in Section 14.11 aligns with that provided for applications of similar scope within northwest BC and meets the requirements of the AIR.
1527.1	round 1	Kitsumkalum First Nation	6.5 (page 6.5-38)	Marine Use and Navigable Waters	"Kitsumkalum First Nation harvests marine resources according to a system where specific resource harvesting locations (e.g. stretches of beach, kelp beds) are owned by house groups; only house group members are allowed to harvest from harvesting locations they own (Kitsumkalum First Nation and Crossroads 2016; LNG Canada 2014). It is reported that Flora Bank and Horsey Banks (near Lelu Island) are important fishing and marine harvesting locations, as well as a number of freshwater systems nearby. Kitsumkalum First Nation members generally do not target eulachon as a result of declining stocks and suspected contamination in local spawning populations. Fish species harvested by Kitsumkalum include halibut, various species of salmon, steelhead, red snapper, herring and herring eggs, eulachon, abalone, crab, mussels, clams, cockles, sea cucumber, sea prune, and seaweed/kelp (Kitsumkalum First Nation and Crossroads 2016; Kitsumkalum Indian Band 2014; LNG Canada 2014; Kitsumkalum First Nation nd)." There is erroneous information presented in this statement in the Application. If this information is considered as baseline for consideration of effects to Kitsumkalum from changes to marine use and navigable waters then there is an issue.	Aurora LNG apologizes for the misleading statement and has included it in the erratum to be submitted to the BC EAO. This statement is misleading because it generalizes information that is relevant to only a few eulachon fishing sites and applies it to the broader understanding of Kitsumkalum's eulachon fishing practices. Consequently, the statement: "Kitsumkalum First Nation members generally do not target eulachon as a result of declining stocks and suspected contamination in local spawning populations.", will be removed from the Application. As described in the report by Kitsumkalum First Nation and Crossroads (2016), eulachon are important for dietary, social, and cultural reasons. In particular, eulachon are rendered down to make highly valued eulachon grease that is eaten and traded. Monitoring eulachon populations and restoring their habitat is of the utmost importance for the Kitsumkalum not only for cultural reasons but also because they are an endangered species (Kitsumkalum First Nation and Crossroads 2016). This errata will not alter the effects determination for marine fisheries. That is, the conclusions in the Application remain the same, and no significant adverse effects are predicted on marine fisheries.
1528.1	round 1	Kitsumkalum First Nation	6.5	Marine Use and Navigable Waters	Because of the scale of the figures throughout the assessment of effects to marine use and navigable waters is not clear the overlap of many of the marine uses and the Casey cove area. Nor is it clear the combined effects (to marine use and navigable waters) here from the pioneer dock, MOF construction and operations, temporary floating work camp and intake and effluent pipes (on sea bed). One would assume that no access will be allowed in Casey cove once project activities (construction and through operations) start, but the assessment and significance of this have not been made clear in the Application.	The figures produced in Section 6.5 of the Application used a geographical scale relevant to the features it was designed to show. Additional details regarding marine construction and access will be determined during the permitting phase through Transport Canada with input provided from the proposed safe shipping workshops and TERMPOL study.
1529.1	round 1	Kitsumkalum First Nation	6.5	Marine Use and Navigable Waters	Kitsumkalum disagrees with the removal of the turning basins from the quantification of project effects. Regardless of duration marine use and navigation will be restricted while ships conduct berthing operations (within the turning basin).	The assessment of Marine Navigation considered the Project footprint, safety zones, and turning zones. However, the two turning basins (one associated with each berth) were not included in the areal calculations because they involve areas that will be used only temporarily during docking as opposed to areas within which navigation will be permanently restricted (i.e. the permanent infrastructure and control zones). During use of the turning basins, all national and international maritime rules and regulations apply, in addition to those set forth by the Prince Rupert Port Authority (PRPA). Turning and docking will make use of four tugs and take approximately 0.5 hours. The PRPA and Pacific Pilotage Authority (PPA) will continue to coordinate large commercial shipping traffic so that turning and docking processes do not interfere with each other, or pose a safety concern (i.e., at present, large shipping traffic do not pass each other in the inner harbour). The PRPA and PPA work collaboratively to design and implement safe turning and docking procedures for use in Prince Rupert Harbour. In most cases, these agencies work with proponents to develop recommendations that are specific for the vessel and the marine terminal. Sophisticated marine simulators are often used to determine what docking scenarios (e.g., location for turning, and number and power of tugs to be used) are best suited to the terminal and vessels involved. Scenarios are tested under various environmental conditions (see Section 6.5.3.2 for further details).
1530.1	round 1	Kitsumkalum First Nation	6.5	Marine Use and Navigable Waters	Kitsumkalum disagrees with the assumption:"The assessment focuses on potential effects of LNG carriers, rather than smaller marine vessels associated with the Project (e.g. tugs). Similarly, the cumulative effects assessment does not include current levels of small vessel transits, which would have made the contribution of the Project to overall shipping traffic appear much less. Large vessels are less maneuverable and require more space and time to make course changes, making them more likely to interfere with the VC compared to other Project-related traffic. For more information on why construction traffic was not included, see Section 6.5.3.2," as the transits across the channel from pilot vessels and tugs (as it is not clear where operational tugs will be housed) will affect marine use and navigation. The characterization of effects is insufficient without consideration of shipping traffic (barges and tugs from construction , tugs transits, pilot vessel transits (attributable to the project)	See the "Effects of Additional Project-related Traffic" technical memo which will be filed with the BC EAO.
1531.1	round 1	Kitsumkalum First Nation	6.5 (Table 6.5-13)	Marine Use and Navigable Waters	How is it that every other project within the PRPA boundary has stipulated (as mitigation) participation on the PRPA's Marine Construction Coordination Committee, but the proponent has not mentioned this as mitigation for effects to Marine Use and Navigable Waters? Nor is there commitment to a Marine Traffic Management Plan? None of the 4 listed mitigation measures are deemed appropriate by Kitsumkalum to avoid or offset adverse effects to Marine Use and Navigable Waters.	As described in Section 6.5.3.3 of the Application, Aurora LNG will develop a Marine Activities Plan (Mitigation 6.5.2) to describe how the Project's marine activities will be managed to avoid or minimize effects on current marine users and other stakeholders. Aurora LNG proposes to develop this plan in consultation with regulatory agencies, Aboriginal Groups, marine users, and other interested stakeholders. It is expected that the safe-shipping workshops, TERMPOL study, and Aurora LNG's participation on the Prince Rupert Port Authorities' Marine Construction and Coordination Committee will lead to additional mitigation measures related to ship design/operation, terminal design, navigational routes, and pollution prevention. Additional information on the nature of the Marine Activities Plan will be shared as the plan is developed.
1532.1	round 1	Kitsumkalum First Nation	6.5	Marine Use and Navigable Waters	The Characterization of residual effects for changes in navigation is misleading. Presenting % of area lost for navigation due to project footprint does not represent the significance of the loss of a t travel route for used for traditional or current uses. If it is the only route used by a community then it represents a 100% loss.	Aurora LNG maintains that, with implementation of the proposed mitigation measures, navigational routes around the marine terminal and into the Port of Prince Rupert will be maintained. The area where the physical structures of the Project will be built will be unavailable for marine navigation, however, the marine terminal will be built close to shore and out of the main navigation channel. As such, it is expected that mariners will be able to navigate around the marine terminal with reasonable ease. The marine terminal will be clearly marked with all appropriate navigational aids. Also, see the "Small Craft Assessment" technical memo which will be filed with the BC EAO.
1533.1	round 1	Kitsumkalum First Nation	6.5	Marine Use and Navigable Waters	Kitsumkalum disagrees with the characterization of residual effects for change in marine fisheries and other uses (salmon fishing specifically) as it is not clear what percentage of salmon fishing time is lost compared to days open for commercial (aboriginal) salmon fishing due to operational LNG traffic and berthing in the LAA. (same could be asked for the characterization of the other fisheries)	See the "Effects of Lost Fishing Time" technical memo which will be filed with the BC EAO.
1534.1	round 1	Kitsumkalum First Nation	6.5	Marine Use and Navigable Waters	Confidence is low in the assessment of residual and cumulative effects to marine use and navigable waters, at minimum the proponent should commit to follow-up programs and monitoring to ensure validity of predictions in the EA.	At present, follow-up monitoring plans are not proposed; however, Aurora LNG is committed to working with regulators and Aboriginal Groups to develop the Marine Activities Plan which could include potential follow-up programs. As described in Section 6.5.3.3 and 14.11 of the Application, Aurora LNG will develop a Marine Activities Plan (Mitigation 6.5.2) to describe how the Project's marine activities will be managed to avoid or reduce effects on current marine users and other stakeholders. Aurora LNG proposes to develop this plan in consultation with regulatory agencies, Aboriginal Groups, marine users, and other interested stakeholders. Safe-shipping workshops and the TERMPOL study are expected to lead to recommendations regarding such issues as ship design/operation, terminal design, navigational routes, risks and accident avoidance, and pollution prevention.More information on the nature of the Marine Activities Plan will be shared as it becomes available.
1535.1	round 1	Kitsumkalum First Nation	Table 6.6-4	Community Health	Administrative Boundaries - should include Kitsumkalum Territory.	The local assessment area (LAA) for Community Health reflects the spatial extent to which Project-related change in population and employment and income could contribute to a direct, predictable, and measurable adverse change in community health and wellness or change in availability of harvested foods. Potential effects on Kitsumkalum are captured within the LAA for potential effects on change in harvested foods, and the regional assessment area (RAA) for change in community health and wellness and change in harvested foods. Administrative boundaries include spatially-defined limits of municipalities, regional districts and health authorities as well as fish and wildlife management areas. The description of existing conditions, both within the LAA and RAA, is largely constrained by administrative boundaries.Administrative boundaries do not include the extent of First Nation territories.
1536.1	round 1	Kitsumkalum First Nation	Section 6.6.2.5	Community Health	Technical Boundaries - although it is difficult to predict the magnitude of potential effects, a commitment to monitoring with established thresholds of impacts to community health could be implemented.	Regarding community health monitoring, while not specifically identified as a proposed mitigation measure, mitigation measures identified in Table 6.6-18 are included in higher-level plans (e.g., the Health and Medical Services Plan, and Social Management Plan) which include varying levels of monitoring. These higher-level plans are identified in Table 6.6-18 under the column 'Management and/or Compensation Plans' with additional information provided in Section 14.
1537.1	round 1	Kitsumkalum First Nation	Section 6.6.2.8	Community Health	Significance of Thresholds for Residual Effects. The words "distinguishable" and "persistent and substantial" need to be defined as they are open to interpretation.	"Distinguishable" means that the adverse effect is measurable, predictable, and attributable to one or more project or cumulative interactions (i.e., it is not within the boundaries of normal variation of the measurable parameter under baseline conditions). "Persistent" refers to effects that exist for a long period of time; in this instance, beyond Project activities. "Substantial"refers to a high magnitude measurable change from baseline conditions.
1538.1	round 1	Kitsumkalum First Nation	Page 6.6-16	Community Health	The sub-index data provided show the people living in the region are extremely vulnerable to impacts to community health. This emphasizes the need for mitigation by the governments and by the proponents collaboratively of all projects to manage socioeconomic effects from large resource developments.	Mitigation described in Tables 6.6-18 and 6.6-21 of the Application will reduce the Project's contribution to cumulative effects on change in health and wellness. Other projects will also likely be subject to similar mitigation through the environmental assessment and permitting process which also would be expected to reduce each project's contribution to cumulative effects. Aurora LNG has committed to participating in provincial and/or regional led initiatives to further reduce cumulative adverse effects on community health and wellness.
1539.1	round 1	Kitsumkalum First Nation	Page 6.6-49	Community Health	The reasons given for focusing only on communities included in the LAA for the assessment of change in community health and wellness are not sufficient. People in the RAA are vulnerable and will be affected.	For the assessment of change in community health and wellness, as noted in Table 6.6-3 of the Application:The LAA reflects the spatial extent to which Project-related physical works and activities could affect the change in community health and wellness.RAA captures an area that establishes context for the determination of significance of Project specific residual effects as well as encompasses the spatial extent where cumulative effects are most likely to occur.These spatial boundaries align with those established in the AIR (see Section 3.3 and 6.6 of the AIR). Section 6.6.5.2 assesses residual effects on community health and wellness within the LAA (noting the potential for vulnerable populations to be disproportionately affected) while Section 6.6.6.3 assesses cumulative residual effects on community health and wellness within the RAA (noting the potential for vulnerable populations to be disproportionately affected).
1540.1	round 1	Kitsumkalum First Nation	Table 6.6-18	Community Health	There is no mitigation to address any of the potential effects to community health from the increased cost of housing resulting in increased homelessness and there is no firm commitment to hiring Aboriginal Peoples to offset these impacts. A Local Content plan is needed with commitments for Nexen to facilitate the hiring of Aboriginal Peoples. For example a commitment could be made to include in its contracts with suppliers (and their subcontractors) that the contractors and subcontractors must hire Aboriginal Peoples first who live within the region. In addition, an Accommodation Plan is needed to address non camp related accommodation issues as there will be impacts to vacancy rates that will drive up the cost of housing. The mitigation measures currently proposed will not address negative impacts to vulnerable people.	The assessment of change in accommodations is provided in Section 6.3 (Infrastructure and Services) with addition of cost of living addressed in Section 13.5.4. Aurora LNG proposes to implement mitigation measures to increase local content (mitigation 5.2.1, 5.2.2, and 5.2.5) and reduce Project-related demand on accommodations (mitigation 6.3.10). Aurora LNG is confident that, when combined with accommodation policies (i.e., the closed-access camp, Project controlled logistics for FIFO workers), mitigation measures to address adverse effects on community health and wellness (not limited to the Social Management Plan [mitigation 6.3.1], Community Engagement Plan [mitigation 6.3.4] and Worker Lodging Plan [Mitigation 6.3.10]) adverse effects on community health and wellness due to changes in accommodations will be effectively managed. Aurora LNG acknowledges that vulnerable populations may disproportionately realize higher magnitude effects than the average LAA and RAA population (as discussed throughout Section 6.6). Commitments or targets to hire Aboriginal persons is currently not proposed. Aurora LNG is an equal opportunity employer and will consider all qualified persons for Project-related employment.

1541.1	round 1	Kitsumkalum First Nation	Page 6.6-68	Community Health	Income and Social Status. It is difficult to ascertain how unemployed or vulnerable populations will be able to secure employment with mitigation measures proposed in this EA. There are no firm commitments to assist these groups in obtaining and maintaining employment but only information providing and engagement. Contractors and sub-contractors will be free to hire who they wish likely to be people from outside the region who have worked on other projects with the companies who win the contracts. It is very difficult to compete with people who have this advantage of training, experience and personal connection and history with the contractors and subcontractors and also unions.	Aurora LNG will inform local residents and Aboriginal Groups of jobs and procurement opportunities in advance of and during Project phases as well as develop work packages that consider the capacity and capabilities of local and regional businesses (mitigation 5.2.1). This mitigation is anticipated to increase local content and enhance beneficial effects of the proposed Project on local communities. Aurora LNG acknowledges that should individuals choose not to work for the proposed Project or have insufficient skills or education, the ability of the proposed Project to employ local workers is lowered. Aurora LNG will identify specific skill requirements and potential shortages of workers in those skill sets, and work with training and education facilities to identify and implement suitable training programs. Aurora LNG will work with Aboriginal Groups, and local communities to increase opportunities for Aboriginal and local community members to obtain the training required for Project participation (mitigation 5.2.5). Aurora LNG further recognizes, as assessed in Section 6.6.5.3 (subsection 'Income and Social Status'), despite mitigation, not all unemployed and vulnerable populations who seek employment during Project construction and operations will be successful in securing work (direct, indirect, and induced).
1542.1	round 1	Kitsumkalum First Nation	Section 6.6	Community Health	Impacts to Community Health General. The EA has provided good baseline and good characterization of the impacts (with the exception of sometimes not including the Terrace area and the Kitsumkalum people, however falls short of providing effective mitigation to minimize effects so that they can be deemed Not Significant.	Aurora LNG is confident that the suite of mitigation measures proposed in Table 6.6-18 (50 referenced mitigation measures) and Table 6.6-21 (108 referenced mitigation measures) will effectively manage adverse residual effects on community health.
1543.1	round 1	Kitsumkalum First Nation	Section 6.6	Community Health	Summary - for the small amount of local and regional employment as identified in the Economic Section of the EA (appears to be a low number inclusive of indirect and induced jobs) the benefits to community health due to increased family income would apply to a small number of people especially considering the short term of employment as the types of trades needed for construction will change throughout the five year period.	Beneficial effects of employment and income on community health and wellness as realized by local residents of the LAA and RAA, based on local employment estimates, would be limited to the estimated 5% of the peak construction workforce. During operations, the percentage of local hire is estimated to increase to 12%, representing a greater number of local residents that could experience beneficial effects on community health and wellness due to changes in employment and income.
1544.1	round 1	Kitsumkalum First Nation	Table 6.6-22	Community Health	With the various ratings of residual effects in this table the effects to community health and wellness with the currently proposed mitigation must be Significant.	Table 6.6-22 of the Application provides a summary of the Project residual effects on Community Health. Since multiple effects (with additional consideration to vulnerable populations) are assessed in Section 6.6.5, numerous characterizations are provided. The detailed assessment which informed the summary provided in Table 6.6-22 is provided in the preceding Sections 6.6.4, 6.6.5 and continues until the completion of the Section. Section 6.6.7 provides significance determinations for Project residual and cumulative residual effects. Significance determinations draw on residual and cumulative effect characterizations provided in Sections 6.6.5 and 6.6.6 and significance thresholds established in Section 6.6.2.8.
1545.1	round 1	Kitsumkalum First Nation	Section 6.6.3	Community Health	Cumulative effects. As per comments made for other Sections of this EA, Kitsumkalum are not happy with the mitigation that has been proposed or the content of the Social Management Plans provided by either PNW LNG or LNG Canada. Also to note is the Aurora LNG project is larger than the PNW LNG project and LNG Canada is in Kitimat.	The proposed content of the Social Management Plan (SMP) as currently detailed in Section 14.12 of the Application represents a preliminary outline of the objectives and potential content which may be included in the SMP. The SMP will be developed with regulators, Aboriginal Groups and interested stakeholders. The level of detail provided in Section 14.12 is consistent with that provided in applications of similar size and scope in northern BC.
1546.1	round 1	Kitsumkalum First Nation	Page 6.6-108	Community Health	The statement is made once again vulnerable people may obtain employment, however there is no information provided on how this will be possible. There is no mitigation offered to enhance this potential benefit.	Section 5.2.5 of the Application outlines proposed mitigation that may help to increase the likelihood of persons defined as "vulnerable populations" in obtaining employment on the Project. These include, but may not be limited to:Mitigation No. 5.2.1: Inform local residents and Aboriginal Groups of job and procurement opportunities during all Project phases. Develop work packages that consider the capacity and capabilities of local and regional businesses.Mitigation No. 5.2.5: Identify potential shortages of workers with specific skill requirements, and work with training and education facilities, Aboriginal Groups, and local communities to increase opportunities for Aboriginal and local community members to obtain training required for Project participation. Mitigation proposed by Aurora LNG, such as those defined above will be further refined and, where applicable, be captured as part of the Social Management Plan (SMP) and procurement planning. Both the SMP and procurement planning will be informed through engagement with regulators, Aboriginal Groups, and concerned stakeholders. While implementation of the above noted mitigation measures may assist LAA and RAA populations, including vulnerable populations, in securing employment, all candidates will be subject to standardized employment requirements. For example, all workers (not inclusive of summer students) 19 years and younger will be required to have completed grade 12 or have obtained an appropriate equivalency to secure employment with the Project (in order to prevent young people from leaving school prematurely; see mitigation No. 5.2.3). Noted in Section 6.6.5.3 (subsection 'Income and Social Status'), Aurora LNG recognizes that not all unemployment and vulnerable populations who seek employment during Project construction and operations will be successful in securing work (direct, indirect, and induced).
1547.1	round 1	Kitsumkalum First Nation	Section 6.6.7	Community Health	Significance of Project Residual Effects. The effect to community health and wellness on Kitsumkalum as a vulnerable population to increased cost of housing and health related effects from boom and bust dynamics is completely missed. In addition, the reliance of access to traditional foods is essential for members' health and sustenance. Reduced access could occur as more income will be required to pay for housing and less will be available to harvest foods, e.g. boat gas, truck gas, etc. No mitigation is proposed to minimize these effects. With current mitigation residual effects to community health is Significant.	Regarding changes in demand for housing from construction to operations see the response to comment 1500.1. Noted in the response, 'boom-and-bust' effects on the supply and demand of accommodations are not expected as increased demand is predicted during the transition from construction (short-term) to operations (long-term). However, as concluded in Section 13.5.4 (Cost of Living), while mitigation measures (i.e., 5.2-1, 5.2-2, 5.2-5, 6.3-1, 6.6-12, 6.3-15, 6.4-8, and 6.4-9) are expected to reduce the magnitude of adverse effect on cost-of-living, Project-related changes in population are anticipated to increase demand for housing and goods and services within the LAA and lead to increased costs. Assessed in Section 6.6.5.3, changes in population and employment and income could have beneficial or adverse effects on the health status of LAA and RAA residents depending on their current situation and ability to secure employment. In some instances, vulnerable populations may realize disproportionate effects (as is characterized in Section 6.6.5.3). With respect to changes in access to harvesting locations, Section 6.6.54 recognizes that if access to preferred harvesting locations is affected, alternative locations may not be favorable and that harvesters could experience additional adverse effects related to the relocation of harvesting activities (e.g., increased costs, increased time spent travelling to harvesting locations, poorer quality yields). As noted by the commenter, increased percentages of income spent on increased housing costs could also affect access and participation in harvesting activities. While Aurora LNG is confident that Project design (i.e., a closed-access camp), FIFO worker logistics plans, and the suite of mitigation measures proposed in Sections 5.2, 6.3, 6.4, 6.5, 6.6 and 13.5.4 will reduce Project residual adverse effects on accommodations, health, harvesting, and cost of living, it is recognized that these mitigation measures do not mitigate existing trends and conditions within the region that are not attributable to the Project. To help address cumulative adverse effects within the RAA, Aurora LNG has committed to participating in provincial and/or regional led initiatives to address cumulative adverse effects on community health and wellness and infrastructure and services. Conclusions regarding the significance of the predicted residual effects on change in community health and wellness remain unchanged and not significant.
1548.1	round 1	Kitsumkalum First Nation	Section 6.6.7	Community Health	Significance of Cumulative Residual Effects. The effect to community health and wellness on Kitsumkalum as a vulnerable population to increased cost of housing and health related effects from boom and bust dynamics is completely missed. In addition, the reliance of access to traditional foods is essential for members' health and sustenance. Reduced access could occur as more income will be required to pay for housing and less will be available to harvest foods, e.g. boat gas, truck gas, etc. No mitigation is proposed to minimize these effects. With current mitigation residual effects to community health is Significant.	Regarding cumulative changes in demand for housing, 'boom-and-bust' effects on the supply and demand of accommodations could occur. However, most proponents of industrial development considered in the cumulative case (see Table 6.3-28 of the Application) have proposed similar mitigation measures as Aurora LNG and most will use project-dedicated or open-camp accommodations to lodge their construction workforce. As such, while 'boom-and-bust' effects could occur, increaseddemand for housing will likely occur during the transition from construction (short-term) to operations (long-term); this is similar to the Project case. Effect characterizations provided in Section 6.3.6.4 and the determination of significance (significant cumulative adverse effects on accommodations; Section 6.3.7.2) remain valid. Assessed in Section 6.6.6.3, cumulative changes in population and employment and income could have beneficial or adverse effects on the health status of RAA residents depending on their current situation and ability to secure employment. In some instances, vulnerable populations may realize disproportionate effects (as is characterized in Section 6.6.6.3). For the purpose of the assessment of change in community health and wellness, Aboriginal Groups are considered vulnerable. With respect to cumulative changes in access to harvesting locations, Section 6.6.6.4 recognizes that if access to preferred harvesting locations is affected, alternative locations may not be favorable and that harvesters could experience additional adverse effects related to the relocation of harvesting activities (e.g., increased costs, increased time spent travelling to harvesting locations, poorer quality yields). As noted by the commenter, increased percentages of income spent on increased housing costs could also affect access and participation in harvesting activities. While Aurora LNG is confident that Project design (i.e., a closed-access camp), logistics plans, and the suite of mitigation measures proposed in Sections 5.2, 6.3, 6.4, 6.5, 6.6 and 13.5.4 will reduce the Project's contribution to cumulative adverse effects on accommodations, health, harvesting, and cost of living, it is recognized that these mitigation measures do not mitigate existing trends and conditions within the region that are not attributable to the Project. To help address cumulative adverse effects within the RAA, Aurora LNG has committed to participating in provincial and/or regional led initiatives to address cumulative adverse effects on community health and wellness and infrastructure and services. Conclusions regarding the significance of residual effects on change in community health and wellness remain unchanged and not significant.
1549.1	round 1	Kitsumkalum First Nation	7.2.2.4	Heritage	Increased human presence should be considered during construction, operations and closure as a potential adverse effect on archaeological sites. Sites such as coastal shell middens are particularly sensitive to increase human presence and it is known that there currently are and will likely to continue to be exposed archaeological materials in the LSA.	Potential Project interactions with archaeological and heritage resources are only anticipated to occur during activities that result in tree removal or ground disturbance (including dredging) during the construction phase. The operation and decommissioning phases are not anticipated to result in additional tree removal or ground disturbance (including dredging) outside of the area affected during the construction phase, and therefore do not have potential to cause a measurable interaction with archaeological and heritage resources. Access to archaeological sites within the LAA/RAA by members of the public is not anticipated to increase during the construction and operation phases, as there will be on-site security services and restricted access to the PDA. Access to archaeological sites by project personnel is not anticipated (see mitigation 6.4.4). Therefore, tree removal or ground disturbance related to increased human presence are not anticipated and human presence is unlikely to cause a measurable interaction with archaeological and heritage resources.
1550.1	round 1	Kitsumkalum First Nation	7.2.2.5	Heritage	The RAA should be larger that than the LAA. As there is no regional setting provided it is not possible to assess the significance of the sites that will be impacted (How rare are the site types that are being impacted? Is the density of sites in the project area normal for this region? . The LAA and RAA are limited to ground disturbance from construction but do not consider disturbance to archaeological sites as a result of increased human presence on the island. Both the LAA and RAA should be increased in size to take this into consideration.	The regional setting for archaeology and heritage is addressed in the permitted AIA report (Appendix W). The AIA was completed in accordance with regulatory guidelines and considers appropriate regional data to assess the significance of, and potential effects to, sites situated in the LAA/RAA.Within the Application process, the AIR describes the LAA and RAA as being the Project Development Area and this is consistent with what is included in the Application, Section 7.2.2.5. The LAA and RAA are used to assess effects during all project phases; however, only construction activities are predicted to have an effect on this VC because vegetation clearing and ground disturbance with the potential to impact archaeological and heritage resources will be completed during the construction phase. Access to archaeological sites within the LAA/RAA by members of the public is not anticipated to increase during the construction and operation phases, as there will be on-site security services and restricted access to the PDA. Access to archaeological sites by project personnel is not anticipated (see mitigation 6.4.4). Therefore, tree removal or ground disturbance related to increased human presence are not anticipated and human presence is unlikely to cause a measurable interaction with archaeological and heritage resources. For these reasons, no change to the Application is considered warranted.
1551.1	round 1	Kitsumkalum First Nation	7.2.2.6	Heritage	The assessment assumes that archaeological sites will only be impacted during the construction phase. This needs to be revised to account for increased human presence that will also occur during operations and construction and closure that may result in impacts to sites. Additionally, buried deposits such as shell midden sites may be disturbed during closure and reclamation.	Potential Project interactions with archaeological and heritage resources are only anticipated to occur during activities that result in tree removal or ground disturbance (including dredging) during the construction phase. The operation and decommissioning phases are not anticipated to result in additional tree removal or ground disturbance (including dredging) outside of the area affected during the construction phase, and therefore do not have potential to cause a measurable interaction with archaeological and heritage resources. Access to archaeological sites within the LAA/RAA by members of the public is not anticipated to increase during the construction and operation phases, as there will be on-site security services and restricted access to the PDA. Access to archaeological sites by project personnel is not anticipated (see mitigation 6.4.4). Therefore, tree removal or ground disturbance related to increased human presence are not anticipated and human presence is unlikely to cause a measurable interaction with archaeological and heritage resources.
1552.1	round 1	Kitsumkalum First Nation	7.2.3.2	Heritage	Kitsumkalum is very concerned with the lack of testing on Spire Island where two rock overhangs were identified and visually examined but not tested. High potential areas like these must be tested or more information provided on the rationale for not testing.	Two rock overhangs were identified on Spire Island during the AIA. Visual examination of the areas did not identify any archaeological materials or remains. However, given the potentially sensitive nature of these features as potential burial places, intrusive subsurface inspection was not conducted. As per the AIA report (Appendix W), avoidance is recommended. If avoidance is not feasible, additional archaeological study would be undertaken prior to construction.
1553.1	round 1	Kitsumkalum First Nation	7.2.9	Heritage	With the large number of sites in very close proximity to the Project, on going monitoring to ensure the sites are not impacted is required. Kitsumkalum would like to see monitoring during construction and yearly monitoring of the sites during operations and monitoring during closure and reclamation activity. In addition due to lack of any Kitsumkalum inclusion in field works to date, Kitsumkalum Must be involved in such field work moving forward!	Potential Project interactions with archaeological and heritage resources are only anticipated to occur during activities that result in tree removal or ground disturbance (including marine dredging) during the construction phase. The operation and decommissioning phases are not anticipated to result in additional tree removal or ground disturbance (including marine dredging) outside of the area affected during the construction phase, and therefore do not have potential to cause a measurable interaction with archaeological and heritage resources. Access to archaeological sites within the LAA/RAA by members of the public is not anticipated to increase during the construction and operation phases, as there will be on-site security services and restricted access to the PDA. Access to archaeological sites by project personnel is not anticipated (see mitigation 6.4.4). Therefore, monitoring of the sites after initial construction (tree removal and ground disturbance) may not be required however Aurora LNG will review the requirement for monitoring on a site by site basis in discussion with the appropriate regulatory authorities. Aurora LNG welcomes further discussions with Kitsumkalum First Nation regarding heritage and archaeological resources. Please refer to the "Aurora LNG's Approach to Consultation with Aboriginal Groups" technical memo for information regarding the field programs conducted for the project. This memo will be filed with the BC EAO. Aurora LNG endeavoured to identify and create opportunities where it could involve Aboriginal Groups in field work. As part of this process, Aurora LNG has prioritized the involvement of those Aboriginal Groups located in closest proximity to the location of the Project on the basis that these Aboriginal Groups have a higher likelihood of being effected by any potential effects associated with the Project. Due to logistical and operational limitations associated with field operations, Aurora LNG has had to limit participation by Aboriginal Groups further removed from the location of the Project including Kitsumkalum First Nation.
1554.1	round 1	Kitsumkalum First Nation	7.2.3.2	Heritage	Fossil sites have been attributed to Digby Island, however the report states that there is no potential for fossil finds. It is not clear from the Paleontology report if a qualified professional paleontologist conducted this assessment. Please state the qualifications of the person who did the study.	Edits were made to Sections 7.2.1, 7.2.2.1, 7.2.2.8, 7.2.3.1, 7.2.3.2, 7.2.3.3, 7.2.8, and 7.2.9 in response to comments from the Heritage Branch during the screening of the application in December 2016 which address this comment. To clarify, a high-level review of paleontology has been conducted for the Project. The review was conducted by a professional Palaeontologist with a PhD who is a member of the British Columbia Paleontological Alliance. A paleontological assessment will be conducted prior to construction and will include review of relevant information and databases. The assessment and reporting will be conducted under a permit issued by the province. If any fossils are identified, they will be managed in consultation with the Heritage Branch. The Archaeological and Heritage Resources Management Plan will include measures to manage any unexpected fossil finds during project activities. The plan will meet Heritage Branch standards regarding management of fossil sites. The management plan will be prepared prior to construction. An edit was made to Table 7-7 during screening to reflect that the Heritage Branch will be consulted during its preparation.

1555.1	round 1	Kitsumkalum First Nation	7.2.4	Heritage	This section needs to include potential impacts from increased human presence throughout the project lifecycle, and impacts to buried deposits during construction, decommissioning and closure.	Potential Project interactions with archaeological and heritage resources are only anticipated to occur during activities that result in tree removal or ground disturbance (including dredging) during the construction phase. The operation and decommissioning phases are not anticipated to result in additional tree removal or ground disturbance (including dredging) outside of the area affected during the construction phase, and therefore do not have potential to cause a measurable interaction with archaeological and heritage resources. Access to archaeological sites within the LAA/RAA by members of the public is not anticipated to increase during the construction and operation phases, as there will be on-site security services and restricted access to the PDA. Access to archaeological sites by project personnel is not anticipated (see mitigation 6.4.4). Therefore, tree removal or ground disturbance related to increased human presence are not anticipated and human presence is unlikely to cause a measurable interaction with archaeological and heritage resources.
1556.1	round 1	Kitsumkalum First Nation	7.2.5.1	Heritage	Kitsumkalum disagrees with the assumption that the affects of the Project on Heritage resources are well understood based on the work done in the LAA and RAA. The LAA and RAA are too small to understand the affects of the Project and Heritage resources and need to be expanded. Additionally, the authors do not appear to fully understand the potential affects of the Project.	The regional setting for archaeology and heritage is addressed in the permitted AIA report (Appendix W). The AIA was completed in accordance with regulatory guidelines and considers appropriate regional data to assess the significance of, and potential effects to, sites situated in the LAA/RAA.Within the Application process, the AIR describes the LAA and RAA as being the Project Development Area and this is consistent with what is included in the Application, Section 7.2.2.5. The LAA and RAA are used to assess effects during all project phases; however, only construction activities are predicted to have an effect on this VC because vegetation clearing and ground disturbance with the potential to impact archaeological and heritage resources will be completed during the construction phase. Access to archaeological sites within the LAA/RAA by members of the public is not anticipated to increase during the construction and operation phases, as there will be on-site security services and restricted access to the PDA. Access to archaeological sites by project personnel is not anticipated (see mitigation 6.4.4). Therefore, tree removal or ground disturbance related to increased human presence are not anticipated and human presence is unlikely to cause a measurable interaction with archaeological and heritage resources. For these reasons, no change to the Application is considered warranted.
1557.1	round 1	Kitsumkalum First Nation	7.2.5.2	Heritage	Kitsumkalum disagrees with the assessment of residual effects. The assessment has not considered the significance of the sites regionally. This project area has a very high density of archaeological and historic sites and is evidence of the high use and significance of the area over a long period of time. There a few places on the coast that have such a high density of sites in such a small area and location. It is also an excellent area for public interpretation to occur. The loss of these sites would have a significant residual impact on the population of archaeological and heritage sites in the larger region. Lack of all first nations involvement has added to this.	The regional setting for archaeology and heritage is addressed in the permitted AIA report (Appendix W). The AIA was completed in accordance with regulatory guidelines and considers appropriate regional data to assess the significance of, and potential effects to, sites situated in the LAA/RAA. Aurora LNG acknowledges the concern of Kitsumkalum First Nation regarding the archaeological and heritage sites in the PDA. Aurora LNG is confident that the correct approach to mitigating the loss of information about or alteration to site contents or contexts resulting from construction of the Project has been employed. Avoidance is recognized as being the preferred option, and the majority of the archaeological sites with high significance within the PDA are situated within the proposed buffer (Figure 7-1 and Figure 7-2). If avoidance is not feasible, a program of systematic data recovery and/or archaeological monitoring will take place under a Section 12 alteration permit issued for HCA protected sites. Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Archaeological and Heritage Resources Management Plan. The success of the measures that are ultimately determined through this engagement is predicted to be high. Therefore, with the implementation of mitigation measures 7.1.1 to 7.1.3, residual effects are assessed to be not significant.
1558.1	round 1	Kitsumkalum First Nation	7.2.5.3	Heritage	The assessment of residual effects needs to be revised to reflect the significance of the very high density of archaeological and heritage sites in this location and how the loss of this resource will carry forward in to the future and result in the loss a significant resource. Mitigation through data recovery and monitoring of the sites will not be enough to offset losing an area like this that has this time depth of occupation, density and diversity of sites.	The regional setting for archaeology and heritage is addressed in the permitted AIA report (Appendix W). The AIA was completed in accordance with regulatory guidelines and considers appropriate regional data to assess the significance of, and potential effects to, sites situated in the LAA/RAA. Aurora LNG acknowledges the concern of Kitsumkalum First Nation regarding the archaeological and heritage sites in the PDA. Aurora LNG is confident that the correct approach to mitigating the loss of information about or alteration to site contents or contexts resulting from construction of the Project has been employed. Avoidance is recognized as being the preferred option, and the majority of the archaeological sites with high significance within the PDA are situated within the proposed buffer (Figure 7-1 and Figure 7-2). If avoidance is not feasible, a program of systematic data recovery and/or archaeological monitoring will take place under a Section 12 alteration permit issued for HCA protected sites. Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Archaeological and Heritage Resources Management Plan. The success of the measures that are ultimately determined through this engagement is predicted to be high. Therefore, with the implementation of mitigation measures 7.1.1 to 7.1.3, residual effects are assessed to be not significant.
1559.1	round 1	Kitsumkalum First Nation	7.2.6 Heritage	Heritage	A cumulative effects assessment is necessary for this project as the logic that the mitigation will offset the residual effects is flawed. The current mitigation plan does not offset the significant loss the collective archaeological and heritage resources in this area.	Aurora LNG is confident that the correct approach to mitigating the loss of information about or alteration to site contents or contexts resulting from construction of the Project has been employed. Avoidance is recognized as being the preferred option, and the majority of the archaeological sites with high significance within the PDA are situated within the proposed buffer (Figure 7-1 and Figure 7-2). If avoidance is not feasible, a program of systematic data recovery and/or archaeological monitoring will take place under a Section 12 alteration permit issued for HCA protected sites. Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Archaeological and Heritage Resources Management Plan. The success of the measures that are ultimately determined through this engagement is predicted to be high. Therefore, with the implementation of mitigation measures 7.1.1 to 7.1.3, residual effects are assessed to be not significant. In accordance with the AIR, an assessment of cumulative effects on archaeological and heritage resources was not undertaken as the following two conditions were not met: 1) proposed Project is assessed as having residual effects on the VC and 2) residual effects could act cumulatively with residual effects of other past, present, or reasonably foreseeable future physical activities. Further assessment of cumulative effects on archaeological and heritage resources is not warranted because the Project effects on archaeological and heritage resources will be mitigated prior to alteration. As a result, there are no predicted residual effects to archaeological and heritage resources. Consequently, the Project is not expected to interact cumulatively with potential residual effects from other projects or activities.
1560.1	round 1	Kitsumkalum First Nation	7.2.1 section	Heritage	"There are 110 sites currently recorded on Digby Island of which 62 are within the Project development area PDA" This over 50% of the known sites on Digby island are located within the PDA and have potential to be disrupted or disturbed. Of which most are located directly across from Casey point which is a Kitsumkalum Village site that was destroyed by the railway.	Aurora LNG acknowledges the comment. Archaeological sites within the PDA will be avoided, where practicable, or mitigated through systematic data recovery and/or archaeological monitoring under a Section 12 alteration permit issued by the Archaeology Branch.
1561.1	round 1	Kitsumkalum First Nation	7.2.1 section	Heritage	Although "In BC there are established processes for identifying, assessing and managing impacts to archaeological and heritage resources, and any potential effects will either be avoided or subject to mitigation measures in accordance with the Heritage Conservation Act (HCA) prior to construction." Kitsumkalum has not been involved in works on site to date, has not had our requests to be involved with cultural works and does not necessarily agree to all mitigations under the HCA.	Aurora LNG's consultation objectives are described in Table 3-1 of Appendix S2 (Second Aboriginal Consultation Report [ACR#2]). In that table, each objective is listed along with specific sections of the ACR#2 that demonstrate Aurora LNG's related consultation activities undertaken to meet the objectives. Section 8 of ACR#2 details engagement and consultation activities undertaken with Kitsumkalum First Nation. Table 8-1 outlines the issues and concerns as understood by Aurora LNG, any recommendations provided by Kitsumkalum, Aurora LNG's proposed response, and the status of the issue/concern. Please refer to technical memo "Aurora LNG's Approach to Consultation with Aboriginal Groups" for additional information regarding the field programs conducted for the project. This technical memo will be filed with the BC EAO.
1562.1	round 1	Kitsumkalum First Nation	7.2.1 section	Heritage	"The provincial HCA automatically protects archaeological and heritage resources that pre-date AD 1846 as well as Aboriginal rock art and human remains, regardless of their age. The HCA also protects heritage wrecks (e.g., aircraft and ships) more than two years old. Sites that post-date AD 1846 may also be protected by the HCA if they have heritage value for BC, a community or an Aboriginal Group." While this is true, it is misleading in that a section 12 alteration permit can be obtained to remove and or destroy heritage features. Kitsumkalum has found that Aboriginal interest has minimal to no impact on this decision.	Aurora LNG acknowledges the comment. Section 7.2.1 provides rationale for selecting archaeological and heritage resources as a VC. The protection status that the HCA provides certain resources is described in this section to support this selection. Aurora LNGrespectfullysuggests that Kitsumkalum First Nation contact theArchaeologyBranch and/or the OGC to discuss the Section 12 alteration permitting process.
1563.1	round 1	Kitsumkalum First Nation	7.2.1 section	Heritage	"Potential archaeological, cultural, and heritage resources have been identified as being of concern to regulators, Aboriginal Groups, stakeholders, and the public." once again, Kitsumkalum has not been involved in order to assess the level of concern on these sites.	Aurora LNG's consultation objectives are described in Table 3-1 of Appendix S2 (Second Aboriginal Consultation Report [ACR#2]). In that table, each objective is listed along with specific sections of the ACR#2 that demonstrate Aurora LNG's related consultation activities undertaken to meet the objectives. Section 8 of ACR#2 details engagement and consultation activities undertaken with Kitsumkalum First Nation. Table 8-1 outlines the issues and concerns as understood by Aurora LNG, any recommendations provided by Kitsumkalum, Aurora LNG's proposed response, and the status of the issue/concern. Please refer to technical memo "Aurora LNG's Approach to Consultation with Aboriginal Groups" for additional information regarding the field programs conducted for the project. This technical memo will be filed with the BC EAO.
1564.1	round 1	Kitsumkalum First Nation	page 7.5	Heritage	HCA values and level of conservation do not always align with FN values.	Aurora LNG acknowledges the commentand welcomes further discussions with from Kitsumkalum First Nation during preparation of the Archaeological and Heritage Resources Management Plan.
1565.1	round 1	Kitsumkalum First Nation	page 7.5	Heritage	"The BCEAA requires consideration of potential significant adverse heritage effects." Although this is true, it is seemingly more and more apparent that Nexen' s view of significant and that of First nations is drastically different.	The significance of adverse effects was evaluated according to methods included in the approved AIR. Aurora LNG will incorporate input from Schedule B and C Aboriginal Groups during preparation of the Archaeological and Heritage Resources Management Plan to supplement conclusions reached in the Application.
1566.1	round 1	Kitsumkalum First Nation	section 7.2.2 page 7.6	Heritage	"The BCEAA requires consideration of potential significant adverse heritage effects." Although this is true, it is seemingly more and more apparent that Nexen' s view of significant and that of First nations is drastically different. The application for Heritage Inspection Permit 2015-0007 and a subsequent permit amendment was sent by the Archaeology Branch to Lax Kw'alaams Band, Metlakatla First Nation, Gitxaala Nation, Kitsumkalum First Nation and Kitselas First Nation for review as part of their standard permit approval process. The Archaeology Branch received comments on the application from Gitxaala Nation and Kitsumkalum First Nation." at this time Kitsumkalum continued to voice our concerns over heritage resources and were not included in field programs.	Aurora LNG's consultation objectives are described in Table 3-1 of Appendix S2 (Second Aboriginal Consultation Report [ACR#2]). In that table, each objective is listed along with specific sections of the ACR#2 that demonstrate Aurora LNG's related consultation activities undertaken to meet the objectives. Section 8 of ACR#2 details engagement and consultation activities undertaken with Kitsumkalum First Nation. Table 8-1 outlines the issues and concerns as understood by Aurora LNG, any recommendations provided by Kitsumkalum, Aurora LNG's proposed response, and the status of the issue/concern. Please refer to technical memo "Aurora LNG's Approach to Consultation with Aboriginal Groups" for additional information regarding the field programs conducted for the project. This technical memo will be filed with the BC EAO.
1567.1	round 1	Kitsumkalum First Nation	section 7.2.2 page 7.8	Heritage	"Metlakatla First Nation was also involved in preparing the Guidelines for the Protection of Archaeological Resources on Digby Island, BC (Nexen 2015), a best management practices (BMPs) document that was adhered to during the AIA field investigations after its issuance in August 2015." Why were other Tsimshian groups not involved?	Aurora LNG has shared archaeological information, including the Archaeological Impact Assessment with all Aboriginal Groups on the Section 11 Order (as amended) including Kitsumkalum First Nation. The Guidelines for the Protection of Archaeological Resources on Digby Island, BC (Nexen 2015) were developed jointly between Kleanza Consulting Ltd, a local archaeological firm and Aurora LNG, with input from Metlakatla First Nation. For further information that provides context related to Aurora LNG's approach to consultation please see the technical memo entitled "Aurora LNG's Approach to Consultation with Aboriginal Groups" which will be filed with the EAO.
1568.1	round 1	Kitsumkalum First Nation	7.2.2.8	Heritage	"For archaeological sites protected under the HCA, the scientific, public, ethnic and economic significance is defined using methods outlined in the BC Archaeological Impact Assessment Guidelines (Archaeology Branch 1998). For palaeontological sites, significance is defined in consultation with the Heritage Branch. For CMTs post-dating AD 1846 and other non-protected heritage resources, significance is determined in consultation with the Heritage Branch and potentially affected Aboriginal Groups, or other stakeholders, as appropriate, and typically follows established provincial best practices." As mentioned above, Kitsumkalum has not been included on site field works and thus has not been adequately consulted in regards to this.	Aurora LNG's consultation objectives are described in Table 3-1 of Appendix S2 (Second Aboriginal Consultation Report [ACR#2]). In that table, each objective is listed along with specific sections of the ACR#2 that demonstrate Aurora LNG's related consultation activities undertaken to meet the objectives. Section 8 of ACR#2 details engagement and consultation activities undertaken with Kitsumkalum First Nation. Table 8-1 outlines the issues and concerns as understood by Aurora LNG, any recommendations provided by Kitsumkalum, Aurora LNG's proposed response, and the status of the issue/concern. Please refer to technical memo "Aurora LNG's Approach to Consultation with Aboriginal Groups" for additional information regarding the field programs conducted for the project. This technical memo will be filed with the BC EAO.
1569.1	round 1	Kitsumkalum First Nation	7.2.3.1	Heritage	"AIA field studies were conducted for the Project under two HCA Section 14 inspection permits: 2013-0101 and 2015-0007. The AIAs followed the Archaeological Impact Assessment Guidelines (Archaeology Branch 1998), and the terms and conditions of Inspection Permits 2013-0101 and 2015-0007, and included representation from Lax Kw'alaams Band and/or Metlakatla First Nation" Again this is Tsimshian territory. These two bands do not represent the nation as a whole. Kitsumkalum was not included in this and therefore have not been adequately involved or consulted.	Further information that provides context related to Aurora LNG's approach to consultation and fieldwork participation is provided in the technical memo entitled "Aurora LNG's Approach to Consultation with Aboriginal Groups" which will be filed with the EAO.
1570.1	round 1	Kitsumkalum First Nation	7.2.3.3	Heritage	"In summary, AIAs have been conducted for the project under two HCA inspection permits, 2013-0101 and 2015-0007, and have covered the entire LAA/RAA, except small areas where there were minor revisions to the northern portion of the PDA (see Section 7.2.9)." then the entire area has not been covered by AIA's. Is there a plan to do this prior to any disturbance on site?	Prior to construction, further field assessment will be completed for the small areas in the revised northern portion of the PDA that have not been assessed. These areas are situated inland and have low potential for archaeological or heritage resources with high scientific significance (e.g. shell middens) however, other types of resources (e.g. CMTs) could potentially be present. The field assessment and reporting will be conducted in accordance with Archaeology Branch standards with input from local Aboriginal Groups (as identified in Schedule B of the amended Section 11 Order) . If any archaeological or heritage resources are identified, they will be managed in accordance with provincially-regulated procedures and policies in consultation with regulatory agencies and local Aboriginal Groups.
1571.1	round 1	Kitsumkalum First Nation	General	Heritage	Although AIA's have been completed, the area is reasonably dense forest and wetland complexes. It is unlikely that all resources have been discovered. This is evident in the density of use and features that have been identified. The project will undergo extreme disturbance using heavy machinery. Any features not identified will be lost. There are Tsimshian stories of grave sites in the project vicinity that have not been identified. We are concerned that these will be found at the end of a bulldozer, or worse, be lost forever.	The archaeological impact assessment consisted of 100% pedestrian survey of the PDA, which is significantly more than the standard practice. However, it is recognized that there is always a possibility that not all archaeological sites will be discovered even in the most thorough archaeological inspection. Accordingly, a Chance Find Procedure will be included in the Archaeological and Heritage Resources Management Plan to specifically address the chance find of an archaeological site during construction. With respect to grave sites, the survey did account for contexts which are most commonly associated with grave sites, such as was identified on Spire Island. When identified, these were either thoroughly inspected, or the appropriate management recommendations were made.

1572.1	round 1	Kitsumkalum First Nation	General	Heritage	It is not only the loss of information that Kitsumkalum has concerns with. Just because a historical item is dug up and put in a museum, it does not mean the impact is mitigated. This is a disruption of sites and a loss of locations of historic significance that has been ongoing since European contact.	Aurora LNG is confident that the correct approach to mitigating the loss of information about or alteration to site contents or contexts resulting from construction of the Project has been employed. Avoidance is recognized as being the preferred option, and the majority of the archaeological sites with high significance within the PDA are situated within the proposed buffer (Figure 7-1 and Figure 7-2). If avoidance is not feasible, a program of systematic data recovery and/or archaeological monitoring will take place under a Section 12 alteration permit issued for HCA protected sites. Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Archaeological and Heritage Resources Management Plan. The success of the measures that are ultimately determined through this engagement is predicted to be high. Therefore, with the implementation of mitigation measures 7.1.1 to 7.1.3, residual effects are assessed to be not significant.
1573.1	round 1	Kitsumkalum First Nation	table 7-7	Heritage	See above two comments. Searching for artifacts and items of significance is a needle in a haystack. I find it hard to believe the high likelihood of success determination. Although these are the SOP's it is hard to believe that these are implementable at all sites.	The archaeological impact assessment consisted of 100% pedestrian survey of the PDA, which is significantly more than the standard practice. However, it is recognized that there is always a possibility that not all archaeological sites will be discovered, even in the most thorough archaeological inspection. Accordingly, a Chance Find Procedure will be included in the Archaeological and Heritage Resources Management Plan to specifically address the chance find of an archaeological site during construction. Aurora LNG welcomes further discussion with Kitsumkalum First Nation during preparation of the Archaeological and Heritage Resources Management Plan.
1574.1	round 1	Kitsumkalum First Nation	page 7-25	Heritage	"However, there are nine archaeological sites with other types of archaeological or cultural features within the PDA that will be wholly or partially affected by the construction of the Project: GbTo…." should read there are nine known arch sites……	Aurora LNG agrees that this statement refers to 'known' archaeological sites. The sentence will be updated to read "...there are nine known archaeological sites...". An errata document is being compiled that captures these corrections and it will be filed with the BC EAO.
1575.1	round 1	Kitsumkalum First Nation	General	Heritage	The density of non HCA CMT's shows the level of continued use and importance of this area to the Tsimshian	Aurora LNG acknowledges the comment.
1576.1	round 1	Kitsumkalum First Nation	Table 7-8	Heritage	"Systematic data recovery" Will Kalum and the other Tsimshian be involved in this or will this be another exclusion of our people while traditional heritage is disrupted?	Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Archaeological and Heritage Resources Management Plan which will include the mitigation measure of systematic data recovery.
1577.1	round 1	Kitsumkalum First Nation	7.2.5.3	Heritage	mitigation measures determined in consultation with regulatory agencies, local governments and local Aboriginal Groups will be implemented to recover data where avoidance is not feasible. This statement is misleading! Please include which Aboriginal groups.	In this context "local Aboriginal Groups" refers to those groups identified by the Archaeology Branch (FLNRO).
1578.1	round 1	Kitsumkalum First Nation	Table 7-9	Heritage	I am baffled how the magnitude of impact to archaeological and heritage resources will be negligible for construction!	Negligible magnitude is defined as "No measurable change from existing (baseline) conditions (i.e., no loss of information". While the construction phase may result in permanent and irreversible alteration to site contents or context, this will be offset by the data gathered from those sites as a mitigation measure determined by the Archaeology Branch (FLNRO), and, therefore, and any loss of information is predicted to have a negligible magnitude.
1579.1	round 1	Kitsumkalum First Nation	7.2.6	Heritage	§ Proposed Project is assessed as having residual effects on the VC § Residual effects could act cumulatively with residual effects of other past, present, or reasonably foreseeable future physical activities. Kitsumkalum disagrees	Aurora LNG is confident that the correct approach to mitigating the loss of information about or alteration to site contents or contexts resulting from construction of the Project has been employed. Avoidance is recognized as being the preferred option, and the majority of the archaeological sites with high significance within the PDA are situated within the proposed buffer (Figure 7-1 and Figure 7-2). If avoidance is not feasible, a program of systematic data recovery and/or archaeological monitoring will take place under a Section 12 alteration permit issued for HCA protected sites. Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Archaeological and Heritage Resources Management Plan. The success of the measures that are ultimately determined through this engagement is predicted to be high. Therefore, with the implementation of mitigation measures 7.1.1 to 7.1.3, residual effects are assessed to be not significant.
1580.1	round 1	Kitsumkalum First Nation	7.2.6.2	Heritage	"While other past, present, or reasonably foreseeable projects and physical activities may impact archaeological and heritage resources in the region, the implementation of mitigation measures will result in the absence of Project residual effects and, therefore, means the Project will not contribute to cumulative effects." Kitsumkalum strongly disagrees with this statement!!! The north coast has historically been rich with Aboriginal tradition, artifacts and historic sites. Removing these sites affects our culture, history and presence on the land. Just because there is another historical site somewhere else does not negate the fact there are sites being destroyed here. It is the same if I were to come and pave your backyard and put in a factory, with the explanation that there are lots of other backyards around so really the impact is negligible. And don't worry, the memory of your backyard was documented with a picture and put in the archive. This would be absurd and not accepted but is what the projects justification is.	Aurora LNG is confident that the correct approach to mitigating the loss of information about or alteration to site contents or contexts resulting from construction of the Project has been employed. Avoidance is recognized as being the preferred option, and the majority of the archaeological sites with high significance within the PDA are situated within the proposed buffer (Figure 7-1 and Figure 7-2). If avoidance is not feasible, a program of systematic data recovery and/or archaeological monitoring will take place under a Section 12 alteration permit issued for HCA protected sites. Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Archaeological and Heritage Resources Management Plan. The success of the measures that are ultimately determined through this engagement is predicted to be high. Therefore, with the implementation of mitigation measures 7.1.1 to 7.1.3, residual effects are assessed to be not significant.
1581.1	round 1	Kitsumkalum First Nation	7.2.9	Heritage	"Prior to construction, further field assessment will be completed for the small areas in the revised northern portion of the PDA that have not been assessed. The field assessment and reporting will be conducted in accordance with Archaeology Branch standards with input from local Aboriginal Groups." There needs to be commitment and discussion on which Aboriginal groups!	In this context "local Aboriginal Groups" refers to those groups identified by the Archaeology Branch (FLNRO).
1582.1	round 1	Kitsumkalum First Nation	7.2.10	Heritage	Kitsumkalum feels this is wrong. In an area with a total of 530 known CMT's and say that there is no residual effect is absurd. Cumulatively this is a huge impact, especially when other projects are taken into account. How can the project determine not having cumulative affect	Aurora LNG is confident that the correct approach to mitigating the loss of information about or alteration to site contents or contexts resulting from construction of the Project has been employed. Avoidance is recognized as being the preferred option, and the majority of the archaeological sites with high significance within the PDA are situated within the proposed buffer (Figure 7-1 and Figure 7-2). If avoidance is not feasible, a program of systematic data recovery and/or archaeological monitoring will take place under a Section 12 alteration permit issued for HCA protected sites. Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Archaeological and Heritage Resources Management Plan. The success of the measures that are ultimately determined through this engagement is predicted to be high. Therefore, with the implementation of mitigation measures 7.1.1 to 7.1.3, residual effects are assessed to be not significant.
1583.1	round 1	Kitsumkalum First Nation	Table 7-10	Heritage	"Loss of information about or alteration to archaeological and heritage site contents or context" "Not Significant. Effects to archaeological or heritage resources will be mitigated through avoidance where feasible, systematic data recovery where appropriate, and/or archaeological monitoring of development. Residual effects on archaeological and heritage resources are, therefore, not significant." this is another faulty determination. there will be a loss of information and alteration to the site. Heritage is more than the age of a CMT scar and a picture! you are altering the site, so by your own definition of potential effects this is false. Culturally, to collect cedar bark, be on site with the smells and sounds of the coastal rainforest in a traditional site. this will be disturbed and lost at this location. Buried tools and undiscovered features etc. will be lost. to say "not significant" is wrong.	Aurora LNG is confident that the correct approach to mitigating the loss of information about or alteration to site contents or contexts resulting from construction of the Project has been employed. Avoidance is recognized as being the preferred option, and the majority of the archaeological sites with high significance within the PDA are situated within the proposed buffer (Figure 7-1 and Figure 7-2). If avoidance is not feasible, a program of systematic data recovery and/or archaeological monitoring will take place under a Section 12 alteration permit issued for HCA protected sites. Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order)(as amended) regarding the development of the Archaeological and Heritage Resources Management Plan. The success of the measures that are ultimately determined through this engagement is predicted to be high. Therefore, with the implementation of mitigation measures 7.1.1 to 7.1.3, residual effects are assessed to be not significant.
1584.1	round 1	Kitsumkalum First Nation	7.2.2.4	Heritage	Increased human presence should be considered during construction, operations and closure as a potential adverse effect on archaeological sites. Sites such as coastal shell middens are particularly sensitive to increase human presence and it is known that there currently are and will likely to continue to be exposed archaeological materials in the LSA.	Potential Project interactions with archaeological and heritage resources are only anticipated to occur during activities that result in tree removal or ground disturbance (including dredging) during the construction phase. The operation and decommissioning phases are not anticipated to result in additional tree removal or ground disturbance (including dredging) outside of the area affected during the construction phase, and therefore do not have potential to cause a measurable interaction with archaeological and heritage resources. Access to archaeological sites within the LAA/RAA by members of the public is not anticipated to increase during the construction and operation phases, as there will be on-site security services and restricted access to the PDA. Access to archaeological sites by project personnel is not anticipated (see mitigation 6.4.4). Therefore, tree removal or ground disturbance related to increased human presence are not anticipated and human presence is unlikely to cause a measurable interaction with archaeological and heritage resources.
1585.1	round 1	Kitsumkalum First Nation	7.2.2.5	Heritage	The RAA should be larger that than the LAA. As there is no regional setting provided it is not possible to assess the significance of the sites that will be impacted (How rare are the site types that are being impacted? Is the density of sites in the project area normal for this region? . The LAA and RAA are limited to ground disturbance from construction but do not consider disturbance to archaeological sites as a result of increased human presence on the island. Both the LAA and RAA should be increased in size to take this into consideration.	The regional setting for archaeology and heritage is addressed in the permitted AIA report (Appendix W). The AIA was completed in accordance with regulatory guidelines and considers appropriate regional data to assess the significance of, and potential effects to, sites situated in the LAA/RAA.Within the Application process, the AIR describes the LAA and RAA as being the Project Development Area and this is consistent with what is included in the Application, Section 7.2.2.5. The LAA and RAA are used to assess effects during all project phases; however, only construction activities are predicted to have an effect on this VC because vegetation clearing and ground disturbance with the potential to impact archaeological and heritage resources will be completed during the construction phase. Access to archaeological sites within the LAA/RAA by members of the public is not anticipated to increase during the construction and operation phases, as there will be on-site security services and restricted access to the PDA. Access to archaeological sites by project personnel is not anticipated (see mitigation 6.4.4). Therefore, tree removal or ground disturbance related to increased human presence are not anticipated and human presence is unlikely to cause a measurable interaction with archaeological and heritage resources.
1586.1	round 1	Kitsumkalum First Nation	7.2.2.6	Heritage	The assessment assumes that archaeological sites will only be impacted during the construction phase. This needs to be revised to account for increased human presence that will also occur during operations and construction and closure that may result in impacts to sites. Additionally, buried deposits such as shell midden sites may be disturbed during closure and reclamation.	Potential Project interactions with archaeological and heritage resources are only anticipated to occur during activities that result in tree removal or ground disturbance (including dredging) during the construction phase. The operation and decommissioning phases are not anticipated to result in additional tree removal or ground disturbance (including dredging) outside of the area affected during the construction phase, and therefore do not have potential to cause a measurable interaction with archaeological and heritage resources. Access to archaeological sites within the LAA/RAA by members of the public is not anticipated to increase during the construction and operation phases, as there will be on-site security services and restricted access to the PDA. Access to archaeological sites by project personnel is not anticipated (see mitigation 6.4.4). Therefore, tree removal or ground disturbance related to increased human presence are not anticipated and human presence is unlikely to cause a measurable interaction with archaeological and heritage resources.
1587.1	round 1	Kitsumkalum First Nation	7.2.4	Heritage	Kitsumkalum disagrees with the assessment of potential project interactions with archaeological sites. This section needs to include potential impacts from increased human presence throughout the project lifecycle, and impacts to buried deposits during construction, decommissioning and closure.	Potential Project interactions with archaeological and heritage resources are only anticipated to occur during activities that result in tree removal or ground disturbance (including dredging) during the construction phase. The operation and decommissioning phases are not anticipated to result in additional tree removal or ground disturbance (including dredging) outside of the area affected during the construction phase, and therefore do not have potential to cause a measurable interaction with archaeological and heritage resources. Access to archaeological sites within the LAA/RAA by members of the public is not anticipated to increase during the construction and operation phases, as there will be on-site security services and restricted access to the PDA. Access to archaeological sites by project personnel is not anticipated (see mitigation 6.4.4). Therefore, tree removal or ground disturbance related to increased human presence are not anticipated and human presence is unlikely to cause a measurable interaction with archaeological and heritage resources.
1588.1	round 1	Kitsumkalum First Nation	7.2.5.3	Heritage	The assessment of residual effects needs to be revised to reflect the significance of the very high density of archaeological and heritage sites in this location and how the loss of this resource will carry forward in to the future and result in the loss a significant resource. Mitigation through data recovery and monitoring of the sites will not be enough to offset losing an area like this that has this time depth of occupation, density and diversity of sites.	Aurora LNG is confident that the correct approach to mitigating the loss of information about or alteration to site contents or contexts resulting from construction of the Project has been employed. Avoidance is recognized as being the preferred option, and the majority of the archaeological sites with high significance within the PDA are situated within the proposed buffer (Figure 7-1 and Figure 7-2). If avoidance is not feasible, a program of systematic data recovery and/or archaeological monitoring will take place under a Section 12 alteration permit issued for HCA protected sites. Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Archaeological and Heritage Resources Management Plan. The success of the measures that are ultimately determined through this engagement is predicted to be high. Therefore, with the implementation of mitigation measures 7.1.1 to 7.1.3, residual effects are assessed to be not significant.

1589.1	round 1	Kitsumkalum First Nation	7.2.6	Heritage	A cumulative effects assessment is necessary for this project as the logic that the mitigation will offset the residual effects is flawed. The current mitigation plan does not offset the significant loss the collective archaeological and heritage resources in this area.	Aurora LNG is confident that the correct approach to mitigating the loss of information about or alteration to site contents or contexts resulting from construction of the Project has been employed. Avoidance is recognized as being the preferred option, and the majority of the archaeological sites with high significance within the PDA are situated within the proposed buffer (Figure 7-1 and Figure 7-2). If avoidance is not feasible, a program of systematic data recovery and/or archaeological monitoring will take place under a Section 12 alteration permit issued for HCA protected sites. Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Archaeological and Heritage Resources Management Plan. The success of the measures that are ultimately determined through this engagement is predicted to be high. Therefore, with the implementation of mitigation measures 7.1.1 to 7.1.3, residual effects are assessed to be not significant. In accordance with the AIR, an assessment of cumulative effects on archaeological and heritage resources was not undertaken as the following two conditions were not met: 1) proposed Project is assessed as having residual effects on the VC and 2) residual effects could act cumulatively with residual effects of other past, present, or reasonably foreseeable future physical activities. Further assessment of cumulative effects on archaeological and heritage resources is not warranted because the Project effects on archaeological and heritage resources will be mitigated prior to alteration. As a result, there are no predicted residual effects to archaeological and heritage resources. Consequently, the Project is not expected to interact cumulatively with potential residual effects from other projects or activities.
1590.1	round 1	Kitsumkalum First Nation	8	Human Health	According to the human health assessment, emissions during the operations phase will exceed those associated with construction of the Project. For that reason, the construction phase of the Project was not assessed in the human health assessment. However, the air quality assessment indicates that construction emissions will exceed operations emissions for certain air contaminants (e.g., PM2.5 and PM10 emissions; see Table 4.2-11 and Table 4.2-12). The health risks associated with construction of the Project should be quantitatively assessed.	The potential health risk associated with the construction phase was not assessed in the Application because the amount of PM10 and PM2.5 produced was similar between the construction and project-alone phase. For example, the Air Quality TDR (Appendix A of the Application), Table 13 (page 21) provides the average annual emissions of PM10 and PM2.5 during the construction phase and project-alone phase. - Construction PM10 emissions = 21.5 tonnes/year. - Construction PM2.5 emissions = 20.9 tonnes/year. - Project operations PM10 emissions = 19.2 tonnes/year. - Project operations PM2.5 emissions = 18.4 tonnes/year. Based on the results of the Human Health assessment (Chapter 8 of the Application), Table 8.2-9 (page 8-34), the potential change in health risk from particulate matter in the operations phase is negligible. In locations such as Dodge Cove (i.e., Receptor ID: D-337D, D-372F and D-385) and the worker camp within the Project fenceline (i.e., Receptor ID: IF-1764, IF-1825, and IF-385), the concentration ratio increases marginally from 0.00 to 0.04 above the Base Case. There are negligible changes in the health risk to people from particulate matter in the communities that are closest to the proposed Project. People in communities more distal from the proposed Project (e.g., Prince Rupert, Port Edward, Metlakatla Village) would experience even lower exposures. Given this information, it is logical to conclude that the assessment of particulate matter in the operations phase (i.e. Application Case) would provide sufficient information to conclude a similar degree of health risk in the construction phase.
1591.1	round 1	Kitsumkalum First Nation	8.3.1	Human Health	Other applications in BC that included a marine traffic component have needed to assess the health effects of diesel particulates. Rationale should be provided why diesel emissions were excluded from the Application. If such rationale cannot be provided, diesel emissions should be included in both the air quality and human health assessment.	The potential health risk associated with the construction phase was not assessed in the Application because the amount of PM10 and PM2.5 produced was similar between the construction and project-alone phase. For example, the Air Quality TDR (Appendix A of the Application), Table 13 (page 21) provides the average annual emissions of PM10 and PM2.5 during the construction phase and project-alone phase. - Construction PM10 emissions = 21.5 tonnes/year. - Construction PM2.5 emissions = 20.9 tonnes/year. - Project operations PM10 emissions = 19.2 tonnes/year. - Project operations PM2.5 emissions = 18.4 tonnes/year. Based on the results of the Human Health assessment (Chapter 8 of the Application), Table 8.2-9 (page 8-34), the potential change in health risk from particulate matter in the operations phase is negligible. In locations such as Dodge Cove (i.e., Receptor ID: D-337D, D-372F and D-385) and the worker camp within the Project fenceline (i.e., Receptor ID: IF-1764, IF-1825, and IF-385), the concentration ratio increases marginally from 0.00 to 0.04 above the Base Case. There are negligible changes in the health risk to people from particulate matter in the communities that are closest to the proposed Project. People in communities more distal from the proposed Project (e.g., Prince Rupert, Port Edward, Metlakatla Village) would experience even lower exposures. Given this information, it is logical to conclude that the assessment of particulate matter in the operations phase (i.e. Application Case) would provide sufficient information to conclude a similar degree of health risk in the construction phase.
1592.1	round 1	Kitsumkalum First Nation	8.2.2.8	Human Health	The relevance of the significance threshold should be further described. For example, according to Table 8.2-5, "*if the baseline HQ for food or water ingestion is greater than 0.2, the significance threshold is reached when the Project or cumulative case HQ is greater than baseline HQ + 0.2* ". No information is provided for why the "HQ + 0.2" benchmark constitutes a significance threshold (i.e., the metric seems somewhat arbitrary). Additional information should be provided as to why this benchmark is considered significant.	The application of adding 0.2 to the baseline CR/HQ was made following comments from the Ministry of Health. The Ministry of Health has commented in working group meetings that the project's contribution to health risk should not exceed 20% (i.e., a CR or HQ of 0.2) of the applicable regulatory guideline.
1593.1	round 1	Kitsumkalum First Nation	8.2.2	Human Health	The Application only focused on a select number of COPC (e.g., CACs like CO, PM, SO2 and NO2). No rationale is provided for excluding trace air contaminants like PAHs, VOCs or metals. Other (similar) applications in BC have included a detailed characterization of health risks associated with TACs. Information should be provided why only CACs were considered.	The Application focused on criteria air contaminants that could be produced in sufficient amounts so as to reasonably pose a risk to human health. The scope of the assessment was determined in collaboration with federal and provincial regulators and other stakeholders. Polycyclic aromatic hydrocarbons, volatile organic compounds and metals were not included in the Application Information Requirements under Section 8 for the assessment of human health. Volatile organic compounds in LNG are predominantly methane, ethane, propane and other short chained hydrocarbons which are not toxic when inhaled. There is no pathway for the project to contribute metals in the air. The assessment of metals in air are typical of mine projects, which produce mineralized dust. A rationale for excluding a chemical substance is only provided for substances that were identified in the Application Information Requirements, which defines the scope of the Application.
1594.1	round 1	Kitsumkalum First Nation	8.2.4	Human Health	Boiling water will neither change the pH nor metal concentrations of water. There is an assumption that the residents use a point of source filtration device rather than boiling the water.	The Application does not state that boiling water will change the pH or metal concentrations in the water, noting that the predicted change in water pH (less than 0.3 pH units in the Dodge Cove water reservoir) does not result in a health concern as described in Section 8.2.4 of the Application (Human Health VC - 8.2.4 Project Interactions with Human Health). The boil water advisory is intended to protect residents from water-borne diseases caused by Escherichia coli (E.coli) and fecal coliforms that could be present in untreated or unboiled water. The Project does not affect fecal coliform levels in the Dodge Cove drinking water reservoir. The Application also states that "some Dodge Cove residents apply a point-of-use personal water filtration system for surface waters collected from Digby Island". This statement only indicates that some residents choose to apply a water filtration device as a personal preference.
1595.1	round 1	Kitsumkalum First Nation	8.2.5.3	Human Health	COPC were selected by comparing measured sediment concentrations against sediment quality guidelines that are intended for the protection of aquatic life. This pathway is not immediately relevant to human health. As a result, it is unclear if the human health includes all COPCs relevant or applicable to the Project. Other screening criteria should be considered for the identification of COPC and the subsequent characterization of multiple exposure pathways.	Aurora LNG stands by the methods used to screen chemicals of potential concern to apply to marine traditional foods. As noted in Section 8.2.2.5.4 of the Application, there are no sediment quality guidelines for the protection of human health from any provincial, federal or international regulatory agency. Other screening criteria (e.g., screening against soil quality guidelines for the protection of human health) would encounter similar issues where guidelines are not entirely applicable. The screening was conducted in a manner that consistent with the assessments of other projects that involved dredging (e.g., Pacific Northwest LNG, Prince Rupert Gas Transmission Pipeline, LNG Canada (in Kitimat)). Aurora LNG acknowledges that during the AIR development in 2014, the Ministry of Health (MOH) indicated that the use of CCME sediment quality guidelines as a screening tool for food pathways is not appropriate. A request was made at that time for MOH to suggest alternative screening methods because the proponent recognized that no environmental guidelines would be entirely applicable. Ministry of Health declined to provide alternative screening methods that would be acceptable. Aurora LNG had considered applying the following methods as screening tools: - Canadian Food Inspection Agency tissue residue limits for dioxins and furans. - BC Contaminated Sites Regulations Soil Quality Guidelines for the Protection of Human Health (residential land). However, if these screening methods were applied, copper, dioxins and furans would be screened out of the assessment because the concentration of dioxins and furans were below the CFIA tissue residue limit, and the concentrations of copper, dioxins and furans in the sediment are below the BC CSR soil quality guidelines defining them as contaminants. Therefore, in order to be consistent with the methods used in other LNG projects that propose dredging, the CCME sediment quality guidelines were applied.
1596.1	round 1	Kitsumkalum First Nation	8.2.5.3	Human Health	Consumption rates lower than those documented by Aboriginal Groups were used in the exposure assessment.	Refer to the document "Supplemental Information for Traditional Marine Foods", which will be submitted to the EAO. The "Supplemental Information for Traditional Marine Foods" technical memo was presented to the Working Group in draft for a pre-read on April 18, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
1597.1	round 1	Kitsumkalum First Nation	8.2.5.3	Human Health	PAH that were below the detection limits were not included in the assessment.	Of the polycyclic aromatic hydrocarbons (PAH's) identified during screening, only a few samples were above the applicable sediment quality guideline. However, the assessment of PAHs in clams and crab meat considered all PAHs in the tissue samples. PAHs are not assessed individually. Since they are a group of substances with similar effects to humans, the standard protocol is to convert the toxicity of all PAHs into an equivalent concentration of benzo-a-pyrene, which is the most toxic PAH. This method was applied in the assessment of human health.
1598.1	round 1	Kitsumkalum First Nation	8.2.5.3	Human Health	Arsenic concentrations were not speciated and were not considered in the assessment although exposure pathways for arsenic are identical to those presented for copper, which was assessed. The rationale for excluding arsenic from further analysis is inconsistent with retaining copper as a COPC (i.e., COPC selection criteria should be consistent).	Arsenic in seafood such as fish, crustaceans and molluscs is predominantly in the form of arsenobetaine, an organometallic which is largely considered non-toxic and harmless to humans when consumed. This rationale was provided in the Human Health Technical Data Report (Appendix R, Section 4.1.2.1 - Rationale for Excluding Arsenic from Marine Harvested Foods). In contrast, there is no supporting body of research that indicates different levels of toxicity associated with inorganic and organic forms of copper. Therefore, all forms of copper were assumed to have the equivalent level of toxic potential. Please refer to the following literature sources regarding the relative toxicity of arsenobetaine in seafood and marine life in general: https://www.iupac.org/publications/pac/pdf/2010/pdf/8202x0373.pdf http://ceqg-rcqe.ccme.ca/download/en/230
1599.1	round 1	Kitsumkalum First Nation	8.2.5.3	Human Health	No analytical results for the crab tissue or the crab hepatopancreas are provided. No details regarding the crab tissues are provided. Analysis should be crab muscle, total crab (including hepatopancreas) and hepatopancreas in order to adequately assess exposure.	The "Supplemental Information for Traditional Marine Foods" technical memo has been created that includes responses to this comment and it will be filed with the BC EAO. The "Supplemental Information for Traditional Marine Foods" technical memo was presented to the Working Group in draft for a pre-read on April 18, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
1600.1	round 1	Kitsumkalum First Nation	8.2.5.3	Human Health	The results of the analysis of 5 clam samples are provided and the mean concentrations of copper from the 5 samples are used in the assessment. Given the small sample size risk for the maximum concentrations should also be calculated. Would a sample size of 5 be a statistically valid sample size?	Health Canada's "Supplemental Guidance on Human Health Risk Assessment for Country Foods" recommends that for simple risk assessments, a minimum of 5 to 10 tissue samples be taken for each species and tissue of interest. Greater sampling numbers are recommended for complex sites with multiple active sources of contaminants. However, the proposed dredge footprint is not near any active effluent discharge pipes or other sources of chemical discharge and thus, would not be considered a complex site. As such the sampling density used to assess COPC levels in marine country foods is considered to be adequate for the Project.
1601.1	round 1	Kitsumkalum First Nation	9	Accidents or Malfunctions	The LNG industry has and exceptional safety record. First of all this is subjective. Second, what about environmental record which is also a main concern as this is an Environmental Assessment?	Comment noted. Natural gas is a clean burning fuel when compared to other fossil fuels. Reference to the exceptional LNG industry safety record is reflected by the GIIGNL 2012 report on the safety of commercial LNG shipping. Stringent safety and environmental regulations in Canada will only serve to improve this record further.
1602.1	round 1	Kitsumkalum First Nation	9.1	Accidents or Malfunctions	The response plans must address FN capacity to respond to emergencies, Communication plans need to involve FN communities and be agreed on between the company and FN (also local small communities such as dodge cove) this includes evacuation plans, who to notify and how. Not just a plan on the web site but how to implement it in real life in case of emergency.	Topics such as appropriate methods for emergency notification and the options available for evacuation, if necessary, will be considered through consultation with First Nations and local communities during the development of the Emergency Response Plan.

1603.1	round 1	Kitsumkalum First Nation	9.1	Accidents or Malfunctions	The HSE plan does not address cumulative environmental impact but does it address cumulative health and safety concerns. Impact to human health and such?	Section 9.11 of the Application describes how cumulative effects are assessed in the context of accidents and malfunctions. In accordance with federal policy (Government of Canada 2012), the environmental effects of accidents or malfunctions are considered in the assessment of cumulative environmental effects if they are likely to result from the interaction between the Project and other physical activities that have or will be carried out. Project accidents or malfunctions that are considered likely to result from the Project in combination with other physical activities that have been or will be carried out within the RAA are limited to those associated with vessel-to-vessel collisions. Cumulative effects associated with other accidents and malfunctions are considered to be highly unlikely given the low probability of these scenarios occurring, and the low probability of temporal or spatial overlap with other projects and activities. If a vessel-to-vessel collision were to occur, resulting in a spill of diesel and/or bunker oil, the potential cumulative effects are expected to be significant for marine mammals and marine birds, but not for community health (see Section 9.9). Effects to human health related to accidents and malfunctions are assessed based on each accident and malfunction scenario independently. Since the nature of the scenario would result in different types of chemical releases (e.g., release of criteria air contaminants, oils and fuels, cryogenic LNG releases), the effects are not the same and are not cumulative in nature. Reference: Government of Canada. 2012. Operational Policy Statement. Assessing Cumulative Environmental Effects under the Canadian Environmental Assessment Act. Available at: http://www.ceaa.gc.ca/default.asp?lang=En&n=1DA9E048-1
1604.1	round 1	Kitsumkalum First Nation	9.1	Accidents or Malfunctions	The response plans must address FN capacity to respond to emergencies, Communication plans need to involve FN communities and be agreed on between the company and FN (also local small communities such as dodge cove) this includes evacuation plans, who to notify and how. Not just a plan on the web site but how to implement it in real life in case of emergency.	Topics such as appropriate methods for emergency notification and the options available for evacuation, if necessary, will be considered through consultation with First Nations and local communities during the development of the Emergency Response Plan.
1605.1	round 1	Kitsumkalum First Nation	9.1	Accidents or Malfunctions	The HSE plan does not address cumulative environmental impact but does it address cumulative health and safety concerns. Impact to human health and such?	Section 9.11 of the Application describes how cumulative effects are assessed in the context of accidents and malfunctions. In accordance with federal policy (Government of Canada 2012), the environmental effects of accidents or malfunctions are considered in the assessment of cumulative environmental effects if they are likely to result from the interaction between the Project and other physical activities that have or will be carried out. Project accidents or malfunctions that are considered likely to result from the Project in combination with other physical activities that have been or will be carried out within the RAA are limited to those associated with vessel-to-vessel collisions. Cumulative effects associated with other accidents and malfunctions are considered to be highly unlikely given the low probability of these scenarios occurring, and the low probability of temporal or spatial overlap with other projects and activities. If a vessel-to-vessel collision were to occur, resulting in a spill of diesel and/or bunker oil, the potential cumulative effects are expected to be significant for marine mammals and marine birds, but not for community health (see Section 9.9). Effects to human health related to accidents and malfunctions are assessed based on each accident and malfunction scenario independently. Since the nature of the scenario would result in different types of chemical releases (e.g., release of criteria air contaminants, oils and fuels, cryogenic LNG releases), the effects are not the same and are not cumulative in nature. Reference: Government of Canada. 2012. Operational Policy Statement. Assessing Cumulative Environmental Effects under the Canadian Environmental Assessment Act. Available at: http://www.ceaa.gc.ca/default.asp?lang=En&n=1DA9E048-1
1606.1	round 1	Kitsumkalum First Nation	table 9.3-1	Accidents or Malfunctions	Facility impacts from air craft. I do not see any reference to impacts of the facility to aircraft? Such as changing micro climate, potential re-routing of air craft etc. What are these impacts?	The Application assessment focuses on potential effects of an aircraft collision with the facility, as required by the final approved Application Information Requirements. Please refer to the "Potential Effects on Aviation as a result of Accidents or Malfunctions" technical memo which has been prepared in response to comments relating to potential effects of Project related Accidents or Malfunctions on aviation associated with the Prince Rupert Airport. The technical memo will be filed with the BC EAO.
1607.1	round 1	Kitsumkalum First Nation	table 9.3-1	Accidents or Malfunctions	Vessels grounding or collision would certainly affect vegetation and wetland resources. Salt marshes, seaweed and kelp beds and harvest, intertidal vegetation, wildlife that feed on inter tidal substances such as be as and deer could likely come into contact with hazardous materials, the economic impact have been proven to be enormous to local economies when disasters like a collision and spill occur. Not to mention the visual eye sore of the spill, wreckage and damage caused by such incidents. Or the change in land and resource use near to the site of a crash, grounding or spill. Table 9.3.1 does not appear well thought out, justified or inclusive of all the potential impacts.	Potential effects of vessel grounding or collision on salt marshes, seaweed and kelp beds, intertidal vegetation are included within the assessment of Marine Fish and Fish Habitat (p. 9-38). The interactions in 9.3-1 are considered based on the measurable parameters, potential effects and characterization of residual effects as described for each VC in their respective sections in Part B. There are other interactions that may occur as a result of these accident or malfunction scenarios however based on the characterization of residual effects criteria, they are not expected to be of concern. Section 9.3 on page 9-5 describes how these determinations where made.
1608.1	round 1	Kitsumkalum First Nation	9.4.1 conclusion	Accidents or Malfunctions	" there are no interactions between motor vehicle collisions within the PDA with any VC's" what about fuel delivery? Service trucks? Crew busses? Heavy equipment?	The potential interactions between a motor vehicle collision involving a fuel delivery truck or other large vehicle and VCs could arise if the collision resulted in an on-shore spill. Potential interactions between an on-shore spill and VCs are described in the Application, Section 9.6.
1609.1	round 1	Kitsumkalum First Nation	9.6.2	Accidents or Malfunctions	Aurora will perform fire and explosion analysis as per company requirements.....What does this look like in comparison to provincial and or federal guidelines (if any) how will this be monitored and recorded? I assume Aurora will be meeting regulations plus, however what does that mean?	The LNG Plant will be designed and built according to the CSA standard for LNG facilities (including completion of a Quantitative Risk Assessment) as well as the fire code standards.
1610.1	round 1	Kitsumkalum First Nation	9.6.2	Accidents or Malfunctions	heated vaporizers? What are these?	Heated vaporizers are systems that provide a heat source to allow cryogenic fluids to be turned to gaseous phase such liquefied natural gas (LNG) vaporized into a natural gas state.
1611.1	round 1	Kitsumkalum First Nation	9.6.2	Accidents or Malfunctions	Old forest communities you have listed that they require 100-250 years to recover. Full old growth recovery is estimated to take 300-500 years to fully recover (http://www.ancientforest.org/what-is-old-growth-forest/). This time can range up to 700 years depending on the plant communities. As mentioned this is much longer than the expected life of the project. Therefore it is imperative to only disturb areas that are absolutely necessary.	Section 4.6.5.3 of the Application states that clearing of old forest will be limited to within the PDA. The loss of old forest within the PDA will be up to 75 ha, which is <1% of old forest in the terrestrial RAA. The loss of old forest is far below the approvec threshold for the landscape units in the Great Bear Rainforest Order, which allows for up to 40% loss of old forest. Therefore, an accidental fire is not likely to approach these threshold areas. The Emergency Response Plan, described in Section 14.16 of the Application, will prioritize the protection of the environment in an emergency, along with protection of emergency response staff, workers, the public and property. This will aid in mitigating the area of old-forest potentially affected by an on-shore fire or explosion.
1612.1	round 1	Kitsumkalum First Nation	9.7.1	Accidents or Malfunctions	"....Full emergency shutdown of a maximum of one production train with associated flaring." What does this mean? What about worse case scenario of all trains shutting down?	The probability of an emergency shutdown of one train is low but more likely than an emergency shutdown of all four trains. Potential effects of an emergency shutdown of one train are therefore assessed for Wildlife Resources (Terrestrial), Marine Birds, Infrastructure and Services (see Table 9.3 1). Potential effects of a four train shutdown are assessed for Air Quality, GHGs , and Human Health VCs, as a result of "worst case" air emission and dispersion modelling assumptions.
1613.1	round 1	Kitsumkalum First Nation		General	What exclusions or shutdowns to vessels or vehicle traffic will occur? Either by order of Nexen, the Port Authority or transport Canada.	As noted in Section 6.5.2.5 of the Application, Aurora LNG has proposed a control zone of 500 m radius surrounding each marine terminal berth which is expected to define the ignition-free areas and areas that will be used to dock the LNG vessels. Other marine traffic will be required to avoid these zones as a matter of safety and security while the LNG carrier is loading. The final size of the control zones is subject to change based on the results of a detailed risk assessment to be undertaken as part of facility design (see Figure 6.5-2). Aurora LNG will be participating in a TERMPOL process and will abide by the recommendations resulting from this process related to safe shipping practices. The recommendations will serve as the basis for additional mitigation measures and may lead to the refinement of the proposed control zone.
1614.1	round 1	Kitsumkalum First Nation	9.7.3	Accidents or Malfunctions	"Flaring activities could temporarily interfere with civil aviation." As the project is in close proximity to the airport, this seems absurd. In the event of emergency flaring how does this impact the airport or aviation in general?	Please see the "Potential Effects on Aviation as a result of Accidents or Malfunctions" technical memo to address the issues raised by this comment. The technical memo will be filed with the BC EAO.
1615.1	round 1	Kitsumkalum First Nation	9.7.3	Accidents or Malfunctions	"concentrations of sulphur dioxide, nitrogen dioxide and particulate matter would be less than applicable health based ambient air quality objectives" does this include if a second plant such as PNW is operating? What will nexin do in the event of an exceedance? does this result in an immediate shut down?	Dispersion modelling was used to predict air quality concentrations relative to a four-train emergency shutdown. resulting in flaring of the full LNG plant inventory. Model predictions were found to be below applicable ambient air quality objectives. If emergency flaring is required as a result of a full scale shutdown, Aurora LNG will activate the Emergency Management Plan (EMP) and inform applicable jurisdictions. Air quality will be monitored relative to applicable thresholds established during facility emissions permitting. If ambient air quality concentrations are found to exceed the applicable thresholds as a result of an emergency shutdown, Aurora LNG will follow the EMP procedures to advise the public. The assessment of multiple concurrent LNG facility malfunctions is considered highly unlikely and is not within the scope of the AIR. As such, this scenario was not included in the assessment.
1616.1	round 1	Kitsumkalum First Nation	9.7.4	Accidents or Malfunctions	"...and accidents and malfunctions scenario involving an LNG plant malfunction, will result in no significant effect to the VC's (i.e. air quality, GHG's, wildlife resources (terrestrial), Marine birds, infrastructure and services, and human health)". What about a major flaring event, large leak or catastrophic failure? Although the table is listed for residual effects, there would be significant acute effects.	Flaring as a result of an all train shutdown is assessed in Section 9.7. Onshore hazardous spills are assessed in Section 9.8. Potential effects of ignited leaks (i.e., natural gas, flammable liquids and vapours) are assessed in Section 9.6.
1617.1	round 1	Kitsumkalum First Nation	9.8.2	Accidents or Malfunctions	"Drainage systems will be in place to collect contaminated water and process effluents" This material must be avoided in the first place but if it occurs it must be treated and mitigated.	Aurora LNG acknowledges and agrees with the comment; this is why spills are considered to be accidents or malfunctions, as opposed to part of normal operations. Contaminated water will be handled as hazardous material and be treated as disposed of in accordance with legislation.
1618.1	round 1	Kitsumkalum First Nation	9.9.1	Accidents or Malfunctions	"Released marine fuel is expected to spread quickly .....Diesel quickly degrades within one to two months through naturally occurring processes." In the event of a grounding and spill of bunker and/or diesel, large impacts to local economies, health and ways of life may be felt. the local communities rely on the ocean for sustenance, for employment and health. in the event of a grounding event, the implications could be severe to many in the local communities. This is particularly true for Bunker oil as you mention on page 9-38 "bunker oil is persistent in the environment". this has potential to significantly impact the community!	Section 9.9.3 recognizes the potential effects of spills resulting in localized closure to marine harvesting of country foods as well as commercial fishing (Community Health). Aurora LNG acknowledges a closure to marine harvesting may affect local communities. The predicted effects are expected to be limited in geographic extent to the LAA and short-term in duration (as defined in the characterization of residual effects tables for these VCs). Aurora LNG notes that the severity of potential effects, on marine fish and fish habitat, from a spill in the marine environment, will vary depending on various factors including the type and volume of material spilled, the location, weather (during and following the spill) and season, marine fish (and life stages) and habitat present; tidal influences, response time and response measures.
1619.1	round 1	Kitsumkalum First Nation	page 9-41 section 9.9.1	Accidents or Malfunctions	Community health: and in Human health: In the event of a spill of diesel or bunker oil you mention that a localized fishing ban will be implemented. There are people and groups who do not have choice on where to fish through house territories, size of boat or issues as simple as no mode of transportation or money and must harvest food close to where they live. A large spill would be catastrophic. For some people to stop harvesting from the ocean is like to say they should stop breathing.	Aurora LNG acknowledges the concern of Kitsumkalum First Nation and understands that Project-related effects on fishing may be felt more acutely by Kitsumkalum First Nation fishers because of their fishing practices, barriers to increased participation in the fishing sector, and the sensitivity of Kitsumkalum First Nation fishing practices to change. As a result of these considerations, in the assessment of effects on Kitsumkalum First Nation Current Use of Lands and Resources for Traditional Purposes (see Section 11.3.10.3) Aboriginal Socio-Economic Conditions (see Section 11.3.10.5), Aurora LNG characterized Kitsumkalum First Nation's fishing practices as having a low level of resilience. See pages 11-233 and 11-251 for this assessment. As described in Section 11.6, Aurora LNG acknowledges that the cumulative effects of a vessel-to-vessel collision causing a release of diesel and/or bunker oil could be significant to Aboriginal Current Use and Aboriginal Physical and Cultural Heritage through the loss or change in quality of harvested resources, or culturally or spiritually important species.
1620.1	round 1	Kitsumkalum First Nation	9.2.2	Accidents or Malfunctions	The assessment of the potential risk of effects from an accident or malfunction is based on a risk matrix that combines the likelihood of a residual effect after mitigation and response measures and the consequence (i.e., severity or magnitude) of the residual effect after mitigation and response measures. Since the mitigation and response measures relevant to accidents that have the potential to affect marine water quality are not described in detail, it is difficult to evaluate the appropriateness of the conclusions made about the risk of an accident and whether that accident will have significant effects.	Mitigation measures for on-shore or marine spill events are provided in section 9.8.2. and 9.9.2, respectively, and will be further detailed in the Emergency Response Plan (described in Section 14.16). Aurora LNG will engage with regulators, Aboriginal Groups, and interested stakeholders in the development of the Emergency Response Plan.
1621.1	round 1	Kitsumkalum First Nation	9.2	Accidents or Malfunctions	In the listing of Accidents or Malfunction scenarios, neither the accidental spill of large volumes of bunker oil due to vessel collision or sinking nor the operational spill of small amounts of oil and other mechanical fluids are mentioned. Please add both of these scenarios to this list and assess their potential risks for the environment.	A spill of marine fuel (bunker or diesel) is considered within section 9.9 (Vessel Grounding or Collision). The On-shore Hazardous Spills section (9.8) assesses the potential for spills (small or large) reaching the marine environment.
1622.1	round 1	Kitsumkalum First Nation	9.9.3	Accidents or Malfunctions	At the end of this chapter it is stated that "Residual effects on marine water quality from diesel or bunker fuel due to vessel grounding or collision event are predicted to be not significant." This sentence does not apply to this chapter where the residual effects for marine fish and fish habitat are supposed to be stated. Please change this sentence and re-think the categorization based on the report statement that "e.g., bunker fuel can persist in the marine environment and if left to weather, clean-up efforts can be difficult and continue over the long-term." In addition, please consider the residual effects of the Exxon Valdez deposition of oil into intertidal habitats that persisted for more than two decades.	Aurora LNG acknowledges that there are two repeated errors in Section 9.9.3 of the Application under the sub-heading Marine Fish and Fish Habitat. The final sentences of paragraphs two and four on p. 9-39 should read: 'Residual effects on marine fish and fish habitat from diesel or bunker fuel due to a vessel grounding or collision event are predicted to be not significant.' An errata document is being created that will capture these corrections and it will be filed with the BC EAO. The potential persistence of portions of unrecovered and stranded oil that may become buried in intertidal sediments is not expected to be synonymous with the persistence of effects on marine fish and fish habitat. The loss of lighter fractions of hydrocarbons through evaporation, dispersal and other weathering processes in the days and weeks after a release is expected to reduce the potential for toxic effects where pathways to exposure exist. Furthermore, pathways to exposure are expected to be limited through burial of weathered oil portions or hard crusts formed over their surface (formation of 'tar balls'). The emergency response community has benefited through experience and technological improvements in oil containment and recovery techniques in the over 27 years since the Exxon Valdez incident. Emergency response to a release of bunker fuel will focus on the containment and recovery of floating oil, and the deflection away from, and booming of, sensitive shorelines to limit the stranding of oil.

1623.1	round 1	Kitsumkalum First Nation	9.8.3	Accidents or Malfunctions	The Application determined that spills are not likely to cause adverse effects on Aboriginal and commercial marine harvest. Accidental discharges of fuel, oil or bilge will likely occur during the life of the project despite all regulations cited as being in place. Should there be an accidental spill of oil or fuel at an anchorage or on route, there may be adverse local effects to fish, invertebrates or marine seaweed/plants depending on the magnitude, location, and timing. To the extent that these effects might be significant will depend on many factors including the time of year, the marine receptors present, and the response measures enacted. For example, a large diesel spill during sensitive egg and larval fish life history stages may have a significant effect on that population if not contained quickly.	Aurora LNG agrees that the severity of potential effects, on marine fish and fish habitat, from a spill in the marine environment, will vary depending on various factors. This is described in Section 9.9.3 of the Application. The levels of mortality that could occur are not expected to measurably affect species at a population level, and are predicted to be not significant (as defined in the threshold for significance in the Marine Fish and Fish Habitat assessment: Section 4.9 of the Application). It is predicted that some amount of mortality may occur. However, with mitigation and relevant response measures in place, these effects should be limited to the immediate spill area but could potentially extend out to the LAA.. The extent of the spill will depend on various factors including the type and volume of material spilled, the location, weather (during and following the spill) and season, marine fish (and life stages) and habitat present; tidal influences, response time and response measures. An LNG spill would be expected to vaporize rapidly (i.e., within hours) and would not leave any residue in the marine environment. A diesel spill would be expected to spread more rapidly due to its lighter nature and evaporate and disperse/break down over the short term. A bunker fuel spill would be expected to spread more slowly and persist for a longer period of time due to its thicker consistency. The potential effects from each event may vary depending on the combination of influencing factors and will need to be evaluated and considered in the Emergency Response Plan developed for the Project.
1624.1	round 1	Kitsumkalum First Nation	9	Accidents or Malfunctions	The Proponent has concluded that the accidental releases of hydrocarbons into the marine environment would have Significant residual and cumulative effects on marine birds, but these conclusions are limited to one sentence in the application. The Proponent has not made the connection between these types of accidents and the chronic effect of oiling that is a common occurrence and threat in coastal waters.	Section 9.0 Accidents and Malfunctions assesses the potential residual effects on marine birds as a result of small-scale and large-scale on-shore hazardous spills, vessel grounding or collision, and releases from LNG carriers (while loading). A description of potential effects of hydrocarbon releases was provided in Sections 9.8, 9.9, and 9.10. As noted in these sections, the potential for exposure and the extent of residual effects for small and large-scale spills depends on the volume and location of the spill, the toxicity of the spilled hazardous substance, the speed of response and containment, in combination with the seasonal presence, abundance, and distribution of different marine bird species. Depending on the nature of the interaction (considering the factors described above), exposure to hazardous materials, including hydrocarbons, could result in acute or chronic effects. The mechanisms for exposure and resulting acute or chronic effects to marine birds are described in each subsection, as applicable. Accidental releases were considered to be have a significant effect to marine birds if a hazardous spill were to result in acute mortality or long-term chronic exposure to the extent that could cause population level effects. Aurora LNG has committed to several preventative measures designed to limit chronic hydrocarbon releases and the Project is not expected to contribute to existing cumulative effects of chronic oiling. See Sections 9.8, 9.9, and 9.10 for more details on these preventative measures. Project accidents or malfunctions that were most likely to result in a potential cumulative effect with other Projects and physical activities within the RAA were associated with vessel-to-vessel collisions. The likelihood of such an event was considered highly unlikely, however, mitigation and response measures are outlined in Section 9.11.
1625.1	round 1	Kitsumkalum First Nation	9.8.3, 9.8.4	Accidents or Malfunctions	The Proponent has stated, "After mitigation and response measures have been implemented following an on-shore hazardous spill, the likelihood and consequence of residual effects to water quality from both small-scale and large-scale spills are very low. Based on these factors, the risk matrix ranking is remote and the residual effects are not significant." However, a large-scale spill of diesel oil into the marine environment would be difficult to clean up, making the consequence (i.e., severity of effects) and likelihood of residual effects both moderate or high (not “very low”) and resulting in residual effects that are significant. A fact sheet cited in Chapter 9 of the EAC application (US FWS 2004) states that "light oils [including diesel] leave a film on intertidal resources and have the potential to cause long-term contamination." In addition, an expert report on oil spill response prepared for the City of Vancouver and the Tsleil-Waututh and Tsawout First Nations stated that “collecting and removing oil from the sea surface is a challenging, time-sensitive, and often ineffective process, even under the most favourable conditions” (Nuka Research and Planning Group, LLC 2015). Therefore, spilled oil is likely to remain in the environment after mitigation and response measures, meaning there could be a determination of significant effects according to the definition provided in Section 4.5.12.8: "A significant residual adverse environmental effect on marine water quality is one that is predicted to result in a change in sediment or water quality that would result in a health risk to a local population of marine biota (toxicity for contaminants, habitat and physical damage to fish for suspended sediments). A health risk is identified considering the water and sediment quality guidelines, the conservatism built into those guidelines, and spatial extent and duration of exposure to altered water quality." Nuka Research and Planning Group, LLC. 2015. Oil Spill Response Analysis: Technical Analysis of Oil Spill Response Capabilities and Limitations for Trans Mountain Expansion Project. Expert Report prepared for Tsleil-Waututh Nation, City of Vancouver, and Tsawout First Nation. Available at: http://vancouver.ca/images/web/pipeline/NUKA-oil-spill-response-capabilities-and-limitations.pdf. Accessed: February 2017.	Following a release of diesel, natural attenuation by evaporation and dispersal are expected to reduce the hydrocarbons toxicity to marine organisms over the short term. If unrecovered following containment and recovery operations, and not cleaned up from shorelines, heavier hydrocarbon fractions may persist in shoreline sediments; however, the toxicity and bioavailability of these heavier fractions is expected to be rapidly reduced through weathering processes (including physical losses and biodegradation) (Lee et al. 2003; Page et al. 2002). Considering the elements of the significance threshold (e.g.,..spatial extent and duration of exposure to altered water quality) the characterization of residual effects from an onshore spill with respect to water quality, remains valid. References Lee, K., R.C. Prince, C.W. Greer, K.G. Doe, J.E.H. Wilson, S.E. Cobanli, G.D. Wohlgeschaffen, D. Alroumi, T. King and G.H. Tremblay. 2003. Composition and toxicity of bunker C fuel oil in intertidal sediments after 30 years. Spill Science & Technology Bulletin, 8(2):187-199. Page, D.S. Page, P.D. Boehm, G.S. Douglas and A.E. Bence. 2002. Identification of hydrocarbon sources in the benthic sediments of Prince William Sound and the Gulf of Alaska following the Exxon Valdez oil spill. In P.G. Wells, J.N. Butler, J.S. Hughes (Eds.), Exxon Valdez Oil Spill: Fate and Effects in Alaskan Waters. ASTM STP1219, American Society for Testing and Materials, Philadelphia, PA (1995), pp. 41–83.
1626.1	round 1	Kitsumkalum First Nation	9.9	Accidents or Malfunctions	For Accidents or Malfunctions, Significant Impacts are expected for On-shore Spills, Vessel Grounding or Collision (only bunker oil, not LNG or diesel), and LNG Spills at Loading Zone. For the Significant impacts, residual effects were deemed to be of moderate magnitude with a medium likelihood, but reversible. It is confusing why LNG Spills at the Loading Zone are assessed to be Significant whereas LNG releases from a Vessel Grounding or Collision are not deemed to have Significant impacts. If residual effects from an LNG spill are assessed to be potentially Significant at the loading zone, they should also be of moderate magnitude, likelihood and consequence, and thus Significant during a Vessel Grounding or Collision.	Aurora LNG acknowledges this discrepancy and agrees that the two accidental LNG release events assessed, whether at the loading facility or along the shipping route, may both result in significant effects to marine mammals if the release results in acute effects (e.g., mortality) on marine mammal species at risk, either from direct exposure or injury from a pressure explosion. We also suggest that the likelihood of a residual effect to marine mammals following the release of LNG under either scenario is more accurately characterized as 'low likelihood' and of 'moderate consequence'. An errata document is being created that will capture these corrections and it will be filed with the BC EAO.
1627.1	round 1	Kitsumkalum First Nation	9.9.2	Accidents or Malfunctions	While response measures to a vessel grounding or collision are outlined briefly in this section, a full oil spill response plan should be included as part of the EAC application. It appears that a spill response plan will be included in the Emergency Response Plan (Section 14.16), but this plan is currently under development.	Emergency response plans are typically prepared during a project's detailed design phase when more information is available to identify appropriate emergency response countermeasures and site-specific emergency response resources.
1628.1	round 1	Kitsumkalum First Nation	Section 9.9.3, 9.9.4	Accidents or Malfunctions	The Proponent has stated, "After mitigation and response measures have been implemented following a vessel grounding or collision event with a spill of diesel or LNG, the likelihood and consequence of residual effects to water quality is low. Based on these factors, the risk matrix ranking is low. Residual effects on marine water quality from a release of diesel or LNG due to a vessel grounding or collision event are predicted to be not significant." However, while a website cited in Chapter 9 of the EAC application (NOAA 2014) states that "Small diesel spills will usually evaporate and disperse naturally within a day or less," it also states that "what is commonly referred to as "marine diesel" is often a heavier intermediate fuel oil that will persist longer when spilled. When spilled on water, diesel oil spreads very quickly to a thin film of rainbow and silver sheens, except for marine diesel, which may form a thicker film of dull or dark colors." In addition, "it is possible for the diesel oil that is dispersed by wave action to form droplets that are small enough [to] be kept in suspension and moved by the currents" (NOAA 2014). Therefore, dispersed oil droplets could have an ongoing effect on marine water quality. Furthermore, in October 2016 a tug boat carrying almost 60,000 gallons (> 200,000 litres) of diesel fuel ran aground near Bella Bella and the spill response was hampered by bad weather. The diesel spread across the water and contaminated the clam beds used by the Heiltsuk First Nation (CBC 2016). The Final Situation Report on this incident from Spill Response BC states that 107,552 litres of the 237,262 litres of diesel fuel (45%) on board the tug was recovered (Seaforth Channel Incident Unified Command 2016). In addition, it took over a month to complete the spill cleanup efforts on the water (Seaforth Channel Incident Unified Command 2016). This is evidence that diesel oil can remain in the water during and after a spill response. Therefore, the consequence (i.e., severity of effects) and likelihood of residual effects could both be moderate or high (not “low”) and result in residual effects that are significant. Since tug boats will be escorting the LNG vessels, there is the potential for a large diesel spill having lasting significant adverse environmental effects on marine water quality. CBC (Canadian Broadcasting Corporation). 2016. Bella Bella diesel spill cleanup complicated by severe weather. Available at: http://www.cbc.ca/news/canada/british-columbia/bella-bella-diesel-spill-cleanup-complicated-by-severe-weather-1.3806058. Accessed: January 2017. Seaforth Channel Incident Unified Command. 2016. Final Situation Report – Nov 21. Seaforth Channel Incident Unified Command Information Site. Available at: http://spillresponsebc.ca/2016/11/22/final-situation-report-nov-21/. Accessed: February 2017.	As noted in this comment, in total, 107,552 litres of diesel out of a loaded volume of 237,262 litres was recovered following the grounding of the tug Nathan E. Stewart. It is important to note that the volume recovered does not account for any evaporative loss in volume (i.e., only a portion of the total 237,262 litres would have been potentially recoverable). Further, the referenced Final Situation Report (November 21, 2016) does not appear to suggest that spill clean up, that was specifically on-water, took one month. Shoreline cleanup assessment technique surveys (SCAT) were conducted between October 14 and November 20, 2016 (Seaforth Channel Incident Unified Command 2016), but involved the assessment of oiling on potentially affected shorelines. The potential persistence of heavier, weathered, hydrocarbon fractions in the marine environment is not expected to be synonymous with an increase in consequence ranking for water quality because toxicity, concentration and bioavailability of these fractions is expected to be reduced through weathering in the short term (e.g., by evaporation, dispersal, dissolution, spreading). Reference Seaforth Channel Incident Unified Command. 2016. Final Situation Report – Nov 21. Seaforth Channel Incident Unified Command Information Site. Available at: http://spillresponsebc.ca/2016/11/22/final-situation-report-nov-21/. Accessed: February 2017.
1629.1	round 1	Kitsumkalum First Nation	9.9.3, 9.9.4	Accidents or Malfunctions	The Proponent has stated, "After mitigation and response measures have been implemented following a vessel grounding or collision event with a spill of bunker oil, the likelihood of residual effects to water quality is low, while the consequence is moderate. Based on these factors, the risk matrix ranking is low. Residual effects on marine water quality from a release [of] bunker oil due to a vessel grounding or collision event are predicted to be not significant." While admitting that a bunker oil spill would have a larger consequence on marine water quality than an LNG or diesel spill, the Proponent still concludes that the risk is low and effects are not significant. However, bunker C oil is persistent. A website discussing bunker C spills (NOAA 2017) says "the oil can be carried hundreds of miles in the form of scattered tar balls by winds and currents. The tar balls will vary in diameter from several yards to a few inches and may be very difficult to detect visually or with remote sensing techniques." In addition, an expert report on oil spill response prepared for the City of Vancouver and the Tsleil-Waututh and Tsawout First Nations stated that “collecting and removing oil from the sea surface is a challenging, time-sensitive, and often ineffective process, even under the most favourable conditions” (Nuka Research and Planning Group, LLC 2015). Therefore, spilled oil is likely to remain in the environment after mitigation and response measures and there could be a health risk to a local population of marine biota, meaning that a vessel grounding or collision resulting in a spill of bunker oil could have a significant residual adverse environmental effect on marine water quality. NOAA (National Oceanic and Atmospheric Administration). 2017. No. 6 Fuel oil (Bunker C) Spills. Available at: http://response.restoration.noaa.gov/oil-and-chemical-spills/oil-spills/resources/no-6-fuel-oil-spills.html. Accessed: January 2017.	In the unlikely scenario that portions of released bunker fuel are not recovered through containment and recovery operations and are not cleaned up from shorelines, heavier hydrocarbon fractions may persist in shoreline sediments or on the water surface. The toxicity of these fractions to marine organisms is, however, expected to be rapidly reduced through weathering processes (including physical losses and biodegradation) (Lee et al. 2003; Page et al. 2002). Floating tar balls may be transported by winds and currents. The hard crust-like surface of tar balls, formed through the oxidation of high-viscosity unrecovered hydrocarbons floating on the sea surface, reduces the bioavailability of contaminants of potential concern (Martin 2011). The prediction for the significance of residual effects remains valid. References Lee, K., R.C. Prince, C.W. Greer, K.G. Doe, J.E.H. Wilson, S.E. Cobanli, G.D. Wohlgeschaffen, D. Alroumi, T. Hughes (Eds.), Exxon Valdez Oil Spill: Fate and Effects in Alaskan Waters. ASTM STP1219, American Society for Testing and Materials, Philadelphia, PA (1995), pp. 41–83.
1630.1	round 1	Kitsumkalum First Nation	Section 9.10.3	Accidents or Malfunctions	There appears to be a typo in the Water Quality Section on p. 9-46. The text states "Consequently, the magnitude of residual effect to air quality is negligible and within the geographic extent of the LAA." Since this is in the Water Quality section it is assumed the words "air quality" should be replaced with "water quality."	Aurora LNG acknowledges this is a wording error. The word 'air' in the sentence on p. 9-46 should be 'water' and this correction will be included in an erratum. An errata document is being created that will capture these corrections and it will be filed with the BC EAO.
1631.1	round 1	Kitsumkalum First Nation	Section 14.9	Environmental and Operational Management Plans	The information on the Marine and Freshwater Resources Management Plan in Section 14.9 (approximately half a page) is insufficient to evaluate the adequacy of the plan. For example, the frequency and locations of water quality monitoring have not been provided.	The Marine and Freshwater Resources Management Plan will be developed prior to commencement of construction activities. The plan will outline avoidance, reduction, mitigation, and monitoring measures to limit potential effects to marine fish and fish habitat during Project construction and operation. The plan will include, at a minimum, the following information (as described in Section 14.2 of the Summary of Proposed Environment and Operational Management Plans, Chapter 14):Purpose and scope of the plan, including which Project phases it applies to Relevant regulatory background, environmental issues and environmentally sensitive areasRoles and responsibilities Key emergency and Aurora LNG contact information Project and site orientation and training requirements Mitigation measures and written procedures, specifications, and controls that direct Project activities Monitoring (e.g., compliance and/or effectiveness) and reporting requirements. Input will be required from front end engineering and design (FEED) to determine appropriate water quality monitoring locations and frequency as these may adjust depending on construction activities planned. Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Marine and Freshwater Resources Management Plan.
1632.1	round 1	Kitsumkalum First Nation	14.9	Environmental and Operational Management Plans	The Marine and Freshwater Resources Management Plan does not include any information regarding post-dredging sediment characterization. Considering that some contaminants of concern (COCs; e.g., dioxins/furans) are present in dredged sediments, it is recommended that a follow-up sediment characterization monitoring program is implemented to analyze deposited sediments within the MOF, Berth 1, and Berth 2 areas.	Section 4.5.15 of the Application concluded that contaminant re-settling will be limited at and around the dredge pockets. Baseline sediment sampling indicated that dioxins and furan levels above CCME ISQG were contained in the upper 0.2 m of sediment. As such, the upper 0.5 m of sediment will be removed during dredging and disposed of on land. A small amount of sediment containing elevated dioxins and furans will re-settle in and around the dredge site, likely at reduced concentrations. Much of this re-settled sediment will be removed in subsequent dredging (down to -15 m chart datum) or covered subsequently with dispersed sediment of lower PCDD/F concentrations. Therefore, it is expected that surface sediment contaminant levels will decrease relative to existing conditions and that post-dredging sediment monitoring is not necessary.
1633.1	round 1	Kitsumkalum First Nation	11 (Table 11.2-2	CEAA 2012	The summary of assessment of CEAA requirements, under Aquatic Species (as defined by SARA) is incorrect. There is a significant effects determination for effects to harbour porpoise (and listed "aquatic" species) and has not been summarized as such in Table 11.2-2	The definition of "aquatic species" under SARA includes fish as defined under the Fisheries Act. To avoid duplication, the summary of effects on aquatic species in Table 11.2-2 indicates "Fish are addressed above under Section 5(1)(a)(i)." The summary for effects as defined under Section 5(1)(a)(i) includes the potential effects to marine mammals, including harbour porpoise.

1634.1	round 1	Kitsumkalum First Nation	11.3 (Seciton 11.3.2.2	CEAA 2012	This statement is false: "Aurora LNG held workshops with Metlakatla First Nation, Gitxaala Nation, Kitsumkalum First Nation, and Kitselas First Nation to discuss the use of their Traditional Knowledge (TK) and Traditional Use (TU) information in the assessment of the Section 5(1)(c) Effects, and to discuss proposed assessment methods, residual effects characterization definitions, and significance thresholds." Kitsumkalum was not "consulted" or engaged in the development of assessment methods, residual effects characterization definitions, and significance thresholds for the characterization of CEAA 2012 5(1)(c) effects. Until such time that the proponent engages on these components of the assessment Kitsumkalum cannot agree with any of the determinations of 5(1)(c) effects (to Kitsumkalum).	Aurora LNG believes that it has undertaken meaningful consultation with Kitsumkalum First Nation on the Project since the spring of 2013, prior to the project description being filed. For more information on consultation activities, refer to the first and second Aboriginal Consultation Reports (available on EAO's website). During a technical workshop with Kitsumkalum First Nation in July 2016, Aurora LNG reviewed and proposed changes to some characterization criteria definitions for the assessment of Project effects under CEAA 2012, section (5)(1)(c), see section 8.2.2.3 of Aboriginal Consultation Report #2. Kitsumkalum First Nation had the opportunity to review the draft Part C and Section 11.3 prior to submission of the Application for screening review and to discuss any views or feedback at Technical Workshop #3, which was held on October 25, 2016. The views provided by Kitsumkalum First Nation as part of that workshop were incorporated into Sections 11.3 and 12.3 of the Application, in accordance with the AIR. As noted in Table 12.9-1, in many cases feedback received from Kitsumkalum First Nation resulted in revisions to the final version of Part C submitted to the BC EAO. On April 4, 2017, Aurora LNG held Technical Workshop #5 with Kitsumkalum First Nation to further discuss the characterization of effects and significance conclusions outlined in the CEAA 2012 Section 5(1)(c) assessment, and the assessment of Project effects related to Aboriginal Interests in Part C. Throughout Technical Workshops, Aurora LNG documented Kitsumkalum First Nation opinions, concerns and feedback.
1635.1	round 1	Kitsumkalum First Nation	11.3 (Seciton 11.3.2.2 and Table 11.7-4	CEAA 2012	This statement is mis-leading and affects the assessment of consultation activities associated with the proponent and Kitsumkalum: "In addition, prior to the submission of this Application, Aurora LNG held workshops with all of the Schedule B Aboriginal Groups to review drafts of the portions of Sections 11.3 (Requirements under CEAA 2012 Section 5(1)(c)) that related to each Aboriginal Group. Aurora LNG, as part of the workshops, recorded the views provided by each Aboriginal Group with respect to the CEAA 2012 Section 5(1)(c) Effects (in accordance with Section 11.3.10 of the AIR). In some instances the discussion at the workshops resulted in revisions to this Section of the Application. The views of Aboriginal Groups and Aurora LNG's response are provided in Section 11.7." This workshop (really an 8 hour meeting) with Kitsumkalum was held 7 working days prior to halting of editing the Application for submission (meeting was October 25th 2016, pens down was November 4th and Application submission was November 14th). There has been no meaningful consultation regarding Section 5(1)(c) effects (on Kitsumkalum) with Kitsumkalum. The "views" presented in Table 11.7-4 absolutely do not represent the discussion at the "workshop" (October 25th 2016) and although the Proponent's response is to "continue consultation" discussion regarding 5(1)(c) effects this engagement is proposed for the beginning of April 2017, 4.5 months into a 6 month Application review period. How can meaningful discussion be capture in the EAO EA report at that stage, if in fact there is agreement on issues? Until such time that the proponent engages on these components of the assessment Kitsumkalum cannot agree with any of the determinations of 5(1)(c) effects (to Kitsumkalum).	Aurora LNG is confident that the environmental assessment presented in the Application is fully compliant with all provincial and federal regulatory requirements. The Application, including Section 11.3, was developed in accordance with the Application Information Requirements (AIR) and informed by pre-application consultation with Aboriginal Groups. Aurora LNG believes that it has undertaken meaningful consultation with Kitsumkalum First Nation on the Project since the spring of 2013, prior to the project description being filed. For more information on consultation activities, refer to the first and second Aboriginal Consultation Reports (available on EAO's website). During a technical workshop with Kitsumkalum First Nation in July 2016, Aurora LNG reviewed and proposed changes to some characterization criteria definitions for the assessment of Project effects under CEAA 2012, section (5)(1)(c), see section 8.2.2.3 of Aboriginal Consultation Report #2. Kitsumkalum First Nation had the opportunity to review the draft Part C and Section 11.3 prior to submission of the Application for screening review and to discuss any views or feedback at Technical Workshop #3, which was held on October 25, 2016. The views provided by Kitsumkalum First Nation as part of that workshop were incorporated into Sections 11.3 and 12.3 of the Application, in accordance with the AIR. As noted in Table 12.9-1, in many cases feedback received from Kitsumkalum First Nation resulted in revisions to the final version of Part C submitted to the BC EAO. In addition to the October 2016 workshop referenced in the information request, Aurora LNG also conducted a 2-day workshop (January 25-26, 2017) for all Aboriginal Groups, including Kitsumkalum First Nation. The workshop focused on assessment conclusions related to Part B Valued Components. As the assessments of Valued Components are a key information source for assessment of CEAA 5(1)(c) effects, this workshop was held early in the Application review period to help guide future discussions regarding CEAA 5(1)(c) effects during Technical Workshop #5. On April 4, 2017, Aurora LNG held Technical Workshop #5 with Kitsumkalum First Nation to further discuss the characterization of effects and significance conclusions outlined in the CEAA 2012 Section 5(1)(c) assessment, and the assessment of Project effects related to Aboriginal Interests in Part C. Throughout Technical Workshops, Aurora LNG documented Kitsumkalum First Nation opinions, concerns and feedback.
1636.1	round 1	Kitsumkalum First Nation	11 (Table 11.3-2)	CEAA 2012	Why is the measureable parameter for changes to harvested foods a qualitative assessment (when the parameters are quantitative in nature, e.g. volume of foods harvested)?	Changes in harvested foods is a qualitative assessment as it considers both volume of foods harvested as well as the quality of harvested food. The quality of harvested food can be measured qualitatively by persons engaged in harvesting and quantitatively measured through potential contaminates in harvested foods as described in the Human Health VC.
1637.1	round 1	Kitsumkalum First Nation	11 (Table 11.3-3)	CEAA 2012	Kitsumkalum suggests that there are missing potential project environmental effects (interactions) on Section 5(1)c effects in Table 11.3-3. For example it is not understood why effects to Aboriginal Socio-Ec conditions related to changes to fish and fish habitat, wildlife resources etc. are expected to be assessed / covered off under the assessment of visual quality and community health. Are the quantitative and/or qualitative (and perceived) changes to traditional or current use then assessment as they related to changes to economic-socio conditions?	The assessment provided in Section 11 is limited to changes to the environment which may affect Section (5)(1)(c) factors (e.g. Aboriginal socio-economics). Effects that are outside of the scope of the Aboriginal Socio-Economic Conditions assessment (and are marked with a dash in Table 11.3-3) are excluded because of: Lack of effects predicted to the environment that would interact with the Section 5(1)(c) Effect (e.g., change in labour supply, change in accommodations, change in transportation infrastructure are not changes to the environment and are excluded) Absence of a clear pathway to the Section 5(1)(c) Effect Residual effects were not predicted in the Part B VC Effects relying on other (already included) VCs for conclusions Potential effects associated with changes in harvested foods are assessed in Section 6.6, Community Health. The assessment of change in harvested foods integrates conclusions from the Land and Resource Use VC and Marine Use and Navigable Waters VC, which rely on results from the following VCs and therefore the potential effects are marked with an asterisk in Table 11.3-3: Vegetation and Wetland Resources, Wildlife Resources (Terrestrial), Freshwater Fish and Fish Habitat, Marine Fish and Fish Habitat, Marine Mammals, Marine Birds. Potential effects on commercial fisheries are assessed in Section 6.5, Marine Use and Navigable Waters. The effects described in that section apply to Kitsumkalum First Nation commercial fishers. The assessment of potential effects associated with changes in harvested foods in the Community Health VC integrates conclusions from the Marine Use and Navigable Waters VC and an asterisk indicating this should have been included in the appropriate row ("marine fisheries and other uses"), acknowledging this interaction. An errata document is being compiled that captures this correction and will be filed with the BC EAO.
1638.1	round 1	Kitsumkalum First Nation	11	CEAA 2012	Kitsumkalum continues to disagree with the boundary of the LAA for economic and socio effects. This carries through to the characterization of Section 5(1)c effects. The LAA for the assessment of socio-economic conditions should include Terrace (and not just the Kitsumkalum IR 1). Please do not suggest in your response that this is because it was presented in the AIR, as Kitsumkalum has expressed this concern since before and during the acceptance of the AIR. Please refer to comments on the dAIR.	In response to comments provided by Kitsumkalum First Nation (IR 376) on the draft AIR, the boundaries for the LAA and RAA for the assessment of potential Project effects were changed to include Terrace and adjacent communities.
1639.1	round 1	Kitsumkalum First Nation	11	CEAA 2012	why under the "Administrative Boundary" has it been limited to "land use planning"? There are marine planning agreements and marine use plans available.	The following marine use plans were considered in the assessment (see Section 11.10) Gitxaala Nation. 2011. Draft Marine Use Plan. Submitted as part of the Enbridge Northern Gateway hearings. Kitsumkalum First Nation. n.d. Marine Use Plan Executive Summary. Lax Kw'alaams Indian Band (LKIB). 2004. Lut'ak Dil Loomsk Txamii Laxyuup Ksi'aamks dil Laxsuulda. Interim Land and Marine Resource Plan of the Allied Tsimshian Tribes of Lax Kw'alaams. June 3, 2004. Confidential Report Provided to Nexen.
1640.1	round 1	Kitsumkalum First Nation	11 (Section 11.3.2.7)	CEAA 2012	Kitsumkalum cannot agree with the significance determination for effects to current use as Kitsumkalum was not consulted on the determination of viability as described in Section 11.3.2.7: "if a residual effect on Current Use results in a condition where participation by Aboriginal people in a current use activity is no longer considered viable within existing conditions, it would be considered significant. The determination of viability is guided by information provided by Aboriginal Groups and applying professional judgement."	The Application, including Section 11.3, was developed in accordance with the Application Information Requirements (AIR) and informed by pre-application consultation with Aboriginal Groups (see the Aboriginal Consultation Reports). In the context of the significance threshold for Current Use, "viability" is the consideration of whether it remains realistically possible and/or feasible to continue to participate in a specific traditional use activity at, or near, current levels (potentially with some level of modification). In accordance with the AIR and the Canadian Environmental Assessment Agency (CEA Agency) document entitled "Reference Guide: Determining Whether a Project is Likely to Cause Significant Adverse Environmental Effects: A Framework" this evaluation considers the assessments of magnitude, geographic extent, duration, reversibility and context (i.e. resilience) for each of the measurable parameters identified for current use. In accordance with the AIR, professional judgement is applied as part of this evaluation in a manner that is consistent with the guidance provided in CEA Agency's document entitled "Technical Guidance for assessing the Current Use of Lands and Resources for Traditional Purposes under the Canadian Environmental Assessment Act, 2012" (December 2015) (see pg. 11). Aurora LNG is confident that the environmental assessment presented in the Application is fully compliant with all provincial and federal regulatory requirements. As a result, the re-assessment, as suggested, is neither warranted nor required.
1641.1	round 1	Kitsumkalum First Nation	11 (Section 11.3.5.1	CEAA 2012	There is a concern that since only "Identify residual effects from those VCs to be referenced in the Section 5(1)(c) Effects assessment (these become the Section 5(1)(c) Effect's CEAA component and subcomponent effects)" that there may in fact be effects to Kitsumkalum (via changes in the environment) which are not assess under 5(1)(c) because those effects were not residual for that particular VC.	The environmental effects from Part B VCs relevant to the assessment of Section 5(1)(c) Effects were established in accordance with the AIR and informed by pre-Application consultation with Aboriginal Groups. As described in Section 11.3.2.3 of the Application, if a residual effect was not predicted in the Part B VC (i.e., changes to human health from changes in water quality), then this potential effect was not carried forward to the CEAA Section 5(1)(c) assessment. A rationale and discussion as to why no residual effect was predicted is contained within the applicable Part B VC. It should be noted that the CEAA Section 5(1)(c) assessment included potential effects related to CEAA 5(1)(c) factors that were not included in the Part B VC assessments, including: Changes in consumptive land and resource use for traditional purposes (Hunting, Trapping, Fishing and Vegetation Gathering);Changes in non-consumptive land and resource use for traditional purposes (Spiritual and cultural species and Spiritual and cultural sites and landscapes); andChanges to socio-economic conditions including, barriers to increased participation in the fishing sector and sensitivity of the fishing practices to change. This comment and Aurora LNG's response was discussed as part of Technical Workshop #5. Additional detail regarding Technical Workshop #5 will be provided in Aboriginal Consultation Report #3.
1642.1	round 1	Kitsumkalum First Nation	11 (Seciton 11.3.10.4	CEAA 2012	Effects to aboriginal health have been characterized similarly to the Human Health VC. Kitsumkalum disagrees with this characterization and therefore disagrees with the characterization of Section 5(1)c effects to Aboriginal health conditions. The only two species used as baseline for the HHRA were crab and horse clams. Neither of these species well represent the consumption of seafoods for northcoast Aboriginal groups (and thus the risk associated with that consumption). Although crabs are used frequently both as a food source and as a test species for tissue analysis they are a highly mobile species; therefore there is likely and underestimation of the potential uptake of (local, project PDA) sediment contaminants. As per the Application citation in the HHRA (Chan et al., 2011) horse clam are not a species frequently harvested / consumed by northcoast First Nations. To adequately assess risks to Aboriginal health different and more species should be considered in the HHRA.	Aurora LNG acknowledges that Kitsumkalum First Nation does not agree with the findings of the Human Health assessment. The assessment of human health related to marine foods is intended to investigate the potential risk to people who harvest and consume seafoods from within the proposed dredge footprint and surrounding plume area. As noted in the Human Health Technical Data Report (Page 10: Appendix R of the Application), seafood species must meet certain criteria to be considered in the assessment; these are: 1. The species are commonly harvested by local people for consumption. 2. The species live and feed in close association with benthic sediments. 3. The species have relatively small home range and would spend the majority of their lives within the proposed dredge footprint and plume area. Marine species that do not meet these criteria remain important traditional foods for Kitsumkalum First Nation, but they are not suitable indicators for changes in marine food quality related to chemicals in dredged sediments. The selection of crabs and horse clams for the assessment was made by First Nations attending working group meetings in November and December, 2014, and were confirmed as suitable indicator species, noting that there is a strong basis in scientific literature for using crabs and bivalves to investigate the types of chemicals in the region.
1643.1	round 1	Kitsumkalum First Nation	11 (Table 11.3-11	CEAA 2012	None of the mitigation measures suggested in Table 11.3-11, Table 11.3-12 and Table 11.3-13 are specific to Kitsumkalum (and 5(1)c effects to Kitsumkalum). In fact Tables 11.3-12 and 13 do not even consider mitigation to offset effects to human health nor to offset socio economic conditions via harvested foods consumption. As stated in previous comments Kitsumkalum disagrees with many of the characterizations of 5(1)c effects; therefore, there may be potential effects to Kitsumkalum which differ from the residual effects characterized in the assessment of Part B VCs, which would required Kitsumkalum specific mitigation measures. How will this be rectified?	The mitigation measures proposed in Part B of the application, and summarized in Tables 11.3-11, 11.3-12, and 11.3-13, are anticipated to avoid or reduce effects relevant to Current Use, Aboriginal Health and Socio-Economic Conditions for all Aboriginal groups. Aurora LNG requested and received specific feedback on proposed mitigation measures from Kitsumkalum First Nation during Technical Workshops #4 and #5. Aurora LNG is currently reviewing feedback received to date on mitigation measures and any revised or new mitigation measures proposed will be included as part of an updated Table 16-1 and 16-2 to be submitted to the BC EAO on Day 90.

1644.1	round 1	Kitsumkalum First Nation	11 (Section 11.3.10.3)	CEAA 2012	The following statement is incorrect: "Potential interference with access to terrestrial hunting locations is not expected outside the PDA and marine infrastructure exclusion zone discussed above. Information on Kitsumkalum First Nation TU did not identify specific trails or travel ways that cross through the PDA." Exclusion zones around the marine berth do in fact intersect with traditional travel routes of Kitsumkalum. The proponent has been provided (on several occasions) an addendum to the Kitsumkalum TU study document (Appendix IV - Addendum of July 2016). Therefore there is potential interference with current use access which has not been adequately assessed. Kitsumkalum does not agree with the characterization of effects to marine use and navigable waters, especially as it pertains to specific travel routes of Kitsumkalum. The loss of a travel route does not equate to a percent of available area in the LAA for travel (as assessed in the Marine Use and Navigable Waters section), it is a significant loss to Kitsumkalum.	Aurora LNG is confident that the environmental assessment presented in the Application is fully compliant with all provincial and federal regulatory requirements. The Application, including Section 11.3, was developed in accordance with the Application Information Requirements and informed by pre-application consultation with Aboriginal Groups (see the Aboriginal Consultation Reports). The specific characterizations for Current Use presented in Section 11.3.10.3 (Assessment of CEAA 2012 5(1)(c) iii—Current Use of Lands and Resources for Traditional Purposes) were assessed based on the information contained in Section 11.3.10.2 (Existing Conditions for Kitsumkalum First Nation) and Section 7 (Kitsumkalum First Nation) of Appendix S.2 (Aboriginal Consultation) and the definitions identified in Section 11.3.2.5 (Residual Effects Description Criteria). Aurora LNG notes that Section 11.3.10.3 was compiled based on the best information available at the time that the Application was drafted. Subsequently, Aurora LNG has prepared a technical memo entitled "Consideration of Additional Information Provided by Kitsumkalum First Nation" to consider the information contained in the Addendum, including any new information provided in relation to travel ways, and to determine the influence of this information on Sections 11.3 and 12 of the Application. A draft of this memo was shared with Kitsumkalum First Nation on May 11, 2017 for their comment and will be filed with the BC EAO. Aurora LNG also notes that on April 4, 2017, it held Technical Workshop #5 with Kitsumkalum First Nation. Part of the workshop focused on discussing and clarifying the information provided in the Addendum and the influence of that information on the assessments completed in Sections 11.3.10 and 12.5.7 the Application.
1645.1	round 1	Kitsumkalum First Nation	11 (Table 11.3-26)	CEAA 2012	Kitsumkalum disagrees with the characterization of residual effects to marine fish and fish habitat; therefore, Kitsumkalum also disagrees with the characterization (and significance determination) of Section 5(1)c effects to quantity and quality of current use locations and access routes. The assessment of the quantity of affected fish habitat and marine use and navigable waters does not adequately assess the potential losses of quantity and quality of current use location and access routes for Kitsumkalum. Loss of one current use sites and/or one current use access route for Kitsumkalum does not equate to a % loss in the LAA if that is the only site or access route available to Kitsumkalum under traditional law..	Aurora LNG is confident that the environmental assessment presented in the Application is fully compliant with all provincial and federal regulatory requirements. The Application, including Section 11.3, was developed in accordance with the Application Information Requirements and informed by pre-application consultation with Aboriginal Groups (see the Aboriginal Consultation Reports). The residual Project effects to current use of lands and resources for traditional purposes were assessed according to the methods outlined in Section 11.3.5.1 (Method for the Assessment of Residual Effects). In the context of each of the each Current Use sub-component (e.g., fishing, vegetation gathering) and the measureable parameters related to "Quantity (Area) and Quality of Current Traditional Use Locations Where Use Will Be Affected" and "Quantity (Area) and Quality of Current Access Routes Where Use Will Be Affected" assessed thereunder the assessment was conducted using the following two-part Application drafting framework (see pg. 11-221): "The first part summarizes information and findings related to the residual effects and VCs that have been deemed relevant to the assessment of Section 5(1)(c) effects (i.e., based on steps #1 and #2 from Section 11.3.5.1) under headings that reflect the… measurable parameters…" "The second part… provides conclusions regarding the characterization of residual effects... based on the results of the first part of this section, the findings related to the residual effects and VCs that have been deemed relevant to the assessment of Section 5(1)(c) effects), the understanding of current [use] (based on existing conditions) and the criteria and definitions outlined in Section 11.3.2.5." Using this process, the specific characterizations for Current Use sub-component (e.g., fishing, vegetation gathering) presented in Section 11.3.10.3 (Assessment of CEAA 2012 5(1)(c) iii—Current Use of Lands and Resources for Traditional Purposes) were assessed based on the information contained in Section 11.3.10.2 (Existing Conditions for Kitsumkalum First Nation) and Section 7 (Kitsumkalum First Nation) of Appendix S.2 (Aboriginal Consultation) and the definitions identified in Section 11.3.2.5 (Residual Effects Description Criteria). Significance was then evaluated against the thresholds established in Section 11.3.2.7 (Significance Thresholds for Residual Effects). Aurora LNG notes that Section 11.3.10.3 was compiled based on the best information available at the time that the Application was drafted. Subsequently, Aurora LNG has prepared a technical memo entitled "Consideration of Additional Information Provided by Kitsumkalum First Nation" to consider the information contained in the Addendum, including any new information provided in relation to current use, and to determine the influence of this information on Sections 11.3 and 12 of the Application. A draft of this memo was shared with Kitsumkalum First Nation on May 11, 2017 for their comment and will be filed with the BC EAO. Aurora LNG also notes that on April 4, 2017, it held Technical Workshop #5 with Kitsumkalum First Nation. Part of the workshop focused on discussing and clarifying the information provided in the Addendum and the influence of that information on the assessments completed in Sections 11.3.10 and 12.5.7 the Application. Please also see the memo titled "Additional Information Regarding the CEAA 5(1)(c) and Part C Assessment Methods and the Consideration of Traditional Use Information in these Assessments". Regarding Kitsumkalum First Nation's disagreement with the characterization of residual effects to marine fish and associated habitat, please see the responses provided for comments received on the Marine Fish and Habitat VC.
1646.1	round 1	Kitsumkalum First Nation	11 (Table 11.3-26)	CEAA 2012	Kitsumkalum disagrees with the characterization of residual effects to marine fish and fish habitat; therefore, Kitsumkalum also disagrees with the characterization (and significance determination) of Section 5(1)c effects to quantity and quality of current use for vegetation gathering. The assessment of the quantity of affected fish habitat does not adequately assess the potential losses of quantity and quality of current use vegetation gathering for Kitsumkalum. Loss of one vegetation gathering site for Kitsumkalum does not equate to a % loss in the LAA if that is the only vegetation gathering site in that area available to Kitsumkalum under traditional law.	Aurora LNG is confident that the environmental assessment presented in the Application is fully compliant with all provincial and federal regulatory requirements. The Application, including Section 11.3, was developed in accordance with the Application Information Requirements and informed by pre-application consultation with Aboriginal Groups (see the Aboriginal Consultation Reports). The residual Project effects to current use of lands and resources for traditional purposes were assessed according to the methods outlined in Section 11.3.5.1 (Method for the Assessment of Residual Effects). In the context of each of the each Current Use sub-component (e.g., fishing, vegetation gathering) and the measureable parameters related to "Quantity (Area) and Quality of Current Traditional Use Locations Where Use Will Be Affected" and "Quantity (Area) and Quality of Current Access Routes Where Use Will Be Affected" assessed thereunder the assessment was conducted using the following two-part Application drafting framework (see pg. 11-221): "The first part summarizes information and findings related to the residual effects and VCs that have been deemed relevant to the assessment of Section 5(1)(c) effects (i.e., based on steps #1 and #2 from Section 11.3.5.1) under headings that reflect the… measurable parameters…" "The second part… provides conclusions regarding the characterization of residual effects... based on the results of the first part of this section, the findings related to the residual effects and VCs that have been deemed relevant to the assessment of Section 5(1)(c) effects), the understanding of current [use] (based on existing conditions) and the criteria and definitions outlined in Section 11.3.2.5." Using this process, the specific characterizations for Current Use sub-component (e.g., fishing, vegetation gathering) presented in Section 11.3.10.3 (Assessment of CEAA 2012 5(1)(c) iii—Current Use of Lands and Resources for Traditional Purposes) were assessed based on the information contained in Section 11.3.10.2 (Existing Conditions for Kitsumkalum First Nation) and Section 7 (Kitsumkalum First Nation) of Appendix S.2 (Aboriginal Consultation) and the definitions identified in Section 11.3.2.5 (Residual Effects Description Criteria). Significance was then evaluated against the thresholds established in Section 11.3.2.7 (Significance Thresholds for Residual Effects). Aurora LNG notes that Section 11.3.10.3 was compiled based on the best information available at the time that the Application was drafted. Subsequently, Aurora LNG has prepared a technical memo entitled "Consideration of Additional Information Provided by Kitsumkalum First Nation" to consider the information contained in the Addendum, including any new information provided in relation to current use, and to determine the influence of this information on Sections 11.3 and 12 of the Application. A draft of this memo was shared with Kitsumkalum First Nation on May 11, 2017 for their comment and will be filed with the BC EAO. Aurora LNG also notes that on April 4, 2017, it held Technical Workshop #5 with Kitsumkalum First Nation. Part of the workshop focused on discussing and clarifying the information provided in the Addendum and the influence of that information on the assessments completed in Sections 11.3.10 and 12.5.7 the Application. Please also see the memo titled "Additional Information Regarding the CEAA 5(1)(C) and Part C Assessment Methodologies and the Consideration of Traditional Use Information in these Assessments". Regarding Kitsumkalum First Nation's disagreement with the characterization of residual effects to marine fish and associated habitat, please see the responses provided for comments received on the Marine Fish and Habitat VC.
1647.1	round 1	Kitsumkalum First Nation	11 (page 11-246)	CEAA 2012	These are misleading statements: "The overall result could be a reduction in health risk over time to Aboriginal people who harvest and consume marine foods from Frederick Point, Delusion Bay and Casey Cove" and "The magnitude of residual effects for changes to human health from changes in marine food quality is rated as negligible during the construction phase because the quality of marine foods is anticipated to improve after dredging occurs." What is not stated is that currently the layer of sediment containing higher than background levels of COPCs is capped with "cleaner" sediments and that disturbance of this cap through project activities (such as dredging) will in fact uncap those sediments containing higher levels of COPCs into the marine environment. This is but one example in the Application of many mis-leading (or leading) statements which should not be part of, what should be, a scientific review of data and information for assessment purposes. Perhaps the proponent should conduct a monitoring program to ensure the that these predictions are true (especially as they pertain to Aboriginal Health).	Aurora LNG adheres to strict guidelines such as the Council of Ministers of the Environment (CCME) Interim Sediment Quality Guidelines for the Protection of Aquatic Life. As stated in Section 11 of the Application, "Removal of up to the top 0.5 m of sediment is expected to improve sediment quality after dredging activities are completed. Once dredging is complete, benthic marine life in the dredge footprint would be exposed to lower concentrations of PCDD/F and PAH in the sediment than under present conditions." As described in Section 14, each Environmental and Operational Management Plan will be developed in accordance with industry best management practices and standards, and applicable regulatory requirements. The Marine and Freshwater Resources Management Plan set out in Section 14.9 describes water quality monitoring programs that will be developed and implemented, including details on water quality thresholds, monitoring frequency, and monitoring locations. Aurora LNG will develop these plans prior to the start of construction. The plans will also set out monitoring (e.g., for compliance and/or effectiveness purposes) and reporting requirements. Aurora LNG will engage with the appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the environmental management plans.
1648.1	round 1	Kitsumkalum First Nation	11 (Section 11.4)	CEAA 2012	Kitsumkalum disagrees with the cumulative effects assessment of Section 5(1)c effects. How do we tie the following together: effects to the environment (and socio-economic and health conditions) and the fact those impacts will be different to each Aboriginal Group because of their differing Interests (Part C)? CEAA 2012 doesn't address this, the BC EAA doesn't address this, yet common sense would say that there is no way that there will not be cumulative impacts to Aboriginal way of life from the development proposed in the Prince Rupert area. There is also currently no appropriate way (although we have management plans coming on all fronts!) to monitor these effects in a timely manner to avoid or reduce those impacts. As stated in the Application p. 11-402 "Aurora LNG anticipates that Current Use of lands and resources by Aboriginal Groups will be able to continue with some modification." The loss of one travel route, one current use location etc.is significant to Kitsumkalum. This process is amazingly frustrating.	Aurora LNG is confident that the environmental assessment presented in the Application is fully compliant with all provincial and federal regulatory requirements. The Application, including Section 11.4 (Assessment of Cumulative Effects for CEAA 2012 Section 5(1)(c)), was developed in accordance with the Application Information Requirements. Aurora LNG acknowledges that past, present, and future development in the Prince Rupert region has the potential to result in cumulative effects to various elements of importance to Aboriginal Groups. As described in Section 11.4 (pg. 11-380), Aurora LNG undertook a combined cumulative effects assessment for all of the Aboriginal Groups due to the incomplete nature of the information available within the respective RAAs for CEAA Section 5(1)(c) Effects for those past, present and future projects listed in Table 11.4-1 of the Application. In particular, Aurora LNG notes data deficiencies related to the extent and duration of Section 5(1)(c) Effects from past, present and reasonably foreseeable future projects in the RAAs, and usage relevant to possible interactions throughout the RAAs. This comment and Aurora LNG's response was discussed as part of Technical Workshop #5. Additional detail regarding Technical Workshop #5 will be provided in Aboriginal Consultation Report #3.
1649.1	round 1	Kitsumkalum First Nation	11 (Section 11.6)	CEAA 2012	As discussed in the comments related to the Part B VC Accidents and Malfunctions there has been no assessment of major spill releases (of petrochemicals) from a breach in a LNG carrier vessel.; therefore, the assessment of Accidents or Malfunctions with respect to CEAA 5(1)c is not complete. Regarding the cumulative effects from Accidents or Malfunctions the proponent states that the senarios assessed (although missing at least one senario as stated above) are "highly unlikely given the low probability of these scenarios occurring", but what is missed is the consequences to Aborinal groups is potential high should even one event occur which destroys important current use, culturally important sites.	Aurora LNG agrees that Project-related accidents or malfunctions would have a variable effect on Section 5(1)(c) Effects depending on the type and scope of the accident or malfunction. As described in Section 11.6 of the Application (starting on page 11-418), several of the accidents or malfunctions assessed in Section 9 would have the potential for significant adverse effects to CEAA 5(1)(c) factors if they were to occur such that they cause a loss or change in quality of harvested or culturally-important species or sites.
1650.1	round 1	Kitsumkalum First Nation	11 (Section 11.8)	CEAA 2012	There were over 190 Conditions attached to the Federal approval of the PNW LNG Project, does Nexen really believe that the 12 follow-up and monitoring program listed in Section 11.8 are sufficient to ensure that the effects assessed in the EA are as predicted? Does CEAA and the Federal government believe this is appropriate also?	Aurora LNG is confident that, in combination with the mitigations listed in Section 11.3.6, the follow-up and monitoring programs in Section 11.8 will effectively mitigate effects on CEAA 5(1)(c) factors. In addition, Aurora LNG is currently reviewing specific feedback on proposed mitigation measures received from Aboriginal Groups during Technical Workshops #4 and #5 and any revised or new mitigation measures proposed will be included as part of an updated Table 16-1 and 16-2 to be submitted to the BC EAO on Day 90.

1651.1	round 1	Kitsumkalum First Nation	12.5.7	Aboriginal Consultation	Kitsumkalum suggests that Aurora LNG should be embarrassed to have submitted this section. They are painting a picture as if they have consulted with Kitsumkalum. This is not true. Kitsumkalum has been actively and continuously prevented by the proponent and BC to engage in consultation and to be involved in field work in assess the survey methodologies and ethics of the proponent and their consultants. Kitsumkalum requests that throughout this application, the phrase: continued consultation gets changed to a commitment by the proponent to consult with Kitsumkalum. The entire Part C is uninformative, untrue and unethical. If the proponent hopes to change the current sour relationship with Kitsumkalum, we suggest a meeting with Kitsumkalum to rewrite this section.	Aurora LNG believes that the assessment set out in Part C of the Application is fair and reasonable given the information available to Aurora LNG at the time of writing. As a result, the re-assessment, as suggested, is neither warranted nor required. Aurora LNG has been committed to ongoing consultation with Kitsumkalum First Nation throughout the Application Review phase to discuss issues and concerns related to the Application. Kitsumkalum First Nation had the opportunity to review the draft Part C (and Section 11.3) prior to submission of the Application for screening review and to discuss any views or feedback at Technical Workshop #3, which was held on October 25, 2016. The views provided by Kitsumkalum First Nation as part of that workshop were incorporated into Sections 11.3 and 12.3 of the Application, in accordance with the AIR. As noted in Table 12.9-1, in many cases feedback received from Kitsumkalum First Nation resulted in revisions to the final version of Part C submitted to the BC EAO. In January 2017, Aurora LNG held Technical Workshop #4 to discuss the assessment of VCs set out in Part B of the Application. On April 4, 2017, Aurora LNG held Technical Workshop #5 with Kitsumkalum First Nation to further discuss the characterization of effects and significance conclusions outlined in the CEAA 2012 Section 5(1)(c) assessment, and the assessment of Project effects related to Aboriginal Interests in Part C. Technical Workshops #4 and #5 were also an opportunity to discuss feedback on mitigation measures, proposed management plans and follow-up programs. Throughout Technical Workshops #4 and #5, Aurora LNG documented Kitsumkalum First Nation opinions, concerns and feedback. Aurora LNG believes that it has undertaken meaningful consultation with Kitsumkalum First Nation on the Project since the spring of 2013, prior to the project description being filed. For more information on consultation activities, refer to the first and second Aboriginal Consultation Reports (available on EAO's website). Aurora LNG will be providing a draft of Aboriginal Consultation Report #3 (i.e. the interim consultation report) at day 90 of the 180 day Application-review period (as per the EAO's letter of December 14, 2016). As part of the draft Aboriginal Consultation Report #3, Aurora LNG will report on its understanding of the status of issues/concerns resolution with Kitsumkalum First Nation for the issues/concerns recorded during all phases of the EA (in table format), including those identified in Aboriginal Consultation Report #2 and recorded as part of Technical Workshops #4 and #5. The final version of Aboriginal Consultation Report #3 will be submitted at day 120 of the 180 day Application-review period (as per the section 11 Order [as amended]). Further information that provides context related Aurora LNG's approach to consultation and fieldwork participation, is provided in the technical memo entitled "Aurora LNG's approach to Consultation with Aboriginal Groups".
1652.1	round 1	Kitsumkalum First Nation	12.5.7.3	Aboriginal Consultation	This section needs to be updated. Kitsumkalum shared with Nexen in July 2016 and again in October 2016 a specific past and current use addendum for the project footprint. Statements like: "Kitsumkalum has not shared information of specific past use" is incorrect.	In preparing the Summary of Past, Present, and Anticipated Future Use of the Project Vicinity (Section 12.5.7.3 starting on page 12-197), Aurora LNG reviewed Kitsumkalum First Nation's project-specific study, publicly-available information, and available information from ongoing consultation activities with Kitsumkalum First Nation. On April 4, 2017, Aurora LNG held Technical Workshop #5 with Kitsumkalum First Nation. Part of the workshop focused on discussing and clarifying the information provided in the Addendum and the influence of that information on the assessments completed in Sections 11.3.10 and 12.5.7 the Application. Aurora LNG prepared a technical memo entitled "Consideration of Additional Information Provided by Kitsumkalum First Nation". A draft of this memo was shared with Kitsumkalum First Nation on May 11, 2017 for their comment and will be filed with the BC EAO. Aurora LNG is confident that the environmental assessment presented in the Application is fully compliant with all provincial and federal regulatory requirements.
1653.1	round 1	Kitsumkalum First Nation	12	Aboriginal Consultation	The proponent needs to take out any reference to Agreement-in Principle discussions and information. The information is not updated. These are active negotiations that are being changed an updated weekly. The statement that Kitsumkalum "would have treaty rights to harvest wildlife and migratory birds for domestic purposes..." is misleading if not incorrect. Kitsumkalum holds shared Title and Rights to the shared Tsimshian lands in and around the project, as well as Kitsumkalum specific Title and Rights to specific lands.	Aurora LNG recognizes that treaty negotiations are ongoing and will evolve over time and the language in Section 12.5.7.2 clearly indicates that the treaty is subject to final agreement and ratification. Information in the publicly-available Kitsumkalum Agreement-in-Principle is relevant to Aurora LNG's understanding of anticipated future use by Kitsumkalum First Nation. The Kitsumkalum Agreement-in-Principle also provided valuable information regarding Kitsumkalum First Nation's efforts toward self-government and the importance of continued use of Sm'algyx language by Kitsumkalum First Nation members. In addition, Aurora LNG provided a draft of Section 12.5.7 to Kitsumkalum First Nation for review and comment prior to submission of the Application for screening. Kitsumkalum First Nation did not indicate a concern with the use of the Kitsumkalum Agreement-in-Principle as a source of information at that time.
1654.1	round 1	Kitsumkalum First Nation	12.5.7.4	Aboriginal Consultation	Kitsumkalum has not been offered the opportunity to engage nor design or review Potential Effects Mechanisms. To state that Kitsumkalum "put forth" these mechanisms is wrong. We did not get a change to do so.	Aurora LNG reviewed Kitsumkalum First Nation's Project-specific study for specific potential effect mechanisms of concern to Kitsumkalum First Nation. As a result of that review, Aurora LNG incorporated new potential effect mechanisms into the assessment of Project-related effects on Kitsumkalum First Nation's Aboriginal Interests. For example, Aurora LNG assessed the effect of perceived risk associated with dredging on harvesting activities (see Section 12.5.7.6 starting on page 12-214) because of Kitsumkalum First Nation's description of that potential effect mechanism in its Project-specific study. Another example of where Aurora LNG incorporated information from Kitsumkalum First Nation is in its description of potential effect mechanisms on page 12-210 ("Increased Pressure on Resources"). There are several other examples throughout Section 12.5.7 of potential effect mechanisms included in the assessment of Aboriginal Interests as a result of input from Kitsumkalum First Nation. In addition, Aurora LNG provided a draft of Section 12.5.7 to Kitsumkalum First Nation for review and comment prior to submission of the Application for screening.Kitsumkalum First Nation was invited to review and request changes to the assessment at that time.
1655.1	round 1	Kitsumkalum First Nation	12.5.7.5	Aboriginal Consultation	Kitsumkalum has made it clear to the proponent and to BC and Canada that the word "asserted" is not acceptable to us. Kitsumkalum holds Title and Rights to their territory, some are shared with other Tsimshian and some are exclusively Kitsumkalum. We again request to delete the word "asserted".	Kitsumkalum First Nation's disagreement with the use of the term "asserted" was included in Table 12.9-1 "Pre-Application Views of Aboriginal Groups on Part C" (see pg. 12-330 of the Application). As described in Table 12.9-1, Aurora LNG responded to this concern by removing the term "asserted" in certain instances where it was not necessary (Section 12.5.7.2, Section 12.5.7.7, Section 12.5.7.9, and Section 12.5.7.11 of the Application in reference to the assessment of Kitsumkalum First Nation's Interests). In addition, in Section 12.2.6.2 and Section 12.5.7.3, Aurora LNG will replace use of "asserted" and "asserts" with substitute language through a filing of an errata document. However, Aurora LNG has chosen to retain the use of the the term "asserted" (as well as related terms "asserts", "assert" etc.) in other sections of the Application when discussing Kitsumkalum First Nation Aboriginal Interests in circumstances where the rights in question have not been specifically determined by a court or included expressly in a finalized treaty.
1656.1	round 1	Kitsumkalum First Nation	12	Aboriginal Consultation	Kitsumkalum has issues with the statement by Aurora LNG that they are "committed to continued consultation with Kitsumkalum.." We reject the assertion by the proponent that they have consulted. Canada has signed on to the United Nations declaration on rights of indigenous peoples in May 2016. This would have allowed ample time for the proponent, BC and Canada to start actual consultation with Kitsumkalum. We are still waiting for this to happen. Kitsumkalum does not share Aurora LNG's confidence that this has been or will be a positive relationship.	Aurora LNG believes that it has undertaken meaningful consultation with Kitsumkalum First Nation on the Project since the spring of 2013, prior to the project description being filed. For more information on consultation activities, refer to the first and second Aboriginal Consultation Reports (available on EAO's website). Aurora LNG has been committed to ongoing consultation with Kitsumkalum First Nation throughout the Application Review phase to discuss issues and concerns related to the Application.In January 2017, Aurora LNG held Technical Workshop #4 to discuss the assessment of VCs set out in Part B of the Application. On April 4, 2017, Aurora LNG held Technical Workshop #5 with Kitsumkalum First Nation to further discuss the characterization of effects and significance conclusions outlined in the CEAA 2012 Section 5(1)(c) assessment, and the assessment of Project effects related to Aboriginal Interests in Part C. Technical Workshops #4 and #5 were also an opportunity to discuss feedback on mitigation measures, proposed management plans and follow-up programs. Throughout Technical Workshops #4 and #5, Aurora LNG documented Kitsumkalum First Nation opinions, concerns and feedback. Aurora LNG will be providing a draft of Aboriginal Consultation Report #3 (i.e. the interim consultation report) at day 90 of the 180 day Application-review period (as per the EAO's letter of December 14, 2016). As part of the draft Aboriginal Consultation Report #3, Aurora LNG will report on its understanding of the status of issues/concerns resolution with Kitsumkalum First Nation for the issues/concerns recorded during all phases of the EA (in table format), including those identified in Aboriginal Consultation Report #2 and recorded as part of Technical Workshops #4 and #5. The final version of Aboriginal Consultation Report #3 will be submitted at day 120 of the 180 day Application-review period (as per the section 11 Order [as amended]). For further information please refer to the technical memo entitled "Aurora LNG's Approach to Consultation with Aboriginal Groups" which will be filed with the BC EAO.
1657.1	round 1	Kitsumkalum First Nation	12	Aboriginal Consultation	The statement that the project "has the potential" to affect Kitsumkalum's ability to decide the land use and management is somewhat ridiculous and needs to be deleted. Is the proponent saying that the leveling out of the footprint and the erection and operation of this proposed project will have any, even the slightest, chance that Kitsumkalum can manage or use the land under the plant? If that is the opinion of the proponent, please explain. If not, change this language to The Project will affect Kitsumkalum... This also goes for other topics such as The Project will affect Kitsumkalum's use of the project area for its own economic purposes.	Aurora LNG is of the opinion that there is not enough specific information available regarding how Kitsumkalum First Nation would manage the PDA, including for economic development, if the Project were to not proceed. Without this information, Aurora LNG is unable to state with confidence that the Project "will" affect these aspects of Kitsumkalum First Nation's Aboriginal Interests. Given the complex and ongoing land and marine use planning initiatives currently underway in the region, including Kitsumkalum First nation's own initiatives, it is unclear to Aurora LNG how Kitsumkalum First Nation would manage the PDA in the absence of the Project. Kitsumkalum First Nation's marine use planning documents do not specify specific planning objectives for the Project vicinity. Aurora LNG remains confident that through continued consultation with Kitsumkalum First Nation throughout the life of the Project, collaborative methods could be developed to help balance Kitsumkalum First Nation's land and marine use planning objectives and Project needs.
1658.1	round 1	Kitsumkalum First Nation	12	Aboriginal Consultation	The proposed mitigation measures were not discussed with Kitsumkalum. Aurora LNG needs to commit to consult with Kitsumkalum, rather than "will continue to consult with Aboriginal Groups". Have any actual benefits and accommodation negotiations happened? Are they progressing if they have not started yet?	Kitsumkalum First Nation had the opportunity to review the draft Part C prior to submission of the Application, including mitigation measures proposed to reduce potential effects on Kitsumkalum First Nation Aboriginal Interests, and to discuss any views or feedback at Technical Workshop #3, which was held on October 25, 2016. Aurora LNG has been committed to ongoing consultation with Kitsumkalum First Nation throughout the Application Review phase regarding the development of mitigation measures. Aurora LNG requested and received specific feedback on proposed mitigation measures from Kitsumkalum First Nation during Technical Workshops #4 and #5. Aurora LNG is currently reviewing feedback received to date on mitigation measures and any revised or new mitigation measures proposed will be included as part of an updated Table 16-1 and 16-2 to be submitted to the EAO on Day 90. Aurora LNG will use reasonable efforts to progress negotiations regarding appropriate long-term benefits and accommodation for project effects with Aboriginal Groups.
1659.1	round 1	Kitsumkalum First Nation	12	Aboriginal Consultation	Out of the 4 mitigation measures proposed by Aurora LNG, 3 are requirements under BC and Canadian laws, regulations and directions. Please delete those from this section. The only one acceptable is that Aurora LNG will commit to negotiating benefits with Kitsumkalum.	Comment noted. Aurora LNG believes that the mitigations listed in Section 12.5.7.5 are relevant and appropriate, and looks forward to on-going consultations with Kitsumkalum First Nation to identify new mitigation measures.
1660.1	round 1	Kitsumkalum First Nation	12	Aboriginal Consultation	Please delete "has the potential" and replace with "will".	Without more specificity, Aurora LNG is unable to address this comment. Please see the response to comment #1314 for a related response.
1661.1	round 1	Kitsumkalum First Nation	12	Aboriginal Consultation	Kitsumkalum would appreciate to hear how construction, operations and decommissioning could NOT preclude Kitsumkalum from using the PDA for its own economic purposes. Please explain.	Based on information available at the time of preparing the Application, Aurora LNG was not able to determine what specific plans, if any, Kitsumkalum First Nation may have to develop the PDA for its own economic purposes.
1662.1	round 1	Kitsumkalum First Nation	12	Aboriginal Consultation	Kitsumkalum takes objection to this section. The proponent has told us that this is a requirement from BC. If this is so and this section needs to stay, we expect the proponent to explain the irrelevance of this information. Kitsumkalum has informed the proponent several times that any one area belongs to a specific house group, or tribe or family. There is no such thing as "if you cant go here, just go to the next bay?! Going to someone else's area without permission, will be illegal according to Tsimshian laws. Going somewhere else with permission will be humiliating and will also put undue strain on the resources. Kitsumkalum requests this addition to the text and also the deletion of the last sentence under this heading as it is not correct.	Without a specific section heading or page number associated with this Kitsumkalum First Nation comment, Aurora LNG is unable to address the comment more directly. Also see the "Additional Information Regarding the CEAA 5(1)(C) and Part C Assessment Methodologies and the Consideration of Traditional Use Information in these Assessments" technical memo which will be filed with the BC EAO.
1663.1	round 1	Kitsumkalum First Nation	12	Aboriginal Consultation	The proponent needs to address the level of reclamation of the site and the expected duration of bringing this site back to current state.	As described in Section 1.2.8 of the Application, the decommissioning phase is anticipated to take two to five years and will be completed in accordance with the laws, regulations, and standards in effect at that time.
1664.1	round 1	Kitsumkalum First Nation	12	Aboriginal Consultation	Kitsumkalum vehemently and categorically rejects the statement by the proponent on page 12-204 under this heading. The interference is not restricted to the PDA. As described to the proponent, the Kitsumkalum villages at Casey Point and at Barrett Rock would be seriously impacted, the life in those villages would be possible with the presence of the plant and the activities associated with it. The travel routes would be impacted if not unsafe or impossible to use, the harvesting and hunting would be impacted. Does the author think that if a Walmart would be built across the street from his or her house, that there would be no impact to their way of live? The listed mitigation measures are not mitigation measures at all. Kitsumkalum rejects the entire section 12.5.7.5. This is a disgrace.	Aurora LNG acknowledges that Kitsumkalum First Nation disagrees with the assessment; however, the assessment was conducted in accordance with the requirements of the AIR and was informed by the pre-application consultation conducted with Kitsumkalum First Nation.
1665.1	round 1	Kitsumkalum First Nation	12.5.7.6	Aboriginal Consultation	There are 8 points listed by the proponent as mitigation measures. None were discussed with Kitsumkalum.	Kitsumkalum First Nation had the opportunity to review the draft Part C prior to submission of the Application, including mitigation measures proposed to reduce potential effects on Kitsumkalum First Nation Aboriginal Interests, and to discuss any views or feedback at Technical Workshop #3 , which was held on October 25, 2016. Aurora LNG has been committed to ongoing consultation with Kitsumkalum First Nation throughout the Application Review phase regarding the development of mitigation measures. Aurora LNG requested and received specific feedback on proposed mitigation measures from Kitsumkalum First Nation during Technical Workshops #4 and #5. Aurora LNG is currently reviewing feedback received to date on mitigation measures and any revised or new mitigation measures proposed will be included as part of an updated Table 16-1 and 16-2 to be submitted to the EAO on Day 90.

1666.1	round 1	Kitsumkalum First Nation	12.5.7.6	Aboriginal Consultation	1. Please delete the word "continue" as this has not happened yet.	Aurora LNG believes that it has undertaken meaningful consultation with Kitsumkalum First Nation on the Project since the spring of 2013, prior to the project description being filed. For more information on consultation activities, refer to the first and second Aboriginal Consultation Reports (available on EAO's website). Aurora LNG has been committed to ongoing consultation with Kitsumkalum First Nation throughout the Application Review phase to discuss issues and concerns related to the Application.In January 2017, Aurora LNG held Technical Workshop #4 to discuss the assessment of VCs set out in Part B of the Application. On April 4, 2017, Aurora LNG held Technical Workshop #5 with Kitsumkalum First Nation to further discuss the characterization of effects and significance conclusions outlined in the CEAA 2012 Section 5(1)(c) assessment, and the assessment of Project effects related to Aboriginal Interests in Part C. Technical Workshops #4 and #5 were also an opportunity to discuss feedback on mitigation measures, proposed management plans and follow-up programs. Throughout Technical Workshops #4 and #5, Aurora LNG documented Kitsumkalum First Nation opinions, concerns and feedback. Aurora LNG will be providing a draft of Aboriginal Consultation Report #3 (i.e. the interim consultation report) at day 90 of the 180 day Application-review period (as per the EAO's letter of December 14, 2016). As part of the draft Aboriginal Consultation Report #3, Aurora LNG will report on its understanding of the status of issues/concerns resolution with Kitsumkalum First Nation for the issues/concerns recorded during all phases of the EA (in table format), including those identified in Aboriginal Consultation Report #2 and recorded as part of Technical Workshops #4 and #5. The final version of Aboriginal Consultation Report #3 will be submitted at day 120 of the 180 day Application-review period (as per the section 11 Order [as amended]). For further information please refer to the technical memo entitled "Aurora LNG's Approach to Consultation with Aboriginal Groups" which will be filed with the BC EAO.
1667.1	round 1	Kitsumkalum First Nation	12.5.7.6	Aboriginal Consultation	2. Please change the word "Aboriginal Groups" to Kitsumkalum to ensure that Kitsumkalum is consulted.	Aurora LNG has made the requested changes in the "Mitigation Measures" section of Section 12.5.7.6, third paragraph, second bullet of the Application so that it reads as follows:"Aurora LNG will consult withKitsumkalum First Nationon the design and implementation of Mitigation 6.5-13, which outlines communication protocols regarding Project activities that may interact with Marine Navigation and Use" An errata document has been created that captures these corrections and will be filed with the BC EAO.
1668.1	round 1	Kitsumkalum First Nation	12.5.7.6	Aboriginal Consultation	3. This is at best a riparian or visual buffer required by most forestry or other related projects. Even through this could be considered a partial mitigation on visual effects, it will not diminish any of the expected impacts of this project and related activities to Kitsumkalum. Please remove.	Aurora LNG respectfully disagrees with Kitsumkalum First Nation on this point. The buffer described in the mitigation measures on page 12-215 will effectively mitigate several potential Project effects related to Kitsumkalum First Nation's Aboriginal Interests:Change in visual quality for Kitsumkalum First Nation members travelling via marine travelways south or east of Digby Island or using the site at Casey Point (see assessment starting on page 12-213)Change in harvested species (see assessment starting on page 12-204)Changes in locations, landforms, natural features, and access routes associated with cultural and spiritual use (see assessment starting on page 12-219)This mitigation measure is relevant to the assessment of effects on Kitsumkalum First Nation Aboriginal Interests.
1669.1	round 1	Kitsumkalum First Nation	12.5.7.6	Aboriginal Consultation	4. Please change "will continue to consult with Aboriginal Groups" to "will consult with Kitsumkalum".	Aurora LNG believes that it has undertaken meaningful consultation with Kitsumkalum First Nation on the Project since the spring of 2013, prior to the project description being filed. For more information on consultation activities, refer to the first and second Aboriginal Consultation Reports (available on EAO's website).
1670.1	round 1	Kitsumkalum First Nation	12.5.7.6	Aboriginal Consultation	5. please add Kitsumkalum to this commitment.	Aurora LNG has made the requested changes in the "Mitigation Measures" section of Section 12.5.7.6 of the Application. Aurora LNG will provide timely and on-going information regarding the status of the Project to Kitsumkalum First Nation. An errata document has been created that will capture these corrections and will be filed with the BC EAO.
1671.1	round 1	Kitsumkalum First Nation	12.5.7.6	Aboriginal Consultation	6. Kitsumkalum has already provided specific harvesting sites within the LAA and the PDA. Please update this point to commit that the proponent will, in cooperation with Kitsumkalum, develop mitigation measures to address the impacts to Kitsumkalum, such as monitoring.	Aurora LNG has been committed to ongoing consultation with Kitsumkalum First Nation throughout the Application Review phase to discuss issues and concerns related to the Application. In January 2017, Aurora LNG held Technical Workshop #4 to discuss the assessment of VCs set out in Part B of the Application. On April 4, 2017, Aurora LNG held Technical Workshop #5 with Kitsumkalum First Nation to further discuss the characterization of effects and significance conclusions outlined in the CEAA 2012 Section 5(1)(c) assessment, and the assessment of Project effects related to Aboriginal Interests in Part C. Technical Workshops #4 and #5 were also an opportunity to discuss feedback on mitigation measures, proposed management plans and follow-up programs. Throughout Technical Workshops #4 and #5, Aurora LNG documented Kitsumkalum First Nation opinions, concerns and feedback. Aurora LNG requested and received specific feedback on proposed mitigation measures from Kitsumkalum First Nation during Technical Workshops #4 and #5. Aurora LNG is currently reviewing feedback received to date on mitigation measures and any revised or new mitigation measures proposed will be included as part of an updated Table 16-1 and 16-2 to be submitted to the EAO on Day 90.
1672.1	round 1	Kitsumkalum First Nation	12.5.7.6	Aboriginal Consultation	7. Please include Kitsumkalum specifically in this commitment.	Aurora LNG will consult with Kitsumkalum First Nation to identify potentially viable timber and vegetation salvage opportunities. Aurora LNG has made the requested changes in the "Mitigation Measures" section of Section 12.5.7.6 of the Application. An errata document has been created that will capture these corrections and will be filed with the BC EAO.
1673.1	round 1	Kitsumkalum First Nation	12.5.7.6	Aboriginal Consultation	8. Please change "will continue to consult with Aboriginal Groups to identify additional mitigation measures…" to "will consult with Kitsumkalum to identify…" as this has never happened before.	Kitsumkalum First Nation had the opportunity to review the draft Part C prior to submission of the Application, including mitigation measures proposed to reduce potential effects on Kitsumkalum First Nation Aboriginal Interests, and to discuss any views or feedback at Technical Workshop #3 , which was held on October 25, 2016. Aurora LNG has been committed to ongoing consultation with Kitsumkalum First Nation throughout the Application Review phase regarding the development of mitigation measures. Aurora LNG requested and received specific feedback on proposed mitigation measures from Kitsumkalum First Nation during Technical Workshops #4 and #5. Aurora LNG is currently reviewing feedback received to date on mitigation measures and any revised or new mitigation measures proposed will be included as part of an updated Table 16-1 and 16-2 to be submitted to the EAO on Day 90.
1674.1	round 1	Kitsumkalum First Nation	12	Aboriginal Consultation	Aurora LNG did some unacceptable word smithing, rather suspect as there was no reference to their information source cited. It is stated that Aurora LNG understands that Kitsumkalum members "may have certain locations where they harvest" and that they may have to alter their current harvesting practices because of the project. Kitsumkalum clearly and several times explained to Aurora LNG that Kitsumkalum members in accordance with Tsimshian laws, hold certain areas where they harvest and that they cannot go somewhere else if they are displaced from their specific areas. Why does Aurora LNG feel they need to change words and meanings, minimizing and discarding Tsimshian laws? There is no mitigation measure proposed, nor were any discussed with Kitsumkalum. This will without doubt change Kitsumkalum's Section 35 constitutional rights and Aurora LNG does not speak to it!	Comment noted. Further information that provides context related to the assessment of the identified potential effects in the Application, including clarification regarding certain assumptions, is provided in the technical memo titled "Additional Information Regarding the CEAA 5(1)(c) and Part C Assessment Methods and the Consideration of Traditional Use Information in these Assessments" which will be filed with the BC EAO.
1675.1	round 1	Kitsumkalum First Nation	12	Aboriginal Consultation	Information in this section is incomplete. Aurora LNG did not include the addendum presented to Aurora LNG in July and again in October 2016. It was again given to them in February 2017. This section needs to be revised with Kitsumkalum's cooperation.	On April 4, 2017, Aurora LNG held Technical Workshop #5 with Kitsumkalum First Nation. Part of the workshop focused on discussing and clarifying the information provided in the Addendum and the influence of that information on the assessments completed in Sections 11.3.10 and 12.5.7 the Application. Aurora LNG prepared a technical memo entitled "Consideration of Additional Information Provided by Kitsumkalum First Nation". A draft of this memo was shared with Kitsumkalum First Nation on May 11, 2017 for their comment and will be filed with the BC EAO. Aurora LNG is confident that the environmental assessment presented in the Application is fully compliant with all provincial and federal regulatory requirements.
1676.1	round 1	Kitsumkalum First Nation	12	Aboriginal Consultation	This section needs to be revised. It clearly shows how little conversations Aurora LNG has had with Kitsumkalum. A statement like "Aurora LNG does not anticipate that the aesthetic effects to the experience of harvesting would be considerably altered from existing conditions. Kitsumkalum does not care much about what Aurora LNG anticipates what our experience is, Aurora LNG should talk to us and then report what we have to say on this topic.	Kitsumkalum First Nation had the opportunity to review the draft Part C (and Section 11.3) prior to submission of the Application for screening review and to discuss any views or feedback at Technical Workshop #3, which was held on October 25, 2016. The views provided by Kitsumkalum First Nation as part of that workshop were incorporated into Sections 11.3 and 12.3 of the Application, in accordance with the AIR. As noted in Table 12.9-1, in many cases feedback received from Kitsumkalum First Nation resulted in revisions to the final version of Part C submitted to the BC EAO. Aurora LNG has been committed to ongoing consultation with Kitsumkalum First Nation throughout the Application Review phase to discuss issues and concerns related to the Application. In January 2017, Aurora LNG held Technical Workshop #4 to discuss the assessment of VCs set out in Part B of the Application. On April 4, 2017, Aurora LNG held Technical Workshop #5 with Kitsumkalum First Nation to further discuss the characterization of effects and significance conclusions outlined in the CEAA 2012 Section 5(1)(c) assessment, and the assessment of Project effects related to Aboriginal Interests in Part C. Technical Workshops #4 and #5 were also an opportunity to discuss feedback on mitigation measures, proposed management plans and follow-up programs. Throughout Technical Workshops #4 and #5, Aurora LNG documented Kitsumkalum First Nation opinions, concerns and feedback. Aurora LNG will be providing a draft of Aboriginal Consultation Report #3 (i.e. the interim consultation report) at day 90 of the 180 day Application-review period (as per the EAO's letter of December 14, 2016). As part of the draft Aboriginal Consultation Report #3, Aurora LNG will report on its understanding of the status of issues/concerns resolution with Kitsumkalum First Nation for the issues/concerns recorded during all phases of the EA (in table format), including those identified in Aboriginal Consultation Report #2 and recorded as part of Technical Workshops #4 and #5. The final version of Aboriginal Consultation Report #3 will be submitted at day 120 of the 180 day Application-review period (as per the section 11 Order [as amended]).
1677.1	round 1	Kitsumkalum First Nation	12	Aboriginal Consultation	It is difficult for us to articulate the disappointment and surprise we feel about the first statement in this section. "Aurora LNG assumes that all the terrestrial area in Kitsumkalum First Nation's traditional territory could be used by Kitsumkalum First Nation members for the harvesting of resources". This entire section is wrong and it seems, purposely so. We do not have any other explanation for the twisting of truths by Aurora LNG.	Further information that provides context related to the assessment of the identified potential effects in the Application, including clarification regarding the assumptions utilized in the assessment, is provided in the technical memo entitled "Additional Information Regarding the CEAA 5(1)(c) and Part C Assessment Methods and the Consideration of Traditional Use Information in these Assessments" which will be filed with the BC EAO
1678.1	round 1	Kitsumkalum First Nation	12	Aboriginal Consultation	Out of the list of 150 mitigation measures listed in the project Kitsumkalum found 15 to be somewhat mitigation measures, none were a full on-mitigation measure that might actually look like it was not totally in Aurora LNG's best interest. That means that 135 mitigation measures where legislative or regulatory requirements. Kitsumkalum has not found any mitigation that resulted in any reduction to anticipated adverse effects by the p[reject on Kitsumkalum. There is no conclusion laid out in this section, only a misleading statement that "Aurora LNG is committed to continued consultation with Kitsumkalum to further reduce any adverse effects…". Kitsumkalum has never been consulted to work with Nexen to reduce any effects, so the word "continue" needs to be deleted. Kitsumkalum also has not see any mitigation or strategies to reduce adverse effects, so the word "further" should be deleted.	In Workshop #4 (January 25-26 2017), Kitsumkalum First Nation indicated its concern with the inclusion of several regulations and management plans as mitigation measures in Table 16-1. In response to this concern, Aurora LNG agreed that it would consider revising the list of mitigation measures to more clearly categorize different types of mitigations (e.g. BMPs, regulatory requirements, etc.). In response, Aurora LNG has drafted a technical memo entitled "Mitigation Measures Categorization Table" that categorizes mitigation measures to indicate whether a mitigation measure is outside of permitting requirements (legal requirement, industry standard/Best management practice and/or Aurora LNG additional mitigation measure). This technical memo will be filed with the BC EAO. In that same workshop, Aurora LNG sought and received feedback from Kitsumkalum First Nation on mitigation measures proposed to mitigate effects on Part B VCs. Aurora LNG has been committed to ongoing consultation with Kitsumkalum First Nation throughout the Application Review phase regarding the development of mitigation measures. Aurora LNG requested and received additional feedback on proposed mitigation measures from Kitsumkalum First Nation during Technical Workshops #5. Aurora LNG is currently reviewing feedback received to date on mitigation measures and any revised or new mitigation measures proposed will be included as part of an updated Table 16-1 and 16-2 to be submitted to the EAO on Day 90.
1679.1	round 1	Kitsumkalum First Nation	12.5.7.7	Aboriginal Consultation	Kitsumkalum has never "indicted an Aboriginal Interest to engage in cultural and spiritual activities …" We have clearly stated to Aurora LNG that we hold Section 35 Title and Rights to our territory. This is more than an assertion, it is Tsimshian Law. We engage in cultural and spiritual activities, please change your language accordingly.	In response to Kitsumkalum First Nation's concern, Aurora LNG has replaced the first paragraph of section 12.5.7.7 with the following: In its "Declaration of the Kitsumkalum Indian Band of the Tsimshian Nation of Aboriginal Title and Rights to Prince Rupert Harbour and Surrounding Coastal Areas" Kitsumkalum First Nation states that its members have Aboriginal rights to "engage in cultural and spiritual activities throughout the coastal part" of Kitsumkalum First Nation territory (KIB 2013). In addition, in their Project-specific traditional use study and socio-economic study, Kitsumkalum First Nation stressed the importance of maintaining a sense of place within the traditional territory and continued cultural transmission between generations of Kitsumkalum people (KFN 2016a)." An errata document is being created that will capture these corrections and it will be filed with the BC EAO.
1680.1	round 1	Kitsumkalum First Nation	12	Aboriginal Consultation	Aurora LNG states that they *acknowledge* that resource harvesting is an important part of cultural well being for Kitsumkalum members. First of all, we wonder about the relevancy of what Aurora LNG acknowledges? Resource harvesting is what Kitsumkalum depends on and who we are. It is not just an important part of who we are, it defines us in so many ways. From intergenerational teachings to food security to contributing to feasts to defining one's station in society to economics.	Aurora LNG acknowledges your comment. For clarity, the importance of resource harvesting to several elements of the exercise of Kitsumkalum First Nation Aboriginal Interests is considered throughout Section 12.5.7. Specific sections include: Section 12.5.7.6 (Harvesting, starting on page 12-204), Section 12.5.7.7 (Cultural Wellbeing, on page 12-218 and again starting on page 12-223), Section 12.5.7.8 (Traditional Governance, starting on page 12-228), and Section 12.5.7.12 (Economic Opportunities, page 12-237).

1681.1	round 1	Kitsumkalum First Nation	12	Aboriginal Consultation	Aurora LNG lists 4 potential effects mechanisms that could affect Kitsumkalum's cultural wellbeing in their minds. Aurora has not discussed this with Kitsumkalum, they have not sought out our information or opinion on this, they have not offered to cooperatively come up with these mechanisms, or offered us the opportunity to do so ourselves. Kitsumkalum rejects these 4 "mechanisms". We invite Aurora LNG to talk to us about this.	Aurora LNG reviewed Kitsumkalum First Nation's Project-specific study for potential effect mechanisms of concern to Kitsumkalum First Nation. As a result of that review, Aurora LNG incorporated new potential effect mechanisms into the assessment of predicted Project-related effects on Kitsumkalum First Nation's Aboriginal Interests. For example, Aurora LNG assessed the effect of perceived risk associated with dredging on harvesting activities (see Section 12.5.7.6 starting on page 12-214) because of Kitsumkalum First Nation's description of that potential effect mechanism in its Project-specific study. Another example of where Aurora LNG incorporated information from Kitsumkalum First Nation in its description of potential effect mechanisms is on page 12-210 ("Increased Pressure on Resources"). There are several other examples throughout Section 12.5.7 of potential effect mechanisms included in the assessment of Aboriginal Interests as a result of input from Kitsumkalum First Nation. In addition, Aurora LNG provided a draft of Section 12.5.7 to Kitsumkalum First Nation for review and comment prior to submission of the Application for screening. Kitsumkalum First Nation was invited to review and request changes to the assessment at that time.
1682.1	round 1	Kitsumkalum First Nation	12	Aboriginal Consultation	Aurora LNG states that Kitsumkalum has not specified any species used for cultural purposes. We do not agree with this statement as we believe we have. Besides that point, we did not know that Aurora LNG was going to address this topic, had they actually consulted with us or even just spoken and listened to us, we could have easily broken this information out for them.	During the development of the assessment of effects of the Project on Kitsumkalum First Nation cultural wellbeing, Aurora LNG reviewed Kitsumkalum First Nation's Project-specific study, publicly-available information, and information received through consultation efforts. Throughout those reviews, Aurora LNG did not find any information regarding Kitsumkalum First Nation use of species for cultural purposes other than for harvesting (as indicated on page 12-219). Aurora LNG assessed the use of species for cultural purposes in Section 12.5.7.7 in order to consider the indirect and less tangible potential effects on Kitsumkalum First Nation cultural wellbeing that may occur because of effects to culturally-important (but not harvested) species.
1683.1	round 1	Kitsumkalum First Nation	12	Aboriginal Consultation	Kitsumkalum will not go into further detail on these 4 mechanisms as we do not agree with them and the issues we see are too many to list. This needs to be completely rethought and rewritten.	It is unclear to Aurora LNG which specific subsection Kitsumkalum First Nation is referring to in this comment. However, Aurora LNG is of the opinion that the assessment set out in Section 12.5.7 of the Application is fair and reasonable. As a result, the re-assessment, as suggested, is neither warranted nor required. Please see the response to comment #1338 for more information regarding the incorporation of Kitsumkalum First Nation information into the development of potential effect mechanisms.
1684.1	round 1	Kitsumkalum First Nation	12	Aboriginal Consultation	Aurora LNG lists 4 mitigation measures they have come up with, without engaging Kitsumkalum. Kitsumkalum rejects that any of the listed points can be called mitigation. We invite Aurora LNG to discuss possible mitigation measures. As it stands now, we see none offered by Aurora LNG.	Aurora LNG requested and received specific feedback on proposed mitigation measures from Kitsumkalum First Nation during Technical Workshops #4 and #5. Aurora LNG is currently reviewing feedback received to date on mitigation measures and any revised or new mitigation measures proposed will be included as part of an updated Table 16-1 and 16-2 to be submitted to the EAO on Day 90.
1685.1	round 1	Kitsumkalum First Nation	12	Aboriginal Consultation	1. please change to: Aurora LNG will consult with Kitsumkalum to identify mitigation measures through the life of the project….	As described in Section 12.2 (page 12-39), Aurora LNG is committed to ongoing consultation with Aboriginal Groups through the life of the project to broaden and deepen its understanding of each Aboriginal Groups interests and concerns. Particular attention will be given to identify new measures to reduce adverse effects on the ability of Aboriginal Groups to exercise their Aboriginal Interests in the Project vicinity.
1686.1	round 1	Kitsumkalum First Nation	12	Aboriginal Consultation	2. Kitsumkalum rejects the notion that Aurora's funding of our TUS is a mitigation. It was a baseline study that Aurora LNG had to do for all VC and other information requirements. Kitsumkalum feels that Aurora LNG just paid lip service to this study, as is revealed by their disregard for actually addressing our information.	As described in Section 12.5.7.7 (on page 12-224), Aurora LNG's funding of the Kitsumkalum Traditional Use Study and Socioeconomic Impact Assessment can support Kitsumkalum First Nation cultural transmission by helping to create a record of traditional use and traditional knowledge within the traditional territory as it may relate to the Project vicinity and the proposed shipping route. This mitigation measure directly addresses potential Project effects relating to loss of information about culturally important species, sites, landforms, natural features, and access routes in the Project Vicinity.
1687.1	round 1	Kitsumkalum First Nation	12	Aboriginal Consultation	3. Kitsumkalum's addendum identified some of our traditional and current use and importance of the PDA. This is therefore an erroneous statement that no cultural sites have been identified so far. This is also a requirement of BC regulations and legislation.	On April 4, 2017, Aurora LNG held Technical Workshop #5 with Kitsumkalum First Nation. Part of the workshop focused on discussing and clarifying the information provided in the Addendum and the influence of that information on the assessments completed in Sections 11.3.10 and 12.5.7 the Application. Aurora LNG prepared a technical memo entitled "Consideration of Additional Information Provided by Kitsumkalum First Nation". A draft of this memo was shared with Kitsumkalum First Nation on May 11, 2017 for their comment and will be filed with the BC EAO. Aurora LNG is confident that the environmental assessment presented in the Application is fully compliant with all provincial and federal regulatory requirements.
1688.1	round 1	Kitsumkalum First Nation	12	Aboriginal Consultation	4. as we have not had any input into the "Indigenous Peoples policy" nor have seen it, we cannot comment on this mitigation proposal other than it should not be listed here as one until Kitsumkalum can at least review it. Kitsumkalum objects to have a policy developed about ourselves without being engaged to co-develop.	Aurora LNG's Indigenous Peoples Policy is a corporate level policy document that helps guide Aurora LNG's engagement with Indigenous Peoples in close proximity to the areas where we operate. More information on this policy can be found on Nexen's website: http://www.nexencnooctld.com/en/ResponsibleDevelopment/SocialResponsibility/AboriginalRelations/IndigenousPolicy.aspx
1689.1	round 1	Kitsumkalum First Nation	12	Aboriginal Consultation	as Aurora LNG has not involved Kitsumkalum in the assessment of effects of the project on Kitsumkalum and as we find many of the statements and assessments faulty	Aurora LNG believes that it has undertaken meaningful consultation with Kitsumkalum First Nation on the Project since the spring of 2013, prior to the project description being filed. For more information on consultation activities, refer to the first and second Aboriginal Consultation Reports (available on EAO's website). Aurora LNG has been committed to ongoing consultation with Kitsumkalum First Nation throughout the Application Review phase to discuss issues and concerns related to the Application. In January 2017, Aurora LNG held Technical Workshop #4 to discuss the assessment of VCs set out in Part B of the Application. On April 4, 2017, Aurora LNG held Technical Workshop #5 with Kitsumkalum First Nation to further discuss the characterization of effects and significance conclusions outlined in the CEAA 2012 Section 5(1)(c) assessment, and the assessment of Project effects related to Aboriginal Interests in Part C. Technical Workshops #4 and #5 were also an opportunity to discuss feedback on mitigation measures, proposed management plans and follow-up programs. Throughout Technical Workshops #4 and #5, Aurora LNG documented Kitsumkalum First Nation opinions, concerns and feedback. Aurora LNG will be providing a draft of Aboriginal Consultation Report #3 (i.e. the interim consultation report) at day 90 of the 180 day Application-review period (as per the EAO's letter of December 14, 2016). As part of the draft Aboriginal Consultation Report #3, Aurora LNG will report on its understanding of the status of issues/concerns resolution with Kitsumkalum First Nation for the issues/concerns recorded during all phases of the EA (in table format), including those identified in Aboriginal Consultation Report #2 and recorded as part of Technical Workshops #4 and #5. The final version of Aboriginal Consultation Report #3 will be submitted at day 120 of the 180 day Application-review period (as per the section 11 Order [as amended]). For further information please refer to the technical memo entitled "Aurora LNG's Approach to Consultation with Aboriginal Groups" which will be filed with the BC EAO.
1690.1	round 1	Kitsumkalum First Nation	12	Aboriginal Consultation	Aurora LNGs assessments and statements under this heading are unacceptable to Kitsumkalum and it shows that Aurora LNG has not listened to Kitsumkalum. This section needs to be rewritten.	Aurora LNG believes that the assessment set out in Part C of the Application is fair and reasonable. The information under the heading "Relative Availability of Other Areas" in Section 12.5.7 fulfills a requirement of the AIR (see Section 12.5 of the AIR, page 12-3). Further information that provides context related to the assessment of the identified potential effects in the Application, including clarification regarding the assumptions utilized in the assessment, is provided in the technical memo entitled "Additional Information Regarding the CEAA 5(1)(C) and Part C Assessment Methodologies and the Consideration of Traditional Use Information in these Assessments". This technical memo will be filed with the BC EAO. In consideration of the foregoing, the re-assessment, as suggested, is neither warranted nor required.
1691.1	round 1	Kitsumkalum First Nation	12	Aboriginal Consultation	the assessment and conclusions listed here are not acceptable to Kitsumkalum. Aurora LNG once again is putting words in our mouths, ignored our comments and in general has not engaged Kitsumkalum at all in this conclusion. Delete the word "continue" out of the last paragraph in this section. There has been no such work done so far and to imply that by using the word "continue" is false.	It is unclear to Aurora LNG which paragraph Kitsumkalum First Nation is referring to in this comment. However, Aurora LNG's response to comment #1335 may offer relevant context if Kitsumkalum First Nation is referring to Aurora LNG's use of the words "continued consultation."
1692.1	round 1	Kitsumkalum First Nation	12.5.7.8	Aboriginal Consultation	Kitsumkalum has not been involved in the assessment, nor in coming up with the potential effects mechanisms, nor with mitigation measures. As Aurora LNG could not think of any mitigation measures themselves, maybe they should talk to Kitsumkalum?	Aurora LNG reviewed Kitsumkalum First Nation's Project-specific study for specific potential effect mechanisms of concern to Kitsumkalum First Nation related to Traditional Governance. As a result of that review, Aurora LNG incorporated the following potential effect mechanism into the assessment of effects on Traditional Governance: "House groups risk losing access to their laxyuup and may be further estranged from their ability to provide traditional resources to their house groups" (KFN 2016a) (see page 12-228). Aurora LNG also incorporated relevant baseline information and insights from Kitsumkalum First Nation's Project-specific study into the assessment of potential effects on Traditional Governance. That information is referenced throughout Section 12.5.7.8. Kitsumkalum First Nation had the opportunity to review the draft Part C (and Section 11.3) prior to submission of the Application for screening review and to discuss any views or feedback at Technical Workshop #3, which was held on October 25, 2016. The views provided by Kitsumkalum First Nation as part of that workshop were incorporated into Sections 11.3 and 12.3 of the Application, in accordance with the AIR. As noted in Table 12.9-1, in many cases feedback received from Kitsumkalum First Nation resulted in revisions to the final version of Part C submitted to the BC EAO. On April 4, 2017, Aurora LNG held Technical Workshop #5 with Kitsumkalum First Nation to further discuss the characterization of effects and significance conclusions outlined in the CEAA 2012 Section 5(1)(c) assessment, and the assessment of Project effects related to Aboriginal Interests in Part C. This workshop was also an opportunity to discuss feedback on mitigation measures, proposed management plans and follow-up programs. Aurora LNG documented Kitsumkalum First Nation opinions, concerns and feedback discussed during Technical Workshop #5. Aurora LNG will be providing a draft of Aboriginal Consultation Report #3 (i.e. the interim consultation report) at day 90 of the 180 day Application-review period (as per the EAO's letter of December 14, 2016). As part of the draft Aboriginal Consultation Report #3, Aurora LNG will report on its understanding of the status of issues/concerns resolution with Kitsumkalum First Nation for the issues/concerns recorded during all phases of the EA (in table format), including those identified in Aboriginal Consultation Report #2 and recorded as part of Technical Workshops #4 and #5. The final version of Aboriginal Consultation Report #3 will be submitted at day 120 of the 180 day Application-review period (as per the section 11 Order [as amended]).
1693.1	round 1	Kitsumkalum First Nation	12.5.7.9	Aboriginal Consultation	Kitsumkalum has not been involved in the assessment, nor in coming up with the potential effects mechanisms, nor with mitigation measures. Aurora LNG came up with 3 mitigation measures. Kitsumkalum cannot consider them mitigation measures.	Aurora LNG reviewed Kitsumkalum First Nation's Project-specific study for specific potential effect mechanisms of concern to Kitsumkalum First Nation related to traditional governance. As a result of that review, Aurora LNG incorporated the following potential effect mechanism into the assessment of effects on Traditional Governance: "House groups risk losing access to their laxyuup and may be further estranged from their ability to provide traditional resources to their house groups" (KFN 2016a) (see page 12-228). Aurora LNG also incorporated relevant baseline information and insights from Kitsumkalum First Nation's Project-specific study into the assessment of potential effects on Traditional Governance. That information is referenced throughout Section 12.5.7.8. Kitsumkalum First Nation had the opportunity to review the draft Part C (and Section 11.3) prior to submission of the Application for screening review and to discuss any views or feedback at Technical Workshop #3, which was held on October 25, 2016. The views provided by Kitsumkalum First Nation as part of that workshop were incorporated into Sections 11.3 and 12.3 of the Application, in accordance with the AIR. As noted in Table 12.9-1, in many cases feedback received from Kitsumkalum First Nation resulted in revisions to the final version of Part C submitted to the BC EAO. On April 4, 2017, Aurora LNG held Technical Workshop #5 with Kitsumkalum First Nation to further discuss the characterization of effects and significance conclusions outlined in the CEAA 2012 Section 5(1)(c) assessment, and the assessment of Project effects related to Aboriginal Interests in Part C. This workshop was also an opportunity to discuss feedback on mitigation measures, proposed management plans and follow-up programs. Aurora LNG documented Kitsumkalum First Nation opinions, concerns and feedback discussed during Technical Workshop #5. Aurora LNG will be providing a draft of Aboriginal Consultation Report #3 (i.e. the interim consultation report) at day 90 of the 180 day Application-review period (as per the EAO's letter of December 14, 2016). As part of the draft Aboriginal Consultation Report #3, Aurora LNG will report on its understanding of the status of issues/concerns resolution with Kitsumkalum First Nation for the issues/concerns recorded during all phases of the EA (in table format), including those identified in Aboriginal Consultation Report #2 and recorded as part of Technical Workshops #4 and #5. The final version of Aboriginal Consultation Report #3 will be submitted at day 120 of the 180 day Application-review period (as per the section 11 Order [as amended]).
1694.1	round 1	Kitsumkalum First Nation	12.5.7.9	Aboriginal Consultation	1. this is not a mitigation measure, it is a regulatory requirement	Aurora LNG respectfully disagrees with Kitsumkalum First Nation. A commitment to continued consultation can serve to reduce potential adverse effects on Kitsumkalum First Nation's right to self-government by helping to fully understand the right, and working together to develop additional mitigation measures.
1695.1	round 1	Kitsumkalum First Nation	12.5.7.9	Aboriginal Consultation	2. this is not a mitigation measure, this is a regulatory requirement. Please explain how Aurora LNG had considered Kitsumkalum's information during planning and permitting. What are some concrete examples? How will this works in the future? Will Aurora LNG meet with Kitsumkalum and actually listen and ask for input or will Aurora LNG come up with documents and ideas and ask Kitsumkalum to review? Kitsumkalum has Section 35 Constitutional Aboriginal Title and Rights in and around the PDA for the project, therefor this is a requirement, not a mitigative measure.	Aurora LNG considered Kitsumkalum First Nation's input in Project planning occurred during the January 25-26 2017 workshop (Workshop#2). At this workshop, Aurora LNG informed Kitsumkalum First Nation of two different plans being considered for the construction of the Marine Offloading Facility. Aurora LNG solicited and received feedback from Kitsumkalum First Nation on the topic. Kitsumkalum First Nation had the opportunity to review the draft Part C (and Section 11.3) prior to submission of the Application for screening review and to discuss any views or feedback at Technical Workshop #3, which was held on October 25, 2016. The views provided by Kitsumkalum First Nation as part of that workshop were incorporated into Sections 11.3 and 12.3 of the Application, in accordance with the AIR. As noted in Table 12.9-1, in many cases feedback received from Kitsumkalum First Nation resulted in revisions to the final version of Part C submitted to the BC EAO. In January 2017, Aurora LNG held Technical Workshop #4 to discuss the assessment of VCs set out in Part B of the Application. On April 4, 2017, Aurora LNG held Technical Workshop #5 with Kitsumkalum First Nation to further discuss the characterization of effects and significance conclusions outlined in the CEAA 2012 Section 5(1)(c) assessment, and the assessment of Project effects related to Aboriginal Interests in Part C. Technical Workshops #4 and #5 were also an opportunity to discuss feedback on mitigation measures, proposed management plans and follow-up programs. Throughout Technical Workshops #4 and #5, Aurora LNG documented Kitsumkalum First Nation opinions, concerns and feedback. This information, and other feedback from Kitsumkalum First Nation, will continue to be considered by Aurora LNG during all stages of the Project.

1696.1	round 1	Kitsumkalum First Nation	12.5.7.9	Aboriginal Consultation	3. this is a mitigation measure? To inform Aboriginal Groups about project schedule and timelines?!?! Please remove this and review regulatory requirements from BC EAO and CEAA.	Aurora LNG is of the opinion that this mitigation measure is appropriate and relevant to the assessment of potential effects to Kitsumkalum First Nation's right to self-government. In particular, the mitigation measure would directly mitigate the following concern from Kitsumkalum First Nation's Project-specific study: "communities are being asked to make decisions that impact present and future generations with limited data and understandings of the long term impacts of the LNG industry" (KFN 2016a) (included in Section 12.5.7.9, page 12-230). By continuing to inform Kitsumkalum First Nation of Project schedules and timelines, Aurora LNG will be providing Kitsumkalum First Nation with important information for incorporation into future decision-making.
1697.1	round 1	Kitsumkalum First Nation	12.5.7.9	Aboriginal Consultation	the assessment and conclusions listed here are not acceptable to Kitsumkalum. Aurora LNG once again is putting words in our mouths, ignored our comments and in general has not engaged Kitsumkalum at all in this conclusion. Delete the word "continue" out of the last paragraph in this section. There has been no such work done so far and to imply that by using the word "continue" is false.	It is unclear to Aurora LNG which paragraph Kitsumkalum First Nation is referring to in this comment. However, Aurora LNG's response to comment #1335 may offer relevant context if Kitsumkalum First Nation is referring to Aurora LNG's use of the words "continued consultation."
1698.1	round 1	Kitsumkalum First Nation	12.5.7.10	Aboriginal Consultation	As with all previous sections, please contact Kitsumkalum to re-write this section. This is silly.	On April 4, 2017, Aurora LNG held Technical Workshop #5 with Kitsumkalum First Nation. Part of the workshop focused on discussing and clarifying the information provided in the Addendum and the influence of that information on the assessments completed in Sections 11.3.10 and 12.5.7 the Application. Aurora LGN prepared a technical memo entitled "Consideration of Additional Information Provided by Kitsumkalum First Nation". A draft of this memo was shared with Kitsumkalum First Nation on May 11, 2017 for their comment and will be filed with the BC EAO. Aurora LNG is confident that the environmental assessment presented in the Application is fully compliant with all provincial and federal regulatory requirements.
1699.1	round 1	Kitsumkalum First Nation	12.5.7.11	Aboriginal Consultation	As with all previous sections, please contact Kitsumkalum to re-write this section. Aurora LNG needs to update this section to include information from the addendum which we submitted to them several times now. The mitigation measures proposed are not mitigation but regulatory requirements. Please delete and then talk to Kitsumkalum so we can tell you acceptable mitigation measures.	On April 4, 2017, Aurora LNG held Technical Workshop #5 with Kitsumkalum First Nation. Part of the workshop focused on discussing and clarifying the information provided in the Addendum and the influence of that information on the assessments completed in Sections 11.3.10 and 12.5.7 the Application. Aurora LGN prepared a technical memo entitled "Consideration of Additional Information Provided by Kitsumkalum First Nation". A draft of this memo was shared with Kitsumkalum First Nation on May 11, 2017 for their comment and will be filed with the BC EAO. Aurora LNG is confident that the environmental assessment presented in the Application is fully compliant with all provincial and federal regulatory requirements. In addition, Kitsumkalum First Nation had the opportunity to review the draft Part C prior to submission of the Application, including mitigation measures proposed to reduce potential effects on Kitsumkalum First Nation Aboriginal Interests, and to discuss any views or feedback at Technical Workshop #3 , which was held on October 25, 2016. Aurora LNG has been committed to ongoing consultation with Kitsumkalum First Nation throughout the Application Review phase regarding the development of mitigation measures. Aurora LNG requested and received specific feedback on proposed mitigation measures from Kitsumkalum First Nation during Technical Workshops #4 and #5. Aurora LNG is currently reviewing feedback received to date on mitigation measures and any revised or new mitigation measures proposed will be included as part of an updated Table 16-1 and 16-2 to be submitted to the EAO on Day 90.
1700.1	round 1	Kitsumkalum First Nation	12.5.7.12	Aboriginal Consultation	As with all previous sections, please contact Kitsumkalum to re-write this section. Aurora LNG did not even bother to come up with mitigation measures. Aurora LNG needs to talk to Kitsumkalum so we can tell you acceptable mitigation measures.	Kitsumkalum First Nation received a draft version of Section 12.5.7.12 of the Application in October 2016 for review and comment prior to submission for screening. Mitigation measures specific to Kitsumkalum First Nation economic opportunities were not included in Section 12.5.7.12 because no potential effect mechanisms were identified that were not already assessed elsewhere in the Application. Aurora LNG believes that the assessment set out in the Application is fair and reasonable. As a result, the re-assessment, as suggested, is neither warranted nor required In addition, Aurora LNG requested and received specific feedback on proposed mitigation measures from Kitsumkalum First Nation during Technical Workshops #4 and #5. Aurora LNG is currently reviewing feedback received to date on mitigation measures and any revised or new mitigation measures proposed will be included as part of an updated Table 16-1 and 16-2 to be submitted to the BC EAO on Day 90.
1701.1	round 1	Gitxaala Nation	3	Assessment Methods	The assessment methodology, as described in the opening paragraph, does not adhere to standard environmental assessment methodology. In the Aurora application, it notes that residual effects will be identified prior to application of mitigation. However, typically, residual effects are determined after the application of mitigation measures. This must be clarified as it is contrary to the process outlined in the Final AIR.	The description of the sequential approach used in the Application has been clarified in an Errata. The Application follows standard environmental assessment methods, consistent with Section 3 of the approved AIR. Residual effects are characterized in consideration of the application of mitigation measures. An errata document is being created that will capture these corrections and it will be filed with the BC EAO.
1702.1	round 1	Gitxaala Nation	3	Assessment Methods	The key steps in the effects assessment, as listed in the bullet list, do not include identification of residual effects following application of mitigation measures. This must be updated to ensure the description of the process is reflective of the actual process.	The methods for the assessment of Project-specific effects are described in Section 3.6 (Assessment of Project Residual Effects) of the Application, and include the characterization of residual effects following application of mitigation measures.
1703.1	round 1	Gitxaala Nation	3.1.1	Assessment Methods	This section states that potential Project-related issues and effects were identified based on ongoing consultation with Aboriginal groups. However, this ongoing consultation remains largely superficial. Gitxaala has provided numerous instances of comment, including comments on the Proposed Valued Components Document. All of which have been discounted without explanation as Gitxaala VCs were not considered in Part B of the application and not fully considered in Part C.	The draft Application Information Requirements (AIR) was issued to the Working Group for comment in August 2015, and finalized by the EAO in November 2015 after incorporation of comments to the satisfaction of the EAO. Gitxaala provided the Gitxaala Valued Components Report to Aurora LNG in June 2016. The Gitxaala Valued Components Report was incorporated in Part C of the Application. Its consideration in Part B of the Application has been addressed in an Errata Document. An errata document is being created that will capture these corrections and it will be filed with the BC EAO.
1704.1	round 1	Gitxaala Nation	3.1.1	Assessment Methods	This section states that the process for selecting VCs involved refinement through on-going discussions with Aboriginal Groups identified in the Section 11 Order. This statement is false as Gitxaala was not collaboratively involved in the VC selection process. In fact, Gitxaala prepared comments on the Proposed Valued Component Document but was not provided a response or rationale for the lack of consideration. This statement must be updated to reflect the actual discussions, rather than a blanket statement.	Aurora LNG incorporated the Gitxaala VC Report into the Part C and CEAA 5(1)(c) assessments. The topics covered in the Gitxaala VC Report, although referred to as Valued Components by Gitxaala Nation, were more relevant to requirements of the AIR for those two Application sections. The AIR was finalized on November 23, 2015. Gitxaala Nation submitted the Gitxaala VC Report to Aurora LNG in June 2016.Aurora LNG consulted with Gitxaala Nation on the selection of VCs and on the development on the AIR prior to finalization of that document. Consultation activities related to the development of the AIR are included in the First Aboriginal Consultation Report and in Section 7.1 of the Second Aboriginal Consultation Report.
1705.1	round 1	Gitxaala Nation	3.1.1	Assessment Methods	The lack of consideration of Gitxaala suggested VCs is apparent in the bulleted listing of selected VCs as well as Table 3-1 of the AIR as no Gitxaala proposed VCs are listed in either document.	Aurora LNG incorporated the Gitxaala VC Report into the Part C and CEAA 5(1)(c) assessments. The topics covered in the Gitxaala VC Report, although referred to as Valued Components by Gitxaala Nation, were more relevant to requirements of the AIR for those two Application sections. The AIR was finalized on November 23, 2015. Gitxaala Nation submitted the Gitxaala VC Report to Aurora LNG in June 2016.Aurora LNG consulted with Gitxaala Nation on the selection of VCs and on the development on the AIR prior to finalization of that document. Consultation activities related to the development of the AIR are included in the First Aboriginal Consultation Report and in Section 7.1 of the Second Aboriginal Consultation Report.
1706.1	round 1	Gitxaala Nation	3.2.2	Assessment Methods	No change to this application section was applied from screening comments. Screening comments still stand: "There is no mention in Section 3.2.2 of use of Traditional Knowledge specifically. This must be explicitly stated."	Section 3.2.2 outlines the influence of consultation on the assessment. Please see Section 3.2.3 for the methods for incorporating Traditional Knowledge into the assessment.
1707.1	round 1	Gitxaala Nation	3.2.3	Assessment Methods	No change to this application section was applied from screening comments. Screening comments still stand: "... the language for inclusion under 3.2.3 is extremely permissive and doesn't specifically require inclusion."	Comment noted. As outlined in Section 3.2.2 of the approved AIR, where made available by Aboriginal Groups, traditional knowledge and traditional use studies and information, First Nation land-use plans, or other documents or sources of information were included in the assessment, where applicable.
1708.1	round 1	Gitxaala Nation	3.2.4	Assessment Methods	As Gitxaala input into VC selection was not completed, there was no Gitxaala information used to identify each potential effect or measurable parameters. This is despite the Section specifying that the application took into consideration the issues and concerns of Aboriginal groups. This statement must be disaggregated to reflect the actual groups involved in selection of the effects and measurable parameters.	Disaggregated consultation information, including information on the consultation efforts related to the development of the AIR and VCs, is described in both the First and Second Aboriginal Consultation Reports. Aurora LNG incorporated the Gitxaala VC Report into the Part C and CEAA 5(1)(c) assessments. The topics covered in the Gitxaala VC Report, although referred to as Valued Components by Gitxaala Nation, were more relevant to requirements of the AIR for those two Application sections. The AIR was finalized on November 23, 2015. Gitxaala Nation submitted the Gitxaala VC Report to Aurora LNG in June 2016.Aurora LNG consulted with Gitxaala Nation on the selection of VCs and on the development on the AIR prior to finalization of that document. Consultation activities related to the development of the AIR are included in the First Aboriginal Consultation Report and in Section 7.1 of the Second Aboriginal Consultation Report.
1709.1	round 1	Gitxaala Nation	4.2.1	Air Quality	This section does not include Aboriginal Interests as being linked to the VC assessment. This is problematic as Gitxaala has submitted a VC report with specific reference to air quality which has not been incorporated or addressed.	References to the links between changes in air quality and effects on Aboriginal Interests are addressed in the Application as follows: Section 4.2.1 includes the following text at paragraph 3 on pg. 4.2-1 that links changes in air quality to effects on Aboriginal Interests and communities: "Other VCs and sections that are supported by components of this assessment include: □ Summary of Statutory Requirements under the Canadian Environmental Assessment Act, 2012 (see Section 11.0) □ Aboriginal Consultation (see Section 12.0)." Traditional knowledge and traditional use information gathered from Project specific studies submitted to Aurora LNG (including the Gitxaala VC Report) and from publicly available sources was reviewed and considered during the preparation of the Application, and was incorporated into the air quality assessment, where applicable. For example; dispersion modelling included Aboriginal Interests-related locations. The findings of the Air Quality VC assessment were carried forward into the assessment of adverse effects on the exercise of Gitxaala Nation Aboriginal Interests in the following sections: 12.5.6.6 Assessment of Effects on Gitxaala Nation Harvesting-Related Aboriginal Interests (Changes in the Harvesting Experience). 12.5.6.7 Assessment of Effects on Gitxaala Nation Cultural Wellbeing (Changes in the experience of using sites and landscape features for rituals and spiritually important purposes) The results of the Air Quality assessment were incorporated into the following CEAA 2012-related sections of the Application that assess Project environmental effects on Gitxaala Nation current use of lands and resources for traditional purposes, the health of Gitxaala Nation members and Gitxaala Nation physical and cultural heritage:"11.3.9.3 Assessment of CEAA 2012 5(1)(c) iii—Current Use of Lands and Resources for Traditional Purposes"Qualitative Changes in the Current Experience of Traditional HarvestingQualitative Changes in the Experience of Using Sites and Landscape Features for Rituals or Spiritually Important Purposes"11.3.9.4 Assessment of CEAA 2012 5(1)(c)(i) – Aboriginal Health"Changes to Aboriginal Health as a result of changes to human health from changes in air quality."11.3.9.6 Assessment of CEAA 2012 5(1)(c) ii and iv—Aboriginal Physical and Cultural Heritage"Change in Consumptive Land and Resource Use for Traditional PurposesChange in Non-consumptive Land and Resource Use for Traditional Purposes
1710.1	round 1	Gitxaala Nation	Table 4.2-1	Air Quality	This table details that dispersion modelling included Aboriginal Interests locations. However, Gitxaala was not involved in the selection of dispersion modelling sites therefore, this statement is misleading. The Aboriginal Interests information must be disaggregated to show which groups were consulted as part of the air dispersion modelling, and which were not.	Aboriginal Groups were not specifically consulted on the development of dispersion modelling sites. Aurora LNG began developing the list of sensitive receptors (dispersion modelling sites) for use in the model before Project-specific traditional use information was available from any Aboriginal Groups. At that time, Aurora LNG created a list of all known Aboriginal use locations within the Air Quality RAA from publicly-available sources, including recently completed Environmental Assessment Applications for other projects in the vicinity. Upon receipt of a Kitselas First Nation Project-specific use study in April 2015, Aurora LNG added locations identified in this study to the list of sensitive receptors. Aurora LNG then revisited the sensitive receptors list in October 2015 in case any new Aboriginal use locations had been identified in Project-specific studies. At that time, Aurora LNG had not received any additional Project-specific studies from Aboriginal Groups. Upon request, information for any identified site can be extracted from the dispersion modelling output owing to the existence of many thousands of 'gridded receptors' in the modelling domain. The absence of a 'sensitive receptor' in the modelling input files does not hinder that process.

1711.1	round 1	Gitxaala Nation	Table 4.2-1	Air Quality	This table states that "Air Quality findings are carried forward into the Aboriginal Interests section of the Environmental Assessment Certificate Application." However, the Part C volume does not specifically address air quality in terms of effects to Aboriginal groups. For example, Table 12.3-2 indicates that potential adverse effects on VCs related to Air Quality are assessed in the Air Quality Volume. Further, when Air Quality is considered, it is only referred to in terms of the previously considered information in Section 4.2 and is not considered in terms of Aboriginal Interests.	The assessment of effects on Gitxaala Nation considers air quality effects in the context of the exercise of Aboriginal Interests in the following sections:Changes in Enjoyment, Experience, and Use of the Land (Section 12.5.6.5, starting on page 12-158) Changes in the Harvesting Experience (Section 12.5.6.6, starting on page 12-170) Changes in the Experience of Using Sites and Landscape Features for Rituals and Spiritually Important Purposes (Section 12.5.6.7, starting on page 12-180)
1712.1	round 1	Gitxaala Nation	4.2.2.3	Air Quality	The description in this section is general and does not provide examples of where and how TK/TLU information was used in the assessment of this VC. These specifics are necessary for confidence that this was actually undertaken. Specifically as the example continually given of inclusion in the dispersion modelling was not undertaken with Gitxaala.	Aurora LNG began developing the list of sensitive receptors (dispersion modelling sites) for use in the Air Quality model before Project-specific traditional use information was available from any Aboriginal Groups. At that time, Aurora LNG created a list of all known Aboriginal use locations within the Air Quality RAA from publicly-available sources, including recently completed Environmental Assessment Applications for other projects in the vicinity. Upon receipt of a Kitselas First Nation Project-specific use study in April 2015, Aurora LNG added locations identified in this study to the list of sensitive receptors. Aurora LNG then revisited the sensitive receptors list in October 2015 in case any new Aboriginal use locations had been identified in Project-specific studies. At that time, Aurora LNG had not received any additional Project-specific studies from Aboriginal Groups. Upon request, information for any identified site can be extracted from the dispersion modelling output owing to the existence of many thousands of 'gridded receptors' in the modelling domain. The absence of a specific 'sensitive receptor' in the modelling input files does not hinder that process.
1713.1	round 1	Gitxaala Nation	4.2.2.5	Air Quality	This Section states that "Selection of the RAA included consideration of nearby communities and traditional use areas." However, Gitxaala's traditional use areas were not collected by Aurora LNG until following the establishment of the RAA. Therefore, this statement is incorrect. In fact, Gitxaala used the boundaries defined for the EAC Application in defining the boundaries for the traditional use study. Therefore, the statement is circular.	Aurora LNG began developing the proposed study area including the RAA for use in the Air Quality model in early 2015, before Gitxaala Nation provided any Project-specific TK/TU information. At that time, Aurora LNG created a list of all known Aboriginal use locations within the Air Quality RAA from publicly-available sources, including recently completed Environmental Assessment Applications for other projects in the vicinity. Upon receipt of Kitselas First Nation's Project-specific use study in April 2015, Aurora LNG added to the dispersion modelling sites with locations identified in Kitselas First Nation's study. Aurora LNG then revisited the dispersion modelling sites list in October 2015 in case any new Aboriginal use locations had been identified in Project-specific studies. At that time, Aurora LNG had not received any additional Project-specific studies from Aboriginal Groups, including Gitxaala Nation.
1714.1	round 1	Gitxaala Nation	4.2.2.5	Air Quality	Gitxaala Nation was not consulted on potential Aboriginal administrative boundaries that could have played a role in determining the air quality assessment methodology outside those noted for spatial boundaries.	The Project spatial boundaries and assessment methodology are consistent with the Application Information Requirements (AIR), the final Detailed Model Plan (Appendix 1, Air Quality - TDR) and the British Columbia Air Quality Dispersion Modelling Guideline. The extent of the spatial boundaries was finalized in consultation with BC MOE and included consideration of nearby communities and traditional use areas. The spatial boundaries are sufficiently large so as to encompass the region influenced by the Project and other major emission sources in the region. Previous air quality assessments were reviewed to provide confidence that the selected spatial boundaries encompass areas where potential cumulative effects may occur.
1715.1	round 1	Gitxaala Nation	4.2.3	Air Quality	There is no reference to TLU/TK in the existing conditions for Air Quality. This is despite the Assessment Methods specifically identifying that TLU/TK would be integrated into the existing conditions for each VC. This must be updated to include specific TLU/TK related to Air Quality for Gitxaala Nation, specifically, information contained in the VC Report.	Aboriginal Groups were not specifically consulted on the development of dispersion modelling sites. Aurora LNG began developing the list of sensitive receptors (dispersion modelling sites) for use in the model before Project-specific traditional use information was available from any Aboriginal Groups. At that time, Aurora LNG created a list of all known Aboriginal use locations within the Air Quality RAA from publicly-available sources, including recently completed Environmental Assessment Applications for other projects in the vicinity. Upon receipt of a Kitselas First Nation Project-specific use study in April 2015, Aurora LNG added locations identified in this study to the list of sensitive receptors. Aurora LNG then revisited the sensitive receptors list in October 2015 in case any new Aboriginal use locations had been identified in Project-specific studies. At that time, Aurora LNG had not received any additional Project-specific studies from Aboriginal Groups, including Gitxaala Nation. Upon request, information for any identified site can be extracted from the dispersion modelling output owing to the existence of many thousands of 'gridded receptors' in the modelling domain. The absence of a 'sensitive receptor' in the modelling input files does not hinder that process.
1716.1	round 1	Gitxaala Nation	4.4.2.2	Acoustic Environment	While this section indicates that locations of special importance were incorporated into the sampling program for noise, there is no mention of these locations in the volume and they are not differentiated from other noise receptors. How can Gitxaala have any confidence in the results without specific information related to their rights and interests?	In the Application, Table 4.4-4 lists noise sensitive receptors with a brief description and Figure 4.4-1 shows the receptor locations. Receptors that represent traditional land use areas (ID# R4, R5, R6, R7, R8, R16, R17, R18, R19, and R21) have been included.
1717.1	round 1	Gitxaala Nation	4.4.2.3	Acoustic Environment	The description in this section is general and does not provide examples of where and how TK/TLU information was used in the assessment of this VC. These specifics are necessary for confidence that this was undertaken.	As a result of the information received from Aboriginal Groups, and summarized in the Aboriginal Consultation Report #2 (see Appendix S.1), TK was used to identify potentially affected locations of special interest to Aboriginal Groups. Sites of Aboriginal importance include residential communities, hunting and gathering, and other habitation and gathering sites. As described in Section 4.4.3 Existing Conditions, noise receptors for the assessment were established at Aboriginal traditional use areas along the islands (i.e., Casey Point, Barrett Rock, Lima Point, Fraser Point, Kinahan Islands, and Pike Island). In addition, noise-related findings at locations of special importance to Aboriginal Groups were used as input for assessing adverse residual effects on Aboriginal resources in Part C of the Application (see Section 12.0). In the Gitxaala VC Report, underwater noise was raised as a potential effect in the context of harvesting. This TK/TLU information is not relevant to the existing conditions in the Acoustic Environment VC, which focuses on existing levels of noise in the region and in nearby communities. Underwater noise was taken into consideration in Section 4.9.5 (Marine Fish and Fish Habitat) and Section 4.10.5 (Marine Mammals) of the Application. In the Gitxaala VC Report, Gitxaala Nation also mentioned that noise effects could affect the experience of exercising Aboriginal Interests. This input has been incorporated into Part C of the Application (see Sections 12.5.6.6 and 12.5.6.7). In the existing conditions for Acoustic Environment VC, noise monitoring was conducted at five locations within the Acoustic Environment local assessment area . These locations represent the closest communities to the Project as well as other uninhabited locations along coastal area of Digby Island. These locations provide representative information on the existing acoustic environment along different coastal area without any land-based residential and land-based commercial activities. The results from the monitoring are applied to other receptors in the assessment, including receptors for traditional land use area (R4 to R8, R16 to R19, and R21) in the Acoustic Environment VC.
1718.1	round 1	Gitxaala Nation	4.4.3	Greenhouse Gases	There is no reference to TLU/TK in the existing conditions for the Acoustic Environment. This is despite the Assessment Methods specifically identifying that TLU/TK would be integrated into the existing conditions for each VC. This must be updated to include specific TLU/TK related to the Acoustic Environment for Gitxaala Nation, specifically, information contained in the VC Report.	As a result of the information received from Aboriginal Groups, and summarized in the Aboriginal Consultation Report #2 (see Appendix S.1), TK was used to identify potentially affected locations of special interest to Aboriginal Groups. Sites of Aboriginal importance include residential communities, hunting and gathering, and other habitation and gathering sites. As described in Section 4.4.3 Existing Conditions, noise receptors for the assessment were established at Aboriginal traditional use areas along the islands (i.e., Casey Point, Barrett Rock, Lima Point, Fraser Point, Kinahan Islands, and Pike Island). In addition, noise-related findings at locations of special importance to Aboriginal Groups were used as input for assessing adverse residual effects on Aboriginal resources in Part C of the Application (see Section 12.0). In the Gitxaala VC Report, underwater noise was raised as a potential effect in the context of harvesting. This TK/TLU information is not relevant to the existing conditions in the Acoustic Environment VC, which focuses on existing levels of noise in the region and in nearby communities. Underwater noise was taken into consideration in Section 4.9.5 (Marine Fish and Fish Habitat) and Section 4.10.5 (Marine Mammals) of the Application. In the Gitxaala VC Report, Gitxaala Nation also mentioned that noise effects could affect the experience of exercising Aboriginal Interests. This input has been incorporated into Part C of the Application (see Sections 12.5.6.6 and 12.5.6.7). In the existing conditions for Acoustic Environment VC, noise monitoring was conducted at five locations within the Acoustic Environment local assessment area . These locations represent the closest communities to the Project as well as other uninhabited locations along coastal area of Digby Island. These locations provide representative information on the existing acoustic environment along different coastal area without any land-based residential and land-based commercial activities. The results from the monitoring are applied to other receptors in the assessment, including receptors for traditional land use area (R4 to R8, R16 to R19, and R21) in the Acoustic Environment VC.
1719.1	round 1	Gitxaala Nation	4.5.2.2	Water Quality	While it is stated that TK/TLU influenced the scope of the assessment, this is not apparent from the assessment itself in regards to Gitxaala TLU/TK information.	Freshwater study design incorporated lakes and streams that were identified as important to Aboriginal groups in TK/TU studies (e.g., Tsook Lake). There was also a focus to incorporate into the freshwater assessment, lakes and streams identified as commercial, recreational, Aboriginal (CRA) fisheries and those identified as supporting culturally critical species. Although no specific freshwater lakes or streams were identified, TK/TU studies noted that hunting and trapping of duck, geese, mink and marten take place on Digby Island and Metlakatla in and around waterbodies and wetlands; therefore the study design incorporated a comprehensive spatial sampling program to assess these areas. Study design details for freshwater and marine water quality were presented at a technical workshop (December 2, 2015) to obtain feedback during development of proposed field programs. Water chemistry of marine and freshwater and storm water runoff was discussed at a subsequent technical workshop (March 16 and 17, 2016).
1720.1	round 1	Gitxaala Nation	4.5.2.3	Water Quality	The description in this section is general and does not provide examples of where and how TK/TLU information was used in the assessment of this VC. These specifics are necessary for confidence that this was actually undertaken.	Freshwater study design incorporated lakes and streams that were identified as important to Aboriginal groups in TK/TU studies (e.g., Tsook Lake). There was also a focus to incorporate into the freshwater assessment, lakes and streams identified as commercial, recreational, Aboriginal (CRA) fisheries and those identified as supporting culturally critical species. Although no specific freshwater lakes or streams were identified, TK/TU studies noted that hunting and trapping of duck, geese, mink and marten take place on Digby Island and Metlakatla in and around waterbodies and wetlands; therefore the study design incorporated a comprehensive spatial sampling program to assess these areas. Study design details for freshwater and marine water quality were presented at a technical workshop (December 2, 2015) to obtain feedback during development of proposed field programs. Water chemistry of marine and freshwater and storm water runoff was discussed at a subsequent technical workshop (March 16 and 17, 2016).
1721.1	round 1	Gitxaala Nation	4.5.6.3	Water Quality	Gitxaala is concerned with the predicated changes in pH levels for the three streams located on Digby Island. The predicted change is above the biological threshold; and while the application states that the levels are still protective of aquatic biota, there is no consideration of whether or not these levels are protective of Gitxaala's use of that same aquatic biota.	The model used to predict pH changes relates pH to acid neutralizing capacity which was based on lake systems, not stream systems. Therefore the model may overestimate potential effects to streams given the continuous movement of water. At existing conditions, these streams were not considered acid sensitive. Therefore, the streams have buffering capacity against acid inputs. The predicted cumulative emissions can also be considered conservative as they include some regional projects that are not expected to be implemented. A more conservative threshold of pH change of 0.3 units was chosen to align with previous regional studies. However, pH changes of up to 0.4 are considered protective of aquatic biota. In the cumulative emissions case, the modelled pH changes for these three streams are at or below the 0.4 threshold of change. It is anticipated that these streams will be considered for inclusion in future monitoring programs to monitor pH change.
1722.1	round 1	Gitxaala Nation	4.5.9	Water Quality	Gitxaala requires full participation in the identification of waterbodies for the follow-up program. This includes fulsome consultation with Aurora LNG on the identification of waterbodies and participation in the monitoring activities contemplated.	The acidification and eutrophication follow-up program is expected to be developed on a regional level.Aurora LNG will engage with the appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development and implementation of this follow-up program.
1723.1	round 1	Gitxaala Nation	4.5.12.3	Water Quality	The description in this section is general and does not provide examples of where and how TK/TLU information was used in the assessment of this VC. These specifics are necessary for confidence that this was actually undertaken.	Freshwater study design incorporated lakes and streams that were identified as important to Aboriginal groups in TK/TU studies (e.g., Tsook Lake). There was also a focus to incorporate into the freshwater assessment, lakes and streams identified as commercial, recreational, Aboriginal (CRA) fisheries and those identified as supporting culturally critical species. Although no specific freshwater lakes or streams were identified, TK/TU studies noted that hunting and trapping of duck, geese, mink and marten take place on Digby Island and Metlakatla in and around waterbodies and wetlands; therefore the study design incorporated a comprehensive spatial sampling program to assess these areas. Study design details for freshwater and marine water quality were presented at a technical workshop (December 2, 2015) to obtain feedback during development of proposed field programs. Water chemistry of marine and freshwater and storm water runoff was discussed at a subsequent technical workshop (March 16 and 17, 2016).

1724.1	round 1	Gitxaala Nation	Table 4.5-20	Water Quality	This table states that the spatial extent was chosen as the RAA as it encompasses waters where Aboriginal fish species and important habitats are present and may be affected by the proposed Project. However, this boundary was developed prior to provision of Gitxaala's Use study, therefore Gitxaala information could not have been used to influence the boundary.	The RAA for marine fish and marine water quality is largely bounded by the area defined as the Skeena River Estuary but also includes some marine waters out to Triple Island pilot boarding station. Based on information available at the time of writing, this area also encompasses marine waters known to be of importance from a commercial, recreational, and Aboriginal (CRA) fisheries perspective. Although the presence of CRA fish species and habitats was considered in the selection of the RAA boundary, the current boundaries of the RAA were selected because it encompasses the area within which a suitable context for identifying potential interactions between Project activities and past, present and reasonably foreseeable future projects and activities are assessed. Although effort was made to include all Aboriginal Use studies, the Gitxaala Use Study was received in June 2016, following completion of field programs.
1725.1	round 1	Gitxaala Nation	Table 4.6-10	Vegetation and Wetland Resources	This table proposes mitigation that will include revegetation activities using traditional use species, where practicable. Gitxaala requires consultation with Aurora LNG on specific locales for traditional use species revegetation and on the species which may or may not be appropriate. Further. this table outlines the expected success/risks and uncertainty associated with this practice. It indicates that this mitigation measure is generally considered an industry standard. Please provide additional detail on Projects where traditional use species were successfully revegetated.	Section 14.17 of the Application states that the Decommissioning and Abandonment Plans, which will include the details of revegetation, will be developed as part of the BC OGC LNG permitting process to meet the laws, regulations and standards in place at that time. They will be developed with input from appropriate provincial and federal regulatory agencies, Aboriginal Groups, and key stakeholders. The references to 'industry standard' practice is to revegetation and reclamation using native plant species, many of which have traditional uses; this reference was not intended to convey that revegetation with traditional use plant species is an industr standard. As stated in section 4.6.5.2 of the Application, the traditional use plant species identified in the PDA are widespread, abundant and commercially-propagated within native plant nurseries, therefore, the feasibility of using them for revegetation purposes is high.
1726.1	round 1	Gitxaala Nation	4.6.5.2	Vegetation and Wetland Resources	This section outlines that 37 traditional use species will be lost due to clearing of vegetation during construction in the PDA. This is of great concern to Gitxaala. Particularly, as specific gathering locales are extremely important. Gitxaala harvesters have specific rules of harvest which must be adhered to and certain areas have stories associated with the location. Simply directing Gitxaala to another location in the LAA or RAA to gather is inappropriate and contrary to case law which indicates that mitigation cannot simply direct Aboriginal groups to go elsewhere.	Effects on the changes in consumptive and non-consumptive land and resource use for traditional purposes are presented in Section 11.3 and 11.4 of the Application, and include an assessment of vegetation gathering. Effects on First Nation harvesting-related Aboriginal interest are presented in Part C, Section 12 of the Application. Together, these sections address the site-specific loss of vegetation resources for traditional use within the PDA. Also see the technical memo titled, "Additional Information Regarding the CEAA 5(1)(C) and Part C Assessment Methodologies and the Consideration of Traditional Use Information in these Assessments" prepared by Aurora LNG in response to comments pertaining to concerns about access and availability of traditional use species.
1727.1	round 1	Gitxaala Nation	Table 4.6-13	Vegetation and Wetland Resources	It is unclear from this table if the wildlife habitat recovery and revegetation includes species of importance to Gitxaala. While the expected success does reference plants of traditional importance, the mitigation measure and mitigation mechanism does not specifically reference species of traditional value.	Mitigation measure 4.7.3 in Table 4.6-13 of the Application refers to native plants and traditional use plants in the context of the Decommissioning and Abandonment Plans. However, the details of the Decommissioning and Abandonment Plans will be developed at a later stage during the BC OGC LNG permitting process to meet the laws, regulations and standards in place at that time. The Decommissioning and Abandonment Plans will be developed with input from appropriate provincial and federal regulatory agencies, Aboriginal Groups, and key stakeholders. Since the traditional use plant species within the PDA are widespread, abundant, commercially-propagated within native plant nurseries, and already suited to the site (PDA), they would be suitable for use in the revegetation plans.
1728.1	round 1	Gitxaala Nation	4.6.6.3	Vegetation and Wetland Resources	The characterization of cumulative effect to traditional use plants is concerning. It is identified that there will be cumulative effects to traditional use plants but it is rationalized as there are species of interest occurring within the RAA. Gitxaala Nation members cannot be expected to go elsewhere in the RAA for their gathering activities. Therefore, this justification is not applicable and the effect should be designated as moderate to high.	Effects on the changes in consumptive and non-consumptive land and resource use for traditional purposes are presented in Section 11.3 and 11.4 of the Application, and include an assessment of vegetation gathering. Effects on First Nation harvesting-related Aboriginal interest are presented in Part C, Section 12 of the Application. Together, these sections address site-specific loss of vegetation resources for traditional use within the PDA. Also see the technical memo titled, "Additional Information Regarding the CEAA 5(1)(C) and Part C Assessment Methodologies and the Consideration of Traditional Use Information in these Assessments" prepared by Aurora LNG in response to comments pertaining to concerns about access and availability of traditional use species.
1729.1	round 1	Gitxaala Nation	4.6.6.6	Vegetation and Wetland Resources	This Section states that the Project will contribute to a loss of up to 763 ha, supporting 37 traditional use species within the PDA. This effect is rationalized by indicating that this represents less than 1% of the vegetated area of the RAA. This rationalization is flawed. The species lost represent loss of harvesting locales of importance to Gitxaala; and for Gitxaala Nation, location is important as harvesting protocols are in place. Further, the use of the RAA in this context is inappropriate as it is for the calculation of cumulative effects. At a minimum, the land calculation should have been completed for the LAA instead. However, even this approach would not take into account the location based nature of Gitxaala exercise of their rights.	Effects on the changes in consumptive and non-consumptive land and resource use for traditional purposes are presented in Section 11.3 and 11.4, and include an assessment of vegetation gathering. Effects on First Nation harvesting-related Aboriginal interest are presented in Part C, Section 12 of the Application. Together, these sections address site-specific loss of vegetation resources for traditional use within the PDA. Also see the "Additional Information Regarding the CEAA 5(1)(C) and Part C Assessment Methodologies and the Consideration of Traditional Use Information in these Assessments" technical memo that discusses comments pertaining to concerns about access and availability of traditional use species. The technical memo will be filed with the BC EAO.
1730.1	round 1	Gitxaala Nation	4.6.7.1	Vegetation and Wetland Resources	Gitxaala disagrees with the rating of 'not significant' for the change in abundance of traditional plant species based on plant species being abundant elsewhere. This argument is invalid as Gitxaala harvesting has a strong location based component.	Effects on the changes in consumptive and non-consumptive land and resource use for traditional purposes are presented in Section 11.3 and 11.4 of the Application, and include an assessment of vegetation gathering. Effects on First Nation harvesting-related Aboriginal interest are presented in Part C, Section 12 of the Application. Together, these sections address site-specific loss of vegetation resources for traditional use within the PDA. Also see the technical memo titled, "Additional Information Regarding the CEAA 5(1)(C) and Part C Assessment Methodologies and the Consideration of Traditional Use Information in these Assessments" prepared by Aurora LNG in response to comments pertaining to concerns about access and availability of traditional use species.
1731.1	round 1	Gitxaala Nation	4.6.10	Vegetation and Wetland Resources	The conclusion that while 37 traditional use species will be lost form the PDA, they are common throughout the PDA fails to consider that Gitxaala harvesting has a strong location based component.	Effects on the changes in consumptive and non-consumptive land and resource use for traditional purposes are presented in Section 11.3 and 11.4, and include an assessment of vegetation gathering. Effects on First Nation harvesting-related Aboriginal interest are presented in Part C, Section 12 of the Application. Together, these sections address the site-specific loss of vegetation resources for traditional use within the PDA. Also see the "Additional Information Regarding the CEAA 5(1)(C) and Part C Assessment Methodologies and the Consideration of Traditional Use Information in these Assessments" technical memo that discusses comments pertaining to concerns about access and availability of traditional use species. The technical memo will be filed with the BC EAO.
1732.1	round 1	Gitxaala Nation	Table 4.7-2	Wildlife Resources (Terrestrial)	As the information within this table is not disaggregated, it is therefore difficult to evaluate the sufficiency of Gitxaala's influence on the Scope of the Wildlife and Terrestrial Resources assessment. Suggest disaggregating this information to identify which party provided which key information or concern.	Aurora LNG acknowledges the comment however the intent of Table 4.7-2 is to provide a summary of the key information and concerns raised during the consultation process and how they influenced the development of the assessment of the Wildlife Resources (Terrestrial) VC. For ease of review, the table focused on the information/concerns and its influence on the assessment.
1733.1	round 1	Gitxaala Nation	Table 4.7-2	Wildlife Resources (Terrestrial)	This table states that "As a result of the comments received, where information is available and relevant, species of importance to Aboriginal Groups are integrated within habitat assessments…" Please provide additional detail on how the determination of relevance was completed for inclusion of species of importance to Aboriginal groups.	For clarification, the use of the term "relevance" is intended to highlight that the assessment considered species that were identified to be of importance to Aboriginal Groups and where there was an identified mechanism for interaction between those species and Project activities and infrastructure.
1734.1	round 1	Gitxaala Nation	4.7.2.3	Wildlife Resources (Terrestrial)	The description in this section is general and does not provide examples of where and how TK/TLU information was used in the assessment of this VC. These specifics are necessary for confidence that this was undertaken.	Sections 4.7.2.2 and 4.7.2.3 describe the Aboriginal Groups from which traditional knowledge and traditional use information was gathered, and how the information was incorporated into the assessment. Table 4.7-2 outlines key information and concerns raised by Aboriginal Groups and how that information influenced the assessment for wildlife resources. Section 4.7.3.2 provides a summary of findings of traditional ecological knowledge for wildlife resources, including identified species and areas of importance for harvesting by Aboriginal Groups; these details are also described in Appendix J. Species identified therein are discussed throughout Sections 4.7.5 and 4.7.6 where there was an identified mechanism for interaction with Project activities and infrastructure.
1735.1	round 1	Gitxaala Nation	4.7.2.5	Wildlife Resources (Terrestrial)	More information is required to elaborate on how traditional ecological knowledge helped form the technical boundaries for the assessment on Wildlife (terrestrial) Resources. This includes specifying which group TEK was collected from that was used to define this boundary and what specific TEK was used and how.	The technical boundaries for wildlife resources were developed in consideration of information included in studies provided by all Aboriginal Groups (described in Section 4.7.2.3 of the Application), and as part of comments raised during consultation. Traditional ecological knowledge provided on traditionally harvested species, seasons, and locations are used in combination with Project and regional studies, and scientific literature to determine the appropriate extent of spatial boundaries, characterize residual Project and cumulative effects, and to assign significance determinations.
1736.1	round 1	Gitxaala Nation	4.7.3.1	Wildlife Resources (Terrestrial)	This section is vague. It simply states that TEK was acquired from sources and reports and has been incorporated into the assessment. No details are provided on what information was incorporated, how it was incorporated, or what the outcomes of this incorporation were/or hoped to be. Further it refers the reader to Section 4.7.2.3 for additional details; That section, Traditional Knowledge and Traditional Use Incorporation does not have any specific detail either and, in a circular reference, refers the reader to Section 4.7.3 for more details. Additional detail must be provided and circular references removed.	Sections 4.7.2.2 and 4.7.2.3 lists the Aboriginal Groups from which traditional knowledge and traditional use information was gathered, and how information was incorporated into the assessment. Table 4.7-2 outlines key information and concerns raised by Aboriginal Groups and how that information influenced the assessment of wildlife resources. Section 4.7.3.2 provides a summary of findings of traditional ecological knowledge for wildlife resources and is described in more detail in Appendix J. Species identified therein are discussed throughout Sections 4.7.5 and 4.7.6 where there was an identified mechanism for interaction with Project activities and infrastructure.
1737.1	round 1	Gitxaala Nation	4.7.3.2	Wildlife Resources (Terrestrial)	This section is vague. It does not include a full listing of traditional species with numbers, as previous sections outline for non-traditional species. It does not include numbers of traditional species having potential to occur in the LAA or RAA. It does not outline important habitats or areas or intensive use similar to previously sections and does not outline any modelling or field studies completed for traditionally used species. Overall, this section highlights that standard environmental assessment methodology was not applied to traditional species. Instead, it was treated anecdotally and only "used" where it overlapped with predetermined species already identified for inclusion in the assessment.	Section 4.7.3.2 provides a summary of findings of traditional ecological knowledge for wildlife resources and is described in more detail in Appendix J, and outlines important areas of use and harvest as identified in supporting traditional knowledge and use studies. Information presented in Section 4.7 of the Application reflects the nature of how information was presented in supporting traditional knowledge and use studies. These sources of information did not necessarily present information on wildlife resources using systematic methods that facilitate quantifying species presence and abundance following similar procedures used to describe existing conditions during Project field studies. This did not preclude species of importance from being incorporated into the assessment for wildlife resources. Table 4.7-2 outlines the ways in which several species or species groups were addressed in the Application, as influenced by information and concerns raised during consultation (e.g., black bear, black-tailed deer, Pacific marten, little brown myotis, marbled murrelet, waterfowl, western toad). Both the wildlife habitat community modelling and the habitat suitability modelling incorporate species identified to be of importance by Aboriginal Groups, recognizing that species of importance may vary among Aboriginal Groups. Please see Section 4.7.5.2 for a discussion of change in habitat for wildlife resources and the species described therein.
1738.1	round 1	Gitxaala Nation	4.7.5	Wildlife Resources (Terrestrial)	This section does not contain a single reference to species of importance to Aboriginal peoples. This is extremely problematic and highlights the cursory and anecdotal treatment these species have been given throughout this assessment.	Aurora LNG acknowledges the comment. Sections 4.7.2.2 and 4.7.2.3 list the Aboriginal Groups from which traditional knowledge and traditional use information was gathered, and how information was incorporated into the assessment. Table 4.7-2 outlines key information and concerns raised by Aboriginal Groups and how that information influenced the assessment for wildlife resources. Section 4.7.3.2 provides a summary of findings of traditional ecological knowledge for wildlife resources and is described in more detail in Appendix J. Species of traditional importance, as outlined in Section 4.7.3.2 (e.g., bear, deer, marten) are described throughout Section 4.7.5 where there was an identified potential for interaction with Project activities and infrastructure.

1739.1	round 1	Gitxaala Nation	Table 4.7-10	Wildlife Resources (Terrestrial)	This mitigation table states that "…activities will be vegetated using … traditional use species, where practicable." This is problematic for a number of reasons. First, Gitxaala has not been consulted by Aurora LNG on specific traditional use species that support wildlife. Secondly, the use of traditional species for revegetation has not been proven or implemented by many, if any, proponents. Therefore this process would require significant consultation between Gitxaala and Aurora LNG, of which none has occurred to date.	Aurora LNG acknowledges the comment. Sections 4.7.2.2 and 4.7.2.3 of the Application list the Aboriginal Groups from which traditional knowledge and traditional use information was gathered, and how that information was incorporated into the assessment. Table 4.7-2 outlines key information and concerns raised by Aboriginal Groups and how that information influenced the assessment for wildlife resources. Tables 4.7-10 and 4.6-10, cite this same mitigation (Number 4.6.5) to reclaim temporary workspaces using native plant seed and traditional use species where practicable as a measure to prevent establishment of non-native invasive plant species. Section 14.6 notes that an Invasive Plant Management Plan will be developed as part of the OGC LNG permitting process to meet the laws, regulations and standards with input from appropriate provincial and federal regulatory agencies, Aboriginal Groups, and key stakeholders. One of the key components of the plan will be to use "native plant seed and traditional use species where practicable". Traditional use plant species identified in the Application are commercially available in plant nurseries and have been used successfully in previous revegetation efforts. Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11Order (as amended) regarding the development of this plan .
1740.1	round 1	Gitxaala Nation	4.7.6	Wildlife Resources (Terrestrial)	This section does not contain any Aboriginal input, specifically, Gitxaala input and, again, highlights the superficial way Gitxaala TEK was used in this assessment.	Aurora LNG acknowledges the comment. Sections 4.7.2.2 and 4.7.2.3 list the Aboriginal Groups from which traditional knowledge and traditional use information was gathered, and how information was incorporated into the assessment. Table 4.7-2 outlines key information and concerns raised by Aboriginal Groups and how that information influenced the assessment for wildlife resources. Section 4.7.3.2 provides a summary of findings of traditional ecological knowledge for wildlife resources and is described in more detail in Appendix J. Species of traditional importance, as outlined in Section 4.7.3.2 are described throughout Section 4.7.6 where there was an identified potential for interaction with Project activities and infrastructure.
1741.1	round 1	Gitxaala Nation	4.8.1	Freshwater Fish and Fish Habitat	This section states that "Fish are important … and have cultural and ceremonial value to Aboriginal communities." However, this misses the key component to Aboriginal fish use: subsistence.	Aurora LNG acknowledges that fish have numerous important roles for Aboriginal communities, and the omission of the acknowledgement that fish being used for subsistence was accidental. This will be included in an errata document being compiled to capture these corrections and it will be filed with the BC EAO.
1742.1	round 1	Gitxaala Nation	4.8.2.3	Freshwater Fish and Fish Habitat	The description in this section is general and does not provide examples of where and how TK/TLU information was used in the assessment of this VC. These specifics are necessary for confidence that this was undertaken.	Minimal location-specific TK/TLU information was provided for the Freshwater Fish and Fish Habitat assessment on Digby Island. Information that was provided identified regional traditional harvest sites, or locations outside of the LAA and RAA. Where TK/TLU information indicated specific locations of species observed or habitat present, this information was incorporated into the data and used to inform and focus the assessment; however, no Digby Island locations were included in this information. Also, specific locations identified as having a high value for Aboriginal cultural, ceremonial, or food fishery use in the TK/TLU data were incorporated into the baseline data used for the assessment; no sites on Digby Island were identified in the received TK/TLU information. Less spatially specific data (i.e., regionally important considerations) were also noted and accounted for in the assessment. Sections of the assessment for Freshwater Fish and Fish Habitat where TK/TLU specific information was incorporated included 4.8.2.5 (recognizing information from resource management plans), otherwise information was used throughout the assessment of the potential effects on freshwater fish and fish habitat and were not specifically defined as TK/TLU information.
1743.1	round 1	Gitxaala Nation	4.8.3.1	Freshwater Fish and Fish Habitat	This section is vague. It simply states that TEK was acquired from sources and reports and has been incorporated into the assessment. No details are provided on what information was incorporated, how it was incorporated, or what the outcomes of this incorporation were/or hoped to be. Additional detail must be provided.	Minimal location-specific TK/TLU information was provided for the Freshwater Fish and Fish Habitat assessment on Digby Island. Information that was provided identified regional traditional harvest sites, or locations outside of the LAA and RAA. Where TK/TLU information indicated specific locations of species observed or habitat present, this information was incorporated into the data and used to inform and focus the assessment; however, no Digby Island locations were included in this information. Also, specific locations identified as having a high value for Aboriginal cultural, ceremonial, or food fishery use in the TK/TLU data were incorporated into the baseline data used for the assessment; no sites on Digby Island were identified in the received TK/TLU information. Less spatially specific data (i.e., regionally important considerations) were also noted and accounted for in the assessment. Sections of the assessment for Freshwater Fish and Fish Habitat where TK/TLU specific information was incorporated included 4.8.2.5 (recognizing information from resource management plans), otherwise information was used throughout the assessment of the potential effects on freshwater fish and fish habitat and were not specifically defined as TK/TLU information.
1744.1	round 1	Gitxaala Nation	4.8.3.2	Freshwater Fish and Fish Habitat	This section does not identify the CRA fish species which were captured in the 19 different watercourses. This does not allow Gitxaala to verify the accuracy of the fish classified as CRA and cross reference that list with the use data provided by Gitxaala.	Table 4.8-8 identifies the CRA fish species captured in the 19 different watercourse reaches where fish were present. Figure 4.8-2 provides the distribution of CRA fish in the LAA.
1745.1	round 1	Gitxaala Nation	4.8.3.2	Freshwater Fish and Fish Habitat	This section does not identify the use of traditional information for designation of areas as important watercourses. This is problematic, as specific watercourses, while not significant in ecological terms, may be of importance to Gitxaala.	Where traditional information indicated specific locations of species observed or habitat present or where locations were identified as having a high value for Aboriginal cultural, ceremonial or food fishery use, this information was incorporated into the data and used to inform and focus the assessment. Specific TK/TLU data sources are indicated in section 4.8.2.3. Less spatially specific data (i.e., regionally important considerations) were also noted and accounted for in the assessment. Aurora LNG welcomes further discussions with Gitxaala Nation regarding fish and fish habitat.
1746.1	round 1	Gitxaala Nation	4.8.5.2	Freshwater Fish and Fish Habitat	This section states that a "...CFHOP will be developed, and refined, through consultation … with … Aboriginal Groups … to identify effective and relevant methods to offset any residual effects from the Project that cause serious harm to fish." Please identify which Aboriginal Groups will be consulted with on this CFHOP. Gitxaala requires fulsome consultation on this item.	Aurora LNG will engage with appropriate regulatory agencies (primarily DFO) and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the fish habitat offset plan during the Fisheries Act authorization application process. The intent of these consultations is to identify offset options that best meet the fisheries management objectives of Aboriginal groups, that are consistent with provincial and federal perspectives, and provide the greatest chance of benefiting the affected fish populations for perpetuity. Aurora LNG welcomes further discussions with Gitxaala Nation regarding fish habitat offsets.
1747.1	round 1	Gitxaala Nation	4.8.9	Freshwater Fish and Fish Habitat	This section states that a "…detailed Fish Habitat Offsetting Plan will be developed in consultation with … Aboriginal Groups…" Please advise which Aboriginal Groups will be consulted on the development of a Fish Habitat Offsetting Plan as Gitxaala requires fulsome consultation on this item.	Aurora LNG will engage with appropriate regulatory agencies (primarily DFO) and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the fish habitat offset plan during the Fisheries Act authorization application process. The intent of these consultations is to identify offset options that best meet the fisheries management objectives of Aboriginal groups, that are consistent with provincial and federal perspectives, and provide the greatest chance of benefiting the affected fish populations for perpetuity. Aurora LNG welcomes further discussions with Gitxaala Nation regarding fish habitat offsets.
1748.1	round 1	Gitxaala Nation	4.9.1	Marine Fish and Fish Habitat	This section states that "…Marine Fish and Fish Habitat Valued Component (VC) was selected because it … has high cultural, ecological and economic importance to ... Aboriginal Groups..." However, this misses a key component to Aboriginal marine fish use: subsistence. Please amend this section to reflect this important aspect of fishing.	Aurora LNG acknowledges subsistence use of marine fish by Gitxaala Nation. Use of marine fish and fish habitats by Gitxaala Nation is assessed in Section 11.3.9.3 of the Assessment of effects on CEAA 5(1)(c) factors and in Section 12.5.6.6 (Aboriginal Consultation, Part C).
1749.1	round 1	Gitxaala Nation	4.9.2.1	Marine Fish and Fish Habitat	This section states that 5(1)(c) "…requires an assessment of potential effects on marine fish and fish habitat due to its potential to affect Aboriginal peoples. This is not the case. 5(1)(c) requires effects be identified for: (i) health and socio-economic conditions, (ii) physical and cultural heritage, (iii) the current use of lands and resources for traditional purposes, or (iv) any structure, site or thing that is of historical, archaeological, paleontological or architectural significance." We assume that the passage in the application refers to (iii), in which case, this asks for effects to the use of lands and resources, not the overall health, quality, etc. of the resource itself; which is what the assessment focuses on. Please advise where the assessment looks at the use of marine fish and fish habitat by Gitxaala harvesters.	Use of marine fish and fish habitats by Gitxaala Nation is assessed in Section 11.3.9.3 of the Assessment of effects on CEAA 5(1)(c) factors and in Section 12.5.6.6 (Aboriginal Consultation, Part C).
1750.1	round 1	Gitxaala Nation	4.9.2.3	Marine Fish and Fish Habitat	This section is vague. It simply states that TEK was acquired from sources and reports and has been incorporated into the assessment. No details are provided on what information was incorporated, how it was incorporated, or what the outcomes of this incorporation were/or hoped to be. Additional detail must be provided.	The Marine Fish and Fish Habitat assessment (Section 4.9) incorporated TEK information from publicly-available sources and Project-specific studies submitted to Aurora LNG. TEK was then reviewed to identify marine fish species of Aboriginal importance in the LAA and RAA, and the presence and locations of important fish habitats in the LAA and RAA. This information was considered in the assessment and characterization of potential effects to marine fish habitat and marine fish (including those that are part of, or support, commercial, recreational, and Aboriginal [CRA] fisheries). Fish that are part of CRA fisheries are interpreted to be those fish that fall within the scope of applicable federal or provincial fisheries regulations, as well as those that can be fished by Aboriginal organizations or their members for food, social, or ceremonial purposes (e.g., Pacific salmon, marine fish species at risk, traditional use marine fish species, and marine plants). TEK information considered in the Marine Fish and Fish Habitat assessment is summarized in Section 4.9.3.2 (Overview) and Section 3 of Appendix L (Marine Fish and Fish Habitat TDR). Information about habitat types and marine fish species included in the Gitxaala Valued Components Report (Calliou Group 2016) was considered in the Marine Fish and Fish Habitat assessment; however, the reference to this report is missing from the list of reports identified in Section 4.9.3.2 (Overview) and Section 3 of Appendix L. This reference will be added; an errata document is being compiled that captures this correction and it will be filed with the BC EAO. Reference: Calliou Group. 2016. Gitxaala Valued Components Report. Aurora LNG Project Environmental Assessment Certification Application. Prepared on behalf of Gitxaala Nation. Prepared for Aurora LNG.
1751.1	round 1	Gitxaala Nation	4.9.3.1	Marine Fish and Fish Habitat	This section is vague. It simply states that TEK was acquired from sources and reports and has been incorporated into the assessment. No details are provided on what information was incorporated, how it was incorporated, or what the outcomes of this incorporation were/or hoped to be. Additional detail must be provided.	The Marine Fish and Fish Habitat assessment (Section 4.9) incorporated TEK information from publicly-available sources and Project-specific studies submitted to Aurora LNG. TEK was then reviewed to identify marine fish species of Aboriginal importance in the LAA and RAA, and the presence and locations of important fish habitats in the LAA and RAA. This information was considered in the assessment and characterization of potential effects to marine fish habitat and marine fish (including those that are part of, or support, commercial, recreational, and Aboriginal [CRA] fisheries). Fish that are part of CRA fisheries are interpreted to be those fish that fall within the scope of applicable federal or provincial fisheries regulations, as well as those that can be fished by Aboriginal organizations or their members for food, social, or ceremonial purposes (e.g., Pacific salmon, marine fish species at risk, traditional use marine fish species, and marine plants). TEK information considered in the Marine Fish and Fish Habitat assessment is summarized in Section 4.9.3.2 (Overview) and Section 3 of Appendix L (Marine Fish and Fish Habitat TDR). Information about habitat types and marine fish species included in the Gitxaala Valued Components Report (Calliou Group 2016) was considered in the Marine Fish and Fish Habitat assessment; however, the reference to this report is missing from the list of reports identified in Section 4.9.3.2 (Overview) and Section 3 of Appendix L. This reference will be added; an errata document is being compiled that captures this correction and it will be filed with the BC EAO. Reference: Calliou Group. 2016. Gitxaala Valued Components Report. Aurora LNG Project Environmental Assessment Certification Application. Prepared on behalf of Gitxaala Nation. Prepared for Aurora LNG.
1752.1	round 1	Gitxaala Nation	4.9.3.2	Marine Fish and Fish Habitat	This section indicates that TK/TU from Gitxaala Nation was used to identify marine fish, invertebrates and algae traditionally harvested. Please provide a disaggregated list of the species identified. Further, please provide detail on where the use of these species was assessed. The abbreviated list is not appropriate.	The list of marine fish, invertebrates, and algae traditionally harvested by Aboriginal Groups included in Section 4.9.3.2 (Overview - Traditional Knowledge and Traditional Use) of the Marine Fish and Fish Habitat VC was not intended to be comprehensive. A comprehensive list of marine fish, invertebrates, and algae traditionally harvested by Gitxaala Nation is included in Table 6-13 of the Aboriginal Consultation TDR (Appendix S.2). Use of marine fish and fish habitats by Gitxaala Nation is assessed in Section 11.3.9.3 of the Assessment of effects on CEAA 5(1)(c) factors and in Section 12.5.6.6 (Aboriginal Consultation, Part C).
1753.1	round 1	Gitxaala Nation	4.9.3.2	Marine Fish and Fish Habitat	The listing of "Areas located within the LAA that are considered culturally and/or spiritually sensitive…" is incomplete. Please see the Gitxaala Use Study, pages 38-42 for additional sites of importance to Gitxaala; and pages 48-125 for site listings for marine species of importance.	The list of culturally and/or spiritually sensitive areas included in Section 4.9.3.2 (Overview - Traditional Knowledge and Traditional Use) of the Marine Fish and Fish Habitat VC was not intended to be comprehensive. A comprehensive list of the sites known at the time of writing to be culturally and/or spiritually sensitive is included in Table 6-6 of the Aboriginal Consultation TDR (Appendix S.2).

1754.1	round 1	Gitxaala Nation	4.9.5	Marine Fish and Fish Habitat	There is no information contained in this section that relates to Gitxaala Nation's Use information or VCs. This suggests that Gitxaala information was only included superficially and not considered in the assessment overall.	The Marine Fish and Fish Habitat VC (Section 4.9) considered potential effects to marine fish habitat and marine fish that are part of, or support, commercial, recreational, and Aboriginal (CRA) fisheries. Fish that are part of CRA fisheries are interpreted to be those fish that fall within the scope of applicable federal or provincial fisheries regulations, as well as those that can be fished by Aboriginal organizations or their members for food, social, or ceremonial purposes (e.g., Pacific salmon, marine fish species at risk, traditional use marine fish species, and marine plants). Information provided by Gitxaala Nation was considered to help identify marine fish species and habitats of Aboriginal importance. Additional details are provided in Section 4.9.3 of the Marine Fish and Fish Habitat VC and Section3.0 of the Marine Fish and Fish Habitat TDR (Appendix L). Use of marine fish and fish habitats by Gitxaala Nation is assessed in Section 11.3.9.3 (Assessment of effects on CEAA 5(1)(c) factors) and in Section 12.5.6.6 (Aboriginal Consultation, Part C).
1755.1	round 1	Gitxaala Nation	Table 4.9-11/ Table 4.9-15/ Table 4.9-18/ Table 4.9-20	Marine Fish and Fish Habitat	There are no mitigation measures specific to Gitxaala Nation or any Aboriginal group. This suggests that Gitxaala information was only included superficially and not considered in the assessment overall.	Mitigation measures included in Table 4.9-11 (Mitigation Measures Proposed to Avoid or Reduce Change in Habitat), Table 4.9-15 (Mitigation Measures Proposed to Avoid or Reduce Change in Behaviour), Table 4.9-18 (Mitigation Measures Proposed to Avoid or Reduce Change in Mortality Risk) and Table 4.9-20 (Mitigation Measures Proposed to Avoid or Reduce Change in Health) of the Marine Fish and Fish Habitat VC apply to marine fish and invertebrate species as a whole, including species of importance to the Gitxaala Nation and other Aboriginal groups. Additional mitigation measures to reduce potential effects on the ability of Gitxaala Nation to exercise their Aboriginal Interests are identified in Section 12.5.6 of the Application (Aboriginal Interests).
1756.1	round 1	Gitxaala Nation	4.9.5	Marine Fish and Fish Habitat	Gitxaala is concerned with the loss of eelgrass as a result of dredging. Further, we disagree that the magnitude of this effect is only moderate. It should be classified as high as per the criteria listed. The effect extends to the LAA, is continuous in nature as the loss is permanent and irreversible. While Casey Cove may be classified as a disturbed environment, it is still used by Gitxaala in the exercise of their rights and therefore important. The evaluation of this effect must be reconsidered.	Aurora LNG acknowledges the ecological value of eelgrass and its importance as fish habitat, which is reflected in the fact that it is one of the focal habitats considered in the Conceptual Fish Habitat Offsetting Plan (Appendix V). The magnitude of the effect of eelgrass loss due to dredging was deemed to be "moderate" since, based on the availability of eelgrass nearby, the use and dependency on this habitat by marine CRA species, existing mitigations and Aurora LNG's commitment to offset any residual serious harm to fish, the long-term persistence of a marine fish population is not expected to be affected via the loss of this eelgrass. Importantly, this ranking reflects Aurora's commitment (and legal requirement) to develop effective offsetting. Further, the residual effectis not considered continuous, but rather, is considered a single event, since the physical removal of eelgrass will only occur once, and will be offset. The rest of the comment echoes the effect characterization for the loss of eelgrass due to dredging: geographic extent - extends to LAA; duration: permanent; reversibility - irreversible; context: disturbedAurora LNG welcomes further discussions with Gitxaala Nation regarding impacts to eelgrass.
1757.1	round 1	Gitxaala Nation	4.9.5	Marine Fish and Fish Habitat	Gitxaala is concerned with the loss of eelgrass as a result of infilling. Please see comments on dredging for similar concerns.	Aurora LNG acknowledges the ecological value of eelgrass and its importance as fish habitat, which is reflected in the fact that it is one of the focal habitats considered in the Conceptual Fish Habitat Offsetting Plan (Appendix V). The magnitude of the effect of eelgrass loss due to infilling was deemed to be "moderate" since, based on the availability of eelgrass nearby, the use and dependency on this habitat by marine CRA species, existing mitigations and Aurora LNG's commitment to offset any residual serious harm to fish, the long-term persistence of a marine fish population is not expected to be affected via the loss of this eelgrass. Importantly, this ranking reflects Aurora's commitment (and legal requirement) to develop effective offsetting.Further, the residual effect is not considered continuous, but rather, is considered a single event, since the physical removal of eelgrass will only occur once, and will be offset. The rest of the comment echoes the effect characterization for the loss of eelgras due to infilling: geographic extent - extends to LAA; duration: permanent; reversibility - irreversible; context: disturbedAurora LNG welcomes further discussions with Gitxaala Nation regarding impacts to eelgrass.
1758.1	round 1	Gitxaala Nation	4.10.2.1	Marine Wildlife - Marine Mammals	This section states that 5(1)(c) "…requires an assessment of potential effects on marine mammals due to their potential to affect Aboriginal peoples." This is not the case. 5(1)(c) requires effects be identified for: (i) health and socio-economic conditions, (ii) physical and cultural heritage, (iii) the current use of lands and resources for traditional purposes, or (iv) any structure, site or thing that is of historical, archaeological, paleontological or architectural significance." We assume that the passage in the application refers to (iii), in which case, this asks for effects to the **use** of lands and resources, not the overall health, quality, etc. of the resource itself; which is what the assessment focuses on. Please advise where the assessment looks at the**use** of marine mammals by Gitxaala harvesters.	Aurora LNG acknowledges this error regarding the wording of CEAA 2012 Section 5(1)(c) and will include a correction in an errata document that will capture these corrections and be filed with the BC EAO. Effects on Gitxaala Nation use of marine mammals are assessed in the following sections of the Application: Assessment of CEAA 2012 5(1)(c) iii--Current Use of Lands and Resources for Traditional Purposes (Section 11.3.9.3, particularly on pages 11-174 to 11-180 and pages 11-193 and 11-194) Assessment of Effects on Gitxaala Nation Harvesting-Related Aboriginal Interests (Section 12.5.6.6, particularly on page 12-163 and 12-164 and again on pages 12-173 to 12-176). Assessment of Effects on Gitxaala Nation Cultural Wellbeing (Section 12.5.6.7, page 12-177 to 12-178 and page 12-184 to 12-186).
1759.1	round 1	Gitxaala Nation	4.10.2.3	Marine Wildlife - Marine Mammals	This section is vague. It simply states that TEK was acquired from sources and reports and has been incorporated into the assessment. No details are provided on what information was incorporated, how it was incorporated, or what the outcomes of this incorporation were/or hoped to be. Additional detail must be provided.	As noted in Section 4.10.2.3, details related to the incorporation of Project specific TK/TU and other available information relevant to marine mammals are outlined in Section 4.10.3.1 (Existing Conditions for Marine Mammals - Traditional Knowledge and Traditional Use Studies). See also Section 2 of the Marine Mammals Technical Data Report (Appendix N of the Application), the Aboriginal Consultation TDR (Appendix S.2 of the Application) and Aboriginal Consultation (Part C, Section 12 of the Application).
1760.1	round 1	Gitxaala Nation	4.10.3.1	Marine Wildlife - Marine Mammals	This section states that "As a result of the past and present traditional importance of marine mammals, the Project's potential effects on this VC are of interest to Aboriginal Groups." While this is true, traditional importance of marine mammals should also be important to Nexen in so far that is contributes to the identification of potential effects.	Aurora LNG is appreciative of all the TK and TU information provided. The TK and TU contributed to the understanding of marine mammal presence, distribution, seasonality, and abundance in the RAA and therefore the assessment of the potential residual effects on marine mammals.
1761.1	round 1	Gitxaala Nation	4.10.3.1	Marine Wildlife - Marine Mammals	This section states that the Use information was "…used within this VC to support Project understanding of marine mammal presence, distribution, seasonality, and abundance in the RAA." As the RAA is generally used in quantifying cumulative effects, how will traditional information related to the LAA and PDA be used in the assessment? Was it included and considered?	There is no PDA for the assessment of marine mammals and the RAA includes within it the spatial boundaries of the LAA. As such, traditional knowledge and traditional use information related to the LAA is captured within the statement concerning the broader RAA.
1762.1	round 1	Gitxaala Nation	4.10.3.2	Marine Wildlife - Marine Mammals	Gitxaala was excluded from the following description: "Sea otters were historically hunted and trapped by Metlakatla First Nation, Kitselas First Nation and Kitsumkalum First Nation…" This is despite 3 identified sea lion hunting areas within the LAA. and an additional 16 sites in the RAA. (page 114 of the Gitxaala Use Study)	Reference to hunting or trapping of sea otters was not found in the Gitxaala Use Study. The description of use of sea lions in Section 4.10.3.2 aligns with the information contained in Gitxaala Nation's comment and is as follows (portions relevant to Gitxaala Nation's comment underlined): "Seals and sea lions were some of the main resources used by all five Aboriginal Groups who provided Project specific TLU studies. These species were used for trade, consumptive (food and material) purposes, and ceremonial purposes. Seal and sea lion meat was often smoked, although it was also eaten half dried and fresh, and this formed a staple food source that was very important to sustain long journeys on the water and while preparing eulachon during this traditional fishery. Gitxaala Nation also reported that seal grease was a good source of iron, and was often used to prepare various meals, such as bannock and herring eggs… " (page 4.10-26). "While many species of marine mammal are recognized as important to Aboriginal Groups, the cultural and social importance of both humpback whales and killer whales, as well as the strong hunting traditions connected to sea lion and seal, were explicitly referenced. Many traditional marine and terrestrial hunting areas exist throughout Chatham Sound, with the areas around Stephens, Melville, Porcher and Digby islands identified as important marine resource harvesting and fishing areas. Gitxaala Nation identified the regular occurrence of porpoise in the waters near Digby and Kinahan islands (amongst other locations). With respect to potential Project activity areas, the waters around Digby Island, the marine shipping route, and the pilot boarding station at Triple Island have been identified as marine mammal hunting areas." (page 4.10-26 and 4.10-27). This information was incorporated into the assessment.
1763.1	round 1	Gitxaala Nation	Table 4.10-8/Table 4.10-9/Table 4.10-10	Marine Wildlife - Marine Mammals	Despite identification that CRA fisheries must be prohibited, there is no mitigation measure which specifically relates to the Aboriginal use of marine mammals.	Aurora LNG welcomes further discussions with Gitxaala Nation, regarding marine mammals and related mitigation measures.
1764.1	round 1	Gitxaala Nation	4.11.2.3	Marine Wildlife - Marine Birds	This section is vague. It simply states that TEK was acquired from sources and reports and has been incorporated into the assessment. No details are provided on what information was incorporated, how it was incorporated, or what the outcomes of this incorporation were/or hoped to be. Additional detail must be provided.	Sections 4.11.2.2 and 4.11.2.3 list the Aboriginal Groups from which traditional knowledge and traditional use information was gathered, and how information was incorporated into the assessment. Table 4.11-2 outlines key information and concerns raised by Aboriginal Groups and how that information influenced the assessment of marine birds. Section 4.11.3.2 provides a summary of findings of traditional ecological knowledge for marine birds and is described in more detail in Appendix Q. Species identified therein are discussed throughout Sections 4.11.5 and 4.11.6 where there was an identified mechanism for interaction with Project activities and infrastructure.
1765.1	round 1	Gitxaala Nation	4.11.3.2	Marine Wildlife - Marine Birds	This section includes a circular reference to Appendix S.2 for additional information on bird TEK; the appendix referenced contains a similar reference back to Section 4.11 for additional detail.	Sections 4.11.2.2 and 4.11.2.3 describe the Aboriginal Groups from which traditional knowledge and traditional use information was gathered, and how information was incorporated into the assessment. Table 4.11-2 outlines key information and concerns raised by Aboriginal Groups and how that information influenced the assessment for marine birds. Section 4.11.3.2 provides a summary of findings of traditional ecological knowledge for marine birds and is described in more detail in Appendix Q. Species identified therein are discussed throughout Section 4.11.5 and 4.11.6 where there was an identified mechanism for interaction with Project activities and infrastructure. Additional details on the timing and location of marine bird harvesting practices are provided in Appendix S.2. Information on harvesting practices was used to support Section 4.11, Section 11, and Part C of the Application.
1766.1	round 1	Gitxaala Nation	4.11.2.5	Marine Wildlife - Marine Birds	This section identifies that the assessment technical boundaries were based on traditional ecological knowledge. However, the boundaries for the assessment were identified prior to Gitxaala providing their TEK information. Please disaggregate the reference to TEK and identify which specific groups influenced the technical boundaries.	The technical boundaries for wildlife resources were developed in consideration of information included in studies provided by all Aboriginal Groups (described in Section 4.7.2.3 of the Application), and as part of comments raised during consultation. Traditional ecological knowledge provided on traditionally harvested species, seasons, and locations are used in combination with Project and regional studies, and scientific literature to determine the appropriate extent of spatial boundaries, characterize residual Project and cumulative effects, and to assign significance determinations.

1767.1	round 1	Gitxaala Nation	4.12	Summary of Potential Environmental Effects	As Gitxaala VCs were not considered in any of the listed effects assessments, the summary of the potential environmental effects is deficient. Merely stating that TK and TU information was used with little to no back-up of this assertion is not sufficient.	Gitxaala Nation submitted the Gitxaala VC Report in June 2016, after finalization of the AIR (including the selection of VCs in Part B). The Gitxaala VC Report was considered as part of Project specific information submitted by Gitxaala Nation and best efforts have been made by Aurora LNG to incorporate and use the information from this study in the assessment. Information from this report was used throughout Section 11.3.9.2 (Existing Conditions) and in the assessment of Section 5(1)(c) Effects for Gitxaala Nation. Several of the topics referred to by Gitxaala Nation as "Valued Components" in the Gitxaala VC Reportare assessed as Aboriginal Interests in Part C of the Application.
1768.1	round 1	Gitxaala Nation	4.12.5.2	Vegetation and Wetland Resources	This section states that the viability of traditional use plants will not be impaired as there are plants throughout the RAA. Gitxaala harvesters cannot be asked to go elsewhere to harvest. This is particularly true for Gitxaala Nation as there are specific location based harvesting protocols which should be adhered to. Case law and custom are clear that going elsewhere is not an appropriate effect reduction technique.	Effects on the changes in consumptive and non-consumptive land and resource use for traditional purposes are presented in Section 11.3 and 11.4 of the Application, and include an assessment of vegetation gathering. Effects on First Nation harvesting-related Aboriginal interest are presented in Part C, Section 12 of the Application. Together, these sections address site-specific loss of vegetation resources for traditional use within the PDA. Also see the technical memo titled, "Additional Information Regarding the CEAA 5(1)(C) and Part C Assessment Methodologies and the Consideration of Traditional Use Information in these Assessments" prepared by Aurora LNG in response to comments pertaining to concerns about access and availability of traditional use species.
1769.1	round 1	Gitxaala Nation	Table 6.5-2	Marine Use and Navigable Waters	This table does not include ship wake as a concern that influenced the scope of the assessment. While Gitxaala acknowledges that onshore ship wake is of concern, ship wake experienced by Aboriginal harvesters while on the water is also of concern and must be considered when describing shipping traffic in terms of interference with Aboriginal fisheries or harvesters.	The potential for Project-related ship wake to interact with fishing vessels on the water is temporally limited. Please refer to the "Effects of Lost Fishing Time" technical memo for a description of expected conditions for a fisher-LNG carrier interaction to occur. This rationale also applies to wake effects. The technical memo will be filed with the BC EAO. Section 6.5.4.2 states that the mean monthly average natural wave height in the Project area is assumed to be between 0.14 m and 1.8 m. The potential maximum wave height (immediately adjacent to the source vessel) of 0.4 m produced by LNG carriers and escort vessels at 12 knots is within the range of anticipated mean monthly average wave height in the Project area. The modeled wake height of LNG carriers (and other vessel types) indicates that wake-related waves attenuate as they travel further from the source vessel (Oceanic Consulting Corporation 2014). This means that the actual wave height when it reaches a fishing vessel is expected to be lower than the wake height at the source vessel, and within the natural wave heigh range currently experienced by fishing vessels. Project-related shipping traffic will travel along the existing and established shipping route currently used by other large marine traffic (e.g., container ships, cargo ships, breakbulk ships, ferries) to enter and exit Prince Rupert harbour. The predicted wake-related wave height 300 m from the centreline of travel of a large, loaded LNG carrier traveling 12 knots (and that modeled for 14 knots) is similar to those predicted for ore carriers, cruise ships, and BC Ferries vessels (Oceanic Consulting Corporation 2014), all of which call at the Port of Prince Rupert. Project-related wake effects are not expected to differ from the variable wave heights and conditions already experienced by fishing vessels, relating to natural weather patterns and existing shipping. Reference Oceanic Consulting Corporation. 2014. Kitimat Ship Wake Study. Prepared for: LNG Canada Development Inc.
1770.1	round 1	Gitxaala Nation	6.5.2.3	Marine Use and Navigable Waters	The description in this section is general and does not provide examples of where and how TK/TLU information was used in the assessment of this VC. These specifics are necessary for confidence that this was undertaken.	Section 6.5.2.3 - Traditional Knowledge and Traditional Use Incorporation, provides a detailed list of documents included in the assessment of Marine Use and Navigable Waters in Section 6.5 of the Application. When information from this list was used in the Application, it was referenced using in-text citations, with the full details of each reference provided in Section 6.5.11 - References. All of the TK/TU studies provided to Aurora LNG by Aboriginal Groups were considered in the assessment. The application of this information specific to marine use and navigation can be found with reference to the in-text citations. Comprehensive information is provided in Section 11.3.9 (Assessment of Section 5(1)(c) Effects - Gitxaala Nation) and Section 12.5.6 (Aboriginal Interests - Gitxaala Nation) of the Application. The information is also included in Section 6 of the Aboriginal Consultation TDR (Appendix S.2). All three of these parts of the Application, referred to above, include description of marine access and use by Gitxaala Nation.
1771.1	round 1	Gitxaala Nation	6.5.3.1	Marine Use and Navigable Waters	This section does not contain any detail on the Aboriginal use information gleaned from the listed TU reports. A summary of the information specifically used should have been provided in some capacity.	Section 6.5.2.3 - Traditional Knowledge and Traditional Use Incorporation, provides a detailed list of documents included in the assessment of Marine Use and Navigable Waters in Section 6.5 of the Application. When information from this list was used in the Application, it was referenced using in-text citations, with the full details of each reference provided in Section 6.5.11 - References. All of the TK/TU studies provided to Aurora LNG by Aboriginal Groups during development of the Application were considered in the assessment. The application of this information specific to marine use and navigation can be found with reference to the in-text citations. Comprehensive information is provided in Section 11.3.9 (Assessment of Section 5(1)(c) Effects - Gitxaala Nation) and Section 12.5.6 (Aboriginal Interests - Gitxaala Nation) of the Application. The information is also included in Section 6 of the Aboriginal Consultation TDR (Appendix S.2). All three of these parts of the Application, referred to above, include description of marine access and use by Gitxaala Nation.
1772.1	round 1	Gitxaala Nation	6.5.3.2	Marine Use and Navigable Waters	Gitxaala Nation also uses Aboriginal fisheries for the establishment and maintenance of a thriving trade network. This was discussed in the Gitxaala Use Report but was not indicated in the assessment.	Aurora LNG acknowledges the importance of Gitxaala Nation's trade economy. See Section 12.5.6.11 of the Application for an assessment of effects on Gitxaala Nation economic opportunities, including commercial fishing and trading harvested resources.
1773.1	round 1	Gitxaala Nation	6.5.3.2	Marine Use and Navigable Waters	Gitxaala makes use of specific landmarks as navigational aids, however only government approved navigational features are discussed in this section.	The 'Overview - Navigational Aids' section is clear in its aim to describe government-approved and -maintained (i.e., Coast Guard-installed and non-natural) aids to navigation. The wording on page 6.5-40 of the Application states that "Gitxaala First Nation boaters use [...] several navigation routes near the south end of Digby Island and throughout the rest of the LAA." Aurora LNG acknowledges that Gitxaala Nation boaters use specific landmarks as navigational aids. The potential Project effects on marine navigational sight lines are discussed in the "Navigational Sight Lines and Glare Effects" technical memo which will be filed with the BC EAO.
1774.1	round 1	Gitxaala Nation	6.5.3.2	Marine Use and Navigable Waters	This section quotes the Gitxaala use study in a misleading manner. It uses the quote "Rupert Harbour is already a busy Harbour" when the quote fully states "Rupert Harbour is already a busy Harbour and are concerned about increased congestion." The omission of the qualifying information of this quote is misleading.	Aurora LNG acknowledges the concerns of Gitxaala Nation with respect to the quotation used in Section 6.5.3 of the Application and the emphasis that they are concerned with additional marine traffic and congestion in the Port of Prince Rupert. Shipping traffic in Prince Rupert harbour is identified as a key concern in Table 6.5-2 and is discussed in Section 6.5.5.
1775.1	round 1	Gitxaala Nation	6.5.4.2	Marine Use and Navigable Waters	While the waves created by LNG carriers may well be within the natural variability of waves occurring in the area, there are a number of issues with this conclusion with respect to Aboriginal harvesting. First, the model used by LNG Canada looked at averages of waves. Gitxaala is concerned with waves overtaking harvesters during low to zero tides. This is a specific situation which requires more thought. Secondly, wake from the ships, without the benefit of attenuation to the shoreline can easily disrupt smaller fishing ships. These factors must be considered by Nexen.	The potential for Project-related ship wake to cause significant adverse effects on shoreline harvesters or small fishing vessels is unlikely because wake waves will be the same size or smaller compared to the average wake wave height in the region. Section 6.5.4.2 describes that the mean monthly average natural wave height in the Project area is assumed to be between 0.14 m and 1.8 m. The potential maximum wake wave height (immediately adjacent to the source vessel) of 0.4 m produced by LNG carriers and escort vessels at 12 knots is within the natural range of wave height in the Project area. Because wake waves attenuate as they travel further from the source vessel (Oceanic Consulting Corporation 2014), those waves potentially experienced by shoreline harvester will be smaller than the source wake. Consequently, shoreline harvester and small fishing vessels are not likely to incur significant adverse residual effects from Project-related traffic. Wake waves from LNG carriers is similar to those predicted for ore carriers, cruise ships, and BC Ferries vessels (Oceanic Consulting Corporation 2014), all of which already use the Port of Prince Rupert, suggesting that shoreline harvesters and small vessels have experience navigating in similar conditions. Overall, Project-related wake effects are not expected to differ from the existing conditions, including natural and ship-generated wave heights. Reference Oceanic Consulting Corporation. 2014. Kitimat Ship Wake Study. Prepared for: LNG Canada Development Inc.
1776.1	round 1	Gitxaala Nation	Table 11.3-2	CEAA 2012	The Potential Project Effects listed in this table does not demonstrate an understanding of what 'Current Use' means. The Referenced Potential Project Effects only focus on the underlying biophysical components and not on the actual use. Aboriginal use has more facets than just the underlying biophysical component. While there still may be consumptive and non-consumptive resources available, access to those resources, quality, quantity and perception all play roles in continued use. Without consideration of these aspects, the assessment is lacking.	The assessment of CEAA Section 5(1)(c) Effects includes Aboriginal use considerations beyond the "underlying biophysical components". For example, the measurable parameters identified in Table 11.3-2, which are utilized for the assessment of Current Use, include:Quantity (area) and quality of current access routes where use will be affectedQualitative changes in the current experience of traditional harvestingQuality of affected sacred sites, cultural sites, spiritual sites, landforms and natural features associated with ritual or spiritual useQualitative changes in the experience of using sites and landscape features for ritual or spiritually important purposes (e.g., changes in acoustic environment and visual quality at identified sites). These measureable parameters (and others like them) were included as part of the assessment in recognition that potential effects on Current Use are not limited to changes to the availability of resources relied upon to exercise current use activities. These measurable parameters allow for potential effects on the experience of Aboriginal peoples' to be incorporated into the assessment of Current Use, rather than focusing the effects assessment only on changes in related biophysical components. In addition, Aurora LNG notes that Section 12.5.6 (Gitxaala Nation) includes a more nuanced assessment that incorporates many intangible elements of Aboriginal use considerations beyond the "underlying biophysical components", including in Sections 12.5.6.6 (Assessment of Effects on Gitxaala Nation Harvesting-Related Aboriginal Interests) and 12.5.6.7 (Assessment of Effects on Gitxaala Nation Cultural Wellbeing). Aurora LNG is confident that the environmental assessment presented in the Application, including the assessment completed in Section 11.3, is fully compliant with all provincial and federal regulatory requirements.
1777.1	round 1	Gitxaala Nation	Table 11.3-2	CEAA 2012	There is no consideration in this table of perceptive effects of the Project. Often, Gitxaala perception of a Project can strongly influence the use and enjoyment of areas in proximity. This must be considered as part of the overall assessment.	The assessment of CEAA Section 5(1)(c) Effects includes considerations of perceptive effects. For example, the measurable parameters identified in Table 11.3-2, which are utilized for the assessment of Current Use, include:Qualitative changes in the current experience of traditional harvestingQuality of affected sacred sites, cultural sites, spiritual sites, landforms and natural features associated with ritual or spiritual useQualitative changes in the experience of using sites and landscape features for ritual or spiritually important purposes (e.g., changes in acoustic environment and visual quality at identified sites). These measurable parameters (and others like them) were included as part of the assessment in recognition of potential perceptive effects. In addition, Aurora LNG notes that Section 12.5.6 (Gitxaala Nation) includes a more nuanced assessment that incorporates many intangible elements of potential perceptive impacts, including in Sections 12.5.6.6 (Assessment of Effects on Gitxaala Nation Harvesting-Related Aboriginal Interests). Aurora LNG is confident that the environmental assessment presented in the Application, including the assessment completed in Section 11.3, is fully compliant with all provincial and federal regulatory requirements.
1778.1	round 1	Gitxaala Nation	Table11.3-3	CEAA 2012	There are potential effects to Current Use from a change in wetland function which are not considered in this Table. A change in wetland function could result in changes to patterns of use and increased avoidance behavior. These effects must be considered for the application to be complete.	Changes in patterns of wildlife use of habitats on Digby Island, including wetland habitats, resulting from direct or indirect changes in habitat from Project activities and infrastructure are considered in the Wildlife Resources (Terrestrial) VC within Section 4.7.5.2 (Change in Habitat) and Section 4.7.5.4 (Change in Movement). Potential residual Project effects are already identified as a potential interaction within the Current Use assessment and have therefore been considered.
1779.1	round 1	Gitxaala Nation	Table 11.3-3	CEAA 2012	There are potential effects to Current Use from a change in resources-based primary industries and subsistence economies. Gitxaala has previously expressed the importance of subsistence harvesting and the underlying trade economy which this harvesting supports. Effects to a subsistence economy must be considered in Current Use as it has a direct effect on the exercise of Gitxaala's rights and interests.	Changes in resource-based primary and subsistence economies was added to the assessment of Economic Conditions as a result of feedback received from the Working Group, Aboriginal Groups, and the public; see Table 5.2-1 and Section 5.2.5.3 of the Application. The assessment of potential effects on Current Use is aligned with Section 11.3.1.3 of the AIR. The assessment is limited to changes to the environment which may affect Current Use (see Section 11.1 of the AIR). The identified effect is outside of the scope of the Current Use assessment. An assessment of potential effects on Gitxaala Nation Aboriginal Interests (including harvesting-related interests and economic opportunities) is provided in Section 12 of the Application.
1780.1	round 1	Gitxaala Nation	Table 11.3-3	CEAA 2012	This table indicates that effects from a change in vibration levels and water quality on Aboriginal Health were captured by another VC. This was not the case through further examination of Section 4.0. Please update this assessment to include an Aboriginal specific look at vibration levels and water quality.	Residual effects to the environment on Aboriginal Health were assessed according to the methods outlined in Section 11.3.5.1 and in Figure 11.3-5. These methods were based on guidance provided by the Canadian Environmental Assessment Agency and are consistent with those described in Figure 11-1 of the AIR. The potential effects from a change in vibration levels and water quality are captured through the conclusions of the Acoustic Environment VC and Human Health VC. The conclusions of the assessment of changes in vibration levels in the Acoustic Environment VC are equally applicable to both Aboriginal and non-Aboriginal persons - as a result this interaction is given an asterisk in Table 11.3-3 in the Application, indicating that the potential effect is captured through another VC's conclusions. Residual effects on human health (including the health of Aboriginal people) were not predicted to result from changes in surface water quality and no further analysis of how changes in surface water quality might affect Aboriginal health was required. Therefore, this potential interaction was excluded from further consideration.

1781.1	round 1	Gitxaala Nation	Table 11.3-3	CEAA 2012	There are potential effects to Aboriginal Socio-Economic Conditions from changes in community infrastructure and services, change in non-tenured land-use, a change in navigation, and a change in community health and wellness which are not considered in this table. These effects must be considered for the application to be considered complete.	The assessment provided in Section 11 is limited to changes to the environment which may affect Section (5)(1)(c) factors, see Section 11.1 of the AIR. The identified effects arenot "changes to the environment" and are outside of the scope of the Aboriginal Socio-Economic Conditions assessment. However, these potential effects are addressed in the following Part B VC assessments; Infrastructure and Services, Land and Resource Use, Marine Use and Navigable Waters, and Community Health.
1782.1	round 1	Gitxaala Nation	11.3.2.4	CEAA 2012	Gitxaala Nation was not consulted on the identified spatial boundary used for Potential Project Environmental Effects on Section 5(1)(c)	The spatial boundaries for the assessment of Section 5(1)(c) Effects were established in accordance with the Application Information Requirements and informed by pre-Application consultation completed by Aurora LNG. Such consultation included the pre-application workshops held with Gitxaala Nation on:June 23, 2016 to discuss the proposed assessment methods and characterization criteria for socio-economic VCs and traditional use sections of the Application; andOctober 20/21, 2016, to discuss and review drafts of the portions of Sections 11.3 (Requirements under CEAA 2012 Section 5(1)(c)) and 12.0 (Aboriginal Consultation) that related to Gitxaala Nation. As described in Section 11.3.2.4 (Boundaries), the spatial boundaries for the assessment of each Section 5(1)(c) Effect were developed by combining the spatial extent of the Local Assessment Areas (LAAs) or Regional Assessment Areas (RAAs) for relevant VCs, considering available Project specific TK and TU information on current land and resource use by Aboriginal Groups, and taking into account relevant ecological, social and cultural information in the public domain. Aurora LNG is confident that the spatial boundaries presented in the Application are fully compliant with all provincial and federal regulatory requirements.
1783.1	round 1	Gitxaala Nation	11.3.2.4	CEAA 2012	Map 11.3-1 displays Harvested Foods Local and Regional Assessment Areas. There is one of these boundaries located on the Kitkatla Reserve, Lach Klan. However, this is an inappropriate locale for a Harvesting Foods Assessment Area in relation to the Aurora LNG Project. This boundary must be placed closer or on Digby Island to represent harvesting undertaken by Gitxaala which may have the potential to be affected by the project.	The spatial boundaries for the assessment of Section 5(1)(c) Effects were established in accordance with the Application Information Requirements and informed by pre-Application consultation completed by Aurora LNG. The Current Use Local Assessment Area (LAA) and Regional Assessment Area (RAA) boundaries were selected to align with the LAA established for change in harvested foods, as assessed in the Community Health VC. The LAA for the assessment of change in harvested foods considers the use of areas overlapped by the LAA for Land and Resource Use, Marine Use and Navigable Waters by persons' within Kitkatla Reserve (Lach Klan) and other communities as outlined in Table 6.6-3 of the Application. The LAA reflects the spatial extent to which Project-related change in population and employment and income could attribute to a direct, predictable, and measurable adverse change in community health and wellness, or change in availability of harvested foods. Aurora LNG is confident that the spatial boundaries presented in the Application are fully compliant with all provincial and federal regulatory requirements.
1784.1	round 1	Gitxaala Nation	11.3.2.4	CEAA 2012	This section refers back to technical limitations in the Part B VCs Sections; however, this is problematic as many of the Part B VCs refer readers to Part C for additional information on Aboriginal related technical boundaries. However, the technical boundaries in Part C relate only to the VC's identified for Part C and do not specifically relate to CEAA 5(1)(c). This section should have all details laid out for the reader to allow for ease of understanding. By referencing the reader to multiple sections, the overall description of technical boundaries is lost.	Please see the Technical Memo titled, "Summary of Part B Technical Boundaries for Gitxaala Nation" which will be filed with the BC EAO.
1785.1	round 1	Gitxaala Nation	11.3.2.7	CEAA 2012	The significance threshold for Current Use and resources must be clarified to be location based. The current use activity may continue to be viable, just not at a particular locale and, for that locale, the effect would be significant. This must be explicit.	The Application, including Section 11.3, was developed in accordance with the Application Information Requirements (AIR) and informed by pre-application consultation with Aboriginal Groups (see the Aboriginal Consultation Reports). In the context of the significance threshold for Current Use, "viability" is the consideration of whether it remains realistically possible and/or feasible to continue to participate in a specific traditional use activity at, or near, current levels (potentially with some level of modification). In accordance with the AIR and the Canadian Environmental Assessment Agency (CEA Agency) document entitled "Reference Guide: Determining Whether a Project is Likely to Cause Significant Adverse Environmental Effects: A Framework" this evaluation considers the assessments of magnitude, geographic extent, duration, reversibility and context (i.e. resilience) for each of the measurable parameters identified for current use. Aurora LNG is confident that the environmental assessment presented in the Application is fully compliant with all provincial and federal regulatory requirements. As a result, further clarification is neither warranted nor required. Please also see the memo titled "Additional Information Regarding the CEAA 5(1)(C) and Part C Assessment Methodologies and the Consideration of Traditional Use Information in these Assessments".
1786.1	round 1	Gitxaala Nation	11.3.5.2	CEAA 2012	The assumption that "Unless available information indicates otherwise, resources harvested on or around Digby Island and in surrounding waters are not considered unique and can be harvested elsewhere within the LAA depending on harvesting protocols and availability of other locations." Does not adhere to assessment methodology to allow for a conservative assessment as outlined above in that Section. Instead, harvesting locales should have been considered unique. This would also fit better with the harvesting protocols which Gitxaala Nation adheres to.	Please also see the memo titled "Additional Information Regarding the CEAA 5(1)(C) and Part C Assessment Methodologies and the Consideration of Traditional Use Information in these Assessments".
1787.1	round 1	Gitxaala Nation	11.3.6.1	CEAA 2012	This section identifies relevant VCs which apply to Current Use. However, it is unclear what additional information was considered in addition to these VCs. As these VCs do not specifically relate to Current Use, reliance on them for the entirety of the assessment is problematic.	As per the six steps outlined in Section 11.3.5.1 (Method for the Assessment of Residual Effects), the identification of residual effects from relevant Part B VCs for consideration as part of the assessment of Section 5(1)(c) Effects is the second step utilized to assess residual effects in Section 11.3 (see Figure 11.3-5 on pg. 11-46). The results of this process step, which are common to all Aboriginal Groups, are presented in Section 11.3.6.1 (Current Use—Relevant VCs and Residual Effects). Following this step, an Aboriginal Group specific assessment is conducted based on information, including information from the identified Part B VCs and the existing condition section compiled for the particular Aboriginal Group. In the context of Gitxaala Nation, Current Use was assessed using the following two-part Application drafting framework (see pg. 11-173): "The first part summarizes information and findings related to the residual effects and VCs that have been deemed relevant to the assessment of Section 5(1)(c) effects (i.e., based on steps #1 and #2 from Section 11.3.5.1) under headings that reflect the… measurable parameters…" "The second part… provides conclusions regarding the characterization of residual effects... based on the results of the first part of this section (i.e., the findings related to the residual effects and VCs that have been deemed relevant to the assessment of Section 5(1)(c) effects), the understanding of current [use] (based on existing conditions) and the criteria and definitions outlined in Section 11.3.2.5." Using this process, the specific characterizations for each Current Use sub-component (e.g. hunting) that were presented in Section 11.3.9.3 (Assessment of CEAA 2012 5(1)(c) iii—Current Use of Lands and Resources for Traditional Purposes) were assessed based on the information contained in Section 11.3.9.2 (Existing Conditions for Gitxaala Nation) and Section 6 (Gitxaala Nation) of Appendix S.2 (Aboriginal Consultation) and the definitions identified in Section 11.3.2.5 (Residual Effects Description Criteria).
1788.1	round 1	Gitxaala Nation	Table 11.3-11	CEAA 2012	Prior to this table, there is no discussion of the potential effects to Current Use, therefore application of mitigation measures is premature. Additionally, there is no description of the effect which the mitigation measures apply to under Current Use, and no description of how the potential effect is reduced by its application.	The Application, including Section 11.3, was developed in accordance with the Application Information Requirements (AIR). As required by the AIR, the assessment of CEAA Section 5(1)(c) Effects in Section 11.3 is completed in accordance with the six steps outlined in Section 11.3.5.1 (Method for the Assessment of Residual Effects) and in a manner that was generally consistent with Section 3 (Assessment Methods). Following these requirements, the mechanism(s) through which potential Project effects on Current Use may take place are discussed in Section 11.3.6.1 (Current Use—Relevant VCs and Residual Effects). In this section, Tables 11.3-9 and 11.3-10 identify the potential Project effects for Consumptive and Non-consumptive Current Use, as well as the related valued components where these potential effects are assessed. Table 11.3-11 then identifies proposed mitigation measures to avoid or reduce predicted effects on Current Use.
1789.1	round 1	Gitxaala Nation	11.3.6.2	CEAA 2012	This section identifies relevant VCs which apply to Aboriginal Health. However, it is unclear what additional information was considered in addition to these VCs. As these VCs do not specifically relate to Aboriginal Health, reliance on them for the entirety of the assessment is problematic.	As per the six steps outlined in Section 11.3.5.1 (Method for the Assessment of Residual Effects), the identification of residual effects from relevant Part B VCs for consideration as part of the assessment of Section 5(1)(c) Effects is the second step utilized to assess residual effects in Section 11.3 (see Figure 11.3-5 on pg. 11-46). The results of this process step, which are common to all Aboriginal Groups, are presented in Section 11.3.6.2 (Aboriginal Health—Relevant VCs and Residual Effects). In applying the six step framework detailed in Section 11.3.5.1, it was determined that the interactions would be consistent for Aboriginal people as non-Aboriginal people, and therefore, the assessment focused on the conclusions originally described for the relevant VCs. In particular, the assessment focused on the following approaches taken in the relevant VC assessments:Human Health receptor sites used in the Human Health assessment included places where health-sensitive people are present (e.g., daycares, schools, hospitals, elderly care homes)The Community Health assessment considers effects on vulnerable populations, including: children and youth, women, seniors, Aboriginal persons, individuals and households on fixed incomes, individuals and households classified as low-income earners, marginally-housed individuals, and individuals classified as homeless. Additional information sources, not included in the VC assessments, were considered to determine if the predicted residual effects would be consistent for Aboriginal and non-Aboriginal peoples. See steps 3-6 outlined in Section 11.3.5.1 and illustrated in Figure 11.3-5.
1790.1	round 1	Gitxaala Nation	Table 11.3-12	CEAA 2012	Prior to this table, there is no discussion of the potential effects to Aboriginal Health, therefore application of mitigation measures is premature. Additionally, there is no description of the effect which the mitigation measures apply to under Aboriginal Health, and no description of how the potential effect is reduced by its application.	The Application, including Section 11.3, was developed in accordance with the Application Information Requirements (AIR). As required by the AIR, the assessment of CEAA Section 5(1)(c) Effects in Section 11.3 is completed in accordance with the six steps outlined in Section 11.3.5.1 (Method for the Assessment of Residual Effects) and in a manner that was consistent with Section 3 (Assessment Methods). Following these requirements, the mechanism(s) through which potential Project effects on Aboriginal Health may take place are discussed in Section 11.3.6.2 (Aboriginal Health—Relevant VCs and Residual Effects). In this section, the paragraphs that precede Table 11.3-12 (and the associated text) identify the potential Project effects for Aboriginal Heath, as well as the related valued components where these potential effects are assessed. Table 11.3-12 then identifies proposed mitigation measures to avoid or reduce predicted effects on Aboriginal Health.
1791.1	round 1	Gitxaala Nation	11.3.6.3	CEAA 2012	This section identifies relevant VCs which apply to Aboriginal Socio-Economic Conditions. However, it is unclear what additional information was considered in addition to these VCs. As these VCs do not specifically relate to Aboriginal Socio-Economic Conditions, reliance on them for the entirety of the assessment is problematic.	As per the six steps outlined in Section 11.3.5.1 (Method for the Assessment of Residual Effects), the identification of residual effects from relevant Part B VCs for consideration as part of the assessment of Section 5(1)(c) Effects is the second step utilized to assess residual effects in Section 11.3 (see Figure 11.3-5 on pg. 11-46). The results of this process step, which are common to all Aboriginal Groups, are presented in Section 11.3.6.3 (Aboriginal Socio-Economic Conditions—Relevant VCs and Residual Effects). In applying the six step framework detailed in Section 11.3.5.1, it was determined that the interactions related to Aboriginal Socio-Economic Conditions would be consistent for Aboriginal people as non-Aboriginal people, and therefore, the assessment focused on the conclusions originally described for the relevant VCs. In particular, the assessment focused on the following approaches taken in the relevant VC assessments:Visual Quality viewpoints were determined in consultation with Aboriginal Groups and are relevant to any land or marine user.The thresholds used in the Acoustic Environment assessment are guidelines set forth by regulators and do not differ for Aboriginal and non-Aboriginal people. The Community Health assessment considers effects on vulnerable populations, including: children and youth, women, seniors, Aboriginal persons, individuals and households on fixed incomes, individuals and households classified as low-income earners, marginally-housed individuals, and individuals classified as homeless. Additional information sources, not included in the VC assessments, were considered to determine if the predicted residual effects would be consistent for Aboriginal and non-Aboriginal peoples. See steps 3-6 outlined in Section 11.3.5.1 and illustrated in Figure 11.3-5.
1792.1	round 1	Gitxaala Nation	Table 11.3-13	CEAA 2012	Prior to this table, there is no discussion of the potential effects to Aboriginal Health, therefore application of mitigation measures is premature. Additionally, there is no description of the effect which the mitigation measures apply to under Aboriginal Health, and no description of how the potential effect is reduced by its application.	Based on the reference to Table 11.3-13, it is assumed that this comment relates to Aboriginal Socio-Economic Conditions (and not Aboriginal Health). The Application, including Section 11.3, was developed in accordance with the Application Information Requirements (AIR). As required by the AIR, the assessment of CEAA Section 5(1)(c) Effects in Section 11.3 is completed in accordance with the six steps outlined in Section 11.3.5.1 (Method for the Assessment of Residual Effects) and in a manner that was consistent with Section 3 (Assessment Methods). Following these requirements, the mechanism(s) through which potential Project effects on Aboriginal Socio-Economic Conditions may take place are discussed in Section 11.3.6.3 (Aboriginal Socio-Economic Conditions—Relevant VCs and Residual Effects). In this section, the paragraphs that precede Table 11.3-13 (and the associated text) identify the potential Project effects for Aboriginal Socio-Economic Conditions, as well as the related valued components where these potential effects are assessed. Table 11.3-13 then identifies proposed mitigation measures to avoid or reduce predicted effects on Aboriginal Socio-Economic Conditions.

1793.1	round 1	Gitxaala Nation	11.3.9.2	CEAA 2012	This section incorrectly characterizes the information provided in the Gitxaala Use Study. It states that "Project specific TK identified numerous hunting locations throughout Gitxaala Nation traditional territory. For example over 145 locations for deer hunting." The identified deer hunting locations in the Gitxaala Use Report were within the LAA and RAA for the Project, not throughout Gitxaala's entire traditional territory. There were 9 sites identified in the LSA and an additional 135 in the RSA. This description must be updated.	Best efforts have been made by Aurora LNG to incorporate and use the information from the study in this assessment. Gitxaala is correct in noticing a reference of hunting locations reported throughout Gitxaala's entire traditional territory, rather than within the LAA and RAA referenced in the Gitxaala's Use Report, (Calliou Group 2016a). An errata document has been created that captures these corrections and it will be filed with the BC EAO.
1794.1	round 1	Gitxaala Nation	11.3.9.2	CEAA 2012	This section lists the locations for hunting within the Current Use LAA but omits Gull Rocks and Alexandra Rocks. Please provide detail on why these locations were not categorized.	Gull Rocks and Alexandra Rocks are located within the Local Assessment Area established for the assessment of Current Use (see Figure 11.3-1). Potential effects on Gitxaala Nation harvesting activities (i.e. seagull egg harvesting, fishing) at, or near, those locations were included in the Current Use assessment. While Section 11.3.9.2 of the Application does not specifically mention Gull Rocks or Alexandra Rocks, the section explains that Gitxaala Nation reports that its members currently hunt along the shorelines and islands "in and around the Prince Rupert Harbour area including Digby Island and locations on either side of the Project shipping route" (this would include Gull Rocks and Alexandra Rocks). Furthermore, Gull Rocks and Alexandra Rocks have been included in relevant places in the lists of current use locations that have been included in the information compiled for Gitxaala Nation in Tables 5-8 to 5-16 (p 89 to 116) of Appendix S.2 (Aboriginal Consultation TDR).
1795.1	round 1	Gitxaala Nation	11.3.9.2	CEAA 2012	There is no discussion of species identified by Gitxaala that were not found, through field work, to be identified	The Application, including Section 11.3, was developed in accordance with the Application Information Requirements (AIR). Aurora LNG notes that a "discussion of species identified by Gitxaala that were not found, through field work" was not a requirement of the AIR, and as such, is not explicitly addressed Section 11.3.9.2 (Existing Conditions for Gitxaala Nation). Nonetheless, this information could be obtained through a review of the Technical Data Reports listed under the relevant headings in Section 11.3.9.2 (see pg. 11-163-168). Furthermore, to aid Gitxaala Nation's review, Aurora LNG has compiled the referenced information for hunting. The TU and TK information provided by Gitxaala Nation for the Project identifies the following wildlife species hunted by Gitxaala Nation members (Calliou Group 2016a; Calliou Group 2016b):Terrestrial Wildlife Species: Deer, Bear, Moose, Mountain goat, Mink, Beaver, Marten, Weasel, River otter Marine Mammal Species: Sea lion, Seal, Sea otter Marine Bird Species: Swan, Geese, Duck, Seagull (eggs), Oystercatcher (eggs) Of the hunted species summarized in the Aboriginal Consultation TDR (Appendix S2) based on Gitxaala Nation's Project specific studies, the following species were not detected within the Wildlife Resources (Terrestrial), Marine Mammals and Marine Birds PDAs, LAAs or RAAs but have potential to occur within the region based on habitat requirements, known range, and traditional knowledge recordsMoose Mountain Goat Mink Weasel Swan As stated in Section 11.3.9.2 of the Application (on pg. 11-163): "Of the wildlife species identified in the Aboriginal Consultation TDR (Appendix S2) in Gitxaala Nation's Project specific information, the following species occur within the PDA and Wildlife Resources (Terrestrial), Marine Mammals and Marine Birds LAAs: Terrestrial Wildlife Species: Deer, Wolf, Bear, Beaver, Marten, River otterMarine Mammal Species: Sea lion, Harbour seal, Sea otter Marine Bird Species: Goose, Duck (common merganser), Seagull (eggs), Oystercatchers (eggs) Additional information, including a list of known wildlife, marine mammal and marine bird species occurring within the Wildlife Resources (Terrestrial), Marine Mammals and Marine Birds LAAs and RAAs and information related to terrestrial wildlife, marine mammals and marine birds habitat availability, is provided in the Wildlife Resources (Terrestrial) TDR (Appendix J), Marine Mammals TDR (Appendix N) and Marine Birds TDR (Appendix Q), respectively."
1796.1	round 1	Gitxaala Nation	11.3.9.2	CEAA 2012	This section states that "The consumption of harvested foods by Gitxaala Nation community members has been discussed above in the description of Existing Conditions for Consumptive Traditional Use." The consumption of harvested foods by Gitxaala was not discussed in detail in the previous section as referenced in the application. There was no discussion of consumption levels for any species, simply a listing of species typically consumed.	The levels of traditional food consumption by Gitxaala Nation was not a data set which was available for consideration. For the purpose of this assessment, Consumptive Traditional Use incorporated Hunting, Trapping, Fishing (including intertidal harvesting) and Vegetation Gathering (including marine vegetation), see Table 11.3-2. A discussion of Gitxaala Nation hunting, fishing trapping and vegetation gathering including harvested species, and harvesting areas is presented from pages 11-161 to 11-168. The quoted statement from page 11-170 is referring to the earlier content.
1797.1	round 1	Gitxaala Nation	11.3.9.2	CEAA 2012	This section states that "The consumption of harvested foods by Gitxaala Nation community members has been discussed above in the description of Existing Conditions for Consumptive Traditional Use." However, the consumption of harvested foods was not previously discussed in terms of socio-economic conditions.	For the purpose of this assessment, Consumptive Traditional Use incorporated Hunting, Trapping, Fishing (including intertidal harvesting) and Vegetation Gathering (including marine vegetation), see Table 11.3-2. A discussion of Gitxaala Nation hunting, fishing trapping and vegetation gathering including harvested species, and harvesting areas is presented from pages 11-161 to 11-168. The quoted statement from page 11-171 is referring to the earlier content.
1798.1	round 1	Gitxaala Nation	11.3.9.2	CEAA 2012	This section states that "Based on Statistics Canada's 2011 Business Registry, there were 189 business locations on BC's north coast that were involved in the fishing industry…" However, no detail is provided on businesses specifically owned or operated by Gitxaala members.	Information regarding Gitxaala Nation businesses is provided in Section 6.3.5 of the Aboriginal Consultation TDR (Appendix S.2).
1799.1	round 1	Gitxaala Nation	11.3.9.2	CEAA 2012	There is no mention in this section of the identified Gitxaala fish trap location.	The Gitxaala Nation fish trap is discussed in Section 11.3.9.2 of the Application. Please see page 11-164.
1800.1	round 1	Gitxaala Nation	11.3.9.2	CEAA 2012	The description of Gitxaala Physical and Cultural Heritage is incomplete. While physical sites and harvested food plays an important part in Gitxaala Physical and Cultural heritage, it is not the entirety - therefore, additional description from the Use Report and VC Report is required.	Section 11.3.9.2 (Existing Conditions—Physical and Cultural Heritage) was developed in accordance with the Application Information Requirements (AIR) and based on the on the best information available at the time. As noted in Section 11.3.9.2, this section draws upon the species and sites information in the Consumptive and Non-Consumptive Traditional Use Existing Conditions, as well as the information contained in Section 7.2.3 (Existing Conditions for Archaeological and Heritage Resources) and the associated Archaeological Impact Assessment (Appendix W). This section also considers the information compiled in Section 6 (Gitxaala Nation) of Appendix S.2 (Aboriginal Consultation). Aurora LNG is confident that Section 11.3.9.2 meets the requirements of the AIR and that the environmental assessment presented in the Application is fully compliant with all provincial and federal regulatory requirements. Furthermore, Aurora LNG notes that a more detailed discussion of similar considerations is provided in Section 12.5.6.7 (Assessment of Effects on Gitxaala Nation Cultural Wellbeing).

1801.1	round 1	Gitxaala Nation	11.3.9.3	CEAA 2012	The effects to current use of land and resources should focus on the use of deer (the selected indicator species) rather than on the resiliency of deer itself. By focusing only on the resiliency of deer the assessment misses key aspects of the use of deer including the quality of the deer and the access to the remaining deer. Further, effects to current use of land and resources should use the residual effects criteria listed in the beginning of this Volume rather than explore it in terms of the Wildlife Resources (Terrestrial) VC residual effects criteria.	Aurora LNG is confident that the environmental assessment presented in the Application is fully compliant with all provincial and federal regulatory requirements. Section 11.3.9.3 (Assessment of CEAA 2012 5(1)(c) iii—Current Use of Lands and Resources for Traditional Purposes) was developed in accordance with the Application Information Requirements (AIR) and informed by pre-Application consultation completed by Aurora LNG. The residual Project effects to current use of lands and resources for traditional purposes were assessed according to the methods outlined in Section 11.3.5.1 (Method for the Assessment of Residual Effects). These methods were based on available guidance, including that provided by the CEA Agency, and are consistent with those described in Section 11.3.4 (Assessment of Residual Effects) of the AIR. In the context of Gitxaala Nation, Current Use was assessed using the following two-part Application drafting framework (see pg. 11-173): "The first part summarizes information and findings related to the residual effects and VCs that have been deemed relevant to the assessment of Section 5(1)(c) effects (i.e., based on steps #1 and #2 from Section 11.3.5.1) under headings that reflect the… measurable parameters…" "The second part… provides conclusions regarding the characterization of residual effects... based on the results of the first part of this section (i.e., the findings related to the residual effects and VCs that have been deemed relevant to the assessment of Section 5(1)(c) effects), the understanding of current [use] (based on existing conditions) and the criteria and definitions outlined in Section 11.3.2.5." Using this process, the specific characterizations for each Current Use sub-component (e.g. hunting) that were presented in Section 11.3.9.3 were assessed based on the information contained in Section 11.3.9.2 (Existing Conditions for Gitxaala Nation) and Section 6 (Gitxaala Nation) of Appendix S.2 (Aboriginal Consultation) and the definitions identified in Section 11.3.2.5 (Residual Effects Description Criteria).
1802.1	round 1	Gitxaala Nation	11.3.9.3	CEAA 2012	This section states that "…it is noted that marine mammals in the shipping channel and Prince Rupert Harbour area appear to be habituated to the current levels of activity and development, which includes marine traffic." This does not include the addition of the Aurora LNG Project and it is unclear from the assessment how the addition of traffic and construction and operation would additionally affect these species as this concept is not further explored.	Refer to Section 4.10 of the Application for the assessment of residual effects on marine mammals. Sections 4.10.5.2, 4.10.5.3 and 4.10.5.4 provide information regarding predicted effects of project-related vessel traffic during all phases of the Project.
1803.1	round 1	Gitxaala Nation	11.3.9.3	CEAA 2012	This section states that "…the residual effects of the Project on marine mammals was assessed … as being moderate in magnitude for marine mammals … meaning that the predicted change from existing conditions could exceed environmental and/or regulatory thresholds; however, it does not have the potential to affect the long-term persistence of local harvested populations." This does apply the residual effects criteria defined for the Assessment of Aboriginal criteria previously listed in this volume. Further, if the Aboriginal residual effects criteria were to be applied, it would alter the determination of effects. It would increase the potential of effect on the long-term persistence of Aboriginal harvest of local populations as changes to the species would persist beyond ~25 years.	The criteria outlined in Table 11.3-6 for the characterization of residual effects on Section 5(1)(c) effects was applied to the characterization of effects on Current Use presented in section 11.3.9.3 of the Application. Aurora LNG understands that residual effects that restrict Traditional Use and extend beyond 25 years, such as those anticipated for marine mammals, can effectively remove a practice from the community's TK. Residual effects on Gitxaala Nation's marine hunting was characterized as permanent in duration, see Table 11.3-22.
1804.1	round 1	Gitxaala Nation	11.3.9.3	CEAA 2012	We disagree with the Summary of Effects as listed as they are based on an impoverished assessment of effects. Current use will not be able to continue at current levels in the PDA and Gitxaala harvesters will be displaced. This is particularly important and Gitxaala harvesters have governance protocols they generally must adhere to and areas where their harvest is allowed. Digby Island is a historically shared area, where harvesting is undertaken by multiple houses.	Aurora LNG acknowledges that the Project will interact with and potentially affect the Gitxaala Nation's Current Use of lands and resources, but maintains that these activities will be able to continue with some modification. Further information that provides context related to the assessment of the identified potential effects in the Application, including clarification regarding the assumptions utilized in the assessment, is provided in the technical memo entitled "Additional Information Regarding the CEAA 5(1)(C) and Part C Assessment Methodologies and the Consideration of Traditional Use Information in these Assessments` which will be filed with the BC EAO.
1805.1	round 1	Gitxaala Nation	11.3.9.3	CEAA 2012	It is concerning that effects in and around the PDA for air emissions, visual quality and noise will be noticeable to Gitxaala harvesters, however, these effects are minimized as they will no longer be present following decommissioning, or diminish the further from the Project the harvesters may be. These effects must be characterized using the residual effects criteria previously identified in this volume for Aboriginal issues and must be considered at their locale, not further away, as Gitxaala harvesters will be present at or near the PDA.	Aurora LNG acknowledges that Project-related qualitative changes in air quality, the acoustic environment, and visual quality may be experienced by Gitxaala harvesters. These effects are predicted to be most noticeable at locations adjacent to the Project Development Area and are expected to diminish further away from the Project. The predicted residual effects on Gitxaala Nation's Current Use have been characterized using the criteria outlined in section 11.3.2.5 of the Application and in compliance with section 11.3.1 of the AIR. Aurora LNG is confident that the environmental assessment presented in the Application, including the assessment completed in Section 11.3, is fully compliant with all provincial and federal regulatory requirements.
1806.1	round 1	Gitxaala Nation	11.3.9.3	CEAA 2012	It is unclear which residual effects criteria was used to identify the summary of characterization of Current Use - Hunting. Please clarify.	The criteria used to characterize predicted residual effects for Current Use - Hunting is provided in Tables 11.3-6 and 11.3-7 of the Application.
1807.1	round 1	Gitxaala Nation	11.3.9.3	CEAA 2012	Gitxaala Nation is concerned with the permanent alteration or destruction of up to 26.5 ha of marine fish habitat (including up to 6.1 ha of eelgrass). This is of particular concern as Gitxaala has not been involved in the development of a Fish Habitat Offsetting Plan to ensure the offsetting occurs in a manner consistent with Gitxaala use of the resources in the exercise of their rights and interests.	Gitxaala Nation's concern about the permanent alteration or destruction of marine fish habitat, including eelgrass, and interest in the development of a Fish Habitat Offsetting Plan have been noted. The fish habitat offsetting plan was included as part of the Application (see Appendix V) and includes proposed habitat restoration and enhancement measures to offset for the loss of eelgrass as a result of the Project. Offsetting measures presented in this plan are conceptual in nature and Aurora LNG expects that the plan will be refined following consultation with regulatory agencies (primarily DFO) and Aboriginal Groups which will contribute to the selection and design of offsetting measures. There is a typing error in the Application. Section 11.3.9.3 identified a permanent alteration or destruction of up to 6.1 ha of eelgrass. This should read the permanent alteration or destruction of up to 0.61 ha of eelgrass. An errata document is being compiled that captures these corrections and it will be filed with the BC EAO.
1808.1	round 1	Gitxaala Nation	11.3.9.3	CEAA 2012	While the assessment finds that underwater noise generated by in-water construction activities and Project-related vessels, as well as artificial lighting from Project infrastructure and LNG carriers are not expected to threaten the long-term persistence of marine fish populations, how does this translate into no effects on Gitxaala's use of marine fish populations? Will the remaining fish populations support Gitxaala's use, in combination with other Nation's use? Will the remain populations be of sufficient quality and will Gitxaala continue to have access to these species in preferred areas around Digby Island?	The following sections of the Application have informed Aurora LNG's response to Gitxaala Nation's questions in this comment. Underwater Noise and Lighting: As described in Section 11.3.9.3 (page 11-182), underwater noise generated by in-water construction activities, Project-related vessels, and artificial lighting from Project infrastructure and LNG carriers are expected to result in localized changes in marine fish behaviour (e.g., temporary avoidance behaviour, altered swimming direction, or startle response). Therefore, Gitxaala Nation's ability to fish for specific species in preferred areas around the Project (especially during in-water construction activities) will be affected. For example, a Gitxaala Nation fisher fishing for salmon near Casey Cove during in-water blasting activities may not catch as many salmon as they would have at another time when in-water blasting activities are not occurring. Access to Fishing Locations: As described on page 11-183, Gitxaala Nation access to fishing locations at Casey Cove and Frederick Point will be lost. This effect is considered permanent in terms of effects on Current Use, as the effect has the potential to affect the intergenerational transfer of knowledge of fishing or intertidal gathering practices at those two locations. Quality of Fished Species: As described on page 11-182, Project-related activities, including dredging activities, are not anticipated to cause toxicity to aquatic life. Aurora LNG does not anticipate that the quality of fished species will be noticeably affected. Quantity of Fished Species: As described on pages 11-182 and 11-183, Project-related effects on marine fish and fish habitat are not anticipated to threaten the long-term persistence of marine fish populations in the Marine Fish and Fish Habitat LAA. Overall Effects on Gitxaala Nation Fishing: As described on page 11-186, the overall residual effect of the Project on Gitxaala Nation freshwater and marine fishing is expected to be moderate in magnitude. This conclusion is primarily because of the loss of access to Casey Cove and Frederick Point for fishing or intertidal gathering activities, and because of the change to Gitxaala Nation experience of using locations near the PDA.
1809.1	round 1	Gitxaala Nation	11.3.9.3	CEAA 2012	This section states that sessile or slow-moving benthic invertebrates and infauna "…are expected to be replaced within one or two generations of affected species…" This is problematic as Gitxaala harvesters use of the referenced species would be interrupted for a significant amount of time and could not return to pre-Project levels. For example, some species of sea urchin have a life span of 30 years or more and do not reach sexual maturity till four to five years. This could constitute an interruption that may result in the loss of cultural transmission of use areas and remove that area from Gitxaala's cultural inventory. This effect was not explored by the application and must be addressed.	Aurora LNG understands that residual effects that restrict Traditional Use and extend beyond a single generation can effectively remove a practice from the community's TK. As such, predicted residual Project effects on land and resources relied on for Traditional Use that are expected to last longer than a single generation will be considered permanent, see Table 11.3-6. Residual effects on Gitxaala Nation hunting (marine) and fishing have been characterized as having a permanent duration.
1810.1	round 1	Gitxaala Nation	11.3.9.3	CEAA 2012	Again, the assessment makes reference to the availability of vegetation species elsewhere in the LAA. This is problematic for Gitxaala due to governance harvesting protocols in place for the Nation. This issue was not explored in the application and must be considered.	Information that provides context related to the assessment of the identified potential effects in the Application, including clarification regarding the assumptions utilized in the assessment, is provided in the technical memo entitled "Additional Information Regarding the CEAA 5(1)(c) and Part C Assessment Methods and the Consideration of Traditional Use Information in these Assessments" which will be filed with the BC EAO.
1811.1	round 1	Gitxaala Nation	11.3.9.3	CEAA 2012	Gitxaala is concerned with the loss of up to 6,180 m2 of eelgrass. This is problematic from a use perspective for Gitxaala as they rely on eelgrass as critical habitat for salmon. For the purposes of Gitxaala use, it doesn't matter whether Casey Cove is disturbed or not, Gitxaala still make use of this area and it is a critical locale for Gitxaala harvesters. As Gitxaala has not been engaged in Fish Habitat Offsetting to date, this loss of eelgrass constitutes an effect to Gitxaala's current use.	Gitxaala Nation's use of Casey Cove was incorporated in the assessment, and was considered in the characterization of residual effects on Gitxaala Nation Current Use. The fish habitat offsetting plan was included as part of the Application (see Appendix V) and includes proposed habitat restoration and enhancement measures to offset for the loss of eelgrass as a result of the Project. Offsetting measures presented in this plan are conceptual in nature and Aurora LNG expects that the plan will be refined following consultation with regulatory agencies (primarily DFO) and Aboriginal Groups which will contribute to the selection and design of offsetting measures.

1812.1	round 1	Gitxaala Nation	11.3.9.3	CEAA 2012	Gitxaala is concerned with the loss of up to 65,349 m2 of hard substrate. This is problematic from a use perspective for Gitxaala as they rely on hard substrate for the production of kelp. As Gitxaala has not been engaged in Fish Habitat Offsetting to date, this loss of hard substrate constitutes an effect to Gitxaala's current use.	Aurora LNG acknowledges that hard substrate within the LAA will be permanently altered or lost during dredging and marine construction activities (e.g., infilling). Infilling will introduce hard substrates into the marine environment that provide attachment surfaces for seaweeds, including kelps. However, such ecological benefits are not fully realized until communities become established on the substrate, which can require up to ten years. Consequently, offsetting is expected to be required to counterbalance the temporary loss of productivity. A Conceptual Fish Habitat Offsetting Plan was included as part of the Application (see Appendix V). Aboriginal consultation will occur throughout the development of the final Fish Habitat Offsetting Plan and will ultimately contribute towards Aurora LNG's selection and design of offsetting features.
1813.1	round 1	Gitxaala Nation	11.3.9.3	CEAA 2012	This section states that "Effects on terrestrial routes or trails used to access vegetation harvesting locations are not expected as the PDA is not anticipated to block access to other areas of Digby Island." This is an incorrect conclusion. The PDA will be fully excluded from use by Gitxaala harvesters as a means of access, for both marine and terrestrial access. Indeed, the PDA will act as a barrier to access from marine access points to other areas on Digby Island.	Aurora LNG acknowledges that the Project will restrict access to the lands within the Project Development Area (PDA). The measurable parameters identified in Table 11.3-2, which are utilized for the assessment of Current Use, include:Quantity (area) and quality of current access routes where use will be affected Gitxaala Nation has not identified any trails or put-in locations, to Aurora LNG, that are within the PDA that would be used to access other areas of Digby Island. In addition, Aurora LNG notes that Section 12.5.6 (Gitxaala Nation) includes a more nuanced assessment that incorporates many intangible elements of Aboriginal use considerations. Refer to Section 12.5.6.10 for the assessment of effects on Gitxaala Nation's Use of Marine Travelways which provides further context regarding this response. Aurora LNG is confident that the environmental assessment presented in the Application, including the assessment completed in Section 11.3, is fully compliant with all provincial and federal regulatory requirements.
1814.1	round 1	Gitxaala Nation	11.3.9.3	CEAA 2012	This section states that "Vegetation harvesting locations identified by Gitxaala Nation occur throughout their traditional territory…" This is not a valid reason to assume that no effects to vegetation harvesting will occur. First, there are Gitxaala specific harvesting protocols which Gitxaala Nation members must adhere to. Second, Gitxaala's traditional territory is vast and many members lack the ability to travel to other locales to harvest. Digby Island is close to Prince Rupert and affords Gitxaala members with a shared place to harvest and maintain their cultural connection. Finally, the 'go elsewhere' reasoning to lessen effect is inappropriate and has been noted in case law as insufficient.	Information that provides context related to the assessment of the identified potential effects in the Application, including clarification regarding the assumptions utilized in the assessment, is provided in the technical memo entitled "Additional Information Regarding the CEAA 5(1)(C) and Part C Assessment Methodologies and the Consideration of Traditional Use Information in these Assessments" which will be filed with the BC EAO .
1815.1	round 1	Gitxaala Nation	11.3.9.3	CEAA 2012	This section indicates that "…the PDA will include a vegetated riparian buffer that avoids most of the identified archaeological and heritage resources with highest significance located within the PDA…" However, non-consumptive traditional use locations are not fully encompassed by heritage resources and therefore the vegetated buffer will not be sufficient to mitigate effects. Secondly, Gitxaala has not been consulted on significance of those heritage resources referenced, therefore, there is no way for Nexen to know which are valued highest by Gitxaala. This must occur prior to any clearing activity.	As outlined in Section 11.3.9.3 Aurora LNG incorporated information from Gitxaala Nation regarding culturally important sites within the PDA, including including habitation structures and a fish trap (Calliou Group 2016a). Aurora LNG also indicates that these sites may be physically altered or no longer accessible to Gitxaala Nation as a result of the Project. Aurora LNG states that maintaining the vegetated riparian buffer will reduce impacts to archaeological sites, but does not conclude that this buffer will mitigate all impacts. Section 11.3.9.3 summarizes that "Given predicted changes to culturally and spiritually important locations, access to those locations and the experience of using them for cultural and spiritual purposes, the overall residual effect of the Project on cultural and spiritual use by Gitxaala Nation community members is anticipated to be low to moderate in magnitude, extend into the Current Use LAA, occur continuously, and be permanent and irreversible with respect to TU and knowledge transfer. Given Gitxaala Nation's demonstrated concern for the protection of remaining culturally and spiritually important locations and maintaining access and use of those sites, the context for the assessment of Project-related changes to Gitxaala Nation's use of identified cultural and spiritual sites and areas is characterized at a low level of resilience" (see page 11-196). It is important to note that an Archaeological and Heritage Management Plan will be developed to mitigate the loss of archaeological and heritage information. Aurora LNG will engage with the appropriate regulatory agencies and Gitxaala Nation during the preparation of this plan. In addition, archaeological resources will be manged in accordance with the Heritage Conservation Act (HCA), and any alteration to protected sites requires appropriate permits in place. Aurora LNG will comply with all requirements of the BC Heritage Branch and the HCA in relation to archaeological resources.
1816.1	round 1	Gitxaala Nation	11.3.9.3	CEAA 2012	We disagree with the determination that effects to Gitxaala Nation's Current Use is not significant. This is due to the above noted discrepancies in determining effect, including effects on use of species, locations of harvest, access or experience using the sites for harvesting purposes. It is anticipated by Gitxaala that many locales within the PDA and LAA will not be able to continue. Based on this and the applied residual effects criteria for Aboriginal issues, these effects are significant.	Aurora LNG acknowledges that the Project will interact with and potentially affect the Gitxaala Nation's Current Use of lands and resources, but maintains that these activities will be able to continue with some modification. The Application, including Section 11.3, was developed in accordance with the Application Information Requirements (AIR) and informed by pre-application consultation with Aboriginal Groups (see the Aboriginal Consultation Reports). In the context of Section 11.3 of the Application, significance was evaluated against the thresholds established in Section 11.3.2.7 (pg. 11-42). For Current Use, the significance threshold is triggered "if a residual effect on Current Use results in a condition where participation by Aboriginal people in a current use activity is no longer considered viable within existing conditions". In accordance with the AIR, professional judgement is applied as part of this evaluation in a manner that is consistent with the guidance provided in CEA Agency's document entitled "Technical Guidance for assessing the Current Use of Lands and Resources for Traditional Purposes under the Canadian Environmental Assessment Act, 2012" (December 2015) (see pg. 11). Aurora LNG acknowledges that Gitxaala Nation may have differing views regarding the significance threshold as it relates to predicted residual effects on Current Use. Aurora LNG is confident that the significance thresholds presented in the Application are fully compliant with all provincial and federal regulatory requirements. As a result, revisions the Current Use significance thresholds are neither warranted nor required.
1817.1	round 1	Gitxaala Nation	11.3.9.4	CEAA 2012	This section is repetition of information previously presented in the Human Health, Acoustic Environment and Community Health VC. There is little consideration of data specifically related to Gitxaala and no evidence of effort to collect information specific to Gitxaala health beyond the Use study and VC Report, both of which were not expressly for this purpose.	The assessment of Aboriginal Health determined that the effects from the Project on the environment on health as assessed collectively in the Human Health, Acoustic Environment, and Community Health VCs accurately capture the potential effects on Aboriginal Health. This conclusion is primarily based on the following approaches taken in the relevant VC assessments:Human Health receptor sites used in the Human Health assessment took into account Project specific information provided by Gitxaala Nation, as well as publicly available information on the location and composition of Aboriginal communities, the location of TU sites and areas, and harvesting and consumption of traditional foods. The Human Health receptor sites included places where health-sensitive people are present (e.g., daycares, schools, hospitals, elderly care homes).The Community Health assessment considers effects on vulnerable populations, including: children and youth, women, seniors, Aboriginal persons, individuals and households on fixed incomes, individuals and households classified as low-income earners, marginally-housed individuals, and individuals classified as homeless. As described in Section 11.3.2.7, if a residual effect that is relevant to Aboriginal Health would have a substantial effect on Aboriginal people's health beyond that considered in the VC analysis in Part B of the Application, it would be considered significant. Aurora LNG did not find this to be the case. The assessments of Community Health, Human Health, and Acoustic Environment are applicable for any Aboriginal (or non-Aboriginal) person living within the LAA for the three VCs listed. In addition, the assessment was conducted in accordance with the Application Information Requirements and informed by pre-application consultation completed by Aurora LNG. Aurora LNG met with Gitxaala Nation on June 23, 2016 to discuss the proposed assessment methods and characterization criteria for socio-economic VCs and traditional use sections of the Application. In addition, Gitxaala Nation had the opportunity to review the draft Part C and Section 11.3 prior to submission of the Application for screening review and to discuss any views or feedback at Technical Workshop #3 , which was held on October 20-21, 2016. Aurora LNG, as part of that workshop, recorded the views provided by Gitxaala Nation with respect to the assessment of CEAA Section 5(1)(c) effects and Aboriginal Interests in Part C. The information recorded as part of the workshop was incorporated into Sections 11.3 and 12.3 of the Application, in accordance with the AIR. In November 2016, Gitxaala Nation provided Aurora LNG with a study entitled Potential Risks, Impacts and Opportunities of the Aurora LNG Project for Gitxaala Nation (Shandro et al., 2016) (the "Gitxaala Nation Report"). As Aurora LNG had completed the analysis and writing for its Application for Environmental Assessment Certificate (the "Application") at the time the Gitxaala Nation Report was received, information contained in the report had not been reviewed or directly incorporated into the Application which was submitted to the BC EAO in November, 2016. Aurora LNG responded to the Gitxaala Nation Report in its technical memo entitled "Aurora LNG's Response to the 'Potential Risks, Impacts and Opportunities of the Aurora LNG Project for Gitxaala Nation'". A draft of this memo was shared with Gitxaala Nation on May 11, 2017 for their comment and will be filed with the BC EAO.
1818.1	round 1	Gitxaala Nation	11.3.9.5	CEAA 2012	This section is repitition of information previously presented in the Visual Quality, Acoustic Environmental and Community Health VC. There is little consideration of data specifically related to Gitxaala and no evidence of effort to collect information specific to Gitxaala socio-economic conditions beyond the Use study and VC Report, both of which were not expressly for this purpose.	For ease of reading section 11.3.9.5 repeats information previously presented under other VC assessments related to Aboriginal Socio-Economic Conditions. However, section 11.3.9.5 provides a discussion of Socio-Economic Conditions specific to Gitxaala Nation, and identifies additional potential Project effects related to changes to Socio-Economic Conditions that were not included in the other VC assessments including:barriers to increased participation in the fishing sector and, sensitivity of the fishing practices to change.
1819.1	round 1	Gitxaala Nation	11.3.9.6	CEAA 2012	As previously noted, Gitxaala physical and cultural heritage encompasses more than just physical objects designated as heritage resources. The omission of additional information from this assessment leaves is deficient.	The assessment of CEAA Section 5(1)(c) Effects includes Aboriginal use considerations beyond "physical objects designated as heritage resources". For example, the measurable parameters identified in Table 11.3-2, which are utilized for the assessment of Current Use, include:Quantity (area) and quality of current access routes where use will be affectedQualitative changes in the current experience of traditional harvestingQuality of affected sacred sites, cultural sites, spiritual sites, landforms and natural features associated with ritual or spiritual useQualitative changes in the experience of using sites and landscape features for ritual or spiritually important purposes (e.g., changes in acoustic environment and visual quality at identified sites). These measurable parameters allow for potential effects on the experience of Aboriginal peoples' to be incorporated into the assessment of Current Use, rather than focusing the effects assessment only on changes to physical objects designated as heritage resources. In addition, As outlined in Section 12.5.6.7, Aurora LNG acknowledges that archaeological and heritage resources do not represent the entirety of Gitxaala Nation's physical and cultural heritage. However, Aurora LNG does not have specific information from Gitxaala Nation regarding use, place names, or cultural or spiritual value locations within the PDA. Aurora LNG acknowledges that it is likely the Project will affect Gitxaala Nation's use of spiritual and cultural sites within the PDA, but maintains that Current Use of lands and resources by Gitxaala Nation members in other parts of their territory will be able to continue with some modification. Aurora LNG is confident that the environmental assessment presented in the Application, including the assessment completed in Section 11.3, is fully compliant with all provincial and federal regulatory requirements.
1820.1	round 1	Gitxaala Nation	11.4	CEAA 2012	As Gitxaala has previously objected to the characterization of the effects listed for the VCs studied for Gitxaala Nation, this objection is carried forward to the cumulative effects assessment. As no new information was incorporated in this assessment than previously identified, the cumulative effects assessment is deficient.	Aurora LNG acknowledges that Gitxaala Nation does not agree with the characterization of CEAA 5(1)(c) effects as related to Gitxaala Nation, and as such, does not agree with the findings of the cumulative effects assessment. Aurora LNG is confident that the cumulative effects assessment set out in the Application is fully compliant with all provincial and federal regulatory requirements. Aurora LNG is confident in the conclusions of the Application, which were developed in accordance with the AIR.
1821.1	round 1	Gitxaala Nation	12.1.1	Aboriginal Consultation	This section states that "All information received from Aboriginal Groups regarding the Project will be meaningfully considered by Aurora LNG." However there is no mention of the tiered approach undertaken by Aurora LNG whereby Metlakatla and Lax Kwaalams were given priority consultation over Gitxaala. This included participation in field studies, for example. Aurora LNG should be clear and transparent in regards to their tiered approach and this information should be included in the application.	Information that provides context related to Aurora LNG's consultation approach to consultation and field work participation, is provided in the technical memo entitled "Aurora LNG's approach to Consultation with Aboriginal Groups", which will be filed with the BC EAO. Details regarding Aurora LNG's consultation approach can also be found in the Aboriginal Consultation Reports posted on the EAO website and in the Section 11 order (as amended) issued by EAO.

1822.1	round 1	Gitxaala Nation	12.1.1	Aboriginal Consultation	This section states that "Aurora LNG will make best efforts to identify and discuss with Aboriginal Groups appropriate mitigation measures…" This has not occurred with Gitxaala Nation to date.	Gitxaala Nation had the opportunity to review the draft Part C (and Section 11.3) prior to submission of the Application for screening review, including mitigation measures proposed to reduce potential effects on Gitxaala Nation Aboriginal Interests, and to discuss any views or feedback at Technical Workshop #3, which was held on October 20-21, 2016. Aurora LNG, as part of that workshop, recorded the views provided by Gitxaala Nation with respect to the assessment of CEAA Section 5(1)(c) effects and Aboriginal Interests in Part C. The information recorded as part of the workshop was incorporated into Sections 11.3 and 12.3 of the Application, in accordance with the AIR. As noted in Table 12.9-1, in many cases feedback received from Gitxaala Nation resulted in revisions to the final version of Part C submitted to the BC EAO. Aurora LNG has been committed to ongoing consultation with Gitxaala Nation throughout the Application Review phase to discuss issues and concerns related to the Application. In January 2017, Aurora LNG held Technical Workshop #4 to discuss the assessment of VCs set out in Part B of the Application. Gitxaala Nation representatives attended the initial sessions of the first day of the workshop. Aurora LNG offered Gitxaala Nation another opportunity to meet regarding the remaining material from Workshop #4, which occurred on March 28, 2017. On March 27, 2017, Aurora LNG held Technical Workshop #5 with Gitxaala Nation to further discuss the characterization of effects and significance conclusions outlined in the CEAA 2012 Section 5(1)(c) assessment, and the assessment of Project effects related to Aboriginal Interests in Part C. Technical Workshops #4 and #5 were also an opportunity to discuss feedback on mitigation measures, proposed management plans and follow-up programs. Throughout Technical Workshops #4 and #5, Aurora LNG documented Gitxaala Nation opinions, concerns and feedback. Aurora LNG is currently reviewing feedback received to date on mitigation measures and any revised or new mitigation measures proposed will be included as part of an updated Table 16-1 and 16-2 to be submitted to the EAO on Day 90.
1823.1	round 1	Gitxaala Nation	12.1-4	Aboriginal Consultation	First, Gitxaala would like additional information on why the Aboriginal Interests assessed differed for each Nation. If the Aboriginal Interests were flexible to be changed, why were Gitxaala's proposed VC's not addressed in a fulsome manner?	The assessment of potential adverse effects on each Aboriginal Group's Aboriginal Interests was guided by assertions of Aboriginal Interests by that Aboriginal Group in the Project vicinity. In identifying assertions of specific Aboriginal Interests, Aurora LNG reviewed Gitxaala Nation's Project-specific studies, publicly-available documents, and consultation records. The VCs presented in Gitxaala Nation's Valued Components Report were considered in Part C of the Application. In several cases, assertions of Aboriginal Interests in the VC report formed the justification for inclusion of an Aboriginal Interest in Section 12.5.6. This was the case for the following Aboriginal Interests:Harvesting-Related Aboriginal Interests (Section 12.5.6.6)Cultural Wellbeing (Section 12.5.6.7)Traditional Governance (Section 12.5.6.8)Right to Economic Opportunities (Section 12.5.6.11) Aurora LNG is of the opinion that the incorporation of the Gitxaala VC Report into Part C is reasonable, given the requirements of the AIR and the content of the VC Report.
1824.1	round 1	Gitxaala Nation	12.1-4	Aboriginal Consultation	Gitxaala asserts Aboriginal title in the Project area and agrees that the Project will "…interfere with Gitxaala Nation's ability to use, make decisions over, or enjoy economic benefits associated with the PDA..."	Comment noted.
1825.1	round 1	Gitxaala Nation	12.1-4	Aboriginal Consultation	Please provide further clarification on why stink currants, high-bush cranberries and horse clams were singled out in this table? Particularly as effects to kelp, eelgrass, etc. were identified in previous sections.	Potential Project-related effects on Gitxaala Nation's ability to harvest stink currents, high-bush cranberries, and horse clams were highlighted in the Key Findings table (Table 12.1-4) because these resources are harvested within the PDA, and, according to the Gitxaala Use Study and the conclusions of the relevant VC assessments, there may not be many other places for Gitxaala Nation harvesters to collect these three resources. The other resources harvested by Gitxaala Nation members within the PDA are harvested elsewhere by Gitxaala Nation (according to the Gitxaala Use Study).
1826.1	round 1	Gitxaala Nation	12.1-4	Aboriginal Consultation	Please provide further clarification on why access to a historic Gitxaala Nation village at Casey Point was singled out in this table. Particularly as additional sites were identified in the PDA and LAA, including a fish trap location, etc.	Aurora LNG highlighted several Key Findings in Table 12.1-4, not just the potential for inference with access to the historic village at Casey Point, including:Archaeological sites within the PDA but outside the shoreline buffer will be permanently altered and inaccessible to Gitxaala Nation members. Gitxaala Nation members may experience some noise and visual quality effects while participating in cultural activities on the landscape. Employment associated with the Project may hinder people's ability to attend some cultural events. Project-related shipping traffic may interfere with (but not prevent) access to a historic Gitxaala Nation village at Casey Point. Project-related shipping may also interfere with Gitxaala Nation access to culturally or spiritually important sites within the channel between Digby Island and Kaien Island. Other than effects on access from higher marine traffic levels within that channel (adjacent to the historic Casey Point village site), Aurora LNG does not anticipate that access to important sites within the LAA will be affected by Project-related activities. As indicated in Table 12.1-4 and Section 12.5.6.7 (starting on page 12-178), the conclusions of the Application are based on the assumption that Gitxaala Nation members will not be able to access sites within the PDA until Project decommissioning is complete.
1827.1	round 1	Gitxaala Nation	12.1-4	Aboriginal Consultation	This section of the table states that "Project-related vessels may interfere with (not prevent) travel through the passage between Digby Island and Kaien Island…" Gitxaala objects to the conclusion that Project related vessels will not prevent travel. This shows a lack of consideration of perceptive effects of the Project related vessel traffic on Gitxaala harvesters as the mere presence of the Project related vessel traffic may deter Gitxaala harvesters from travelling through the designated route.	Gitxaala Nation is encouraged to read the full assessment of effects on Use of Marine Travelways (Section 12.5.6.10). The Key Findings table (Table 12.1-4) is not meant to capture the full analysis and all conclusions in Section 12.5.6. Perceptive effects to Gitxaala Nation marine users were assessed in both Sections 12.5.6.6 (starting on page 12-170) and 12.5.6.7 (starting on page 12-180).
1828.1	round 1	Gitxaala Nation	12.1-4	Aboriginal Consultation	Please explain the relevance of the notation that the Tuck Landscape was included as a Unit of the Great Bear Rainforest Land Use Objectives Order in terms of Importance to Gitxaala for the exercise of their Aboriginal rights?	In determining potential Project-related effects to Gitxaala Nation's right to self-government, Aurora LNG reviewed existing Gitxaala Nation self-governance documents, including available land and marine use planning documents. In the original draft of Part C, Aurora LNG had relied on the Draft Gitxaala Land Use Plan (2003). During its review of the draft Part C sections prior to submission of the Application for screening (and again in Workshop #3 in October 2016), Gitxaala Nation indicated to Aurora LNG that the 2003 Draft Gitxaala Land Use Plan should not be referenced in the Application. Instead, Gitxaala Nation requested that Aurora LNG reference the North Coast Land and Resources Management Plan (LRMP). The North Coast LRMP is a document prepared by several different organizations, including the government of British Columbia. The North Coast LRMP was replaced in 2016 with the Great Bear Rainforest Order. Given this evolution of land use planning efforts and the feedback received from Gitxaala Nation during consultation, Aurora LNG decided to present the most recent land use planning designation in its assessment of potential effects on Gitxaala Nation right to self-government.
1829.1	round 1	Gitxaala Nation	12.1-4	Aboriginal Consultation	This section states that "Aurora LNG was unable to identify any potential adverse economic effects not already assessed elsewhere in the Application." This was due to Nexen's unwillingness to collect Gitxaala specific economic data as part of the application execution. Had Nexen collected specific economic data from Gitxaala sources, Gitxaala is confident that they would have been able to identify potential adverse economic effects that were not already assessed elsewhere in the application.	Gitxaala Nation has had multiple opportunities to supply Gitxaala-specific economic data so that it could be incorporated into the Application. On December 31, 2015, Aurora LNG and Gitxaala Nation entered into an Environmental Assessment Agreement related to the Project. The purpose of the agreement was to provide capacity funding to support Gitxaala Nation's participation in the EA and related regulatory approval processes associated with the Project. The agreement also provided capacity funding to facilitate: the identification of Gitxaala Nation issues and concerns related to the Project, including socio-economic effects; the provision of input on the assessment of effects and proposed mitigation measures; and the completion of a traditional use study related to the Project. In March 2016, Gitxaala Nation supplied Aurora LNG with the Project-specific draft Gitxaala Use Study. Further conversations between Aurora LNG and Gitxaala Nation occurred on June 24, 2016, to discuss the incorporation of this information into the Application and the concerns outlined in their 'Proposed Valued Components' letter of January 2014 (see additional detail in ACR #1 Section 4.2). Gitxaala Nation provided Aurora LNG with the final version of the Gitxaala Use Study and the Gitxaala Valued Components Report in June of 2016. Both reports were incorporated into the Application. In addition, in November 2016, Gitxaala Nation provided Aurora LNG with a study entitled Potential Risks, Impacts and Opportunities of the Aurora LNG Project for Gitxaala Nation (the "Gitxaala Nation Report"). As Aurora LNG had completed the analysis and writing for its Application for Environmental Assessment Certificate (the "Application") at the time that the Gitxaala Nation Report was received, information contained in the report had not been reviewed or directly incorporated into the Application which was submitted to the BC EAO in November, 2016. Aurora LNG responded to the above noted Gitxaala Nation Report in its technical memo entitled "Aurora LNG's Response to the 'Potential Risks, Impacts and Opportunities of the Aurora LNG Project for Gitxaala Nation'". A draft of this memo was shared with Gitxaala Nation on May 11, 2017 for their comment and will be filed with the BC EAO.
1830.1	round 1	Gitxaala Nation	12.2.2	Aboriginal Consultation	Gitxaala objects to the categorization as a Southern Tsimshian group. This categorization was based on a, in Gitxaala's opinion, flawed ethnographic assumption and does not represent the classification of Gitxaala Nation. Indeed, the fact that these division are not recognized universally is noted in the application. So it is unclear why this is stated in the first place.	As indicated in the first paragraph of Section 12.2.2, the different Tsimshian sub-groups are presented to provide additional context to the assessment in Part C and Aurora LNG appropriately identified that there is no universal view.
1831.1	round 1	Gitxaala Nation	12.2.5	Aboriginal Consultation	Gitxaala Nation is not "...located in the village of Kitkatla (Lach Klan…" rather, throughout their traditional territory with membership living in Prince Rupert and other surrounding towns. Please amend this description.	A correction to the description of Gitxaala Nation on page 12-23 of the Application has been captured in an errata document that captures these corrections and will be filed with the BC EAO.
1832.1	round 1	Gitxaala Nation	12.3	Aboriginal Consultation	This section outlines how consultation activities influenced the environmental assessment. However, based on this listing there are a number of issues with the consultation program which still remain unresolved. First, using TK or TU information to identify potentially affected locations of special interests to Aboriginal groups is not the appropriate method for their identification. Instead, Gitxaala should have been specifically consulted on these locales to ensure the site selected best represented their interests. Secondly, adding viewpoints to the Visual Quality assessment without consultation with Gitxaala on those viewpoints is not sufficient; and finally, exploring ship wake on archaeological resources alone is not sufficient as wake has the potential to affect shore harvesting and boat traffic, as previously discussed.	Note: it is assumed that the first part of the Gitxaala Nation comment refers to Acoustic Environment: With regard to the Acoustic Environment VC assessment (see Section 4.4 of the Application), in response to concerns raised by Aboriginal Groups, Aurora LNG reviewed available TK/TU information [Project-specific and public domain] for candidate receptor sites. Based on that work, a number of potentially-affected locations of special interest to Aboriginal Groups (including residential communities, hunting and gathering, and other habitation and gathering sites) were identified and included in the assessment. Noise receptors for the assessment were established at identified Aboriginal traditional use areas along the islands (i.e., Casey Point, Barrett Rock, Lima Point, Fraser Point, Kinahan Islands, and Pike Island). Aurora LNG provided capacity funding to all Schedule B Aboriginal Groups to, among other things, provide TK/TU information that would be utilized in the Environmental Assessment of the Project. Table 4.4-4 in the Application lists noise sensitive receptors and Figure 4.4-1 shows the receptor locations (including receptors that represent traditional land use areas - ID# R4, R5, R6, R7, R8, R16, R17, R18, R19, and R21). Noise monitoring was conducted at five locations within the Acoustic Environment local assessment area . These locations represent the closest communities to the Project as well as other uninhabited locations along coastal areas of Digby Island, and provide representative information on the existing acoustic environment along different coastal area without any land-based residential and land-based commercial activities. The results from the monitoring were applied to other receptors in the assessment, (including receptors for traditional land use area - R4 to R8, R16 to R19, and R21) in the Acoustic Environment VC. Noise findings at locations of special importance to Aboriginal Groups were used as input for assessing adverse residual effects on Aboriginal resources in Part C of the Application (please refer to Section 12.0). Gitxaala Nation decided not to fully participate in Technical Workshop #4 held on January 25th and 26th in Prince Rupert. This workshop provided an opportunity to discuss concerns and issues associated with the assessment of VCs in Part B of the Application (including the Acoustics Environment), and to explore new mitigation ideas. Aurora LNG also notes that Gitxaala Nation chose not to participate at the EAO's Working Group session held on February 6th and 7th in Prince Rupert. A key purpose of both of these sessions was to facilitate a discussion of issues and concerns with the Application. Aurora LNG has made extensive efforts to date to consult with Gitxaala Nation during the course of the environmental assessment. These efforts and the issues raised during consultation will be incorporated into the Third Aboriginal Consultation Report. Gitxaala Nation will be provided an opportunity to review and comment on the draft Third Aboriginal Consultation Report before it is finalized and submitted to the EAO. Visual Quality Viewpoints: During Workshop #2 (March 16-17 2016), Aurora LNG consulted with Aboriginal Groups, including Gitxaala Nation, on the various viewpoints being considered for the Visual Quality analysis. Ship Wake: As a result of feedback from Gitxaala Nation during consultation, Aurora LNG added an assessment of ship wake on harvesting activities. That assessment is in Section12.5.6.6 start on page 12-171. In addition, please also refer to the "Effects of Lost Fishing Time" technical memo for a description of expected conditions for a fisher-LNG carrier interaction to occur. This rationale also applies to wake effects. The technical memo will be filed with the BC EAO.
1833.1	round 1	Gitxaala Nation	Table 12.3-3	Aboriginal Consultation	The key concerns listed for Gitxaala do not capture the depth and breadth of concerns raised by Gitxaala Nation during the pre-Application phase of the environmental assessment; rather, these concerns just encompass the Gitxaala VCs proposed in the Gitxaala VC Report. This table must be updated to reflect the entirety of Gitxaala concerns raised in the pre-Application phase of the environmental assessment as referenced in the application.	The full list of concerns raised by Gitxaala Nation at the time of filing the Application is found in Table 7-1 of ACR #2 (see Appendix S.1). Table 12.3-3 of the Application includes Aurora LNG's understanding of key issues raised by Gitxaala Nation during the pre-Application phase of the environmental assessment. This table was provided to Gitxaala Nation for review in advance of the pre-submission workshop in October 2016. In addition to those two tables, Table 12.9-1 includes Gitxaala Nation views specific to the assessment completed in Part C. Aurora LNG is of the opinion that, taken together, these tables provide a reasonable record of Gitxaala Nation's views and concerns raised in the pre-Application phase.

1834.1	round 1	Gitxaala Nation	Table 12.4-1	Aboriginal Consultation	This table outlines, in extremely general terms, the integration of TK and TU into the Part B assessment. There is no additional details provided here that was not included in the Part B assessments themselves and no further elaboration on the integration. This is insufficient and highlights the superficial way TK and TU was used by Aurora LNG.	Aurora LNG is of the view that TK and TU information provided by Aboriginal Groups was appropriately incorporated into the assessment of VCs in Part B of the Application, and met the requirements of the AIR.
1835.1	round 1	Gitxaala Nation	12.5.3.2	Aboriginal Consultation	This section states that "…Aurora LNG has been actively consulting with Aboriginal Groups set out in Schedule B of the Section 11 Order since November 2013 to understand how the Project and associated Crown approvals may adversely affect the exercise of their asserted or determined Aboriginal rights (including title)." This section does not describe the tiered systems of consultation which Aurora LNG has, to date, employed. Please update to provide additional detail on this tiered system, including the exclusion of Gitxaala Nation for field studies.	Information that provides context related to Aurora LNG's consultation approach to consultation and field work participation, is provided in the technical memo entitled "Aurora LNG's Approach to Consultation with Aboriginal Groups". This technical memo will be filed with the BC EAO. Details regarding Aurora LNG's consultation approach can also be found in the Aboriginal Consultation Reports posted on the EAO website and in the Section 11 order issued by EAO, as amended.
1836.1	round 1	Gitxaala Nation	12.5.3.2	Aboriginal Consultation	This section states that "…Aurora LNG will continue to discharge procedural aspects of the duty to consult that have been delegated to Aurora LNG from the Crown … This includes…" At no point in the listing does Aurora LNG identify that they will complete an effects assessment on Aboriginal rights and interests. Instead, it just says they will obtain and discuss "...information with Aboriginal Groups about specific Aboriginal interests that may be affected." Please clarify whether Aurora LNG is responsible for identifying potential adverse effects to Aboriginal rights and interests or whether this will be completed by the BC EAO.	The BC EAO has delegated the following specific consultation activities to Aurora LNG in the Section 11 Order (as amended) for the Project: - providing a response to comments received from Aboriginal Groups - preparing an Aboriginal Consultation Plan and supporting Aboriginal Consultation Reports with opportunities for review and comment by Aboriginal Groups - specifying Aboriginal Interests identified by Aboriginal Groups, and identifying measures to avoid or mitigate such potential adverse effects and/or to otherwise accommodate the concerns of Aboriginal Groups as appropriate; and - demonstrating fair consideration given to incorporating feedback from Aboriginal Groups Aurora LNG has prepared the Aboriginal Interests section of the Application in a manner consistent with the Section 11 Order (as amended) and with Section 12.5 of the approved Application Information Requirements.
1837.1	round 1	Gitxaala Nation	12.5.6.3	Aboriginal Consultation	The Past Use section indicates that "…Gitxaala Nation may have had … fish traps in the area." The fish trap identified by Gitxaala harvesters was identified as a historical fish trapthat was made by Gitxaala and still exisits today. It should be referenced as such.	Page 12-153 (Present Use) includes the following text that addresses Gitxaala Nation's request: "Several Gitxaala Nation members identified a past fish trap site just east of Frederick Point (Calliou Group 2016a). According to Gitxaala Nation, this fish trap site is still present today (Calliou Group 2016a)." Because this fish trap is an historic site, Aurora LNG also assumes that it was used in the past, and therefore included it in its summary of Gitxaala Nation past use of the Project Vicinity.
1838.1	round 1	Gitxaala Nation	12.5.6.3	Aboriginal Consultation	In the Future Use section it is noted that "During consultation, Gitxaala Nation indicated that it has a strong interests in the future management of resources." This statement is a weak substitute by Aurora LNG for a more fulsome consultation with Gitxaala on potential future use. Had Gitxaala been engaged by Aurora LNG on potential future use, more information could have and would have been provided.	The Future Use section on page 12-156 presents "Existing Conditions" to the extent that Aurora LNG was able to make reasonable predictions based on available information at the time the Application was prepared. As described in Section 12.5.6.5 (page 12-157), Aurora LNG will continue to consult with Aboriginal Groups, including Gitxaala Nation, throughout the life of the Project to address Project-related issues, includingissues related to potential future use of the Project area by Aboriginal Groups.
1839.1	round 1	Gitxaala Nation	12.5.6.5	Aboriginal Consultation	There is little to no discussion on the potential effects mechanisms and the application, instead, jumps immediately to mitigation - of which Gitxaala had no input. This is deficient and problematic.	Section 12.5.3 of the Application provides detailed information on Aurora LNG's approach to assessing the effects of the Project on Aboriginal title, including the identification of potential effects. Section 12.5.6.5 specifically applies these methods to Gitxaala Nation. Aurora LNG has been committed to ongoing consultation with Gitxaala Nation throughout the Application Review phase to discuss issues and concerns related to the Application. In January 2017, Aurora LNG held Technical Workshop #4 to discuss the assessment of VCs set out in Part B of the Application. Gitxaala Nation representatives attended the initial sessions of the first day of the workshop. Aurora LNG offered Gitxaala Nation another opportunity to meet regarding the remaining material from Workshop #4, which occurred on March 28, 2017. On March 27, 2017, Aurora LNG held Technical Workshop #5 with Gitxaala Nation to further discuss the characterization of effects and significance conclusions outlined in the CEAA 2012 Section 5(1)(c) assessment, and the assessment of Project effects related to Aboriginal Interests in Part C. Technical Workshops #4 and #5 were also an opportunity to discuss feedback on mitigation measures, proposed management plans and follow-up programs. Throughout Technical Workshops #4 and #5, Aurora LNG documented Gitxaala Nation opinions, concerns and feedback. Aurora LNG will be providing a draft of Aboriginal Consultation Report #3 (i.e. the interim consultation report) at day 90 of the 180 day Application-review period (as per the EAO's letter of December 14, 2016). As part of the draft Aboriginal Consultation Report #3, Aurora LNG will report on its understanding of the status of issues/concerns resolution with Gitxaala Nation for the issues/concerns recorded during all phases of the EA (in table format), including those identified in Aboriginal Consultation Report #2 and recorded as part of Technical Workshops #4 and #5. The final version of Aboriginal Consultation Report #3 will be submitted at day 120 of the 180 day Application-review period (as per the section 11 Order [as amended]). Aurora LNG will be providing a draft of Aboriginal Consultation Report #3 (i.e. the interim consultation report) at day 90 of the 180 day Application-review period (as per the EAO's letter of December 14, 2016). As part of the draft Aboriginal Consultation Report #3, Aurora LNG will report on its understanding of the status of issues/concerns resolution with Gitxaala Nation for the issues/concerns recorded during all phases of the EA (in table format), including those identified in Aboriginal Consultation Report #2 and recorded as part of Technical Workshops #4 and #5. The final version of Aboriginal Consultation Report #3 will be submitted at day 120 of the 180 day Application-review period (as per the section 11 Order [as amended]). For further information please refer to the technical memo entitled "Aurora LNG's Approach to Consultation with Aboriginal Groups" which will be filed with the BC EAO.
1840.1	round 1	Gitxaala Nation	12.5.6.5	Aboriginal Consultation	Ongoing consultation as a mitigation measure is not sufficient. Particularly, as Gitxaala has experienced a sub-par consultation effort from Aurora LNG to date.	Aurora LNG believes that it has undertaken meaningful consultation with Gitxaala Nation on the Projectsince early 2014, prior to the project description being filed. For more information on consultation activities, refer to the first and second Aboriginal Consultation Reports (available on EAO's website). Aurora LNG has been committed to ongoing consultation with Gitxaala Nation throughout the Application Review phase to discuss issues and concerns related to the Application. In January 2017, Aurora LNG held Technical Workshop #4 to discuss the assessment of VCs set out in Part B of the Application. Gitxaala Nation representatives attended the initial sessions of the first day of the workshop. Aurora LNG offered Gitxaala Nation another opportunity to meet regarding the remaining material from Workshop #4, which occurred on March 28, 2017. On March 27, 2017, Aurora LNG held Technical Workshop #5 with Gitxaala Nation to further discuss the characterization of effects and significance conclusions outlined in the CEAA 2012 Section 5(1)(c) assessment, and the assessment of Project effects related to Aboriginal Interests in Part C. Technical Workshops #4 and #5 were also an opportunity to discuss feedback on mitigation measures, proposed management plans and follow-up programs. Throughout Technical Workshops #4 and #5, Aurora LNG documented Gitxaala Nation opinions, concerns and feedback. Aurora LNG will be providing a draft of Aboriginal Consultation Report #3 (i.e. the interim consultation report) at day 90 of the 180 day Application-review period (as per the EAO's letter of December 14, 2016). As part of the draft Aboriginal Consultation Report #3, Aurora LNG will report on its understanding of the status of issues/concerns resolution with Gitxaala Nation for the issues/concerns recorded during all phases of the EA (in table format), including those identified in Aboriginal Consultation Report #2 and recorded as part of Technical Workshops #4 and #5. The final version of Aboriginal Consultation Report #3 will be submitted at day 120 of the 180 day Application-review period (as per the section 11 Order [as amended]). For further information please refer to the technical memo entitled "Aurora LNG's Approach to Consultation with Aboriginal Groups" which will be filed with the BC EAO.
1841.1	round 1	Gitxaala Nation	12.5.6.5	Aboriginal Consultation	This section glosses over the loss of the PDA for enjoyment, experience and use of the land by Gitxaala and instead focuses on use outside of the PDA, which would also be affected to some undefined degree. While Gitxaala would not be prevented from using these areas, they may no longer prefer to use these areas and therefore use and enjoyment of these areas would indirectly be affected.	In Section 12.5.6.5, page 12 - 158, Aurora LNG specifically acknowledges that potential indirect effects on Gitxaala Nation users at locations outside of the PDA are also possible. In addition, Gitxaala Nation had the opportunity to review the draft Part C (and Section 11.3) prior to submission of the Application for screening review and to discuss any views or feedback at Technical Workshop #3 , which was held on October 20-21, 2016. Aurora LNG, as part of that workshop, recorded the views provided by Gitxaala Nation with respect to the assessment of CEAA Section 5(1)(c) effects and Aboriginal Interests in Part C. The information recorded as part of the workshop was incorporated into Sections 11.3 and 12.3 of the Application, in accordance with the AIR. As noted in Table 12.9-1, in many cases feedback received from Gitxaala Nation resulted in revisions to the final version of Part C submitted to the BC EAO. Aurora LNG has been committed to ongoing consultation with Gitxaala Nation throughout the Application Review phase to discuss issues and concerns related to the Application. In January 2017, Aurora LNG held Technical Workshop #4 to discuss the assessment of VCs set out in Part B of the Application. Gitxaala Nation representatives attended the initial sessions of the first day of the workshop. Aurora LNG offered Gitxaala Nation another opportunity to meet regarding the remaining material from Workshop #4, which occurred on March 28, 2017. On March 27, 2017, Aurora LNG held Technical Workshop #5 with Gitxaala Nation to further discuss the characterization of effects and significance conclusions outlined in the CEAA 2012 Section 5(1)(c) assessment, and the assessment of Project effects related to Aboriginal Interests in Part C. Technical Workshops #4 and #5 were also an opportunity to discuss feedback on mitigation measures, proposed management plans and follow-up programs. Throughout Technical Workshops #4 and #5, Aurora LNG documented Gitxaala Nation opinions, concerns and feedback. Aurora LNG will be providing a draft of Aboriginal Consultation Report #3 (i.e. the interim consultation report) at day 90 of the 180 day Application-review period (as per the EAO's letter of December 14, 2016). As part of the draft Aboriginal Consultation Report #3, Aurora LNG will report on its understanding of the status of issues/concerns resolution with Gitxaala Nation for the issues/concerns recorded during all phases of the EA (in table format), including those identified in Aboriginal Consultation Report #2 and recorded as part of Technical Workshops #4 and #5. The final version of Aboriginal Consultation Report #3 will be submitted at day 120 of the 180 day Application-review period (as per the section 11 Order [as amended]).
1842.1	round 1	Gitxaala Nation	12.5.6.5	Aboriginal Consultation	The section on Importance, Special Characteristics or Unique Features of the Project Vicinity does not contain information related to that topic. Please update this text.	This information was inadvertently omitted. The following additional text has been captured in an errata document that has been created and filed with the BC EAO.: "Aurora LNG understands that the PDA is within an area traditionally shared between several Gitxaala Nation house groups and that two house groups have traditional stewardship areas nearby at Porpoise Harbour, Watson Island, Lelu Island, Ridley Island, and Tugwell Island. Gitxaala Nation community members currently live in and use the area around the Prince Rupert Harbour. In addition, the Project vicinity is approximately 60 km by boat from the village of Kitkatla—a distance that could be covered in a few hours by a Gitxaala Nation member. Gitxaala Nation members have historically used the Prince Rupert Harbour area "as an important camping and resource harvesting area" while traveling to the Nass River eulachon harvest, and there is some evidence that Gitxaala Nation may have had winter villages in the area (Gitxaala Nation 2014; Calliou Group 2016a)."
1843.1	round 1	Gitxaala Nation	12.5.6.5	Aboriginal Consultation	The calculation of the PDA relative to the entire Gitxaala Nation traditional territory is inappropriate. It should, instead, be calculated from the shared territory which Digby Island is a part of for an accurate representation of land lost to those harvesters that use that area.	Further information that provides context related to the assessment of the identified potential effects in the Application, including clarification regarding the assumptions utilized in the assessment, is provided in the technical memo entitled "Additional Information Regarding the CEAA 5(1)(C) and Part C Assessment Methodologies and the Consideration of Traditional Use Information in these Assessments" which will be filed with the BC EAO.
1844.1	round 1	Gitxaala Nation	12.5.6.5	Aboriginal Consultation	In the Conclusions Regarding Residual Adverse Effects on Gitxaala Nation Aboriginal Title Section loosely applies characterization of residual effects assessment criteria when discussing the persistence of the effect. However, this is the only mention of these characterizations despite this being part of the methodology in Section 3. In fact, this entire volume (Volume 12) does not have any mention of characterization of residual effects and does not list any criteria. Further, there is no determination of the likelihood of the residual effects, no discussion of the significance and no discussion of the confidence or risk. This is contrary to section 12.5.1 which states that the degree to which the Project may result in adverse residual effects would be based upon "...the methodology described in Section 3.0 of the Application..."	The assessment of effects on Aboriginal Interests in Section 12 of the Application relies on several methods described in Section 3, including the identification of existing conditions, effects mechanisms, and mitigation measures. Due to the qualitative and intangible nature of some of the Aboriginal Interests considered in Section 12.5.6, and in light of the CEAA 2012 Section 5(1)(c) assessment completed in Sections 11.3 - 11.6 of the Application, the characterization of effects as described in Section 3 (i.e., magnitude, duration, frequency, geographic extent, reversibility, likelihood, significance) was not utilized for Section 12.5.6. To avoid redundancy and address the qualitative nature of Aboriginal Interests, the "Degree of Effects" sections describe the Project's potential interference with the exercise of an Aboriginal Interest (similar to a magnitude characterization) taking into account the relative importance of the Project vicinity, as well as the availability of other areas within the traditional territory of an Aboriginal Group (similar to a context characterization). This is consistent with the Application Information Requirements. Section 11.3 of the Application incorporates a more quantitative assessment of CEAA 2012 section 5(1)(c) effects. Many of these effects are closely related to the exercise of Aboriginal Interests (e.g., current use of lands and resources for traditional purposes). As a result, readers are encouraged to read both Section 11.3 (Requirements Under CEAA 2012 Section 5(1)(c)) and Section 12.5 (Aboriginal Interests) to obtain a comprehensive understanding of how the Project has the potential to affect Aboriginal Groups.

1845.1	round 1	Gitxaala Nation	12.5.6.6	Aboriginal Consultation	Gitxaala access to the harvestable species and preference for harvesting in specific locales and perception of those same harvesting locales must also be considered for harvesting-related Aboriginal interests.	Gitxaala Nation access to harvestable species is assessed in Section 12.5.6.6 starting on page 12-168. This was also informed from information contained in Section 6 of Appendix S.2 (Aboriginal Consultation). Aurora LNG does not have adequate data indicating the preferred harvest locales of different Gitxaala Nation people and why they prefer those sites. This lack of data prevents Aurora LNG from undertaking further assessments of potential Project-effects on harvest locale preferences and perceptions. As such, Aurora LNG presented the relevant constraints generally and theoretically in the assessment of effects to Gitxaala Nation harvesting (see pages 12-174 to 12-176).Further information that provides context related to the assessment of the identified potential effects in the Application, including clarification regarding the assumptions utilized in the assessment, is provided in the technical memo entitled "Additional Information Regarding the CEAA 5(1)(C) and Part C Assessment Methodologies and the Consideration of Traditional Use Information in these Assessments" which will be filed with the BC EAO.
1846.1	round 1	Gitxaala Nation	12.5.6.6	Aboriginal Consultation	Reliance fully on the Wildlife Resources Section 4.7 assessment means that there was no consideration of Gitxaala's use of the species in this assessment. That is problematic and must be amended.	Gitxaala Nation's statement in this comment is inaccurate. The assessment in Section 12.5.6.6 considered Gitxaala Nation use of various species. See pages 12-160 to 12-162 for the extensive list of known Gitxaala Nation use species and the locations of use of the various species within the Project vicinity. The summary of conclusions from the relevant VC assessments was developed based on which species Gitxaala Nation indicated it uses and values in publicly available documents and Project-specific studies.
1847.1	round 1	Gitxaala Nation	12.5.6.6	Aboriginal Consultation	Reliance fully on the Freshwater Fish and Fish Habitat Section 4.8 assessment means that there was no consideration of Gitxaala's use of the species in this assessment. That is problematic and must be amended.	Gitxaala Nation's statement in this comment is inaccurate. The assessment in Section 12.5.6.6 considered Gitxaala Nation use of various species. See pages 12-160 to 12-162 for the extensive list of known Gitxaala Nation use species and the locations of use of the various species within the Project vicinity. The summary of conclusions from the relevant VC assessments was developed based on which species Gitxaala Nation indicated it uses and values in publicly available documents and Project-specific studies.
1848.1	round 1	Gitxaala Nation	12.5.6.6	Aboriginal Consultation	Reliance fully on Marine Fish and Fish Habitat (Section 4.9), Marine Mammals (Section 4.10) and Marine Birds (Section 4.11) assessments means that there was no consideration of Gitxaala's use of the species in this assessment. That is problematic and must be amended.	Gitxaala Nation's statement in this comment is inaccurate. The assessment in Section 12.5.6.6 considered Gitxaala Nation use of various species. See pages 12-160 to 12-162 for the extensive list of known Gitxaala Nation use species and the locations of use of the various species within the Project vicinity. The summary of conclusions from the relevant VC assessments was developed based on which species Gitxaala Nation indicated it uses and values in publicly available documents and Project-specific studies.
1849.1	round 1	Gitxaala Nation	12.5.6.6	Aboriginal Consultation	Reliance fully on the Vegetation and Wetland Resources Section 4.6 assessment means that there was no consideration of Gitxaala's use of the species in this assessment. That is problematic and must be amended.	Gitxaala Nation's statement in this comment is inaccurate. The assessment in Section 12.5.6.6 considered Gitxaala Nation use of various species. See pages 12-160 to 12-162 for the extensive list of known Gitxaala Nation use species and the locations of use of the various species within the Project vicinity. The summary of conclusions from the relevant VC assessments was developed based on which species Gitxaala Nation indicated it uses and values in publicly available documents and Project-specific studies.
1850.1	round 1	Gitxaala Nation	12.5.6.6	Aboriginal Consultation	Travel routes were not assessed in terms of Gitxaala harvester preference and avoidance behavior related to this preference was not explored.	Potential effects on Gitxaala Nation use of marine travelways are assessed in Section 12.5.6.10. Potential effects on the experience of harvesting, including air quality, noise, and visual quality effects, are assessed in Section 12.5.6.6 (pages 12-170 to 12-176).Gitxaala Nation did not provide Aurora LNG with adequate data indicating the preferred marine travelways used by Gitxaala Nation members, and why those routes are preferred. This lack of data prevented Aurora LNG from being able to predict specific avoidance behaviours by Gitxaala Nation members.As such, Aurora LNG presented the relevant constraints generally and theoretically in the assessment of effects to Gitxaala Nation harvesting (see pages 12-174 to 12-176).
1851.1	round 1	Gitxaala Nation	12.5.6.6	Aboriginal Consultation	The section on Harvesting Grounds within the Shipping Route does not take into account Gitxaala harvesters preferences in terms of Project-related shipping, while the shipping may not increase to levels where Gitxaala harvesters are fully excluded from the area, they may still prefer not to harvest in the area where the ships are due to perceived risk.	Aurora LNG acknowledged that the physical presence of shipping vessels may interfere with (but not prevent) Gitxaala Nation use of the Project vicinity. This conclusion aligns with Gitxaala Nation's comment.
1852.1	round 1	Gitxaala Nation	12.5.6.6	Aboriginal Consultation	In the section on Access Routes within the Shipping Route it states that "Because shipping has occurred along the shipping route for decades, Aurora LNG anticipates that mariners will be accustomed to navigating around large vessel traffic." However, while Gitxaala harvesters are accustomed to the current level of marine traffic, the addition of the Project will increase that level of traffic. This level must be assessed in terms of Gitxaala's perceptions and preferences.	Aurora LNG considered the cumulative effects of shipping activity in the region on Gitxaala Nation harvesting activities in Section 12.5.6.6 (on page 12-170). Gitxaala Nation did not provide Aurora LNG with adequate data indicating the preferred marine travelways used by Gitxaala Nation members, and why those routes are preferred. This lack of data prevented Aurora LNG from being able to predict specific avoidance behaviours by Gitxaala Nation members.As such, Aurora LNG presented the relevant constraints generally and theoretically in the assessment of effects to Gitxaala Nation harvesting (see pages 12-174 to 12-176).
1853.1	round 1	Gitxaala Nation	12.5.6.6	Aboriginal Consultation	How were the identified exceedances for Air Quality and Human Health cross referenced with Gitxaala harvested species and harvesting calendars to identify times of risk for Gitxaala harvesters? Further, how will Gitxaala harvesters be notified of times of air quality risk?	The assessment of human health related to air quality considered areas on land that are populated (e.g., residential and commercial areas). In these areas, the air quality would be less (i.e., better air quality) than the BC ambient air quality objectives, and there is no significant human health risk predicted related to air quality. The areas identified where criteria air contaminants were greater (i.e., poorer air quality) than the BC ambient air quality objectives were associated with existing industrial sites (e.g. Fairview Terminal) and are not sites that are expected to offer harvesting opportunities for Gitxaala Nation members.
1854.1	round 1	Gitxaala Nation	12.5.6.6	Aboriginal Consultation	As previously noted, the effects of wake must be calculated differently. While the wake may occur within the natural variability of waves, Gitxaala is concerned with wake specifically at times of low or zero tide and how that will affect Gitxaala harvesters. This specifically has not been addressed.	Aurora LNG believes that this concern has been adequately addressed in the assessment of the potential effects of wake on the experience of harvesting (starting on page 12-171). The assessment specifically considers Gitxaala Nation harvesting activities at zero or low tides, right at the water's edge, on a particularly calm day, in a location that is directly exposed to shipping traffic. In those circumstances, it is possible that Gitxaala Nation harvesters would notice wake waves, however waves are not anticipated to pose any safety risk to Gitxaala Nation harvesters, nor interfere with harvesting activities.
1855.1	round 1	Gitxaala Nation	12.5.6.6	Aboriginal Consultation	In the Section related to Conclusions Regarding Residual Adverse Effects on Gitxaala Nation Harvesting-Related Aboriginal Interests the conclusion is repeated that Gitxaala harvesters can go elsewhere. This conclusion that Gitxaala harvesters may harvest elsewhere is problematic for numerous reasons which have been outlined previously. In this section it is bolstered by the following statement: "...the degree to which the Project interferes with harvesting could be reduced given that resources are anticipated to be available elsewhere nearby, often in locations closer to the community of Kitkatla." This is problematic for Gitxaala as there are many Gitxaala harvesters who do not reside in Kitkatla and locations closer to the reserve are not preferred or easily accessible. Please remove this conclusion.	Further information that provides context related to the assessment of the identified potential effects in the Application, including clarification regarding the assumptions utilized in the assessment, is provided in the technical memo entitled "Additional Information Regarding the CEAA 5(1)(C) and Part C Assessment Methodologies and the Consideration of Traditional Use Information in these Assessments" which will be filed with the BC EAO.
1856.1	round 1	Gitxaala Nation	12.5.6.6	Aboriginal Consultation	In the Conclusions Regarding Residual Adverse Effects on Gitxaala Nation Harvesting-Related Aboriginal Interests it states that "The Project would not prevent Gitxaala Nation members from harvesting resources within or adjacent to the shipping routes…" However, this does not take into account the preferences or perceptions of Gitxaala harvesters. This is problematic as it may increase avoidance behaviors in the Project and Project traffic vicinity.	Gitxaala Nation did not provide Aurora LNG with adequate data indicating the preferred marine travelways and marine harvest sites used by Gitxaala Nation members, and why those routes and sites are preferred. This lack of data prevented Aurora LNG from being able to predict specific avoidance behaviours by Gitxaala Nation members. As such, Aurora LNG presented the relevant constraints generally and theoretically in the assessment of effects to Gitxaala Nation harvesting (see pages 12-174 to 12-176).
1857.1	round 1	Gitxaala Nation	12.5.6.6	Aboriginal Consultation	In the Conclusions Regarding Residual Adverse Effects on Gitxaala Nation Harvesting-Related Aboriginal Interests, it states that "Given the results of previous studies, it is not anticipated that there will be any risk to the safety of harvesters from shipping-related wake. As previously noted, the effects of wake must be calculated differently. While the wake may occur within the natural variability of waves, Gitxaala is concerned with wake specifically at times of low or zero tide and how that will affect Gitxaala harvesters. This specifically has not been addressed.	Aurora LNG believes that this concern has been adequately addressed in the assessment of the potential effects of wake on the experience of harvesting (starting on page 12-171). The assessment specifically considers Gitxaala Nation harvesting activities at zero or low tides, right at the water's edge, on a particularly calm day, in a location that is directly exposed to shipping traffic. In those circumstances, it is possible that Gitxaala Nation harvesters would notice wake waves, however waves are not anticipated to pose any safety risk to Gitxaala Nation harvesters, nor interfere with harvesting activities.

1858.1	round 1	Gitxaala Nation	12.5.6.6	Aboriginal Consultation	In the Conclusions Regarding Residual Adverse Effects on Gitxaala Nation Harvesting-Related Aboriginal Interests Section does not apply characterizations of residual effects despite this being part of the methodology in Section 3. In fact, this entire volume (Volume 12) does not have any mention of characterization of residual effects and does not list any criteria. Further, there is no determination of the likelihood of the residual effects, no discussion of the significance and no discussion of the confidence or risk. This is contrary to section 12.5.1 which states that the degree to which the Project may result in adverse residual effects would be based upon "...the methodology described in Section 3.0 of the Application..."	The assessment of effects on Aboriginal Interests in Section 12 of the Application relies on several methods described in Section 3, including the identification of existing conditions, effects mechanisms, and mitigation measures. Due to the qualitative and intangible nature of some of the Aboriginal Interests considered in Section 12.5.6, and in light of the CEAA 2012 Section 5(1)(c) assessment completed in Sections 11.3 - 11.6 of the Application, the characterization of effects as described in Section 3 (i.e., magnitude, duration, frequency, geographic extent, reversibility, likelihood, significance) was not utilized for Section 12.5.6. To avoid redundancy and address the qualitative nature of Aboriginal Interests, the "Degree of Effects" sections describe the Project's potential interference with the exercise of an Aboriginal Interest (similar to a magnitude characterization) taking into account the relative importance of the Project vicinity, as well as the availability of other areas within the traditional territory of an Aboriginal Group (similar to a context characterization). This is consistent with the Application Information Requirements. Section 11.3 of the Application incorporates a more quantitative assessment of CEAA 2012 section 5(1)(c) effects. Many of these effects are closely related to the exercise of Aboriginal Interests (e.g., current use of lands and resources for traditional purposes). As a result, readers are encouraged to read both Section 11.3 (Requirements Under CEAA 2012 Section 5(1)(c)) and Section 12.5 (Aboriginal Interests) to obtain a comprehensive understanding of how the Project has the potential to affect Aboriginal Groups.
1859.1	round 1	Gitxaala Nation	12.5.6.7	Aboriginal Consultation	In the Access to Specific Locations Section, it is noted that the Project avoids the majority of the most complex archaeological and heritage sites, however, this does not account for Sacred sites or named sites of importance to Gitxaala which may not have archaeological significance within the LAA. This is problematic as access to these other sites must be considered.	Gitxaala Nation is correct that sites protected under the Heritage and Conservation Act are considered in the Access to Specific Locations section of the assessment in Section 12.5.6.7 (starting on page 12-178). However, Aurora LNG also considers Project effects to locations, landforms, natural features, and access routes associated with cultural and spiritual use that are not HCA-protected sites (on pages 12-178 and 12-180).
1860.1	round 1	Gitxaala Nation	12.5.6.7	Aboriginal Consultation	In the Conclusions Regarding Residual Adverse Effects on Gitxaala Nation Cultural Wellbeing Section does not apply characterizations of residual effects despite this being part of the methodology in Section 3. In fact, this entire volume (Volume 12) does not have any mention of characterization of residual effects and does not list any criteria. Further, there is no determination of the likelihood of the residual effects, no discussion of the significance and no discussion of the confidence or risk. This is contrary to section 12.5.1 which states that the degree to which the Project may result in adverse residual effects would be based upon "...the methodology described in Section 3.0 of the Application..."	The assessment of effects on Aboriginal Interests in Section 12 of the Application relies on several methods described in Section 3, including the identification of existing conditions, effects mechanisms, and mitigation measures. Due to the qualitative and intangible nature of some of the Aboriginal Interests considered in Section 12.5.6, and in light of the CEAA 2012 Section 5(1)(c) assessment completed in Sections 11.3 - 11.6 of the Application, the characterization of effects as described in Section 3 (i.e., magnitude, duration, frequency, geographic extent, reversibility, likelihood, significance) was not utilized for Section 12.5.6. To avoid redundancy and address the qualitative nature of Aboriginal Interests, the "Degree of Effects" sections describe the Project's potential interference with the exercise of an Aboriginal Interest (similar to a magnitude characterization) taking into account the relative importance of the Project vicinity, as well as the availability of other areas within the traditional territory of an Aboriginal Group (similar to a context characterization). This is consistent with the Application Information Requirements. Section 11.3 of the Application incorporates a more quantitative assessment of CEAA 2012 section 5(1)(c) effects. Many of these effects are closely related to the exercise of Aboriginal Interests (e.g., current use of lands and resources for traditional purposes). As a result, readers are encouraged to read both Section 11.3 (Requirements Under CEAA 2012 Section 5(1)(c)) and Section 12.5 (Aboriginal Interests) to obtain a comprehensive understanding of how the Project has the potential to affect Aboriginal Groups.
1861.1	round 1	Gitxaala Nation	12.5.6.7	Aboriginal Consultation	In the Conclusions Regarding Residual Adverse Effects on Gitxaala Nation Cultural Wellbeing Section it does not discuss Sacred sites within the LAA and the potential Project interference with these sites. This is problematic as Gitxaala perception and preference could result in potential impacts to the use of these areas. Further, it is noted that Project shipping will not interfere with use of cultural, historic or spiritual sites but that the presence may affect Gitxaala experience, however, this concept should be further explored.	The spatial boundary of the assessment of effects on Aboriginal Interests is not a LAA. Rather, Part C considers activities and effects within the Project vicinity. "Project vicinity" means the spatial and temporal area where interactions between predicted Project-related effects and an Aboriginal Interest are anticipated to occur. Effects on Gitxaala Nation's use of culturally and spiritually important sites within the Project vicinity are described in detail on page 12-184 (Degree of Predicted Residual Effects). In that assessment, Aurora LNG considered effects on the sacred site between Kaien Island and Venn Passage. The assessment concluded that construction activities could interfere with Gitxaala Nation's access to that site. The assessment (on page 12-184) also considers aesthetic effects to Gitxaala Nation use of cultural, historic, and spiritual sites from shipping activities. Gitxaala Nation members' experience of exercising cultural Aboriginal Interests may be affected at the following known sites: camping areas on the Tree Nob group of islands and around Stephens Island, and a past camp on Barrett Rock. The assessment also concluded that the Project would be visible to Gitxaala Nation members participating in activities related to cultural well-being in Dodge Cove, on Barrett Rock, or on Lima Point and may be able to hear noise from the Project.
1862.1	round 1	Gitxaala Nation	12.5.6.8	Aboriginal Consultation	The section on Erosion of House-Based Jurisdiction and Management of the Project Vicinity states that "Aurora LNG has not received information from Gitxaala Nation indicating how house groups currently manage their stewardship areas." However, Section 3.5 of the Gitxaala Use Report outlines the Gitxaala Resource Management Principles. Please refer to this section for details to bolster the assessment. Additionally, further consultation with Gitxaala on areas where more information is required is recommended rather than simply stating that this information is not available.	Aurora LNG appreciated the information provided by Gitxaala Nation in the Project-specific studies, including both the Gitxaala Use Study and the Gitxaala VC Report. Both of these studies contained information that was relevant and useful for the assessment of effects of Gitxaala Nation traditional governance. The information provided by Gitxaala Nation regarding traditional governance systems, responsibilities, and principles formed the basis of the assessment in Section 12.5.6.8. The quote highlighted by Gitxaala Nation contains an error and should read: "Aurora LNG has not received information from Gitxaala Nation indicating how these two house groups currently manage their stewardship areas. As a result, Aurora LNG cannot predict how traditional jurisdiction and management of the Project vicinity would be affected by the Project." An errata document has been created that captures these corrections and it will be filed with the BC EAO.
1863.1	round 1	Gitxaala Nation	12.5.6.8	Aboriginal Consultation	In the Conclusions Regarding Residual Adverse Effects on Gitxaala Nation Traditional Governance Section does not apply characterizations of residual effects despite this being part of the methodology in Section 3. In fact, this entire volume (Volume 12) does not have any mention of characterization of residual effects and does not list any criteria. Further, there is no determination of the likelihood of the residual effects, no discussion of the significance and no discussion of the confidence or risk. This is contrary to section 12.5.1 which states that the degree to which the Project may result in adverse residual effects would be based upon "...the methodology described in Section 3.0 of the Application..."	The assessment of effects on Aboriginal Interests in Section 12 of the Application relies on several methods described in Section 3, including the identification of existing conditions, effects mechanisms, and mitigation measures. Due to the qualitative and intangible nature of some of the Aboriginal Interests considered in Section 12.5.6, and in light of the CEAA 2012 Section 5(1)(c) assessment completed in Sections 11.3 - 11.6 of the Application, the characterization of effects as described in Section 3 (i.e., magnitude, duration, frequency, geographic extent, reversibility, likelihood, significance) was not utilized for Section 12.5.6. To avoid redundancy and address the qualitative nature of Aboriginal Interests, the "Degree of Effects" sections describe the Project's potential interference with the exercise of an Aboriginal Interest (similar to a magnitude characterization) taking into account the relative importance of the Project vicinity, as well as the availability of other areas within the traditional territory of an Aboriginal Group (similar to a context characterization). This is consistent with the Application Information Requirements. Section 11.3 of the Application incorporates a more quantitative assessment of CEAA 2012 section 5(1)(c) effects. Many of these effects are closely related to the exercise of Aboriginal Interests (e.g., current use of lands and resources for traditional purposes). As a result, readers are encouraged to read both Section 11.3 (Requirements Under CEAA 2012 Section 5(1)(c)) and Section 12.5 (Aboriginal Interests) to obtain a comprehensive understanding of how the Project has the potential to affect Aboriginal Groups.
1864.1	round 1	Gitxaala Nation	12.5.6.9	Aboriginal Consultation	Gitxaala does not agree that continued consultation will negate effects to Gitxaala self-governance as Aurora LNG has little to no control over management of lands outside of the PDA and the PDA will be completely lost to Gitxaala Nation.	Aurora LNG respectfully disagrees with Gitxaala Nation. A commitment to continued consultation can serve to reduce potential adverse effects on Gitxaala Nation's right to self-government by helping to fully understand the right, and working together to develop additional mitigation measures.
1865.1	round 1	Gitxaala Nation	12.5.6.9	Aboriginal Consultation	The comparison of the Project vicinity to Gitxaala's entire traditional territory is inappropriate as Gitxaala Nation is divided into house and shared territories. Additonally, neither the LAA and RAA encompasses Gitxaala territory and project effects are assesed at the LAA and RAA scale - this should be no different for this potential effect.	The spatial boundary of the assessment of effects on Aboriginal Interests is not a LAA or RAA. Rather, Part C considers activities and effects within the Project vicinity. "Project vicinity" means the spatial and temporal area where interactions between predicted Project-related effects and an Aboriginal Interest are anticipated to occur. Gitxaala Nation raised the concern about the comparison of the Project vicinity to the Gitxaala territory during its review of a draft version of this part of the Application prior to submission of the Application for screening. As a result of that conversation, Aurora LNG added the following caveat to the description of the Relative Availability of Other Areas (which is a requirement of the AIR): "Aurora LNG understands, through consultation with Gitxaala Nation, that the locations that are available for Gitxaala Nation community members for land and marine use planning may be restricted by various factors including habitat differences, commercial or residential development, or private and restricted lands." Aurora LNG assumes that traditional Gitxaala governance practices would not prevent land and marine use planning efforts. Please also see the technical memo entitled "Additional Information Regarding the CEAA 5(1)(C) and Part C Assessment Methodologies and the Consideration of Traditional Use Information in these Assessments" which will be filed with the BC EAO.
1866.1	round 1	Gitxaala Nation	12.5.6.9	Aboriginal Consultation	In the Conclusions Regarding Residual Adverse Effects on Gitxaala Nation Right to Self-Government Section does not apply characterizations of residual effects despite this being part of the methodology in Section 3. In fact, this entire volume (Volume 12) does not have any mention of characterization of residual effects and does not list any criteria. Further, there is no determination of the likelihood of the residual effects, no discussion of the significance and no discussion of the confidence or risk. This is contrary to section 12.5.1 which states that the degree to which the Project may result in adverse residual effects would be based upon "...the methodology described in Section 3.0 of the Application..."	The assessment of effects on Aboriginal Interests in Section 12 of the Application relies on several methods described in Section 3, including the identification of existing conditions, effects mechanisms, and mitigation measures. Due to the qualitative and intangible nature of some of the Aboriginal Interests considered in Section 12.5.6, and in light of the CEAA 2012 Section 5(1)(c) assessment completed in Sections 11.3 - 11.6 of the Application, the characterization of effects as described in Section 3 (i.e., magnitude, duration, frequency, geographic extent, reversibility, likelihood, significance) was not utilized for Section 12.5.6. To avoid redundancy and address the qualitative nature of Aboriginal Interests, the "Degree of Effects" sections describe the Project's potential interference with the exercise of an Aboriginal Interest (similar to a magnitude characterization) taking into account the relative importance of the Project vicinity, as well as the availability of other areas within the traditional territory of an Aboriginal Group (similar to a context characterization). This is consistent with the Application Information Requirements. Section 11.3 of the Application incorporates a more quantitative assessment of CEAA 2012 section 5(1)(c) effects. Many of these effects are closely related to the exercise of Aboriginal Interests (e.g., current use of lands and resources for traditional purposes). As a result, readers are encouraged to read both Section 11.3 (Requirements Under CEAA 2012 Section 5(1)(c)) and Section 12.5 (Aboriginal Interests) to obtain a comprehensive understanding of how the Project has the potential to affect Aboriginal Groups.
1867.1	round 1	Gitxaala Nation	12.5.6.10	Aboriginal Consultation	This section indicated that "...Gitxaala Nation has asserted a right to use water within its traditional territory. Aurora LNG understands "use of water" to mean marine navigation." This is an impoverish view of "use of water" which can mean many things; including, but not limited to, spiritual uses, harvesting uses and cultural learnings.	Potential effects to use of waterways for harvesting purposes are assessed in Section 12.5.6.6. Potential effects to spiritual and cultural use of sites on or near water are assessed in Section 12.5.6.7.
1868.1	round 1	Gitxaala Nation	12.5.6.10	Aboriginal Consultation	Similar to previous comments on marine travel routes, Aurora LNG did not consider the perception or preference of Gitxaala harvesters when evaluating route and Project-related marine traffic. This is an omission which must be rectified prior to application approval.	Potential effects on Gitxaala Nation use of marine travelways are assessed in Section 12.5.6.10. Potential effects on the experience of harvesting, including air quality, noise, and visual quality effects, are assessed in Section 12.5.6.6 (pages 12-170 to 12-176).Gitxaala Nation did not provide Aurora LNG with adequate data indicating the preferred marine travelways used by Gitxaala Nation members, and why those routes are preferred. This lack of data prevented Aurora LNG from being able to predict specific avoidance behaviours by Gitxaala Nation members.As such, Aurora LNG presented the relevant constraints generally and theoretically in the assessment of effects to Gitxaala Nation harvesting (see pages 12-174 to 12-176).
1869.1	round 1	Gitxaala Nation	12.5.6.10	Aboriginal Consultation	In the Conclusions Regarding Residual Adverse Effects on Gitxaala Nation Use of Marine Travelways Section does not apply characterizations of residual effects despite this being part of the methodology in Section 3. In fact, this entire volume (Volume 12) does not have any mention of characterization of residual effects and does not list any criteria. Further, there is no determination of the likelihood of the residual effects, no discussion of the significance and no discussion of the confidence or risk. This is contrary to section 12.5.1 which states that the degree to which the Project may result in adverse residual effects would be based upon "...the methodology described in Section 3.0 of the Application..."	The assessment of effects on Aboriginal Interests in Section 12 of the Application relies on several methods described in Section 3, including the identification of existing conditions, effects mechanisms, and mitigation measures. Due to the qualitative and intangible nature of some of the Aboriginal Interests considered in Section 12.5.6, and in light of the CEAA 2012 Section 5(1)(c) assessment completed in Sections 11.3 - 11.6 of the Application, the characterization of effects as described in Section 3 (i.e., magnitude, duration, frequency, geographic extent, reversibility, likelihood, significance) was not utilized for Section 12.5.6. To avoid redundancy and address the qualitative nature of Aboriginal Interests, the "Degree of Effects" sections describe the Project's potential interference with the exercise of an Aboriginal Interest (similar to a magnitude characterization) taking into account the relative importance of the Project vicinity, as well as the availability of other areas within the traditional territory of an Aboriginal Group (similar to a context characterization). This is consistent with the Application Information Requirements. Section 11.3 of the Application incorporates a more quantitative assessment of CEAA 2012 section 5(1)(c) effects. Many of these effects are closely related to the exercise of Aboriginal Interests (e.g., current use of lands and resources for traditional purposes). As a result, readers are encouraged to read both Section 11.3 (Requirements Under CEAA 2012 Section 5(1)(c)) and Section 12.5 (Aboriginal Interests) to obtain a comprehensive understanding of how the Project has the potential to affect Aboriginal Groups.

1870.1	round 1	Gitxaala Nation	12.5.6.11	Aboriginal Consultation	There is no information contained in this section that is specific to Gitxaala economic conditions and simply regurgitates information from previous sections. This is problematic and ensures that Gitxaala economic conditions are never fully assessed.	Aurora LNG believes that Gitxaala Nation's ability to access economic opportunities is adequately assessed in other parts of the Application (see Sections 5.0, 11.3, 12.5.6.6, and 12.5.6.10). Economic benefits arising from Aboriginal title-related rights are discussed in Section 12.5.6.5. Aurora LNG is also of the view that there will be no additional adverse effects on Gitxaala Nation economic opportunities other than what has already been assessed in those sections. As such, no additional interference is anticipated beyond the anticipated effects predicted for Aboriginal harvesting and the characterizations in Section 5 and Section 11.3. Gitxaala Nation had the opportunity to review the draft Part C (and Section 11.3) prior to submission of the Application for screening review and to discuss any views or feedback at Technical Workshop #3 , which was held on October 20-21, 2016. Aurora LNG, as part of that workshop, recorded the views provided by Gitxaala Nation with respect to the assessment of CEAA Section 5(1)(c) effects and Aboriginal Interests in Part C. The information recorded as part of the workshop was incorporated into Sections 11.3 and 12.3 of the Application, in accordance with the AIR. As noted in Table 12.9-1, in many cases feedback received from Gitxaala Nation resulted in revisions to the final version of Part C submitted to the BC EAO. Aurora LNG has been committed to ongoing consultation with Gitxaala Nation throughout the Application Review phase to discuss issues and concerns related to the Application. In January 2017, Aurora LNG held Technical Workshop #4 to discuss the assessment of VCs set out in Part B of the Application. Gitxaala Nation representatives attended the initial sessions of the first day of the workshop. Aurora LNG offered Gitxaala Nation another opportunity to meet regarding the remaining material from Workshop #4, which occurred on March 28, 2017. On March 27, 2017, Aurora LNG held Technical Workshop #5 with Gitxaala Nation to further discuss the characterization of effects and significance conclusions outlined in the CEAA 2012 Section 5(1)(c) assessment, and the assessment of Project effects related to Aboriginal Interests in Part C. Technical Workshops #4 and #5 were also an opportunity to discuss feedback on mitigation measures, proposed management plans and follow-up programs. Throughout Technical Workshops #4 and #5, Aurora LNG documented Gitxaala Nation opinions, concerns and feedback. Aurora LNG will be providing a draft of Aboriginal Consultation Report #3 (i.e. the interim consultation report) at day 90 of the 180 day Application-review period (as per the EAO's letter of December 14, 2016). As part of the draft Aboriginal Consultation Report #3, Aurora LNG will report on its understanding of the status of issues/concerns resolution with Gitxaala Nation for the issues/concerns recorded during all phases of the EA (in table format), including those identified in Aboriginal Consultation Report #2 and recorded as part of Technical Workshops #4 and #5. The final version of Aboriginal Consultation Report #3 will be submitted at day 120 of the 180 day Application-review period (as per the section 11 Order [as amended]).
1871.1	round 1	Gitxaala Nation	12.5.6.11	Aboriginal Consultation	This section is even more abbreviated than previous sections and does not contain a listing of potential mitigation measures. This highlights the cursory nature which economic conditions were approached.	Aurora LNG chose to present this section in an abbreviated format because potential effects to Gitxaala Nation's economic opportunities are extensively addressed elsewhere in the Application (as described in Section 12.5.6.11).
1872.1	round 1	Gitxaala Nation	12.5.6.11	Aboriginal Consultation	In the Conclusions Regarding Residual Adverse Effects on Gitxaala Nation Economic Opportunities Section does not apply characterizations of residual effects despite this being part of the methodology in Section 3. In fact, this entire volume (Volume 12) does not have any mention of characterization of residual effects and does not list any criteria. Further, there is no determination of the likelihood of the residual effects, no discussion of the significance and no discussion of the confidence or risk. This is contrary to section 12.5.1 which states that the degree to which the Project may result in adverse residual effects would be based upon "...the methodology described in Section 3.0 of the Application..."	The assessment of effects on Aboriginal Interests in Section 12 of the Application relies on several methods described in Section 3, including the identification of existing conditions, effects mechanisms, and mitigation measures. Due to the qualitative and intangible nature of some of the Aboriginal Interests considered in Section 12.5.6, and in light of the CEAA 2012 Section 5(1)(c) assessment completed in Sections 11.3 - 11.6 of the Application, the characterization of effects as described in Section 3 (i.e., magnitude, duration, frequency, geographic extent, reversibility, likelihood, significance) was not utilized for Section 12.5.6. To avoid redundancy and address the qualitative nature of Aboriginal Interests, the "Degree of Effects" sections describe the Project's potential interference with the exercise of an Aboriginal Interest (similar to a magnitude characterization) taking into account the relative importance of the Project vicinity, as well as the availability of other areas within the traditional territory of an Aboriginal Group (similar to a context characterization). This is consistent with the Application Information Requirements. Section 11.3 of the Application incorporates a more quantitative assessment of CEAA 2012 section 5(1)(c) effects. Many of these effects are closely related to the exercise of Aboriginal Interests (e.g., current use of lands and resources for traditional purposes). As a result, readers are encouraged to read both Section 11.3 (Requirements Under CEAA 2012 Section 5(1)(c)) and Section 12.5 (Aboriginal Interests) to obtain a comprehensive understanding of how the Project has the potential to affect Aboriginal Groups.
1873.1	round 1	Gitxaala Nation	12.5.6.12	Aboriginal Consultation	This section states that "Aurora LNG is unaware of any outstanding Aboriginal Interests issues identified by Gitxaala Nation that have not already been addressed in Part B or Part C of the application." Please take the comments contained within this table as outstanding Aboriginal interests issues and update this section of the report to reflect these concerns. Additionally, Gitxaala has provided numerous sources of comment to Aurora LNG to date. None of these comments were reflected in this section, despite Aurora LNG and Gitxaala not coming to agreement on a variety of issues. This mischaracterizes the consultation that has taken place to date and mischaracterizes the process with Gitxaala overall.	The following records included in the Application present Gitxaala Nation's concerns, issues, and views with the Application: Table 7-1 of Appendix S1 (ACR#2): Gitxaala Nation Interests, Concerns, and Status Table 11.7-3: Views of Gitxaala Nation on the Assessment of Section 5(1)(c) Effects Table 12.3-3: Key Concerns for Gitxaala Nation Table 12.9-1: Pre-Application Views of Aboriginal Groups on Part C (starting on page 12-325). Aurora LNG is of the opinion that the pre-Application views of Gitxaala Nation have been appropriately and accurately presented in the tables listed above. Gitxaala Nation views and topics of concern raised since the filing of the Second Aboriginal Consultation Report, including the Application review phase of the environmental assessment, will be included in the Third Aboriginal Consultation Report. Gitxaala Nationwill have an opportunity to review and comment on a draft version of the report before it is finalized and filed with the EAO.
1874.1	round 1	Gitxaala Nation	12.7	Aboriginal Consultation	This section identifies that Aurora LNG "…believes it has adequately assessed matters of concern to Aboriginal Groups. Therefore no other matters of concern have been assessed here." As evidenced by the this table - this is not the case. Please review this table and update Section 12.7 accordingly.	While Aurora LNG acknowledges that the items described in Gitxaala Nation's comments represent Gitxaala Nation concerns with the assessment, "Other Matters of Concern" as described in Section 12.7 of the AIR are "matters of concern raised by Schedule B Aboriginal Groups related to potential adverse environmental, economic, social, heritage and health effects of the proposed Project that are not addressed in Part B of the Application." Aurora LNG is of the opinion that the concerns raised in Gitxaala Nation's IR comments do not necessarily fall under the description of "Other Matters of Concern" in the AIR, but are rather Gitxaala Nation's issues and concerns with assessments of effects contained in the Application.
1875.1	round 1	Gitxaala Nation	Table 12.8-1	Aboriginal Consultation	This table does not relate to the many specific consultation issues Gitxaala has with Aurora LNG and this Project. For example, there is no mention of the lack of inclusion of Gitxaala in the ongoing field programs and Gitxaala's significant issues with that exclusion. In fact, it seems Aurora LNG has only characterized issues which it has immediate mitigation measures available, rather than summarizing all Gitxaala related issues.	Consistent with Section 12.8 of the AIR, Table 12.8-1 identifies the Aboriginal Interests that may be impacted by the proposed Project and "Other Matters of Concern" (defined in Section 12.7 of the AIR as "potential adverse environmental, economic, social, heritage and health effects of the proposed Project that are not addressed in Part B of the Application") and measures to avoid, mitigate or otherwise manage the effects. Table 12.8-1 also provides Aurora LNG's perspective on the status of each topic. During consultation with Aboriginal Groups, Aurora LNG sought to address concerns raised by Aboriginal Groups related to potential adverse environmental, economic, social, heritage and health effects of the proposed Project in one of the following sections: (a) the assessment of a specific VC in Part B of the Application (b) as a component of the assessment of the requirements under CEAA 2012 5(1)(c) (see Section 11.3) (c) as an Aboriginal Interest discussed in Part C. For this reason, Table 12.8-1 does not include any "Other Matters of Concern". Table 12.3-3 of the Application provides a brief summary of key issues raised by Aboriginal Groups during the pre-Application phase of the environmental assessment, and Aurora LNG's responses to these concerns. Detailed tables of Gitxaala Nation interests, concerns and status are provided in Table 7-1 of the ACR #2 (see Appendix S.1). Further information that provides context related Aurora LNG's approach to consultation and fieldwork participation is provided in the technical memo entitled "Aurora LNG's approach to Consultation with Aboriginal Groups".
1876.1	round 1	Gitxaala Nation	Table 12.9-1	Aboriginal Consultation	In almost all cases, all instances of an issue with the pre-Application have remained without resolution. Simply including Gitxaala's wording in the application does not alleviate the underlying issue. This is an extremely problematic approach as it reduces Gitxaala's thoughtful commentary on the pre-application to ancillary information which does not inform the assessment at all. This is particularly apparent in the comments listed below, but it should be noted that in almost every instance of a previous comment, it went unaddressed.	Gitxaala Nation had the opportunity to review the draft Part C (and Section 11.3) prior to submission of the Application for screening review and to discuss any views or feedback at Technical Workshop #3, which was held on October 20-21, 2016. Aurora LNG, as part of that workshop, recorded the views provided by Gitxaala Nation with respect to the assessment of CEAA Section 5(1)(c) effects and Aboriginal Interests in Part C. The information recorded as part of the workshop was incorporated into Sections 11.3 and 12.3 of the Application, in accordance with the AIR. As noted in Table 12.9-1, in many cases feedback received from Gitxaala Nation resulted in revisions to the final version of Part C submitted to the BC EAO. Aurora LNG has been committed to ongoing consultation with Gitxaala Nation throughout the Application Review phase to discuss issues and concerns related to the Application. In January 2017, Aurora LNG held Technical Workshop #4 to discuss the assessment of VCs set out in Part B of the Application. Gitxaala Nation representatives attended the initial sessions of the first day of the workshop. Aurora LNG offered Gitxaala Nation another opportunity to meet regarding the remaining material from Workshop #4, which occurred on March 28, 2017. On March 27, 2017, Aurora LNG held Technical Workshop #5 with Gitxaala Nation to further discuss the characterization of effects and significance conclusions outlined in the CEAA 2012 Section 5(1)(c) assessment, and the assessment of Project effects related to Aboriginal Interests in Part C. Technical Workshops #4 and #5 were also an opportunity to discuss feedback on mitigation measures, proposed management plans and follow-up programs. Throughout Technical Workshops #4 and #5, Aurora LNG documented Gitxaala Nation opinions, concerns and feedback. Aurora LNG will be providing a draft of Aboriginal Consultation Report #3 (i.e. the interim consultation report) at day 90 of the 180 day Application-review period (as per the EAO's letter of December 14, 2016). As part of the draft Aboriginal Consultation Report #3, Aurora LNG will report on its understanding of the status of issues/concerns resolution with Gitxaala Nation for the issues/concerns recorded during all phases of the EA (in table format), including those identified in Aboriginal Consultation Report #2 and recorded as part of Technical Workshops #4 and #5. The final version of Aboriginal Consultation Report #3 will be submitted at day 120 of the 180 day Application-review period (as per the section 11 Order [as amended]). For further information please refer to the technical memo entitled "Aurora LNG's Approach to Consultation with Aboriginal Groups" which will be filed with the BC EAO.
1877.1	round 1	Gitxaala Nation	Table 12.9-1	Aboriginal Consultation	Gitxaala identified in this table that there is a lack of understanding of some components by Aurora LNG which could have been remedied with further consultation with Gitxaala Nation, specifically related to cultural wellbeing being equated to archaeological and heritage sites as well as the development of mitigation measures. Aurora LNG's response to this item is not sufficient and has not addressed the original concern, which, as evidenced by this table - has yet to be remedied.	Gitxaala Nation had the opportunity to review the draft Part C (and Section 11.3) prior to submission of the Application for screening review and to discuss any views or feedback at Technical Workshop #3 , which was held on October 20-21, 2016. Aurora LNG, as part of that workshop, recorded the views provided by Gitxaala Nation with respect to the assessment of CEAA Section 5(1)(c) effects and Aboriginal Interests in Part C. The information recorded as part of the workshop was incorporated into Sections 11.3 and 12.3 of the Application, in accordance with the AIR. As noted in Table 12.9-1, in many cases feedback received from Gitxaala Nation resulted in revisions to the final version of Part C submitted to the BC EAO. Aurora LNG has been committed to ongoing consultation with Gitxaala Nation throughout the Application Review phase to discuss issues and concerns related to the Application. In January 2017, Aurora LNG held Technical Workshop #4 to discuss the assessment of VCs set out in Part B of the Application. Gitxaala Nation representatives attended the initial sessions of the first day of the workshop. Aurora LNG offered Gitxaala Nation another opportunity to meet regarding the remaining material from Workshop #4, which occurred on March 28, 2017. On March 27, 2017, Aurora LNG held Technical Workshop #5 with Gitxaala Nation to further discuss the characterization of effects and significance conclusions outlined in the CEAA 2012 Section 5(1)(c) assessment, and the assessment of Project effects related to Aboriginal Interests in Part C. Technical Workshops #4 and #5 were also an opportunity to discuss feedback on mitigation measures, proposed management plans and follow-up programs. Throughout Technical Workshops #4 and #5, Aurora LNG documented Gitxaala Nation opinions, concerns and feedback. Aurora LNG will be providing a draft of Aboriginal Consultation Report #3 (i.e. the interim consultation report) at day 90 of the 180 day Application-review period (as per the EAO's letter of December 14, 2016). As part of the draft Aboriginal Consultation Report #3, Aurora LNG will report on its understanding of the status of issues/concerns resolution with Gitxaala Nation for the issues/concerns recorded during all phases of the EA (in table format), including those identified in Aboriginal Consultation Report #2 and recorded as part of Technical Workshops #4 and #5. The final version of Aboriginal Consultation Report #3 will be submitted at day 120 of the 180 day Application-review period (as per the section 11 Order). Aurora LNG is currently reviewing feedback received to date on mitigation measures and any revised or new mitigation measures proposed will be included as part of an updated Table 16-1 and 16-2 to be submitted to the EAO on Day 90.

1878.1	round 1	Gitxaala Nation	Table 12.9-1	Aboriginal Consultation	Gitxaala identified in this table that Gitxaala required ongoing consultation on mitigation measures. This was not completed by Aurora LNG to date, as evidenced by Gitxaala's lack of input into mitigation measures outlined in the Application.	Gitxaala Nation had the opportunity to review the draft Part C (and Section 11.3) prior to submission of the Application for screening review, including mitigation measures proposed to reduce potential effects on Gitxaala Nation Aboriginal Interests, and to discuss any views or feedback at Technical Workshop #3 , which was held on October 20-21, 2016. Aurora LNG, as part of that workshop, recorded the views provided by Gitxaala Nation with respect to the assessment of CEAA Section 5(1)(c) effects and Aboriginal Interests in Part C. The information recorded as part of the workshop was incorporated into Sections 11.3 and 12.3 of the Application, in accordance with the AIR. As noted in Table 12.9-1, in many cases feedback received from Gitxaala Nation resulted in revisions to the final version of Part C submitted to the BC EAO. Aurora LNG has been committed to ongoing consultation with Gitxaala Nation throughout the Application Review phase to discuss issues and concerns related to the Application. In January 2017, Aurora LNG held Technical Workshop #4 to discuss the assessment of VCs set out in Part B of the Application. Gitxaala Nation representatives attended the initial sessions of the first day of the workshop. Aurora LNG offered Gitxaala Nation another opportunity to meet regarding the remaining material from Workshop #4, which occurred on March 28, 2017. On March 27, 2017, Aurora LNG held Technical Workshop #5 with Gitxaala Nation to further discuss the characterization of effects and significance conclusions outlined in the CEAA 2012 Section 5(1)(c) assessment, and the assessment of Project effects related to Aboriginal Interests in Part C. Technical Workshops #4 and #5 were also an opportunity to discuss feedback on mitigation measures, proposed management plans and follow-up programs. Throughout Technical Workshops #4 and #5, Aurora LNG documented Gitxaala Nation opinions, concerns and feedback. Aurora LNG will be providing a draft of Aboriginal Consultation Report #3 (i.e. the interim consultation report) at day 90 of the 180 day Application-review period (as per the EAO's letter of December 14, 2016). As part of the draft Aboriginal Consultation Report #3, Aurora LNG will report on its understanding of the status of issues/concerns resolution with Gitxaala Nation for the issues/concerns recorded during all phases of the EA (in table format), including those identified in Aboriginal Consultation Report #2 and recorded as part of Technical Workshops #4 and #5. The final version of Aboriginal Consultation Report #3 will be submitted at day 120 of the 180 day Application-review period (as per the section 11 Order [as amended]). Aurora LNG is currently reviewing feedback received to date on mitigation measures and any revised or new mitigation measures proposed will be included as part of an updated Table 16-1 and 16-2 to be submitted to the EAO on Day 90.
1879.1	round 1	Gitxaala Nation	Table 12.9-1	Aboriginal Consultation	This table also outlines Gitxaala's pre-Application concern that the characterization of residual effects was not completed in accordance with methodology outline in Section 3.0. This is a remaining issue in the Application and has been noted by Gitxaala numerous times.	The assessment of effects on Aboriginal Interests in Section 12 of the Application relies on several methods described in Section 3, including the identification of existing conditions, effects mechanisms, and mitigation measures. Due to the qualitative and intangible nature of some of the Aboriginal Interests considered in Section 12.5.6, and in light of the CEAA 2012 Section 5(1)(c) assessment completed in Sections 11.3 - 11.6 of the Application, the characterization of effects as described in Section 3 (i.e., magnitude, duration, frequency, geographic extent, reversibility, likelihood, significance) was not utilized for Section 12.5.6. To avoid redundancy and address the qualitative nature of Aboriginal Interests, the "Degree of Effects" sections describe the Project's potential interference with the exercise of an Aboriginal Interest (similar to a magnitude characterization) taking into account the relative importance of the Project vicinity, as well as the availability of other areas within the traditional territory of an Aboriginal Group (similar to a context characterization). This is consistent with the Application Information Requirements. Section 11.3 of the Application incorporates a more quantitative assessment of CEAA 2012 section 5(1)(c) effects. Many of these effects are closely related to the exercise of Aboriginal Interests (e.g., current use of lands and resources for traditional purposes). As a result, readers are encouraged to read both Section 11.3 (Requirements Under CEAA 2012 Section 5(1)(c)) and Section 12.5 (Aboriginal Interests) to obtain a comprehensive understanding of how the Project has the potential to affect Aboriginal Groups. Gitxaala Nation had the opportunity to review the draft Part C (and Section 11.3) prior to submission of the Application for screening review and to discuss any views or feedback at Technical Workshop #3 which was held on October 20-21, 2016. Aurora LNG, as part of that workshop, recorded the views provided by Gitxaala Nation with respect to the assessment of CEAA Section 5(1)(c) effects and Aboriginal Interests in Part C. The information recorded as part of the workshop was incorporated into Sections 11.3 and 12.3 of the Application, in accordance with the AIR. As noted in Table 12.9-1, in many cases feedback received from Gitxaala Nation resulted in revisions to the final version of Part C submitted to the BC EAO.
1880.1	round 1	Gitxaala Nation	Table 12.9-1	Aboriginal Consultation	Similar to the above comments on percentage calculation, Gitxaala commented, pre-application, on the inappropriate subtraction of the PDA from Gitxaala's full traditional territory. This comment was not resolved.	Gitxaala Nation raised the concern about the comparison of the Project vicinity to the Gitxaala territory during its review of a draft version of this part of the Application prior to submission of the Application for screening. As a result of that conversation, Aurora LNG added caveats to the incorporation of percentages of the Relative Availability of Other Areas (which is a requirement of the AIR) for several Aboriginal Interests: Section 12.5.6.5 (page 12-159), Section 12.5.6.6 (page 12-175), Section 12.5.6.7 (pages 12-185 and 12-186), and Section 12.5.6.9 (page 12-191). Further information that provides context related to the assessment of the identified potential effects in the Application, including clarification regarding the assumptions utilized in the assessment, is provided in the technical memo entitled "Additional Information Regarding the CEAA 5(1)(C) and Part C Assessment Methodologies and the Consideration of Traditional Use Information in these Assessments". This technical memo will be filed with the BC EAO.
1881.1	round 1	Gitxaala Nation	3.6	Assessment Methods	Concerning proposed management plans as mitigation measures, any proposed plan should have components and enforcement frameworks detailed in the appendices, or a commitment to minimum standards such as IFC PS, WB EHS Guidelines, etc. See Memo "0217_AGIforGitxaala_Social Impacts" for comments on management plans.	Details of the Environmental Management Plans will be developed prior to commencement of the Project phase to which they apply, consistent with any requirements outlined in Environmental Assessment Certification Conditions. The Project will comply with all applicable federal and provincial legislation, regulations, and permitting requirements. Mitigation measures will be developed in accordance with industry best management practices (BMPs) and applicable regulations as summarized in the technical memo "Mitigation Measures Categorization Table".
1882.1	round 1	Gitxaala Nation	3.7	Assessment Methods	See Memo "0217_AGIforGitxaala_Social Impacts" for comments on cumulative effects. These comments apply to all cumulative effects sections in the Application.	The memo "0217_AGIforGidaala_Social Impacts" provides background context about the use of zoning and policy tools for strategic management of cumulative impacts from development, and recommends that the EAO "elevate the importance of coordination of efforts in the form of zoning, regional management bodies, or government managed strategic planning to facilitate better assessment and mitigation of potential adverse impacts on communities." The cumulative effects sections in the Application were completed in accordance with the Application Information Requirements (AIR) for the Aurora LNG Project. The draft AIR was circulated to the members of the working group (including regulatory agencies and Aboriginal Groups) for comment, and finalized once comments had been addressed to the satisfaction of the EAO. The assessments of residual and cumulative effects in the Application consider the zoning, regulatory context, and land and marine use planning applicable to each Valued Component.
1883.1	round 1	Gitxaala Nation	3.10	Assessment Methods	Proponent should describe a management system for monitoring predicted impacts and effectiveness of mitigation measures. A management system should include roles and responsibilities, budgeting, reporting linkages, and enforcement at the very least. Some of these are present in section 14 Proposed Operational and Management Plans, and we provide recommendations for the inclusion of others. We recommend benchmarking management plans against IFC Performance Standards for Environmental and Social Responsibility (in particular, Performance Standard 1 - Environemental and Social Management Systems) and consulting with Aboriginal groups when finalizing key management plans and monitoring systems. See Memo "0217_AGIforGitxaala_Social Impacts" for comments on management plans.	Section 3.10 of the Application outlines the methods used in the Application for follow-up and monitoring, consistent with section 3.8.5 of the Application Information Requirements. See the "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment" technical memo for consideration of the referenced memo '0217_AGIforGitxaala_Social Impacts'. The technical memo will be filed with the BC EAO.
1884.1	round 1	Gitxaala Nation	3.1	Assessment Methods	The Community Health VC does not specifically integrate accepted Aboriginal determinants of health that reflect sensitivity to environmental change and impacts to cultural continuity.	Aurora LNG acknowledges that not all social determinants of health (SDOH) that apply to Aboriginal Groups have been included in the assessment of change in community health and wellness provided in Section 6.6; however, with respect to Gitxaala, numerous indicators, overarching themes and pathways (effect mechanisms) associated with additional SDOH and contributors to wellness presented in the Shandro Report are captured under SDOH assessed in Section 6.6. This is accomplished either through reference to other sections of the Application or through direct mention in the assessment. While not all of the contributors to wellness provided by Gitxaala Nation are included, consistent messaging that Aboriginal Groups are more susceptible to changes in baseline conditions is established and characterized where applicable (as vulnerable populations). See the "Response to the Potential Risks, Impacts and Opportunities of the Aurora LNG Project for Gitxaala Nation Report" technical memo for additional consideration of SDOH and contributors of wellness presented by Gitxaala Nation. The technical memo will be filed with the BC EAO.
1885.1	round 1	Gitxaala Nation	3.2.2	Assessment Methods	The report "Potential Risks, Impacts, and Opportunities of the Aurora LNG Project for Gitxaala Nation" (referred to as "Shandro et al., 2016") is not cited as reference material.	In November 2016, Gitxaala Nation provided Aurora LNG with a study entitled Potential Risks, Impacts and Opportunities of the Aurora LNG Project for Gitxaala Nation (the "Shandro Report"). As Aurora LNG had completed the analysis and writing for its Application for Environmental Assessment Certificate (the "Application") at the time that the Shandro Report was received, information contained in the report had not been reviewed or directly incorporated into the Application which was submitted to the BC EAO in November, 2016. Aurora LNG has prepared a memo titled "Response to the Potential Risks, Impacts, and Opportunities of the Aurora LNG Project for Gitxaala Nation Report" toprovide a summary of its review and analysis of the information presented in the Shandro Report. New information contained within the Shandro Report that was not previously considered in the Application has been analyzed, and subsequent implications to the conclusions provided in the Application, including any required changes, are described in the memo. This technical memo will be filed with the BC EAO.
1886.1	round 1	Gitxaala Nation	3.2.3	Assessment Methods	The report "Potential Risks, Impacts, and Opportunities of the Aurora LNG Project for Gitxaala Nation" (referred to as "Shandro et al., 2016") is not cited as reference material.	In November 2016, Gitxaala Nation provided Aurora LNG with a study entitled Potential Risks, Impacts and Opportunities of the Aurora LNG Project for Gitxaala Nation (the "Shandro Report"). As Aurora LNG had completed the analysis and writing for its Application for Environmental Assessment Certificate (the "Application") at the time that the Shandro Report was received, information contained in the report had not been reviewed or directly incorporated into the Application which was submitted to the BC EAO in November, 2016. Aurora LNG has prepared a memo titled "Response to the Potential Risks, Impacts, and Opportunities of the Aurora LNG Project for Gitxaala Nation Report" to provide a summary of its review and analysis of the information presented in the Shandro Report. New information contained within the Shandro Report that was not previously considered in the Application has been analyzed, and subsequent implications to the conclusions provided in the Application, including any required changes, are described in the memo. This technical memo will be filed with the BC EAO.
1887.1	round 1	Gitxaala Nation	3.4	Assessment Methods	This section outlines an approach for discussing and describing existing conditions, including collecting primary data where possible. However there is very little reference to any primary data collected or utilized in the socioeconomic chapters (sections 5 and 6).	The description of primary data collected and utilized in sections 5 and 6 is included in those sections, as appropriate. This includes information on primary data collected during key informant interviews, emails and telephone correspondence.
1888.1	round 1	Gitxaala Nation	4.2.3.3	Air Quality	This section outlines an approach for discussing and describing existing conditions, including collecting primary data where possible. However there is very little reference to any primary data collected or utilized in the socioeconomic chapters (sections 5 and 6).	Section 4.2.3.3 is the summary of existing conditions section for Air Quality. Aurora LNG is requesting clarification on the comment from Gitxaala Nation as we are not sure how this applies to the section.
1889.1	round 1	Gitxaala Nation	4.3	Greenhouse Gases	This section outlines an approach for discussing and describing existing conditions, including collecting primary data where possible. However there is very little reference to any primary data collected or utilized in the socioeconomic chapters (sections 5 and 6).	Section 4.3 is the effects assessment for Greenhouse Gases. Aurora LNG is requesting clarification on the comment from Gitxaala Nation as we are not sure how this applies to the section.
1890.1	round 1	Gitxaala Nation	4.4.3.3	Acoustic Environment	This section outlines an approach for discussing and describing existing conditions, including collecting primary data where possible. However there is very little reference to any primary data collected or utilized in the socioeconomic chapters (sections 5 and 6).	Section 4.4.3.3 is the summary of existing conditions section for Acoustic Environment. Aurora LNG is requesting clarification on the comment from Gitxaala Nation as we are not sure how this applies to the section.
1891.1	round 1	Gitxaala Nation	4.5.3.3	Water Quality	This section outlines an approach for discussing and describing existing conditions, including collecting primary data where possible. However there is very little reference to any primary data collected or utilized in the socioeconomic chapters (sections 5 and 6).	Section 4.5.3.3 is the summary of existing conditions section for Freshwater Quality. Aurora LNG is requesting clarification on the comment from Gitxaala Nation as we are not sure how this applies to the section.
1892.1	round 1	Gitxaala Nation	4.5.13.4	Water Quality	This section outlines an approach for discussing and describing existing conditions, including collecting primary data where possible. However there is very little reference to any primary data collected or utilized in the socioeconomic chapters (sections 5 and 6).	Section 4.5.13.4 is the summary of existing conditions section for Marine Water Quality. Aurora LNG is requesting clarification on the comment from Gitxaala Nation as we are not sure how this applies to the section.
1893.1	round 1	Gitxaala Nation	4.6.3.2	Vegetation and Wetland Resources	This section outlines an approach for discussing and describing existing conditions, including collecting primary data where possible. However there is very little reference to any primary data collected or utilized in the socioeconomic chapters (sections 5 and 6).	Section 4.6.3.2 is the overview of existing conditions section for Vegetation and Wetland Resources. Aurora LNG is requesting clarification on the comment from Gitxaala Nation as we are not sure how this applies to the section.
1894.1	round 1	Gitxaala Nation	4.7	Wildlife Resources (Terrestrial)	This section outlines an approach for discussing and describing existing conditions, including collecting primary data where possible. However there is very little reference to any primary data collected or utilized in the socioeconomic chapters (sections 5 and 6).	Section 4.7 is the effects assessment for Wildlife Resources. Aurora LNG is requesting clarification on the comment from Gitxaala Nation as we are not sure how this applies to the section.
1895.1	round 1	Gitxaala Nation	4.8.3.3	Freshwater Fish and Fish Habitat	This section outlines an approach for discussing and describing existing conditions, including collecting primary data where possible. However there is very little reference to any primary data collected or utilized in the socioeconomic chapters (sections 5 and 6).	Section 4.8.3.3 is the summary of existing conditions section for Freshwater Fish and Fish Habitat. Aurora LNG is requesting clarification on the comment from Gitxaala Nation as we are not sure how this applies to the section.

1896.1	round 1	Gitxaala Nation	4.9.3.2	Marine Fish and Fish Habitat	This section outlines an approach for discussing and describing existing conditions, including collecting primary data where possible. However there is very little reference to any primary data collected or utilized in the socioeconomic chapters (sections 5 and 6).	The following primary data used in sections 5 and 6 of the Application includes information collected directly by the Aurora LNG research team, information from government agencies and data warehouses, as well as information collected by various Aboriginal Communities during socio-economic research related to the Project, supported by Aurora LNG. Section 5.2 - Economic Conditions Statistical data from 2006, 2011 Metlakatla First Nation 2015 membership census Kitsumkalum First Nation membership survey Kitsumkalum Traditional Use Study Lax Kw'aalams Socio-economic Impact Study - addressed in post-Application memo Gitxaala Socio-economic data - addressed in post-Application memo Section 6.2 - Visual Quality Photo-documentation of viewpoints for visual quality analysis Spatial data and meta data from Visual Landscape Inventory from Data BC Section 6.3 - Infrastructure and services Information interviews with service providers and government officials (see Section 6.3.11.2) informed baseline conditions, effect mechanisms, the characterization of residual and cumulative effects and proposed mitigation measures. Aviation studies completed for the Project and referenced throughout Section 6.3 also involved primary research and data gathering. Section 6.4 - Land use Incidental observations of land use within the PDA and nearby areas by crews completing bio-physical and visual quality assessments in support of the Project informed baseline conditions (see Section 6.4.3). Spatial data and meta data for land tenure, land use, and visual from government databases (e.g., BC's data warehouse, DataBC, the Integrated Land Management Bureau's data warehouse, and the Agricultural Land Commission [ALC]) were also used to inform baseline conditions. Section 6.5 - Marine use an Navigable Waters Pacific Pilotage Authority data on shipping movements to and from the Port of Prince Rupert Quantitative data (e.g. landings, value, and licencing information) on CRA fisheries from DFO Spatial data on marine fisheries and marine recreation and tourism activities obtained from BCMCA Marine species harvested identified in Project-specific traditional use studies provided by the following Aboriginal Groups prior to Application submission: Metlakatla First Nation, Gitxaala Nation, Kitsumkalum First Nation, and Gitga'at First Nation. Marine species harvested identified in Project-specific traditional use studies provided by the following Aboriginal Groups after Application submission: Lax Kw'alaams Band. Section 6.6 - Community Health Information interviews conducted with service providers and government officials, primarily in support of the Infrastructure and Services VC, helped inform the scope of issues to be included in Section 6.6 (see Section 6.3.11.2). Qualitative information related to crime and drug and alcohol use, which could not be cited at the request of the key informant, was also gathered. Primary data included in Section 6.6 also includes the results of surveys and studies provided to Aurora LNG in project-specific socio-economic studies provided by Aboriginal Groups (see Section 6.6.2.3). In addition to primary data referenced within the above sections, the Aurora LNG socio-economic research team considered relevant first-hand information collected during Aboriginal and public engagement activities (see Section 12 Aboriginal Consultation and Section 13 Public Consultation)
1897.1	round 1	Gitxaala Nation	4.10.3.2	Marine Wildlife - Marine Mammals	This section outlines an approach for discussing and describing existing conditions, including collecting primary data where possible. However there is very little reference to any primary data collected or utilized in the socioeconomic chapters (sections 5 and 6).	Section 4.10.3.2 is the overview of existing conditions section for Marine Mammals. Aurora LNG is requesting clarification on the comment from Gitxaala Nation as we are not sure how this applies to the section.
1898.1	round 1	Gitxaala Nation	4.11.3.2	Marine Wildlife - Marine Birds	This section outlines an approach for discussing and describing existing conditions, including collecting primary data where possible. However there is very little reference to any primary data collected or utilized in the socioeconomic chapters (sections 5 and 6).	Section 4.11.3.2 is the overview of existing conditions section for Marine Birds. Aurora LNG is requesting clarification on the comment from Gitxaala Nation as we are not sure how this applies to the section.
1899.1	round 1	Gitxaala Nation	5.2.3.3	Economic Conditions	This section outlines an approach for discussing and describing existing conditions, including collecting primary data where possible. However there is very little reference to any primary data collected or utilized in the socioeconomic chapters (sections 5 and 6).	The following primary data used in sections 5 and 6 of the Application includes information collected directly by the Aurora LNG research team, information from government agencies and data warehouses, as well as information collected by various Aboriginal Communities during socio-economic research related to the Project, supported by Aurora LNG. Section 5.2 - Economic Conditions Statistical data from 2006, 2011 Metlakatla First Nation 2015 membership census Kitsumkalum First Nation membership survey Kitsumkalum Traditional Use Study Lax Kw'aalams Socio-economic Impact Study - addressed in post-Application memo Gitxaala Socio-economic data - addressed in post-Application memo Section 6.2 - Visual Quality Photo-documentation of viewpoints for visual quality analysis Spatial data and meta data from Visual Landscape Inventory from Data BC Section 6.3 - Infrastructure and services Information interviews with service providers and government officials (see Section 6.3.11.2) informed baseline conditions, effect mechanisms, the characterization of residual and cumulative effects and proposed mitigation measures. Aviation studies completed for the Project and referenced throughout Section 6.3 also involved primary research and data gathering. Section 6.4 - Land use Incidental observations of land use within the PDA and nearby areas by crews completing bio-physical and visual quality assessments in support of the Project informed baseline conditions (see Section 6.4.3). Spatial data and meta data for land tenure, land use, and visual from government databases (e.g., BC's data warehouse, DataBC, the Integrated Land Management Bureau's data warehouse, and the Agricultural Land Commission [ALC]) were also used to inform baseline conditions. Section 6.5 - Marine use an Navigable Waters Pacific Pilotage Authority data on shipping movements to and from the Port of Prince Rupert Quantitative data (e.g. landings, value, and licencing information) on CRA fisheries from DFO Spatial data on marine fisheries and marine recreation and tourism activities obtained from BCMCA Marine species harvested identified in Project-specific traditional use studies provided by the following Aboriginal Groups prior to Application submission: Metlakatla First Nation, Gitxaala Nation, Kitsumkalum First Nation, and Gitga'at First Nation. Marine species harvested identified in Project-specific traditional use studies provided by the following Aboriginal Groups after Application submission: Lax Kw'alaams Band. Section 6.6 - Community Health Information interviews conducted with service providers and government officials, primarily in support of the Infrastructure and Services VC, helped inform the scope of issues to be included in Section 6.6 (see Section 6.3.11.2). Qualitative information related to crime and drug and alcohol use, which could not be cited at the request of the key informant, was also gathered. Primary data included in Section 6.6 also includes the results of surveys and studies provided to Aurora LNG in project-specific socio-economic studies provided by Aboriginal Groups (see Section 6.6.2.3). In addition to primary data referenced within the above sections, the Aurora LNG socio-economic research team considered relevant first-hand information collected during Aboriginal and public engagement activities (see Section 12 Aboriginal Consultation and Section 13 Public Consultation)
1900.1	round 1	Gitxaala Nation	6.2.3.2	Visual Quality	This section outlines an approach for discussing and describing existing conditions, including collecting primary data where possible. However there is very little reference to any primary data collected or utilized in the socioeconomic chapters (sections 5 and 6).	The following primary data used in sections 5 and 6 of the Application includes information collected directly by the Aurora LNG research team, information from government agencies and data warehouses, as well as information collected by various Aboriginal Communities during socio-economic research related to the Project, supported by Aurora LNG. Section 5.2 - Economic Conditions Statistical data from 2006, 2011 Metlakatla First Nation 2015 membership census Kitsumkalum First Nation membership survey Kitsumkalum Traditional Use Study Lax Kw'aalams Socio-economic Impact Study - addressed in post-Application memo Gitxaala Socio-economic data - addressed in post-Application memo Section 6.2 - Visual Quality Photo-documentation of viewpoints for visual quality analysis Spatial data and meta data from Visual Landscape Inventory from Data BC Section 6.3 - Infrastructure and services Information interviews with service providers and government officials (see Section 6.3.11.2) informed baseline conditions, effect mechanisms, the characterization of residual and cumulative effects and proposed mitigation measures. Aviation studies completed for the Project and referenced throughout Section 6.3 also involved primary research and data gathering. Section 6.4 - Land use Incidental observations of land use within the PDA and nearby areas by crews completing bio-physical and visual quality assessments in support of the Project informed baseline conditions (see Section 6.4.3). Spatial data and meta data for land tenure, land use, and visual from government databases (e.g., BC's data warehouse, DataBC, the Integrated Land Management Bureau's data warehouse, and the Agricultural Land Commission [ALC]) were also used to inform baseline conditions. Section 6.5 - Marine use an Navigable Waters Pacific Pilotage Authority data on shipping movements to and from the Port of Prince Rupert Quantitative data (e.g. landings, value, and licencing information) on CRA fisheries from DFO Spatial data on marine fisheries and marine recreation and tourism activities obtained from BCMCA Marine species harvested identified in Project-specific traditional use studies provided by the following Aboriginal Groups prior to Application submission: Metlakatla First Nation, Gitxaala Nation, Kitsumkalum First Nation, and Gitga'at First Nation. Marine species harvested identified in Project-specific traditional use studies provided by the following Aboriginal Groups after Application submission: Lax Kw'alaams Band. Section 6.6 - Community Health Information interviews conducted with service providers and government officials, primarily in support of the Infrastructure and Services VC, helped inform the scope of issues to be included in Section 6.6 (see Section 6.3.11.2). Qualitative information related to crime and drug and alcohol use, which could not be cited at the request of the key informant, was also gathered. Primary data included in Section 6.6 also includes the results of surveys and studies provided to Aurora LNG in project-specific socio-economic studies provided by Aboriginal Groups (see Section 6.6.2.3). In addition to primary data referenced within the above sections, the Aurora LNG socio-economic research team considered relevant first-hand information collected during Aboriginal and public engagement activities (see Section 12 Aboriginal Consultation and Section 13 Public Consultation)

1901.1	round 1	Gitxaala Nation	6.3.3.3	Infrastructure and Services	This section outlines an approach for discussing and describing existing conditions, including collecting primary data where possible. However there is very little reference to any primary data collected or utilized in the socioeconomic chapters (sections 5 and 6).	The following primary data used in sections 5 and 6 of the Application includes information collected directly by the Aurora LNG research team, information from government agencies and data warehouses, as well as information collected by various Aboriginal Communities during socio-economic research related to the Project, supported by Aurora LNG. Section 5.2 - Economic Conditions Statistical data from 2006, 2011 Metlakatla First Nation 2015 membership census Kitsumkalum First Nation membership survey Kitsumkalum Traditional Use Study Lax Kw'aalams Socio-economic Impact Study - addressed in post-Application memo Gitxaala Socio-economic data - addressed in post-Application memo Section 6.2 - Visual Quality Photo-documentation of viewpoints for visual quality analysis Spatial data and meta data from Visual Landscape Inventory from Data BC Section 6.3 - Infrastructure and services Information interviews with service providers and government officials (see Section 6.3.11.2) informed baseline conditions, effect mechanisms, the characterization of residual and cumulative effects and proposed mitigation measures. Aviation studies completed for the Project and referenced throughout Section 6.3 also involved primary research and data gathering. Section 6.4 - Land use Incidental observations of land use within the PDA and nearby areas by crews completing bio-physical and visual quality assessments in support of the Project informed baseline conditions (see Section 6.4.3). Spatial data and meta data for land tenure, land use, and visual from government databases (e.g., BC's data warehouse, DataBC, the Integrated Land Management Bureau's data warehouse, and the Agricultural Land Commission [ALC]) were also used to inform baseline conditions. Section 6.5 - Marine use an Navigable Waters Pacific Pilotage Authority data on shipping movements to and from the Port of Prince Rupert Quantitative data (e.g. landings, value, and licencing information) on CRA fisheries from DFO Spatial data on marine fisheries and marine recreation and tourism activities obtained from BCMCA Marine species harvested identified in Project-specific traditional use studies provided by the following Aboriginal Groups prior to Application submission: Metlakatla First Nation, Gitxaala Nation, Kitsumkalum First Nation, and Gitga'at First Nation. Marine species harvested identified in Project-specific traditional use studies provided by the following Aboriginal Groups after Application submission: Lax Kw'alaams Band. Section 6.6 - Community Health Information interviews conducted with service providers and government officials, primarily in support of the Infrastructure and Services VC, helped inform the scope of issues to be included in Section 6.6 (see Section 6.3.11.2). Qualitative information related to crime and drug and alcohol use, which could not be cited at the request of the key informant, was also gathered. Primary data included in Section 6.6 also includes the results of surveys and studies provided to Aurora LNG in project-specific socio-economic studies provided by Aboriginal Groups (see Section 6.6.2.3). In addition to primary data referenced within the above sections, the Aurora LNG socio-economic research team considered relevant first-hand information collected during Aboriginal and public engagement activities (see Section 12 Aboriginal Consultation and Section 13 Public Consultation)
1902.1	round 1	Gitxaala Nation	6.4.3.5	Land and Resource Use	This section outlines an approach for discussing and describing existing conditions, including collecting primary data where possible. However there is very little reference to any primary data collected or utilized in the socioeconomic chapters (sections 5 and 6).	The following primary data used in sections 5 and 6 of the Application includes information collected directly by the Aurora LNG research team, information from government agencies and data warehouses, as well as information collected by various Aboriginal Communities during socio-economic research related to the Project, supported by Aurora LNG. Section 5.2 - Economic Conditions Statistical data from 2006, 2011 Metlakatla First Nation 2015 membership census Kitsumkalum First Nation membership survey Kitsumkalum Traditional Use Study Lax Kw'aalams Socio-economic Impact Study - addressed in post-Application memo Gitxaala Socio-economic data - addressed in post-Application memo Section 6.2 - Visual Quality Photo-documentation of viewpoints for visual quality analysis Spatial data and meta data from Visual Landscape Inventory from Data BC Section 6.3 - Infrastructure and services Information interviews with service providers and government officials (see Section 6.3.11.2) informed baseline conditions, effect mechanisms, the characterization of residual and cumulative effects and proposed mitigation measures. Aviation studies completed for the Project and referenced throughout Section 6.3 also involved primary research and data gathering. Section 6.4 - Land use Incidental observations of land use within the PDA and nearby areas by crews completing bio-physical and visual quality assessments in support of the Project informed baseline conditions (see Section 6.4.3). Spatial data and meta data for land tenure, land use, and visual from government databases (e.g., BC's data warehouse, DataBC, the Integrated Land Management Bureau's data warehouse, and the Agricultural Land Commission [ALC]) were also used to inform baseline conditions. Section 6.5 - Marine use an Navigable Waters Pacific Pilotage Authority data on shipping movements to and from the Port of Prince Rupert Quantitative data (e.g. landings, value, and licencing information) on CRA fisheries from DFO Spatial data on marine fisheries and marine recreation and tourism activities obtained from BCMCA Marine species harvested identified in Project-specific traditional use studies provided by the following Aboriginal Groups prior to Application submission: Metlakatla First Nation, Gitxaala Nation, Kitsumkalum First Nation, and Gitga'at First Nation. Marine species harvested identified in Project-specific traditional use studies provided by the following Aboriginal Groups after Application submission: Lax Kw'alaams Band. Section 6.6 - Community Health Information interviews conducted with service providers and government officials, primarily in support of the Infrastructure and Services VC, helped inform the scope of issues to be included in Section 6.6 (see Section 6.3.11.2). Qualitative information related to crime and drug and alcohol use, which could not be cited at the request of the key informant, was also gathered. Primary data included in Section 6.6 also includes the results of surveys and studies provided to Aurora LNG in project-specific socio-economic studies provided by Aboriginal Groups (see Section 6.6.2.3). In addition to primary data referenced within the above sections, the Aurora LNG socio-economic research team considered relevant first-hand information collected during Aboriginal and public engagement activities (see Section 12 Aboriginal Consultation and Section 13 Public Consultation).
1903.1	round 1	Gitxaala Nation	6.5.3.3	Marine Use and Navigable Waters	This section outlines an approach for discussing and describing existing conditions, including collecting primary data where possible. However there is very little reference to any primary data collected or utilized in the socioeconomic chapters (sections 5 and 6).	The following primary data used in sections 5 and 6 of the Application includes information collected directly by the Aurora LNG research team, information from government agencies and data warehouses, as well as information collected by various Aboriginal Communities during socio-economic research related to the Project, supported by Aurora LNG. Section 5.2 - Economic Conditions Statistical data from 2006, 2011 Metlakatla First Nation 2015 membership census Kitsumkalum First Nation membership survey Kitsumkalum Traditional Use Study Lax Kw'aalams Socio-economic Impact Study - addressed in post-Application memo Gitxaala Socio-economic data - addressed in post-Application memo Section 6.2 - Visual Quality Photo-documentation of viewpoints for visual quality analysis Spatial data and meta data from Visual Landscape Inventory from Data BC Section 6.3 - Infrastructure and services Information interviews with service providers and government officials (see Section 6.3.11.2) informed baseline conditions, effect mechanisms, the characterization of residual and cumulative effects and proposed mitigation measures. Aviation studies completed for the Project and referenced throughout Section 6.3 also involved primary research and data gathering. Section 6.4 - Land use Incidental observations of land use within the PDA and nearby areas by crews completing bio-physical and visual quality assessments in support of the Project informed baseline conditions (see Section 6.4.3). Spatial data and meta data for land tenure, land use, and visual from government databases (e.g., BC's data warehouse, DataBC, the Integrated Land Management Bureau's data warehouse, and the Agricultural Land Commission [ALC]) were also used to inform baseline conditions. Section 6.5 - Marine use an Navigable Waters Pacific Pilotage Authority data on shipping movements to and from the Port of Prince Rupert Quantitative data (e.g. landings, value, and licencing information) on CRA fisheries from DFO Spatial data on marine fisheries and marine recreation and tourism activities obtained from BCMCA Marine species harvested identified in Project-specific traditional use studies provided by the following Aboriginal Groups prior to Application submission: Metlakatla First Nation, Gitxaala Nation, Kitsumkalum First Nation, and Gitga'at First Nation. Marine species harvested identified in Project-specific traditional use studies provided by the following Aboriginal Groups after Application submission: Lax Kw'alaams Band. Section 6.6 - Community Health Information interviews conducted with service providers and government officials, primarily in support of the Infrastructure and Services VC, helped inform the scope of issues to be included in Section 6.6 (see Section 6.3.11.2). Qualitative information related to crime and drug and alcohol use, which could not be cited at the request of the key informant, was also gathered. Primary data included in Section 6.6 also includes the results of surveys and studies provided to Aurora LNG in project-specific socio-economic studies provided by Aboriginal Groups (see Section 6.6.2.3). In addition to primary data referenced within the above sections, the Aurora LNG socio-economic research team considered relevant first-hand information collected during Aboriginal and public engagement activities (see Section 12 Aboriginal Consultation and Section 13 Public Consultation)

1904.1	round 1	Gitxaala Nation	6.6.3.3	Community Health	This section outlines an approach for discussing and describing existing conditions, including collecting primary data where possible. However there is very little reference to any primary data collected or utilized in the socioeconomic chapters (sections 5 and 6).	The following primary data used in sections 5 and 6 of the Application includes information collected directly by the Aurora LNG research team, information from government agencies and data warehouses, as well as information collected by various Aboriginal Communities during socio-economic research related to the Project, supported by Aurora LNG. Section 5.2 - Economic Conditions Statistical data from 2006, 2011 Metlakatla First Nation 2015 membership census Kitsumkalum First Nation membership survey Kitsumkalum Traditional Use Study Lax Kw'aalams Socio-economic Impact Study - addressed in post-Application memo Gitxaala Socio-economic data - addressed in post-Application memo Section 6.2 - Visual Quality Photo-documentation of viewpoints for visual quality analysis Spatial data and meta data from Visual Landscape Inventory from Data BC Section 6.3 - Infrastructure and services Information interviews with service providers and government officials (see Section 6.3.11.2) informed baseline conditions, effect mechanisms, the characterization of residual and cumulative effects and proposed mitigation measures. Aviation studies completed for the Project and referenced throughout Section 6.3 also involved primary research and data gathering. Section 6.4 - Land use Incidental observations of land use within the PDA and nearby areas by crews completing bio-physical and visual quality assessments in support of the Project informed baseline conditions (see Section 6.4.3). Spatial data and meta data for land tenure, land use, and visual from government databases (e.g., BC's data warehouse, DataBC, the Integrated Land Management Bureau's data warehouse, and the Agricultural Land Commission [ALC]) were also used to inform baseline conditions. Section 6.5 - Marine use an Navigable Waters Pacific Pilotage Authority data on shipping movements to and from the Port of Prince Rupert Quantitative data (e.g. landings, value, and licencing information) on CRA fisheries from DFO Spatial data on marine fisheries and marine recreation and tourism activities obtained from BCMCA Marine species harvested identified in Project-specific traditional use studies provided by the following Aboriginal Groups prior to Application submission: Metlakatla First Nation, Gitxaala Nation, Kitsumkalum First Nation, and Gitga'at First Nation. Marine species harvested identified in Project-specific traditional use studies provided by the following Aboriginal Groups after Application submission: Lax Kw'alaams Band. Section 6.6 - Community Health Information interviews conducted with service providers and government officials, primarily in support of the Infrastructure and Services VC, helped inform the scope of issues to be included in Section 6.6 (see Section 6.3.11.2). Qualitative information related to crime and drug and alcohol use, which could not be cited at the request of the key informant, was also gathered. Primary data included in Section 6.6 also includes the results of surveys and studies provided to Aurora LNG in project-specific socio-economic studies provided by Aboriginal Groups (see Section 6.6.2.3). In addition to primary data referenced within the above sections, the Aurora LNG socio-economic research team considered relevant first-hand information collected during Aboriginal and public engagement activities (see Section 12 Aboriginal Consultation and Section 13 Public Consultation)
1905.1	round 1	Gitxaala Nation	7.2.3.2	Heritage	This section outlines an approach for discussing and describing existing conditions, including collecting primary data where possible. However there is very little reference to any primary data collected or utilized in the socioeconomic chapters (sections 5 and 6).	Section 7.2.3.2 is the overview of existing conditions section for Heritage and Archaeological Resources. Aurora LNG is requesting clarification on the comment from Gitxaala Nation as we are not sure how this applies to the section.
1906.1	round 1	Gitxaala Nation	8.2.3.2	Human Health	This section outlines an approach for discussing and describing existing conditions, including collecting primary data where possible. However there is very little reference to any primary data collected or utilized in the socioeconomic chapters (sections 5 and 6).	Section 8.2.3.2 is the overview of existing conditions section for Human Health. Aurora LNG is requesting clarification on the comment from Gitxaala Nation as we are not sure how this applies to the section.
1907.1	round 1	Gitxaala Nation	3.10	Assessment Methods	See Memo "0217_AGIforGitxaala_Social Impacts" for comments on monitoring and follow-up programs.	Section 3.10 of the Application outlines the methods used in the Application for follow-up and monitoring, consistent with section 3.8.5 of the Application Information Requirements. See the technical memorandum "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment' for consideration of the referenced memo '0217_AGIforGitxaala_Social Impacts '.
1908.1	round 1	Gitxaala Nation	4.2.9	Air Quality	See Memo "0217_AGIforGitxaala_Social Impacts" for comments on monitoring and follow-up programs.	Section 4.2.9 of the Application outlines proposed follow-up and monitoring for air quality, as applicable. Aurora LNG has reviewed the memo "0217_AGIforGitxaala_Social Impacts" and has identified no further recommendations regarding monitoring and follow-up programs specific to the Air Quality Valued Component. See the technical memorandum "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment' for consideration of the referenced memo '0217_AGIforGitxaala_Social Impacts'.
1909.1	round 1	Gitxaala Nation	4.3.9	Greenhouse Gases	See Memo "0217_AGIforGitxaala_Social Impacts" for comments on monitoring and follow-up programs.	Section 4.3.9 of the Application outlines the proposed follow-up and monitoring for greenhouse gases, as applicable. Aurora LNG has reviewed the memo "0217_AGIforGitxaala_Social Impacts" and has identified no further recommendations regarding monitoring and follow-up programs specific to the Greenhouse Gases Valued Component. See the "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment' technical memo for consideration of the referenced memo '0217_AGIforGitxaala_Social Impacts '. The technical memo will be filed with the BC EAO.
1910.1	round 1	Gitxaala Nation	4.4.9	Acoustic Environment	See Memo "0217_AGIforGitxaala_Social Impacts" for comments on monitoring and follow-up programs.	Section 4.4.9 of the Application outlines proposed follow-up and monitoring for acoustic environment, as applicable. Aurora LNG has reviewed the memo "0217_AGIforGitxaala_Social Impacts" and has identified no further recommendations regarding monitoring and follow-up programs specific to the Acoustic Environment Valued Component. See the technical memorandum "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment' for consideration of the referenced memo '0217_AGIforGitxaala_Social Impacts '.
1911.1	round 1	Gitxaala Nation	4.5.9	Water Quality	See Memo "0217_AGIforGitxaala_Social Impacts" for comments on monitoring and follow-up programs.	Section 4.5.9 of the Application outlines proposed follow-up and monitoring for water quality (freshwater), as applicable. Aurora LNG has reviewed the memo "0217_AGIforGitxaala_Social Impacts" and has identified no further recommendations regarding monitoring and follow-up programs specific to Freshwater Quality . See the technical memorandum "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment' for consideration of the referenced memo '0217_AGIforGitxaala_Social Impacts'.
1912.1	round 1	Gitxaala Nation	4.5.9	Water Quality	See Memo "0217_AGIforGitxaala_Social Impacts" for comments on monitoring and follow-up programs.	Sections 4.5.9 and 4.5.19 of the Application outline proposed follow-up and monitoring for water quality (freshwater and marine, respectively), as applicable. Aurora LNG has reviewed the memo "0217_AGIforGitxaala_Social Impacts" and has identified no further recommendations regarding monitoring and follow-up programs specific to the Water Quality Valued Component. See the technical memorandum "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment' for consideration of the referenced memo '0217_AGIforGitxaala_Social Impacts'.
1913.1	round 1	Gitxaala Nation	4.6.9	Vegetation and Wetland Resources	See Memo "0217_AGIforGitxaala_Social Impacts" for comments on monitoring and follow-up programs.	Section 4.6.9 of the Application outlines proposed follow-up and monitoring for vegetation and wetland resources, as applicable. Aurora LNG has reviewed the memo "0217_AGIforGitxaala_Social Impacts" and has identified no further recommendations regarding monitoring and follow-up programs specific to the Vegetation and Wetland Resources Valued Component. See the technical memorandum "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment' for consideration of the referenced memo '0217_AGIforGitxaala_Social Impacts'.
1914.1	round 1	Gitxaala Nation	4.7.9	Wildlife Resources (Terrestrial)	See Memo "0217_AGIforGitxaala_Social Impacts" for comments on monitoring and follow-up programs.	Section 4.7.9 of the Application outlines proposed follow-up and monitoring for wildlife resources (terrestrial), as applicable. Aurora LNG has reviewed the memo "0217_AGIforGitxaala_Social Impacts" and has identified no further recommendations regarding monitoring and follow-up programs specific to the Wildlife Resources (Terrestrial) Valued Component. See the technical memorandum "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment' for consideration of the referenced memo '0217_AGIforGitxaala_Social Impacts'.
1915.1	round 1	Gitxaala Nation	4.8.9	Freshwater Fish and Fish Habitat	See Memo "0217_AGIforGitxaala_Social Impacts" for comments on monitoring and follow-up programs.	Section 4.8.9 of the Application outlines proposed follow-up and monitoring for freshwater fish and fish habitat, as applicable. Aurora LNG has reviewed the memo "0217_AGIforGitxaala_Social Impacts" and has identified no further recommendations regarding monitoring and follow-up programs specific to the Freshwater Fish and Fish Habitat Valued Component. See the technical memorandum "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment' for consideration of the referenced memo '0217_AGIforGitxaala_Social Impacts'.
1916.1	round 1	Gitxaala Nation	4.9.9	Marine Fish and Fish Habitat	See Memo "0217_AGIforGitxaala_Social Impacts" for comments on monitoring and follow-up programs.	Section 4.9.9 of the Application outlines proposed follow-up and monitoring for marine fish and fish habitat, as applicable. Aurora LNG has reviewed the memo "0217_AGIforGitxaala_Social Impacts" and has identified no further recommendations regarding monitoring and follow-up programs specific to the Marine Fish and Fish Habitat Valued Component. See the technical memorandum "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment' for consideration of the referenced memo '0217_AGIforGitxaala_Social Impacts'.
1917.1	round 1	Gitxaala Nation	4.10.9	Marine Wildlife - Marine Mammals	See Memo "0217_AGIforGitxaala_Social Impacts" for comments on monitoring and follow-up programs.	Section 4.10.9 of the Application outlines proposed follow-up and monitoring for marine mammals, as applicable. Aurora LNG has reviewed the memo "0217_AGIforGitxaala_Social Impacts" and has identified no further recommendations regarding monitoring and follow-up programs specific to the Marine Mammals Valued Component. See the technical memorandum "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment' for consideration of the referenced memo '0217_AGIforGitxaala_Social Impacts'.
1918.1	round 1	Gitxaala Nation	4.11.9	Marine Wildlife - Marine Birds	See Memo "0217_AGIforGitxaala_Social Impacts" for comments on monitoring and follow-up programs.	Section 4.11.9 of the Application outlines proposed follow-up and monitoring for marine birds, as applicable. Aurora LNG has reviewed the memo "0217_AGIforGitxaala_Social Impacts" and has identified no further recommendations regarding monitoring and follow-up programs specific to the Marine Birds Valued Component. See the technical memorandum "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment' for consideration of the referenced memo '0217_AGIforGitxaala_Social Impacts'.
1919.1	round 1	Gitxaala Nation	5.2.9	Economic Conditions	See Memo "0217_AGIforGitxaala_Social Impacts" for comments on monitoring and follow-up programs.	See the "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment' technical memo with respect to the referenced memo '0217_AGIforGitxaala_Social Impacts'. The technical memo will be filed with the BC EAO.
1920.1	round 1	Gitxaala Nation	6.2.9	Visual Quality	See Memo "0217_AGIforGitxaala_Social Impacts" for comments on monitoring and follow-up programs.	See the "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment' technical memo with respect to the referenced memo '0217_AGIforGitxaala_Social Impacts'. The technical memo will be filed with the BC EAO.
1921.1	round 1	Gitxaala Nation	6.3.9	Infrastructure and Services	See Memo "0217_AGIforGitxaala_Social Impacts" for comments on monitoring and follow-up programs.	See the "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment' technical memo which will be filed with the BC EAO.
1922.1	round 1	Gitxaala Nation	6.4.9	Land and Resource Use	See Memo "0217_AGIforGitxaala_Social Impacts" for comments on monitoring and follow-up programs.	See the "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment' technical memo which will be filed with the BC EAO.
1923.1	round 1	Gitxaala Nation	6.5.9	Marine Use and Navigable Waters	See Memo "0217_AGIforGitxaala_Social Impacts" for comments on monitoring and follow-up programs.	See the "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment' technical memo with respect to the referenced memo '0217_AGIforGitxaala_Social Impacts'. The technical memo will be filed with the BC EAO.
1924.1	round 1	Gitxaala Nation	6.6.9	Community Health	See Memo "0217_AGIforGitxaala_Social Impacts" for comments on monitoring and follow-up programs.	See the "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment' technical memo which will be filed with the BC EAO.
1925.1	round 1	Gitxaala Nation	7.2.9	Heritage	See Memo "0217_AGIforGitxaala_Social Impacts" for comments on monitoring and follow-up programs.	Section 7.2.9 of the Application outlines proposed follow-up and monitoring for archaeological and heritage resources, as applicable. Aurora LNG has reviewed the memo "0217_AGIforGitxaala_Social Impacts" and has identified no further recommendations regarding monitoring and follow-up programs specific to the Archaeological and Heritage Resources Valued Component. See the technical memorandum "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment' for consideration of the referenced memo '0217_AGIforGitxaala_Social Impacts'.
1926.1	round 1	Gitxaala Nation	8.2.9	Human Health	See Memo "0217_AGIforGitxaala_Social Impacts" for comments on monitoring and follow-up programs.	See the "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment' technical memo which will be filed with the BC EAO.
1927.1	round 1	Gitxaala Nation	5.2.3.2	Economic Conditions	Data was disaggregated for Gitxaala.	See the "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment' technical memo which will be filed with the BC EAO.
1928.1	round 1	Gitxaala Nation	5.2.5.1	Economic Conditions	**Assessment of Subsistence Economies:** The analytical assesment techniques for change in subsistence economies do not consider the cultural importance of these activities. The presence of subsistence economies (including harvesting, selling, trading, and sharing) are discussed in detail, and disaggregated by community, only in Section 5, but the element of cultural importance is discussed only briefly in this section. The significance of sharing is acknowledged to be important to Gitxaala, but the analytical assessment takes into account only residual effects on tenured land uses and their economic value (referencing Section 6.4 Land and Resource Use). We question whether this approach can accurately capture the cultural significance of impacts on subsistence economies for Gitxaala members. See Memo "0217_AGIforGitxaala_Social Impacts" for further comments.	The assessment of potential Project effects on resource based primary and subsistence economic activities focuses on potential change in resource quality and quantity, change in access to a resource, and the value of affected resources (see Table 5.2.2 for effects and measurable parameters). The cultural aspects related to economic activities of Aboriginal Groups (i.e. the traditional economy) is addressed in Section 12 Aboriginal Consultation, and specifically in regards to Gitxaala Nation in Section 12.5.6.11.

1929.1	round 1	Gitxaala Nation	5.2.5.2	Economic Conditions	**Assessment of Subsistence Economies:** The analytical assesment techniques for change in subsistence economies do not consider the cultural importance of these activities. The presence of subsistence economies (including harvesting, selling, trading, and sharing) are discussed in detail, and disaggregated by community, only in Section 5, but the element of cultural importance is discussed only briefly in this section. The significance of sharing is acknowledged to be important to Gitxaala, but the analytical assessment takes into account only residual effects on tenured land uses and their economic value (referencing Section 6.4 Land and Resource Use). We question whether this approach can accurately capture the cultural significance of impacts on subsistence economies for Gitxaala members. See Memo "0217_AGIforGitxaala_Social Impacts" for further comments.	The assessment of potential Project effects on resource based primary and subsistence economic activities focuses on potential change in resource quality and quantity, change in access to a resource, and the value of affected resources (see Table 5.2.2 for effects and measurable parameters). The cultural aspects related to economic activities of Aboriginal Groups (i.e. the traditional economy) is addressed in Section 12 Aboriginal Consultation, and specifically in regards to Gitxaala Nation in Section 12.5.6.11.
1930.1	round 1	Gitxaala Nation	5.2.5.3	Economic Conditions	**Assessment of Subsistence Economies:** The analytical assesment techniques for change in subsistence economies do not consider the cultural importance of these activities. The presence of subsistence economies (including harvesting, selling, trading, and sharing) are discussed in detail, and disaggregated by community, only in Section 5, but the element of cultural importance is discussed only briefly in this section. The significance of sharing is acknowledged to be important to Gitxaala, but the analytical assessment takes into account only residual effects on tenured land uses and their economic value (referencing Section 6.4 Land and Resource Use). We question whether this approach can accurately capture the cultural significance of impacts on subsistence economies for Gitxaala members. See Memo "0217_AGIforGitxaala_Social Impacts" for further comments.	The assessment of potential Project effects on resource based primary and subsistence economic activities focuses on potential change in resource quality and quantity, change in access to a resource, and the value of affected resources (see Table 5.2.2 for effects and measurable parameters). The cultural aspects related to economic activities of Aboriginal Groups (i.e. the traditional economy) is addressed in Section 12 Aboriginal Consultation, and specifically in regards to Gitxaala Nation in Section 12.5.6.11.
1931.1	round 1	Gitxaala Nation	5.2.5.1 – Assessment of Change in Labour Supply and Demand	Economic Conditions		No comment noted
1932.1	round 1	Gitxaala Nation	5.2.5.1	Economic Conditions	See Memo "0217_AGIforGitxaala_Social Impacts" for comments on mitigation measures.	See the "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment" technical memo which will be filed with the BC EAO.
1933.1	round 1	Gitxaala Nation	5.2.5.2	Economic Conditions	See Memo "0217_AGIforGitxaala_Social Impacts" for comments on mitigation measures.	See the "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment' technical memo which will be filed with the BC EAO.
1934.1	round 1	Gitxaala Nation	5.2.5.3	Economic Conditions	See Memo "0217_AGIforGitxaala_Social Impacts" for comments on mitigation measures.	See the "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment" technical memo which will be filed with the BC EAO.
1935.1	round 1	Gitxaala Nation	5.2.5.1	Economic Conditions	**Assessment of Labour Supply and Demand**: Effects of economic shock at the end of project construction are "expected to occur in a resilient context." However, this is not consistent with findings in Section 6.6 Community Health, which identifies that health and social services in the area are at a critical shortage in meeting even baseline demands. These services are instrumental in helping communities cope with temporary economic shocks. Given this, it is not accurate to assume that communities have the resilience to absorb an economic shock without adverse impacts. **Assessment of Subsistence Economies:** "*The Project is predicted to have a low economic effect on subsistence economic activities because of the small degree of overlap of the area within which land or marine based subsistence economic activities will occur, and through the application of mitigation measures designed to avoid interference between Project activities and subsistence harvesting, Project effects will be low magnitude, occur on an LAA scale, either continuous (land based effects) or multiple regular (marine based effects), be permanent, but reversible upon Project decommissioning.*" This statement is problematic with regards to comments submitted by Gitxaala in Section 11.7.3; and AGI's comments in Section 6.4 Land and Resource Use. Gitxaala members may have particular reasons for harvesting certain species from specific areas (family history, house territory, sacred site, distance to home, etc.) in the PDA and LAA. The proponent may want to conduct further field work to gain more insight into such areas and why modifications to harvesting in them may be more significant to Gitxaala members than anticipated.	Section 6.6 does not find that there is a "critical shortage" in meeting baseline health and social services, as indicated by the commenter. The baseline conditions for health and social services are described in Section 6.3.3 (Existing Conditions for Infrastructure and Services). While Aurora LNG has concluded in Section 6.3.5.5 that health care infrastructure within the LAA has "low" resilience, this conclusion relates to the ability of such services to respond to increased demand. Such additional demand could come from the change in economic conditions, as described in Section 5.2, but is addressed directly as an effect on infrastructure and services, rather than an effect on economic conditions. It is stated in Section 5.2.5.1 of the Application that the economic context is "moderately resilient." In accordance with the criteria presented in Table 5.2-1, this means the "Economy in assessment area has moderate diversity, is slowly increasing or decreasing in size, and can accommodate a moderate economic shock." The communities within the LAA have a moderately sized labour force, which is diversified across a number of sectors (see table 5.2-19 and 5.2-20). This diversity provides resilience to the economy because it is not dependent only one or two industries. However, the relative decline in basic economic sectors, such as manufacturing and resource industries, from 2006 to 2011 likely reduces the economic resiliency of the area because basic sectors are generally the core economic engines of a region, upon which other sectors depend. It is for this reason that the LAA is considered only moderately resilient. From an economic perspective, the Project will bring basic sector employment to the region, both during construction, and operation, and will diversify the economic base with the creation of an LNG sector. The assessment of effects on resource based primary industries and subsistence economies is conducted on an LAA basis, with the LAA defined in Table 5.2-3. Aurora LNG respects that Gitxaala and other Aboriginal Groups may limit their harvest areas to particular sites, which could be disproportionately affected by the proposed Project activities. Project effects on Aboriginal interests are addressed in Section 12 Aboriginal Consultation.
1936.1	round 1	Gitxaala Nation	5.2.5.2	Economic Conditions	**Assessment of Labour Supply and Demand**: Effects of economic shock at the end of project construction are "expected to occur in a resilient context." However, this is not consistent with findings in Section 6.6 Community Health, which identifies that health and social services in the area are at a critical shortage in meeting even baseline demands. These services are instrumental in helping communities cope with temporary economic shocks. Given this, it is not accurate to assume that communities have the resilience to absorb an economic shock without adverse impacts. **Assessment of Subsistence Economies:** "*The Project is predicted to have a low economic effect on subsistence economic activities because of the small degree of overlap of the area within which land or marine based subsistence economic activities will occur, and through the application of mitigation measures designed to avoid interference between Project activities and subsistence harvesting, Project effects will be low magnitude, occur on an LAA scale, either continuous (land based effects) or multiple regular (marine based effects), be permanent, but reversible upon Project decommissioning.*" This statement is problematic with regards to comments submitted by Gitxaala in Section 11.7.3; and AGI's comments in Section 6.4 Land and Resource Use. Gitxaala members may have particular reasons for harvesting certain species from specific areas (family history, house territory, sacred site, distance to home, etc.) in the PDA and LAA. The proponent may want to conduct further field work to gain more insight into such areas and why modifications to harvesting in them may be more significant to Gitxaala members than anticipated.	Section 6.6 does not find that there is a "critical shortage" in meeting baseline health and social services, as indicated in the comment. The baseline conditions for health and social services are described in Section 6.3.3 (Existing Conditions for Infrastructure and Services). While Aurora LNG has concluded in Section 6.3.5.5 that health care infrastructure within the LAA has "low" resilience, this conclusion relates to the ability of such services to respond to increased demand. Such additional demand could come from the change in economic conditions, as described in Section 5.2, but this would be addressed directly as an effect on infrastructure and services, rather than an effect on economic conditions. It is stated in Section 5.2.5.1 of the Application that the economic context is "moderately resilient." In accordance with the criteria presented in Table 5.2-1, this means the "Economy in assessment area has moderate diversity, is slowly increasing or decreasing in size, and can accommodate a moderate economic shock." The communities within the LAA have a moderately sized labour force, which is diversified across a number of sectors (see table 5.2-19 and 5.2-20). This diversity provides resilience to the economy because it is not dependent only one or two industries. However, the relative decline in basic economic sectors, such as manufacturing and resource industries, from 2006 to 2011 likely reduces the economic resiliency of the area because basic sectors are generally the core economic engines of a region, upon which other sectors depend. It is for this reason that the LAA is considered only moderately resilient. From an economic perspective, the Project will bring basic sector employment to the region, both during construction, and operation, and will diversify the economic base with the creation of an LNG sector. The assessment of effects on resource based primary industries and subsistence economies is conducted on an LAA basis, with the LAA defined in Table 5.2-3. Aurora LNG respects that Gitxaala and other Aboriginal Groups may limit their harvest areas to particular sites, which could be disproportionately affected by the proposed Project activities. Project effects on Aboriginal interests are addressed in Section 12 Aboriginal Consultation.
1937.1	round 1	Gitxaala Nation	5.2.5.3	Economic Conditions	**Assessment of Labour Supply and Demand**: Effects of economic shock at the end of project construction are "expected to occur in a resilient context." However, this is not consistent with findings in Section 6.6 Community Health, which identifies that health and social services in the area are at a critical shortage in meeting even baseline demands. These services are instrumental in helping communities cope with temporary economic shocks. Given this, it is not accurate to assume that communities have the resilience to absorb an economic shock without adverse impacts. **Assessment of Subsistence Economies:** "*The Project is predicted to have a low economic effect on subsistence economic activities because of the small degree of overlap of the area within which land or marine based subsistence economic activities will occur, and through the application of mitigation measures designed to avoid interference between Project activities and subsistence harvesting, Project effects will be low magnitude, occur on an LAA scale, either continuous (land based effects) or multiple regular (marine based effects), be permanent, but reversible upon Project decommissioning.*" This statement is problematic with regards to comments submitted by Gitxaala in Section 11.7.3; and AGI's comments in Section 6.4 Land and Resource Use. Gitxaala members may have particular reasons for harvesting certain species from specific areas (family history, house territory, sacred site, distance to home, etc.) in the PDA and LAA. The proponent may want to conduct further field work to gain more insight into such areas and why modifications to harvesting in them may be more significant to Gitxaala members than anticipated.	Section 6.6 does not find that there is a "critical shortage" in meeting baseline health and social services, as indicated in the comment. The baseline conditions for health and social services are described in Section 6.3.3 (Existing Conditions for Infrastructure and Services). While Aurora LNG has concluded in Section 6.3.5.5 that health care infrastructure within the LAA has "low" resilience, this conclusion relates to the ability of such services to respond to increased demand. Such additional demand could come from the change in economic conditions, as described in Section 5.2, but then this would be regarded as an effect on infrastructure and services, rather than an effect on economic conditions. It is stated in Section 5.2.5.1 of the Application that the economic context is "moderately resilient." In accordance with the criteria presented in Table 5.2-1, this means the "Economy in assessment area has moderate diversity, is slowly increasing or decreasing in size, and can accommodate a moderate economic shock." The communities within the LAA have a moderately sized labour force, which is diversified across a number of sectors (see table 5.2-19 and 5.2-20). This diversity provides resilience to the economy because it is not dependent only one or two industries. However, the relative decline in basic economic sectors, such as manufacturing and resource industries, from 2006 to 2011 likely reduces the economic resiliency of the area because basic sectors are generally the core economic engines of a region, upon which other sectors depend. It is for this reason that the LAA is considered only moderately resilient. From an economic perspective, the Project will bring basic sector employment to the region, both during construction, and operation, and will diversify the economic base with the creation of an LNG sector. The assessment of effects on resource based primary industries and subsistence economies is conducted on an LAA basis, with the LAA defined in Table 5.2-3. Aurora LNG respects that Gitxaala and other Aboriginal Groups may limit their harvest areas to particular sites, which could be disproportionately affected by the proposed Project activities. Project effects on Aboriginal interests are addressed in Section 12 Aboriginal Consultation.
1938.1	round 1	Gitxaala Nation	5.2.5.4	Economic Conditions	**Assessment of Labour Supply and Demand**: Effects of economic shock at the end of project construction are "expected to occur in a resilient context." However, this is not consistent with findings in Section 6.6 Community Health, which identifies that health and social services in the area are at a critical shortage in meeting even baseline demands. These services are instrumental in helping communities cope with temporary economic shocks. Given this, it is not accurate to assume that communities have the resilience to absorb an economic shock without adverse impacts. **Assessment of Subsistence Economies:** "*The Project is predicted to have a low economic effect on subsistence economic activities because of the small degree of overlap of the area within which land or marine based subsistence economic activities will occur, and through the application of mitigation measures designed to avoid interference between Project activities and subsistence harvesting, Project effects will be low magnitude, occur on an LAA scale, either continuous (land based effects) or multiple regular (marine based effects), be permanent, but reversible upon Project decommissioning.*" This statement is problematic with regards to comments submitted by Gitxaala in Section 11.7.3; and AGI's comments in Section 6.4 Land and Resource Use. Gitxaala members may have particular reasons for harvesting certain species from specific areas (family history, house territory, sacred site, distance to home, etc.) in the PDA and LAA. The proponent may want to conduct further field work to gain more insight into such areas and why modifications to harvesting in them may be more significant to Gitxaala members than anticipated.	Section 6.6 does not find that there is a "critical shortage" in meeting baseline health and social services, as indicated in the comment. The baseline conditions for health and social services are described in Section 6.3.3 (Existing Conditions for Infrastructure and Services). While Aurora LNG has concluded in Section 6.3.5.5 that health care infrastructure within the LAA has "low" resilience, this conclusion relates to the ability of such services to respond to increased demand. Such additional demand could come from the change in economic conditions, as described in Section 5.2, but then this would be regarded as an effect on infrastructure and services, rather than an effect on economic conditions. It is stated in Section 5.2.5.1 of the Application that the economic context is "moderately resilient." In accordance with the criteria presented in Table 5.2-1, this means the "Economy in assessment area has moderate diversity, is slowly increasing or decreasing in size, and can accommodate a moderate economic shock." The communities within the LAA have a moderately sized labour force, which is diversified across a number of sectors (see table 5.2-19 and 5.2-20). This diversity provides resilience to the economy because it is not dependent only one or two industries. However, the relative decline in basic economic sectors, such as manufacturing and resource industries, from 2006 to 2011 likely reduces the economic resiliency of the area because basic sectors are generally the core economic engines of a region, upon which other sectors depend. It is for this reason that the LAA is considered only moderately resilient. From an economic perspective, the Project will bring basic sector employment to the region, both during construction, and operation, and will diversify the economic base with the creation of an LNG sector. The assessment of effects on resource based primary industries and subsistence economies is conducted on an LAA basis, with the LAA defined in Table 5.2-3. Aurora LNG respects that Gitxaala and other Aboriginal Groups may limit their harvest areas to particular sites, which could be disproportionately affected by the proposed Project activities. Project effects on Aboriginal interests are addressed in Section 12 Aboriginal Consultation.
1939.1	round 1	Gitxaala Nation	5.2.6	Economic Conditions	See Memo "0217_AGIforGitxaala_Social Impacts" for comments on mitigation measures.	See the "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment" technical memo which will be filed with the BC EAO.
1940.1	round 1	Gitxaala Nation	6.2.2.2	Visual Quality	There is no reference to Shandro et al., 2016 in these sections.	See the "Response to the Potential Risks, Impacts and Opportunities of the Aurora LNG Project for Gitxaala Nation Report" technical memo which will be filed with the BC EAO.
1941.1	round 1	Gitxaala Nation	6.2.3.1	Visual Quality	There is no reference to Shandro et al., 2016 in these sections.	See the "Response to the Potential Risks, Impacts and Opportunities of the Aurora LNG Project for Gitxaala Nation Report" technical memo which will be filed with the BC EAO.
1942.1	round 1	Gitxaala Nation	6.2.3.2	Visual Quality	There is no reference to Shandro et al., 2016 in these sections.	See the "Aurora LNG Response to Gitxaala Report: Potential Risks, Impacts and Opportunities of the Aurora LNG Project for Gitxaala Nation" technical memo which will be filed with the BC EAO.

1943.1	round 1	Gitxaala Nation	6.3.2.2	Infrastructure and Services	It is not clear what information specific to Gitxaala was referenced for this chapter.	The description of existing conditions within the LAA and RAA includes disaggregated data from Statistics Canada on population demographics and housing and accommodations and information from Gitxaala Nation on the Kitkatla Health Station. Aggregated data on LAA populations and Aboriginal populations also include Gitxaala Nation members (population, core housing need, shelter-cost-to-income ratio [STIR]). The description of existing levels of service and capacity related to community, health care and transportation infrastructure and services within Prince Rupert, as accessed by Gitxaala Members, is also relevant to Gitxaala Nation. For additional consideration of Gitxaala-specific information, see the "Review of the Potential Risks, Impacts and Opportunities of the Aurora LNG Project for Gitxaala Nation Report" technical memo and the "Response to Gitxaala Nation's Review of the Aurora LNG Environmental Assessment" technical memo. These technical memos will be filed with the BC EAO.
1944.1	round 1	Gitxaala Nation	6.3.2.3	Infrastructure and Services	It is not clear what information specific to Gitxaala was referenced for this chapter.	The description of existing conditions within the LAA and RAA includes disaggregated data from Statistics Canada on population demographics and housing and accommodations and information from Gitxaala Nation on the Kitkatla Health Station. Aggregated data on LAA populations and Aboriginal populations also include Gitxaala Nation members (population, core housing need, shelter-cost-to-income ratio [STIR]). The description of existing levels of service and capacity related to community, health care and transportation infrastructure and services within Prince Rupert, as accessed by Gitxaala Members, is also relevant to Gitxaala Nation. For additional consideration of Gitxaala-specific information, see the "Review of the Potential Risks, Impacts and Opportunities of the Aurora LNG Project for Gitxaala Nation Report" technical memo and the "Response to Gitxaala Nation's Review of the Aurora LNG Environmental Assessment" technical memo. These technical memos will be filed with the BC EAO.
1945.1	round 1	Gitxaala Nation	6.3.2.5	Infrastructure and Services	**Technical Boundaries** regarding the shortage of public data on infrastructure and services at levels consistent with LAAs are well documented in many EAs. These gaps could be supplemented by referencing community-level socioeconomic studies or collecting primary data in communities themselves.	The technical boundaries identified in Section 6.6.2.5 of the Application, such as the availability, quality, relevancy and timeliness of baseline data, are documented limitations of the assessment and acknowledged by Aurora LNG. Section 6.6.8 (Prediction Confidence) further recognizes that technical limitations associated with the description of existing conditions affects overall prediction confidence (which is moderate for change in community health and wellness and moderate to high for change in harvested foods).
1946.1	round 1	Gitxaala Nation	6.3.3	Infrastructure and Services	Housing security is a key health determinant for Aboriginal Groups in BC. There is little to no baseline data on housing conditions and security for Gitxaala.	Housing security was not included in the assessment of change in community health and wellness. Housing security was not identified in the AIR as an included topic (see Table 3-2) or measurable parameter (see Table 6-9). See the "Response to the Potential Risks, Impacts and Opportunities of the Aurora LNG Project for Gitxaala Nation" technical memo for consideration of additional baseline information provided in Shandro et al. (2016). The technical memorandum also includes a discussion of whether the additional baseline information affects conclusions presented in the assessment. The technical memo will be filed with the BC EAO.
1947.1	round 1	Gitxaala Nation	6.3.3.2	Infrastructure and Services	Housing security is a key health determinant for Aboriginal Groups in BC. There is little to no baseline data on housing conditions and security for Gitxaala.	Housing security was not included in the assessment of change in community health and wellness. Housing security was not identified in the AIR as an included topic (see Table 3-2) or measurable parameter (see Table 6-9). See the "Response to the Potential Risks, Impacts and Opportunities of the Aurora LNG Project for Gitxaala Nation" technical memo for consideration of additional baseline information provided in Shandro et al. (2016). The technical memo also includes a discussion of whether the additional baseline information affects conclusions presented in the assessment. The technical memo will be filed with the BC EAO.
1948.1	round 1	Gitxaala Nation	6.3.3.2	Infrastructure and Services	**Demand for Health and Social Services**: There is little characterization of the availability of culturally appropriate health and social services for Aboriginal people in the LAA. **Housing:** No data or discussion on housing specific to Gitxaala was included in the baseline section. Some additional qualitative data that could be included in this section can be found in Shandro et al., 2016.	Health and Social Services Baseline information, in sufficient detail to support the assessment of Project residual and cumulative residual effects on health care infrastructure and services within the LAA and RAA, is provided in Section 6.3.3.2 subsection Health Care Infrastructure and Services. Additional information on health care infrastructure and services, including Gitxaala-specific information, is provided in the "Supplemental Baseline Information for Infrastructure and Services" technical memo. The memo also includes a discussion as to whether the supplemental information affects the conclusions of the VC. Housing See the "Response to the Potential Risks, Impacts and Opportunities of the Aurora LNG Project for Gitxaala Nation" technical memo for consideration of additional baseline information provided in Shandro et al. (2016). The technical memorandum also includes a discussion of whether baseline the supplemental information affects conclusions presented in the VC. The technical memos will be filed with the BC EAO.
1949.1	round 1	Gitxaala Nation	6.3.5	Infrastructure and Services	It is difficult to assess the impacts of the project on housing without specific baseline data on housing conditions for rural Aboriginal communities like Gitxaala.	Baseline information on housing and accommodations is provided in Section 6.3.3.2 (subsection 'Housing and Accommodations'). Additional baseline information on housing provided by Gitxaala in the report "Potential Risks, Impacts and Opportunities for the Aurora LNG Project for Gitxaala Nation" is provided in the "Response to the Potential Risks, Impacts and Opportunities of the Aurora LNG Project for Gitxaala Nation" technical memo. The technical memo includes a discussion as to whether the additional information affects the conclusions of the Application. The technical memo will be filed with the BC EAO.
1950.1	round 1	Gitxaala Nation	6.3.5.2	Infrastructure and Services	Housing: There is no discussion of steps taken to minimize the adverse effects of increased housing demand on vulnerable individuals and groups, given that the baseline identifies an increasing trend of households with core housing need (estimated 15% of households according to 2011 figures). Health and Social Services: The proponent proposes reasonable mitigation measures to mitigate adverse effects on health and social services. However, residual effects are identified to be moderate to high. A community health surveillance system is necessary to monitor these effects over the project lifecycle. In addition, engagement and collaboration with local health service providers and health authorities is required to address any issues that emerge in relation to the identified residual impacts. See Memo "0217_AGIforGitxaala_Social Impacts" for more details. Mitigation Measures: See Memo "0217_AGIforGitxaala_Social Impacts" for comments on mitigation measures.	Summarized through baseline information presented in Section 6.3.3.2 (subsection 'Housing and Accommodations'; and further qualified in the "Supplemental Information for Infrastructure and Services"" technical memo and characterized in Sections 6.3.5 and 6.3.6, adverse effects on accommodations are anticipated to occur within a socio-economic context that has moderate resiliency (the LAA) and low resiliency (the RAA) to change. As such, the predicted residual and cumulative effects on accommodations would occur within a baseline setting that is sensitive to change. This understanding is applied across the population of the LAA and RAA. Disaggregated characterizations are not provided for vulnerable populations. Mitigation Measures 6.3.1 (Social Management Plan [SMP]) requires Aurora LNG to engage with concerned stakeholders, Working Group members (e.g., Northern Health) and Aboriginal Groups to develop metrics used to monitor changes in demand on infrastructure and services (e.g., health care infrastructure and services). On-going monitoring of changes in health status is completed at the federal and provincial level. Federally, Health Canada, Statistics Canada and the Canadian Institute for Health Information monitor and report on various measures of health status. Provincially, BC Stats, the Provincial Health Services Authority, Local Health Authorities (e.g., Northern Health) and the Aboriginal Health Authority monitor and report on various measures of health status. Also see the "Response to Gitxaala Nation's Review of the Aurora LNG Environmental Assessment" technical memo for consideration of the referenced memo '0217_AGIforGitxaala_Social Impacts'. The technical memos will be filed with the BC EAO.
1951.1	round 1	Gitxaala Nation	6.3.5.3	Infrastructure and Services	Housing: There is no discussion of steps taken to minimize the adverse effects of increased housing demand on vulnerable individuals and groups, given that the baseline identifies an increasing trend of households with core housing need (estimated 15% of households according to 2011 figures). Health and Social Services: The proponent proposes reasonable mitigation measures to mitigate adverse effects on health and social services. However, residual effects are identified to be moderate to high. A community health surveillance system is necessary to monitor these effects over the project lifecycle. In addition, engagement and collaboration with local health service providers and health authorities is required to address any issues that emerge in relation to the identified residual impacts. See Memo "0217_AGIforGitxaala_Social Impacts" for more details. Mitigation Measures: See Memo "0217_AGIforGitxaala_Social Impacts" for comments on mitigation measures.	Summarized through baseline information presented in Section 6.3.3.2 (subsection 'Housing and Accommodations'; and further qualified in the "Supplemental Baseline Information for Infrastructure and Services"" technical memo and characterized in Sections 6.3.5 and 6.3.6, adverse effects on accommodations are anticipated to occur within a socio-economic context that has moderate resiliency (the LAA) and low resiliency (the RAA) to change. As such, the predicted residual and cumulative effects on accommodations would occur within a baseline setting that is sensitive to change. This understanding is applied across the population of the LAA and RAA. Disaggregated characterizations are not provided for vulnerable populations. Mitigation Measures 6.3.1 (Social Management Plan [SMP]) requires Aurora LNG to engage with concerned stakeholders, Working Group members (e.g., Northern Health) and Aboriginal Groups to develop metrics used to monitor changes in demand on infrastructure and services (e.g., health care infrastructure and services). On-going monitoring of changes in health status is completed at the federal and provincial level. Federally, Health Canada, Statistics Canada and the Canadian Institute for Health Information monitor and report on various measures of health status. Provincially, BC Stats, the Provincial Health Services Authority, Local Health Authorities (e.g., Northern Health) and the Aboriginal Health Authority monitor and report on various measures of health status. Also see the "Response to Gitxaala Nation's Review of the Aurora LNG Environmental Assessment" technical memo for consideration of the referenced memo '0217_AGIforGitxaala_Social Impacts'. The technical memos will be filed with the BC EAO.
1952.1	round 1	Gitxaala Nation	6.3.5.4	Infrastructure and Services	Housing: There is no discussion of steps taken to minimize the adverse effects of increased housing demand on vulnerable individuals and groups, given that the baseline identifies an increasing trend of households with core housing need (estimated 15% of households according to 2011 figures). Health and Social Services: The proponent proposes reasonable mitigation measures to mitigate adverse effects on health and social services. However, residual effects are identified to be moderate to high. A community health surveillance system is necessary to monitor these effects over the project lifecycle. In addition, engagement and collaboration with local health service providers and health authorities is required to address any issues that emerge in relation to the identified residual impacts. See Memo "0217_AGIforGitxaala_Social Impacts" for more details. Mitigation Measures: See Memo "0217_AGIforGitxaala_Social Impacts" for comments on mitigation measures.	Summarized through baseline information presented in Section 6.3.3.2 (subsection 'Housing and Accommodations'; and further qualified in the "Supplemental Baseline Information for Infrastructure and Services"" technical memo and characterized in Sections 6.3.5 and 6.3.6, adverse effects on accommodations are anticipated to occur within a socio-economic context that has moderate resiliency (the LAA) and low resiliency (the RAA) to change. As such, the predicted residual and cumulative effects on accommodations would occur within a baseline setting that is sensitive to change. This understanding is applied across the population of the LAA and RAA. Disaggregated characterizations are not provided for vulnerable populations. Mitigation Measures 6.3.1 (Social Management Plan [SMP]) requires Aurora LNG to engage with concerned stakeholders, Working Group members (e.g., Northern Health) and Aboriginal Groups to develop metrics used to monitor changes in demand on infrastructure and services (e.g., health care infrastructure and services). On-going monitoring of changes in health status is completed at the federal and provincial level. Federally, Health Canada, Statistics Canada and the Canadian Institute for Health Information monitor and report on various measures of health status. Provincially, BC Stats, the Provincial Health Services Authority, Local Health Authorities (e.g., Northern Health) and the Aboriginal Health Authority monitor and report on various measures of health status. Also see the "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment" technical memo for consideration of the referenced memo '0217_AGIforGitxaala_Social Impacts'. The technical memos will be filed with the BC EAO.
1953.1	round 1	Gitxaala Nation	6.3.5.5	Infrastructure and Services	Housing: There is no discussion of steps taken to minimize the adverse effects of increased housing demand on vulnerable individuals and groups, given that the baseline identifies an increasing trend of households with core housing need (estimated 15% of households according to 2011 figures). Health and Social Services: The proponent proposes reasonable mitigation measures to mitigate adverse effects on health and social services. However, residual effects are identified to be moderate to high. A community health surveillance system is necessary to monitor these effects over the project lifecycle. In addition, engagement and collaboration with local health service providers and health authorities is required to address any issues that emerge in relation to the identified residual impacts. See Memo "0217_AGIforGitxaala_Social Impacts" for more details. Mitigation Measures: See Memo "0217_AGIforGitxaala_Social Impacts" for comments on mitigation measures.	Summarized through baseline information presented in Section 6.3.3.2 (subsection 'Housing and Accommodations'; and further qualified in the "Supplemental Baseline Information for Infrastructure and Services"" technical memo and characterized in Sections 6.3.5 and 6.3.6, adverse effects on accommodations are anticipated to occur within a socio-economic context that has moderate resiliency (the LAA) and low resiliency (the RAA) to change. As such, the predicted residual and cumulative effects on accommodations would occur within a baseline setting that is sensitive to change. This understanding is applied across the population of the LAA and RAA. Disaggregated characterizations are not provided for vulnerable populations. Mitigation Measures 6.3.1 (Social Management Plan [SMP]) requires Aurora LNG to engage with concerned stakeholders, Working Group members (e.g., Northern Health) and Aboriginal Groups to develop metrics used to monitor changes in demand on infrastructure and services (e.g., health care infrastructure and services). On-going monitoring of changes in health status is completed at the federal and provincial level. Federally, Health Canada, Statistics Canada and the Canadian Institute for Health Information monitor and report on various measures of health status. Provincially, BC Stats, the Provincial Health Services Authority, Local Health Authorities (e.g., Northern Health) and the Aboriginal Health Authority monitor and report on various measures of health status. Also see the "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment" technical memo for consideration of the referenced memo '0217_AGIforGitxaala_Social Impacts'. The technical memos will be filed with the BC EAO.
1954.1	round 1	Gitxaala Nation	6.3.9	Infrastructure and Services	See Memo "0217_AGIforGitxaala_Social Impacts."	See the "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment" technical memo which will be filed with the BC EAO.
1955.1	round 1	Gitxaala Nation	6.3.10	Infrastructure and Services	See Memo "0217_AGIforGitxaala_Social Impacts."	See the "Response to Gitxaala Nation's Review of the Aurora LNG Environmental Assessment" technical memo which will be filed with the BC EAO.
1956.1	round 1	Gitxaala Nation	6.4.2.2	Land and Resource Use	Shandro et al., 2016 is not referenced here.	See the "Response to the Potential Risks, Impacts and Opportunities of the Aurora LNG Project for Gitxaala Nation" technical memo which will be filed with the BC EAO.
1957.1	round 1	Gitxaala Nation	6.4.2.3	Land and Resource Use	Shandro et al., 2016 is not referenced here.	See the "Response to the Potential Risks, Impacts and Opportunities of the Aurora LNG Project for Gitxaala Nation Report" technical memo which will be filed with the BC EAO.
1958.1	round 1	Gitxaala Nation	6.4.5.3	Land and Resource Use	Existing Land Use Planning: "Effects related to existing land use planning will be managed through the implementation of mitigation measures identified in the relevant plans through the permitting process required by the BC OGC" (6.4-59). It is unclear where and how the proponent is addressing any potential conflicts of the project with the objectives of the North Coast LRMP, in which Gitxaala and other First Nations may have defined interests. Mitigation Measures: See Memo "0217_AGIforGitxaala_Social Impacts" for further details.	See Section 6.4.3.3 subsection 'North Coast LRMP' for a detailed description of the North Coast LRMP (as replaced by the Great Bear Rainforest Land Use Order) as it relates to the Project's spatial boundaries. Also see Section 6.4.5.2 subsection 'Land Use Planning Areas' for a description of Project interactions with land and resource use management plans. From Section 6.4.5.2, The PDA and LAA are located within identified planning areas, including those established under the North Coast Land and Resource Management Plan; however, these planning areas do not preclude development when defined mitigation measures are applied and appropriate permits are obtained. Effects related to existing land use planning will be managed through the implementation of mitigation measures identified in the relevant plans through the permitting process required by the BC OGC. Also see the "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment" technical memo which will be filed with the BC EAO.
1959.1	round 1	Gitxaala Nation	6.4.5.4	Land and Resource Use	Existing Land Use Planning: "Effects related to existing land use planning will be managed through the implementation of mitigation measures identified in the relevant plans through the permitting process required by the BC OGC" (6.4-59). It is unclear where and how the proponent is addressing any potential conflicts of the project with the objectives of the North Coast LRMP, in which Gitxaala and other First Nations may have defined interests. Mitigation Measures: See Memo "0217_AGIforGitxaala_Social Impacts" for further details.	See Section 6.4.3.3 subsection 'North Coast LRMP' for a detailed description of the North Coast LRMP (as replaced by the Great Bear Rainforest Land Use Order) as it relates to the Project's spatial boundaries. Also see Section 6.4.5.2 subsection 'Land Use Planning Areas' for a description of Project interactions with land and resource use management plans. From Section 6.4.5.2, The PDA and LAA are located within identified planning areas, including those established under the North Coast Land and Resource Management Plan; however, these planning areas do not preclude development when defined mitigation measures are applied and appropriate permits are obtained. Effects related to existing land use planning will be managed through the implementation of mitigation measures identified in the relevant plans through the permitting process required by the BC OGC. Also see the "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment" technical memo which will be filed with the BC EAO.

1960.1	round 1	Gitxaala Nation	6.4.10	Land and Resource Use	See Memo: "0217_AGIforGitxaala_Social Impacts."	See the "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment" technical memo which will be filed with the BC EAO.
1961.1	round 1	Gitxaala Nation	6.4.9	Land and Resource Use	See Memo: "0217_AGIforGitxaala_Social Impacts."	See the "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment" technical memo which will be filed with the BC EAO.
1962.1	round 1	Gitxaala Nation	6.5.2.2	Marine Use and Navigable Waters	Shandro et al., 2016 is not referenced here.	See the "Aurora LNG Response to Gitxaala Report: Potential Risks, Impacts and Opportunities of the Aurora LNG Project for Gitxaala Nation" technical memo which will be filed with the BC EAO.
1963.1	round 1	Gitxaala Nation	6.5.2.3	Marine Use and Navigable Waters	Shandro et al., 2016 is not referenced here.	See the "Response to the Potential Risks, Impacts and Opportunities of the Aurora LNG Project for Gitxaala Nation Report" technical memo which will be filed with the BC EAO.
1964.1	round 1	Gitxaala Nation	6.5.5.2	Marine Use and Navigable Waters	The proponent should outline the communications strategy for relevant information reaching marine users and also implement a monitoring system. The monitoring system should ensure that unmitigated worse-case adverse impacts (loss of up to one hour of fishing per day) are as expected and do not exceed these projections regularly. If the disturbance is greater than expected, mitigation measures will need to be evaluated and adjusted. This can be done only through a system for monitoring.	The Marine Activities Plan will provide a framework for adaptive management measures to be implemented. Aurora LNG's framework for adaptive management is as follows: The Marine Activities Plan, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plan will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plan will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended). At present, Aurora LNG does not propose any formal follow-up monitoring plans for effects on fishers, but remains open to working with regulators and Aboriginal Groups to develop the Marine Activities Plan (further details of the Marine Activities Plan is provided below). As described in Section 6.5.3.3 and 14.11 of the Application, Aurora LNG will develop a Marine Activities Plan (Mitigation 6.5.2) to describe how the Project's marine activities will be managed to avoid or reduce effects on current marine users and other stakeholders. Aurora LNG proposes to develop this plan in consultation with regulatory agencies, Aboriginal Groups, marine users, and other interested stakeholders. The safe-shipping workshops and the TERMPOL study are expected to lead to recommendations regarding such issues as ship design/operation, terminal design, navigational routes, risks and accident avoidance, and pollution prevention. More information on the nature of the Marine Activities Plan will be shared as it becomes available.
1965.1	round 1	Gitxaala Nation	6.5.5.3	Marine Use and Navigable Waters	The proponent should outline the communications strategy for relevant information reaching marine users and also implement a monitoring system. The monitoring system should ensure that unmitigated worse-case adverse impacts (loss of up to one hour of fishing per day) are as expected and do not exceed these projections regularly. If the disturbance is greater than expected, mitigation measures will need to be evaluated and adjusted. This can be done only through a system for monitoring.	The Marine Activities Plan will provide a framework for adaptive management measures to be implemented. Aurora LNG's framework for adaptive management is as follows: The Marine Activities Plan, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plan will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plan will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended). At present, Aurora LNG does not propose any formal follow-up monitoring plans for effects on fishers, but remains open to working with regulators and Aboriginal Groups to develop the Marine Activities Plan (further details of the Marine Activities Plan is provided below). As described in Section 6.5.3.3 and 14.11 of the Application, Aurora LNG will develop a Marine Activities Plan (Mitigation 6.5.2) to describe how the Project's marine activities will be managed to avoid or reduce effects on current marine users and other stakeholders. Aurora LNG proposes to develop this plan in consultation with regulatory agencies, Aboriginal Groups, marine users, and other interested stakeholders. The safe-shipping workshops and the TERMPOL study are expected to lead to recommendations regarding such issues as ship design/operation, terminal design, navigational routes, risks and accident avoidance, and pollution prevention. More information on the nature of the Marine Activities Plan will be shared as it becomes available.
1966.1	round 1	Gitxaala Nation	6.6.2.2	Community Health	Shandro et al., 2016 is not referenced here.	See the "Response to the Potential Risks, Impacts and Opportunities of the Aurora LNG Project for Gitxaala Nation Report" technical memo which will be filed with the BC EAO.
1967.1	round 1	Gitxaala Nation	6.6.2.3	Community Health	Shandro et al., 2016 is not referenced here.	See the "Response to the Potential Risks, Impacts and Opportunities of the Aurora LNG Project for Gitxaala Nation Report" technical memo which will be filed with the BC EAO.
1968.1	round 1	Gitxaala Nation	6.6.2.5	Community Health	**Spatial Boundaries** for the LAA are too broad. It is difficult to discuss community health figures and statistics of this diverse area as a single geographical unit, as it contains urban, rural, Aboriginal and non-Aboriginal communities. **Technical Boundaries** regarding the shortage of public data on psychological well-being and socioeconomic factors at levels consistent with LAAs are well documented in many EAs. These gaps could be supplemented by referencing community-level studies on health and well-being or collecting primary data in communities themselves.	The spatial boundaries used in the assessment of change in community health and wellness and change in harvested foods (as provided in Table 6.6-2) align with those established in the AIR (specifically, Tables 3-3 and 6-9). The technical boundaries identified in Section 6.6.2.5, such as the availability, quality, relevancy and timeliness of baseline data, are documented limitations of the assessment and acknowledged by Aurora LNG. Section 6.6.8 (Prediction Confidence) further recognizes that technical limitations associated with the description of existing conditions affects overall prediction confidence (which is moderate for change in community health and wellness and moderate to high for change in harvested foods).
1969.1	round 1	Gitxaala Nation	6.6.2.8	Community Health	The threshold on community health and wellness does not consider the need to evaluate the effectiveness of mitigation measures regarding community health and wellness before considering whether or not effects can be managed by adjustments to programs, policies, plans, or other mitigation. This threshold depends substantially on the implementation of a detailed community health monitoring system.	The assessment of change in community health and wellness considers both the expected success of the proposed mitigation measures as well as the risk and uncertainty regarding the successful implementation of the proposed mitigation measures (see Table 6.6-18 under the column 'Expected Success/Risk and Uncertainty'). This information is then used to inform the characterization of Project residual effects and cumulative residual effects from which the significance determinations are made (see Section 6.6.7). Regarding community health monitoring, while not specifically identified as a proposed mitigation measure, mitigation measures identified in Table 6.6-18 are included in higher-level plans (e.g., the Health and Medical Services Plan, and Social Management Plan [SMP]) which include varying levels of monitoring. These higher-level plans are identified in Table 6.6-18 under the column 'Management and/or Compensation Plans' with additional information provided in Section 14. In particular, mitigation Measures 6.3.1 (SMP) requires Aurora LNG to engage with concerned stakeholders, Working Group members (e.g., Northern Health) and Aboriginal Groups to develop metrics used to monitor changes in demand on infrastructure and services (e.g., health care infrastructure and services). On-going monitoring of changes in health status is completed at the federal and provincial level. Federally, Health Canada, Statistics Canada and the Canadian Institute for Health Information monitor and report on various measures of health status. Provincially, BC Stats, the Provincial Health Services Authority, Local Health Authorities (e.g., Northern Health) and the Aboriginal Health Authority monitor and report on various measures of health status.
1970.1	round 1	Gitxaala Nation	6.6.3	Community Health	There is virtually no baseline data cited that relates specifically to Gitxaala. While it is understood that data at this geographic level is difficult to obtain from public databases, the LAA is quite diverse, including urban and rural areas and Aboriginal and non-Aboriginal communities. The baseline data discussed here does not necessarily reflect conditions in Gitxaala. Baseline data on key issues such as health status, family and household dynamics, sense of community belonging, crime, vulnerable populations, and food security are not specified for Gitxaala or any other Aboriginal communities. There is no reference to Shandro et al., 2016 in this section. Determinants of health included for assessment are limited and do not reflect the breadth of potential impacts specific to Gitxaala Nation as identified in Shandro et al., 2016. Refer to Memo "0217_AGIforGitxaala_Social Impacts" or Shandro et al., 2016 for further comments.	As noted in the comment, baseline information specific to Gitxaala Nation is limited and not readily available; however, baseline data presented at the Local Health Area (LHA) and Northwest Regional Health Service Delivery Area (NW HSDA) includes consideration of Aboriginal and non-Aboriginal populations, including Gitxaala members, within the LAA and RAA (see Section 6.6.2.5). The baseline overview provided in Section 6.6.3 therefore provides an accurate characterization of conditions at the aggregate LAA and RAA level from which effects on community health and wellness are assessed. While adverse effects are assessed at the LAA and RAA level, where appropriate, differing characterizations are provided for vulnerable populations, such as Aboriginal Groups, in recognition of the potential for these populations to be disproportionately affected. Aurora LNG acknowledges that not all social determinants of health are assessed. See the "Response to Potential Risks, Impacts and Opportunities of the Aurora LNG Project for Gitxaala Nation Report" technical memo for consideration of the referenced Shandro et al. 2016 report. This technical memo includes a discussion of Gitxaala provided baseline information and social determinants of health and whether this information affects the conclusions presented in Section 6.6 of the Application. Also see the "Response to Gitxaala Nation's Review of the Aurora LNG Environmental Assessment" technical memo for consideration of the referenced memo '0217_AGIforGitxaala_Social Impact'. The technical memos will be filed with the BC EAO.
1971.1	round 1	Gitxaala Nation	6.6.4	Community Health	Several project activities, specifically natural gas pre-treatment, LNG production, and waste management are not considered to have interactions with harvested foods. Adherence to federal and provincial guidelines are expected to mitigate any interaction. However the proponent should have a very clear plan on emergency response and communications in case of unexpected events in order to keep Gitxaala and local emergency response authorities informed on any potential impacts from these activities. Refer to comments on Accidents and Malfunctions.	Through mitigation 6.3.8, an Emergency Response Plan will be developed and implemented. The Emergency Response Plan (ERP) will describe the procedures to be implemented to respond to all incidents and emergencies, which will be submitted to the BC OGC under s.8 of the Liquefied Natural Gas Facilities Regulation. (see Section 14.16). The ERP will be developed in consultation with regulators, Aboriginal Groups, and interested stakeholders. The ERP will be prepared according to the guidance found in Emergency Preparedness and Response for Petroleum and Natural Gas Industry Systems (CAN/CSA-Z246.2-14). Protection of the environment will be one of several priorities of the plan.
1972.1	round 1	Gitxaala Nation	6.6.5.1	Community Health	Vulnerable Groups: The application identifies the following vulnerable groups: children and youth, women, seniors, Aboriginal persons, individuals and households on fixed incomes; low income earners; marginally housed, homeless, or at-risk individuals, and households; temporarily housed individuals and households;and other groups with lack of secure housing tenure. While the chapter concludes that vulnerable groups and individuals may experience disproportionate adverse effects, we question whether mitigation measures proposed are strong enough to minimize these. See Memo "0217_AGIforGitxaala_Social Impacts" for comments on vulnerable groups and mitigation measures. Gender is not discussed in detail in the residual effects on social support networks section. While the proponent proposes an employee assistance program to mitigate impacts to social support networks, there is no means to verify whether this program will mitigate potential adverse outcomes related to domestic violence and alcohol and drug abuse without a monitoring system in place. Emotional Stress and Mental Health; Communicable Disease; Crime and Substance Abuse; Housing: These issues are discussed in Section 6.6.5.3 and are important health outcomes (as well as determinants) for First Nations in BC. Some appropriate mitigation measures are proposed, including employee support programs; onsite camp lodgings and basic first aid services; worker codes of conduct; project orientation; and a number of measures to minimize changes in environmental quality that may adversely affect levels of stress and anxiety. However it is impossible to monitor the presence of potential adverse impacts or the effectiveness of these measures in addressing them without a community health monitoring system in place. Mitigation Measures: Refer to Memo "0217_AGIforGitxaala_Social Impacts."	As part of Aurora LNG's conservative assessment approach, vulnerable populations include multiple measurable parameters, including women. As noted is Section 6.6.5.2 of the Application, where disproportionate effects could be realized by vulnerable populations (e.g., women) disaggregated characterizations have been provided. The disaggregated characterizations are provided for 'communicable diseases and STIs', 'Income and Social Status', 'Personal Health Practices and Coping Skills'. Noted in Table 6.6-6, Aurora LNG is an equal opportunity employer; therefore, for assessment of the determinant of health (DOH) gender is not included. However, the assessment of change in community health and wellness considers changes in the demographic composition of LAA communities (which informs other DOH assessed in Section 6.6). Stated in Section 6.6.5.3 (subsection 'Presence of Workers') mobile oil and gas workers tend to be primarily non-Aboriginal males, over the age of 35, half of whom are married or in a common-law relationship. Therefore, during the construction phase, a substantial increase in the proportion of non-Aboriginal males in the LAA will occur; most of these individuals will be FIFO workers. Mitigation measures proposed by Aurora LNG in Table 6.6-18, such as the employee assistance program (mitigation 6.6.1), worker code of conduct and orientation (mitigation 6.3.3) will be further refined and, where applicable, captured as part of the Social Management Plan (SMP; mitigation 6.3.1). Noted in Section 14.12, the SMP will include metrics from which to measure changes in baseline conditions due to Project-related effects on infrastructure and services. While metrics used in the SMP will not directly align with determinants of health (DOH) assessed in Section 6.6 (i.e., Income and Social Status, Social Support Networks, Social Environments, Personal Health Practices and Coping Skills), indicators associated with these DOH could be included in the SMP. For example, indicators associated with 'social environments' such as crime rates and indicators associated with 'personal health practices and coping skills' such as hospital registrations related to drug and alcohol (if made available by Northern Health) could be included in the SMP. Noted in Section 14.12 development of the SMP, including selection of metrics, will be informed through engagement with regulators, Aboriginal Groups, and interested stakeholders. In consideration of the conservative approach taken in the assessment of change in community health and wellness, the mitigation measures proposed in Table 6.6-18 and commitments to ongoing engagement and monitoring through the SMP, Aurora LNG is confident that the proposed mitigation measures will reduce the magnitude of predicted adverse Project effects on community health and wellness within the LAA (including vulnerable populations). Also, see the "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment' technical memo with respect to the referenced memo '0217_AGIforGitxaala_Social Impacts'. The technical memo will be filed with the BC EAO.

1973.1	round 1	Gitxaala Nation	6.6.5.2	Community Health	Vulnerable Groups: The application identifies the following vulnerable groups: children and youth, women, seniors, Aboriginal persons, individuals and households on fixed incomes; low income earners; marginally housed, homeless, or at-risk individuals, and households; temporarily housed individuals and households;and other groups with lack of secure housing tenure. While the chapter concludes that vulnerable groups and individuals may experience disproportionate adverse effects, we question whether mitigation measures proposed are strong enough to minimize these. See Memo "0217_AGIforGitxaala_Social Impacts" for comments on vulnerable groups and mitigation measures. Gender is not discussed in detail in the residual effects on social support networks section. While the proponent proposes an employee assistance program to mitigate impacts to social support networks, there is no means to verify whether this program will mitigate potential adverse outcomes related to domestic violence and alcohol and drug abuse without a monitoring system in place. Emotional Stress and Mental Health; Communicable Disease; Crime and Substance Abuse; Housing: These issues are discussed in Section 6.6.5.3 and are important health outcomes (as well as determinants) for First Nations in BC. Some appropriate mitigation measures are proposed, including employee support programs; onsite camp lodgings and basic first aid services; worker codes of conduct; project orientation; and a number of measures to minimize changes in environmental quality that may adversely affect levels of stress and anxiety. However it is impossible to monitor the presence of potential adverse impacts or the effectiveness of these measures in addressing them without a community health monitoring system in place. Mitigation Measures: Refer to Memo "0217_AGIforGitxaala_Social Impacts."	As part of Aurora LNG's conservative assessment approach, vulnerable populations include multiple measurable parameters, including women. As noted is Section 6.6.5.2 of the Application, where disproportionate effects could be realized by vulnerable populations (e.g., women) disaggregated characterizations have been provided. The disaggregated characterizations are provided for 'communicable diseases and STIs', 'Income and Social Status', 'Personal Health Practices and Coping Skills'. Noted in Table 6.6-6, Aurora LNG is an equal opportunity employer; therefore, for assessment of the determinant of health (DOH) gender is not included. However, the assessment of change in community health and wellness considers changes in the demographic composition of LAA communities (which informs other DOH assessed in Section 6.6). Stated in Section 6.6.5.3 (subsection 'Presence of Workers') mobile oil and gas workers tend to be primarily non-Aboriginal males, over the age of 35, half of whom are married or in a common-law relationship. Therefore, during the construction phase, a substantial increase in the proportion of non-Aboriginal males in the LAA will occur; most of these individuals will be FIFO workers. Mitigation measures proposed by Aurora LNG in Table 6.6-18, such as the employee assistance program (mitigation 6.6.1), worker code of conduct and orientation (mitigation 6.3.3) will be further refined and, where applicable, captured as part of the Social Management Plan (SMP; mitigation 6.3.1). Noted in Section 14.12, the SMP will include metrics from which to measure changes in baseline conditions due to Project-related effects on infrastructure and services. While metrics used in the SMP will not directly align with determinants of health (DOH) assessed in Section 6.6 (i.e., Income and Social Status, Social Support Networks, Social Environments, Personal Health Practices and Coping Skills), indicators associated with these DOH could be included in the SMP. For example, indicators associated with 'social environments' such as crime rates and indicators associated with 'personal health practices and coping skills' such as hospital registrations related to drug and alcohol (if made available by Northern Health) could be included in the SMP. Noted in Section 14.12 development of the SMP, including selection of metrics, will be informed through engagement with regulators, Aboriginal Groups, and interested stakeholders. In consideration of the conservative approach taken in the assessment of change in community health and wellness, the mitigation measures proposed in Table 6.6-18 and commitments to ongoing engagement and monitoring through the SMP, Aurora LNG is confident that the proposed mitigation measures will reduce the magnitude of predicted adverse Project effects on community health and wellness within the LAA (including vulnerable populations). Also, see the "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment' technical memo with respect to the referenced memo '0217_AGIforGitxaala_Social Impacts'. The technical memo will be filed with the BC EAO.
1974.1	round 1	Gitxaala Nation	6.6.5.3	Community Health		No comment provided.
1975.1	round 1	Gitxaala Nation	6.6.5.4	Community Health	Vulnerable Groups: The application identifies the following vulnerable groups: children and youth, women, seniors, Aboriginal persons, individuals and households on fixed incomes; low income earners; marginally housed, homeless, or at-risk individuals, and households; temporarily housed individuals and households;and other groups with lack of secure housing tenure. While the chapter concludes that vulnerable groups and individuals may experience disproportionate adverse effects, we question whether mitigation measures proposed are strong enough to minimize these. See Memo "0217_AGIforGitxaala_Social Impacts" for comments on vulnerable groups and mitigation measures. Gender is not discussed in detail in the residual effects on social support networks section. While the proponent proposes an employee assistance program to mitigate impacts to social support networks, thee is no means to verify whether this program will mitigate potential adverse outcomes related to domestic violence and alcohol and drug abuse without a monitoring system in place. Emotional Stress and Mental Health; Communicable Disease; Crime and Substance Abuse; Housing: These issues are discussed in Section 6.6.5.3 and are important health outcomes (as well as determinants) for First Nations in BC. Some appropriate mitigation measures are proposed, including employee support programs; onsite camp lodgings and basic first aid services; worker codes of conduct; project orientation; and a number of measures to minimize changes in environmental quality that may adversely affect levels of stress and anxiety. However it is impossible to monitor the presence of potential adverse impacts or the effectiveness of these measures in addressing them without a community health monitoring system in place. Mitigation Measures: Refer to Memo "0217_AGIforGitxaala_Social Impacts."	As part of Aurora LNG's conservative assessment approach, vulnerable populations include multiple measurable parameters, including women. As noted is Section 6.6.5.2 of the Application, where disproportionate effects could be realized by vulnerable populations (e.g., women) disaggregated characterizations have been provided. The disaggregated characterizations are provided for 'communicable diseases and STIs', 'Income and Social Status', 'Personal Health Practices and Coping Skills'. However, the assessment of change in community health and wellness considers changes in the demographic composition of LAA communities (which informs other DOH assessed in Section 6.6). Stated in Section 6.6.5.3 (subsection 'Presence of Workers') mobile oil and gas workers tend to be primarily non-Aboriginal males, over the age of 35, half of whom are married or in a common-law relationship. Therefore, during the construction phase, a substantial increase in the proportion of non-Aboriginal males in the LAA will occur; most of these individuals will be FIFO workers. Mitigation measures proposed by Aurora LNG in Table 6.6-18, such as the employee assistance program (mitigation 6.6.1), worker code of conduct and orientation (mitigation 6.3.3) will be further refined and, where applicable, captured as part of the Social Management Plan (SMP; mitigation 6.3.1). Noted in Section 14.12, the SMP will include metrics from which to measure changes in baseline conditions due to Project-related effects on infrastructure and services. While metrics used in the SMP will not directly align with determinants of health (DOH) assessed in Section 6.6 (i.e., Income and Social Status, Social Support Networks, Social Environments, Personal Health Practices and Coping Skills), indicators associated with these DOH could be included in the SMP. For example, indicators associated with 'social environments' such as crime rates and indicators associated with 'personal health practices and coping skills' such as hospital registrations related to drug and alcohol (if made available by Northern Health) could be included in the SMP. Noted in Section 14.12 development of the SMP, including selection of metrics, will be informed through engagement with regulators, Aboriginal Groups, and interested stakeholders. In consideration of the conservative approach taken in the assessment of change in community health and wellness, the mitigation measures proposed in Table 6.6-18 and commitments to ongoing engagement and monitoring through the SMP, Aurora LNG is confident that the proposed mitigation measures will reduce the magnitude of predicted adverse Project effects on community health and wellness within the LAA (including vulnerable populations). Also, see the "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment' technical memo with respect to the referenced memo '0217_AGIforGitxaala_Social Impacts'. The technical memo will be filed with the BC EAO.
1976.1	round 1	Gitxaala Nation	6.6.5.5	Community Health	Vulnerable Groups: The application identifies the following vulnerable groups: children and youth, women, seniors, Aboriginal persons, individuals and households on fixed incomes; low income earners; marginally housed, homeless, or at-risk individuals, and households; temporarily housed individuals and households;and other groups with lack of secure housing tenure. While the chapter concludes that vulnerable groups and individuals may experience disproportionate adverse effects, we question whether mitigation measures proposed are strong enough to minimize these. See Memo "0217_AGIforGitxaala_Social Impacts" for comments on vulnerable groups and mitigation measures. Gender is not discussed in detail in the residual effects on social support networks section. While the proponent proposes an employee assistance program to mitigate impacts to social support networks, there is no means to verify whether this program will mitigate potential adverse outcomes related to domestic violence and alcohol and drug abuse without a monitoring system in place. Emotional Stress and Mental Health; Communicable Disease; Crime and Substance Abuse; Housing: These issues are discussed in Section 6.6.5.3 and are important health outcomes (as well as determinants) for First Nations in BC. Some appropriate mitigation measures are proposed, including employee support programs; onsite camp lodgings and basic first aid services; worker codes of conduct; project orientation; and a number of measures to minimize changes in environmental quality that may adversely affect levels of stress and anxiety. However it is impossible to monitor the presence of potential adverse impacts or the effectiveness of these measures in addressing them without a community health monitoring system in place. Mitigation Measures: Refer to Memo "0217_AGIforGitxaala_Social Impacts."	As part of Aurora LNG's conservative assessment approach, vulnerable populations include multiple measurable parameters, including women. As noted is Section 6.6.5.2 of the Application, where disproportionate effects could be realized by vulnerable populations (e.g., women) disaggregated characterizations have been provided. The disaggregated characterizations are provided for 'communicable diseases and STIs', 'Income and Social Status', 'Personal Health Practices and Coping Skills'. Noted in Table 6.6-6, Aurora LNG is an equal opportunity employer; therefore, for assessment of the determinant of health (DOH) gender is not included. However, the assessment of change in community health and wellness considers changes in the demographic composition of LAA communities (which informs other DOH assessed in Section 6.6). Stated in Section 6.6.5.3 (subsection 'Presence of Workers') mobile oil and gas workers tend to be primarily non-Aboriginal males, over the age of 35, half of whom are married or in a common-law relationship. Therefore, during the construction phase, a substantial increase in the proportion of non-Aboriginal males in the LAA will occur; most of these individuals will be FIFO workers. Mitigation measures proposed by Aurora LNG in Table 6.6-18, such as the employee assistance program (mitigation 6.6.1), worker code of conduct and orientation (mitigation 6.3.3) will be further refined and, where applicable, captured as part of the Social Management Plan (SMP; mitigation 6.3.1). Noted in Section 14.12, the SMP will include metrics from which to measure changes in baseline conditions due to Project-related effects on infrastructure and services. While metrics used in the SMP will not directly align with determinants of health (DOH) assessed in Section 6.6 (i.e., Income and Social Status, Social Support Networks, Social Environments, Personal Health Practices and Coping Skills), indicators associated with these DOH could be included in the SMP. For example, indicators associated with 'social environments' such as crime rates and indicators associated with 'personal health practices and coping skills' such as hospital registrations related to drug and alcohol (if made available by Northern Health) could be included in the SMP. Noted in Section 14.12 development of the SMP, including selection of metrics, will be informed through engagement with regulators, Aboriginal Groups, and interested stakeholders. In consideration of the conservative approach taken in the assessment of change in community health and wellness, the mitigation measures proposed in Table 6.6-18 and commitments to ongoing engagement and monitoring through the SMP, Aurora LNG is confident that the proposed mitigation measures will reduce the magnitude of predicted adverse Project effects on community health and wellness within the LAA (including vulnerable populations). Also, see the "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment' technical memo with respect to the referenced memo '0217_AGIforGitxaala_Social Impacts'. The technical memo will be filed with the BC EAO.
1977.1	round 1	Gitxaala Nation	6.6.9	Community Health	No follow-up programs are proposed for community health. While the proponent states that the social management plan will include performance metrics, it is not clear what data and metrics will be used. Without continuous monitoring of key community health outcomes, it is impossible to assess the effectiveness of any measures proposed to avoid or reduce adverse impacts on community health. See Memo "0217_AGIforGitxaala_Social Impacts".	The Social Management Plan (SMP; see mitigation 6.3.1) will focus on managing direct Project-related effects on community level infrastructure and services. While metrics used in the SMP will not directly align with social determinants of health (SDOH) assessed in Section 6.6 (i.e., Income and Social Status, Social Support Networks, Social Environments, Personal Health Practices and Coping Skills) indicators associated with these SDOH could be included. For example, indicators associated with income and social status such as Project-related employment, and indicators associated with 'social environments' such as crime rates could be included in the SMP. Noted in Section 14.12 development of the SMP, including selection of metrics, will include engagement with regulators, Aboriginal Groups, and interested stakeholders.
1978.1	round 1	Gitxaala Nation	6.6.10	Community Health	No follow-up programs are proposed for community health. While the proponent states that the social management plan will include performance metrics, it is not clear what data and metrics will be used. Without continuous monitoring of key community health outcomes, it is impossible to assess the effectiveness of any measures proposed to avoid or reduce adverse impacts on community health. See Memo "0217_AGIforGitxaala_Social Impacts".	The Social Management Plan (SMP; see mitigation 6.3.1) will focus on managing direct Project-related effects on community level infrastructure and services. While metrics used in the SMP will not directly align with social determinants of health (SDOH) assessed in Section 6.6 (i.e., Income and Social Status, Social Support Networks, Social Environments, Personal Health Practices and Coping Skills) indicators associated with these SDOH could be included. For example, indicators associated with income and social status such as Project-related employment, and indicators associated with 'social environments' such as crime rates could be included in the SMP. Noted in Section 14.12 development of the SMP, including selection of metrics, will include engagement with regulators, Aboriginal Groups, and interested stakeholders.
1979.1	round 1	Gitxaala Nation	8	Human Health	We stress the importance of implementing a community health monitoring system and a mechanism for sharing routine environmental monitoring data in a transparent, timely, and culturally appropriate manner. While a community health monitoring system does not necessarily need to include sampling of human tissues to check for the presence of adverse impacts due to change in air, water, or marine food quality, the timely disclosure of other monitoring data may help mitigate human health impacts perceived by community members. See Memo "0217_AGIforGitxaala_Social Impacts" for details on proposed monitoring programs.	Aurora LNG does not propose follow up or monitoring programs that involve sampling of human tissues. Mitigation Measures 6.3.1 (Social Management Plan commits Aurora LNG to engaging with concerned stakeholders, Working Group members (e.g., Northern Health) and Aboriginal Groups to develop metrics used to monitor changes in demand on infrastructure and services (e.g., health care infrastructure and services). On-going monitoring of changes in health status is already completed at the federal and provincial level. Federally, Health Canada, Statistics Canada and the Canadian Institute for Health Information monitor and report on various measures of health status. Provincially, BC Stats, the Provincial Health Services Authority, Local Health Authorities (e.g., Northern Health) and the Aboriginal Health Authority monitor and report on various measures of health status. The results of monitoring programs will be reported to the required agencies or organizations consistent with any requirements outlined in the conditions of an Environmental Assessment Certificate approval. Also, see the "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment' technical memo with respect to the referenced memo '0217_AGIforGitxaala_Social Impacts. The technical memo will be filed with the BC EAO.
1980.1	round 1	Gitxaala Nation	9	Accidents or Malfunctions	This section fails to assess risks from accidents and malfunctions to Aboriginal Groups, including Gitxaala. It does not reference Shandro et al., 2016. In addition, the mitigation measures outlined in the "Preventative and Response Measures" sections are insufficient. These sections state that Aboriginal Groups will be notified of an incident, but limited additional detail is provided. Finally, the Proponent does not commit to compensating affected communities for adverse impacts related to accidents or malfunctions. While Section 12.4 does identify risk from accidents and malfunctions that are specific to Aboriginal Interests, it similarly does not outline appropriate mitigation or compensation measures.	Potential effects of accidents and malfunctions to Aboriginal Groups are summarized in Sections 11.6 and 12.6 of the Application. Aurora LNG is preparing a memo to provide a summary of its review and analysis of the information presented in the Shandro et al. report. New information contained within the Shandro et al. report that was not previously considered in the Application will be analyzed, and subsequent implications to the conclusions provided in the Application, including any required changes, will be described by Aurora LNG in the memo. The memo will be filed with the BC EAO. In addition, please see the "Accidents or Malfunctions - Effects on Aboriginal Interests or CEAA 2012 Section 5(1)(c) Factors" technical memo which will be filed with the BC EAO which provides more information on methods used by Aurora LNG to summarize interactions between potential accident or malfunction events and Aboriginal Interests or CEAA 2012 section 5(1)(c) factors.
1981.1	round 1	Gitxaala Nation	9.9	Accidents or Malfunctions	Shandro et al. (2016) identfied that Gitxaala people are very concerned about marine vessels grounding. The Application concludes that the likelihood and consequence of residual effects from a grounding incident are very low and, consequently, that the residual effects are not significant. This assessment of risk does not take into consideration baseline information specific to Gitxaala, and therefore inappropriately characterizes the risks for this community. As discussed above, response measures listed are insufficient and do not include the commitment to compensate affected communities.	As described in Section 9.9.4 of the Application, Aurora LNG concluded that an accident scenario involving a vessel grounding or collision may have significant residual effects on marine mammals (for events involving a spill of bunker oil) and on marine birds. Other potential residual effects to assessed VCs from interactions from a vessel grounding or collision event are predicted to not be significant (see Section 9.9.3). In addition, Aurora LNG also includes consideration in Section 12.6 of potential interactions between a vessel grounding or a vessel collision incident and the exercising of Aboriginal Interests. Section 12.6 says the following: "A vessel grounding or collision could interfere with Aboriginal Groups' ability to harvest marine species, including species of cultural or economic importance. In this case, Aboriginal Groups could experience interference with their cultural wellbeing (culturally important species) and their ability to access economic opportunities (commercial fishing). Depending on the scale of a marine emergency response, a vessel collision or grounding could also interfere temporarily with Aboriginal Groups' use of the marine travelways in the vicinity of the event." (page 12-312) Section 11.6 of the Application Aurora LNG also states the following with regard to vessel grounding and collisions: "if such an event were to occur, this may result in significant residual effects to marine mammals and community health (if the event results in a serious injury or loss of human life), and significant residual effects to Aboriginal Current Use or Aboriginal Physical and Cultural Heritage through the loss or change in quality of harvested resources or culturally or spiritually important species." Aurora LNG is preparing a memo to provide a summary of its review and analysis of the Gitxaala-related baseline information presented in the Shandro Report. New information contained within the Shandro Report that was not previously considered in the Application will be analyzed, and subsequent implications to the conclusions provided in the Application, including any required changes, will be described by Aurora LNG in the memo. Please see technical memo titled "Response to Gitxaala Nation's Review of the Aurora LNG Environmental Assessment". This memo will be filed with the BC EAO.

1982.1	round 1	Gitxaala Nation	9.2	Accidents or Malfunctions	**Methods for Assessing the Potential Risk:** As previously stated, the methods used in the Application for risk assessment are problematic, as they do not take into account the vulnerability of Aboriginal Groups and specific sub-populations, such as women and children. The impacts of an accident or malfunction would disproportionately affect vulnerable groups. For example, for a Gitxaala person who relies on traditional food and harvesting for subsistence, the consequences of even one year's worth of reduced fishing would be high or very high. A precautionary approach to risk assessment should be utilized so that appropriate mitigation measures and monitoring systems may be developed. The Application should also provide more detailed justification for the assignment of likelihood and consequence ratings, which incorporates baseline information for Aboriginal Groups and other potentially affected communities. **Emergency Response Measures:** In Section 14, the Application identifies that Aurora LNG will be the primary responder when emergencies or incidents occur and that response protocols will be detailed in the Emergency Response Plan. This plan should characterize existing emergency services in the area, including those available to Aboriginal Groups living on reserve, and outline protocols for collaborating with these emergency service providers, in the event that this is required. We also suggest that the Proponent support and fund industry-specific training to relevant emergency service providers, including first responders in remote communities such as Gitxaala. We recommend that the Emergency Response Plan identify the Proponent's intended sources of funding for emergency response, as well as a commitment to uphold the Polluter Pays Principle (i.e. the party responsible for producing pollution must pay for the damage caused by it) with Full Cost Accounting (i.e. accounting that recognizes the direct and indirect economic, environmental, health and social costs of a project or action). Finally, we recommend that the Emergency Response Plan identify opportunities to involve Aboriginal Groups, including Gitxaala, in emergency planning and response, in recognition of their intimate understanding of the environment, ongoing role in environmental management and stewardship, and to provide economic opportunity to Aboriginal People.	The Application (Section 12.6) describes interactions considered between accidents and malfunctions and Aboriginal Interests. In that section, Aurora LNG concluded that several accidents or malfunctions could interfere with the exercise of Aboriginal Interests. For health risk related to exposure to chemicals in the environment, the risks are assessed based on exposure to humans and vulnerable sub-populations when applicable. Sub-populations are considered when there is a clear line of evidence showing that those populations are more sensitive (e.g., health risk from changes in air quality are based on guidelines to protect health sensitive people with existing respiratory issues and sensitive people such as children and elderly). Health risk from consuming marine foods were based on chemical exposure to both adults and toddlers. Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Emergency Response Plan. Aurora LNG has requested specific feedback on proposed mitigation measures from Gitxaala Nation during Technical Workshops #4 and #5. Aurora LNG is currently reviewing feedback received to date on mitigation measures and any revised or new mitigation measures proposed will be included as part of an updated Table 16-1 and 16-2 to be submitted to the EAO on Day 90. Please also see the "Accidents or Malfunctions - Effects on Aboriginal Interests or CEAA 2012 Section 5(1)(c) Factors" technical memo which will be filed with the BC EAO.
1983.1	round 1	Gitxaala Nation	9.11	Accidents or Malfunctions	See Memo "0217_AGIforGitxaala_Social Impacts" for comments on cumulative effects.	See the "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment" technical memo which will be filed with the BC EAO.
1984.1	round 1	Gitxaala Nation	11.3.2.7	CEAA 2012	The criteria for significance thresholds for Aboriginal Health, Aboriginal Socio-Economic Conditions, and Aboriginal Cultural and Physical Heritage should consider that Aboriginal people may be more vulnerable to adverse impacts to certain VCs outlined in Part B. Qualified professionals involved in determining significance should have familiarity and background with concepts of health and wellness of Aboriginal people.	The Application, including Section 11.3, was developed in accordance with the Application Information Requirements (AIR) and informed by pre-application consultation with Aboriginal Groups (see the Aboriginal Consultation Reports). As outlined in Section 11.3.2.7, the significance determination for Aboriginal Health, Aboriginal Socio-Economic Conditions, and Aboriginal Cultural and Physical Heritage took into account the residual effects characterizations for relevant associated VCs, information provided by Aboriginal groups, as well as whether the residual effect takes place in a context that has low resilience as defined in Table 11.3-6. The effect was considered significant if a key component (Table 11.3-2) that is relevant to Aboriginal Health, Aboriginal Socio-Economic Conditions and Aboriginal Cultural and Physical Heritage would have a substantial effect on Aboriginal people's health, socio-economics or cultural and physical heritage beyond that considered in the VC analysis in Part B of the Application. In applying the six step framework detailed in Section 11.3.5.1 (Method for the Assessment of Residual Effects), where it was determined that the interactions would be consistent for Aboriginal people as non-Aboriginal people, the assessment focused on the conclusions originally described for the relevant VCs. In particular, the assessment focused on the following approaches taken in the relevant VC assessments: Human Health receptor sites used in the Human Health assessment included places where health-sensitive people are present (e.g., daycares, schools, hospitals, elderly care homes) The Community Health assessment considers effects on vulnerable populations, including: children and youth, women, seniors, Aboriginal persons, individuals and households on fixed incomes, individuals and households classified as low-income earners, marginally-housed individuals, and individuals classified as homeless. Visual Quality viewpoints were determined in consultation with Aboriginal Groups and are relevant to any land or marine user. The thresholds used in the Acoustic Environment assessment are guidelines set forth by regulators and do not differ for Aboriginal and non-Aboriginal people. Additional information sources, not included in the VC assessments, were considered to determine if the predicted residual effects would be consistent for Aboriginal and non-Aboriginal peoples. See steps 3-6 outlined in Section 11.3.5.1 and illustrated in Figure 11.3-5. Aurora LNG is confident that the assessment methodology for Section 5(1)(c) Effects presented in the Application is fully compliant with all provincial and federal regulatory requirements.
1985.1	round 1	Gitxaala Nation	11.3.5.1	CEAA 2012	As stated in Section 11.7.3, Gitxaala members may have particular reasons for harvesting certain species from specific areas (family history, house territory, sacred site, distance to home, etc.) in the PDA and LAA. The proponent should gain further insight into these areas and why modifications to harvesting in them may be more significant to Gitxaala members than anticipated, for instance through additional field work.	Aurora LNG acknowledges that the Project vicinity may have importance and features related to harvesting not found elsewhere. However,Aurora LNG was not provided with information that identified the Project area or the surrounding waters as a unique harvesting area. Aurora LNG maintains that, based on information available at the time of Application development and submission, its assumptions regarding the uniqueness of the Project vicinity for Current Use activities and the continued availability of other areas outside the Project vicinity was reasonable. Please refer to the technical memo titled, "Additional Information Regarding the CEAA 5(1)(C) and Part C Assessment Methodologies and the Consideration of Traditional Use Information in these Assessments" which will be filed with the BC EAO.
1986.1	round 1	Gitxaala Nation	11.3.5.2	CEAA 2012	As stated in Section 11.7.3, Gitxaala members may have particular reasons for harvesting certain species from specific areas (family history, house territory, sacred site, distance to home, etc.) in the PDA and LAA. The proponent should gain further insight into these areas and why modifications to harvesting in them may be more significant to Gitxaala members than anticipated, for instance through additional field work.	Aurora LNG acknowledges that the Project vicinity may have importance and features related to harvesting not found elsewhere. However,Aurora LNG was not provided with information that identified the Project area or the surrounding waters as a unique harvesting area. Aurora LNG maintains that, based on information available at the time of Application development and submission, its assumptions regarding the uniqueness of the Project vicinity for Current Use activities and the continued availability of other areas outside the Project vicinity was reasonable. Please refer to the technical memo titled, "Additional Information Regarding the CEAA 5(1)(C) and Part C Assessment Methodologies and the Consideration of Traditional Use Information in these Assessments" which will be filed with the BC EAO.
1987.1	round 1	Gitxaala Nation	11.3.6.1	CEAA 2012	The listed mitigation measures focus only on heavily mitigating impacts to visual effects and the acoustic environment. There is no reference to any additional measures to accommodate unique determinants of Aboriginal Health, including anxiety due to resource and environmental uncertainty. The same can be said for unique components of socio-economic conditions for Aboriginal people, such as the importance of being able to maintain traditional livelihoods that enable sharing harvested resources between community members.	As per CEAA 2012 5(1)(c), the focus of the assessment is on effects to the environment on the various CEAA 5(1)(c) factors. The assessment of Aboriginal Health determined that the effects from the Project to the environment on health as assessed collectively in the Human Health, Acoustic Environment, and Community Health VCs accurately capture the potential effects on Aboriginal Health. Similarly, the assessment of Aboriginal Socio-Economic Conditions determined that the effects to the environment on socio-economic conditions as assessed collectively in the Visual Quality, Acoustic Environment, and Community Health VCs accurately capture the potential effects on Aboriginal Socio-Economic Conditions. The assessments of Human Health, Community Health, Acoustic Environment and Visual Quality, including associated mitigation measures, are applicable for any Aboriginal (or non-Aboriginal) person living within the LAA for the four VCs listed. Aurora LNG maintains that the scope of the assessment is in alignment with the requirements of the AIR and provincial and federal regulatory requirements. On March 27, 2017, Aurora LNG held Technical Workshop #5 with Gitxaala Nation to further discuss the characterization of effects and significance conclusions outlined in the CEAA 2012 Section 5(1)(c) assessment, and the assessment of Project effects related to Aboriginal Interests in Part C. Technical Workshop #5 was also an opportunity to discuss feedback on mitigation measures, proposed management plans and follow-up programs. Throughout Technical Workshop #5, Aurora LNG documented Gitxaala Nation's opinions, concerns and feedback. Aurora LNG will be providing a draft of Aboriginal Consultation Report #3 (i.e. the interim consultation report) at day 90 of the 180 day Application-review period (as per the EAO's letter of December 14, 2016). As part of the draft Aboriginal Consultation Report #3, Aurora LNG will report on its understanding of the status of issues/concerns resolution with Gitxaala Nation for the issues/concerns recorded during all phases of the EA (in table format), including those identified in Aboriginal Consultation Report #2 and recorded as part of Technical Workshops #4 and #5. The final version of Aboriginal Consultation Report #3 will be submitted at day 120 of the 180 day Application-review period (as per the section 11 Order [as amended]). Aurora LNG is currently reviewing feedback received to date on mitigation measures and any revised or new mitigation measures proposed will be included as part of an updated Table 16-1 and 16-2 to be submitted to the EAO on Day 90.
1988.1	round 1	Gitxaala Nation	11.3.6.2	CEAA 2012	The listed mitigation measures focus only on heavily mitigating impacts to visual effects and the acoustic environment. There is no reference to any additional measures to accommodate unique determinants of Aboriginal Health, including anxiety due to resource and environmental uncertainty. The same can be said for unique components of socio-economic conditions for Aboriginal people, such as the importance of being able to maintain traditional livelihoods that enable sharing harvested resources between community members.	As per CEAA 2012 5(1)(c), the focus of the assessment is on effects to the environment on the various CEAA 5(1)(c) factors. The assessment of Aboriginal Health determined that the effects from the Project to the environment on health as assessed collectively in the Human Health, Acoustic Environment, and Community Health VCs accurately capture the potential effects on Aboriginal Health. Similarly, the assessment of Aboriginal Socio-Economic Conditions determined that the effects to the environment on socio-economic conditions as assessed collectively in the Visual Quality, Acoustic Environment, and Community Health VCs accurately capture the potential effects on Aboriginal Socio-Economic Conditions. The assessments of Human Health, Community Health, Acoustic Environment and Visual Quality, including associated mitigation measures, are applicable for any Aboriginal (or non-Aboriginal) person living within the LAA for the four VCs listed. Aurora LNG maintains that the scope of the assessment is in alignment with the requirements of the AIR and provincial and federal regulatory requirements. On March 27, 2017, Aurora LNG held Technical Workshop #5 with Gitxaala Nation to further discuss the characterization of effects and significance conclusions outlined in the CEAA 2012 Section 5(1)(c) assessment, and the assessment of Project effects related to Aboriginal Interests in Part C. Technical Workshop #5 was also an opportunity to discuss feedback on mitigation measures, proposed management plans and follow-up programs. Throughout Technical Workshop #5, Aurora LNG documented Gitxaala Nation's opinions, concerns and feedback. Aurora LNG will be providing a draft of Aboriginal Consultation Report #3 (i.e. the interim consultation report) at day 90 of the 180 day Application-review period (as per the EAO's letter of December 14, 2016). As part of the draft Aboriginal Consultation Report #3, Aurora LNG will report on its understanding of the status of issues/concerns resolution with Gitxaala Nation for the issues/concerns recorded during all phases of the EA (in table format), including those identified in Aboriginal Consultation Report #2 and recorded as part of Technical Workshops #4 and #5. The final version of Aboriginal Consultation Report #3 will be submitted at day 120 of the 180 day Application-review period (as per the section 11 Order [as amended]). Aurora LNG is currently reviewing feedback received to date on mitigation measures and any revised or new mitigation measures proposed will be included as part of an updated Table 16-1 and 16-2 to be submitted to the EAO on Day 90.
1989.1	round 1	Gitxaala Nation	11.3.6.3	CEAA 2012	The listed mitigation measures focus only on heavily mitigating impacts to visual effects and the acoustic environment. There is no reference to any additional measures to accommodate unique determinants of Aboriginal Health, including anxiety due to resource and environmental uncertainty. The same can be said for unique components of socio-economic conditions for Aboriginal people, such as the importance of being able to maintain traditional livelihoods that enable sharing harvested resources between community members.	As per CEAA 2012 5(1)(c), the focus of the assessment is on effects to the environment on the various CEAA 5(1)(c) factors. The assessment of Aboriginal Health determined that the effects from the Project to the environment on health as assessed collectively in the Human Health, Acoustic Environment, and Community Health VCs accurately capture the potential effects on Aboriginal Health. Similarly, the assessment of Aboriginal Socio-Economic Conditions determined that the effects to the environment on socio-economic conditions as assessed collectively in the Visual Quality, Acoustic Environment, and Community Health VCs accurately capture the potential effects on Aboriginal Socio-Economic Conditions. The assessments of Human Health, Community Health, Acoustic Environment and Visual Quality, including associated mitigation measures, are applicable for any Aboriginal (or non-Aboriginal) person living within the LAA for the four VCs listed. Aurora LNG maintains that the scope of the assessment is in alignment with the requirements of the AIR and provincial and federal regulatory requirements. On March 27, 2017, Aurora LNG held Technical Workshop #5 with Gitxaala Nation to further discuss the characterization of effects and significance conclusions outlined in the CEAA 2012 Section 5(1)(c) assessment, and the assessment of Project effects related to Aboriginal Interests in Part C. Technical Workshop #5 was also an opportunity to discuss feedback on mitigation measures, proposed management plans and follow-up programs. Throughout Technical Workshop #5, Aurora LNG documented Gitxaala Nation's opinions, concerns and feedback. Aurora LNG will be providing a draft of Aboriginal Consultation Report #3 (i.e. the interim consultation report) at day 90 of the 180 day Application-review period (as per the EAO's letter of December 14, 2016). As part of the draft Aboriginal Consultation Report #3, Aurora LNG will report on its understanding of the status of issues/concerns resolution with Gitxaala Nation for the issues/concerns recorded during all phases of the EA (in table format), including those identified in Aboriginal Consultation Report #2 and recorded as part of Technical Workshops #4 and #5. The final version of Aboriginal Consultation Report #3 will be submitted at day 120 of the 180 day Application-review period (as per the section 11 Order [as amended]). Aurora LNG is currently reviewing feedback received to date on mitigation measures and any revised or new mitigation measures proposed will be included as part of an updated Table 16-1 and 16-2 to be submitted to the EAO on Day 90.
1990.1	round 1	Gitxaala Nation	11.3.6.4	CEAA 2012	The listed mitigation measures focus only on heavily mitigating impacts to visual effects and the acoustic environment. There is no reference to any additional measures to accommodate unique determinants of Aboriginal Health, including anxiety due to resource and environmental uncertainty. The same can be said for unique components of socio-economic conditions for Aboriginal people, such as the importance of being able to maintain traditional livelihoods that enable sharing harvested resources between community members.	As per CEAA 2012 5(1)(c), the focus of the assessment is on effects to the environment on the various CEAA 5(1)(c) factors. The assessment of Aboriginal Health determined that the effects from the Project to the environment on health as assessed collectively in the Human Health, Acoustic Environment, and Community Health VCs accurately capture the potential effects on Aboriginal Health. Similarly, the assessment of Aboriginal Socio-Economic Conditions determined that the effects to the environment on socio-economic conditions as assessed collectively in the Visual Quality, Acoustic Environment, and Community Health VCs accurately capture the potential effects on Aboriginal Socio-Economic Conditions. The assessments of Human Health, Community Health, Acoustic Environment and Visual Quality, including associated mitigation measures, are applicable for any Aboriginal (or non-Aboriginal) person living within the LAA for the four VCs listed. Aurora LNG maintains that the scope of the assessment is in alignment with the requirements of the AIR and provincial and federal regulatory requirements. On March 27, 2017, Aurora LNG held Technical Workshop #5 with Gitxaala Nation to further discuss the characterization of effects and significance conclusions outlined in the CEAA 2012 Section 5(1)(c) assessment, and the assessment of Project effects related to Aboriginal Interests in Part C. Technical Workshop #5 was also an opportunity to discuss feedback on mitigation measures, proposed management plans and follow-up programs. Throughout Technical Workshop #5, Aurora LNG documented Gitxaala Nation's opinions, concerns and feedback. Aurora LNG will be providing a draft of Aboriginal Consultation Report #3 (i.e. the interim consultation report) at day 90 of the 180 day Application-review period (as per the EAO's letter of December 14, 2016). As part of the draft Aboriginal Consultation Report #3, Aurora LNG will report on its understanding of the status of issues/concerns resolution with Gitxaala Nation for the issues/concerns recorded during all phases of the EA (in table format), including those identified in Aboriginal Consultation Report #2 and recorded as part of Technical Workshops #4 and #5. The final version of Aboriginal Consultation Report #3 will be submitted at day 120 of the 180 day Application-review period (as per the section 11 Order [as amended]). Aurora LNG is currently reviewing feedback received to date on mitigation measures and any revised or new mitigation measures proposed will be included as part of an updated Table 16-1 and 16-2 to be submitted to the EAO on Day 90.

1991.1	round 1	Gitxaala Nation	11.3.9	CEAA 2012	**Existing Conditions:** The Shandro et al., 2016 report is not referenced. In addition, information on the degree to which Gitxaala members are dependent on traditional or subsistence livelihoods is not discussed. **Current Use:** Adverse impacts on current use are considered to be insignificant, despite acknowledgement that some modification of harvesting activities in the PDA or LAA is expected. The proponent should consider proposing ways in which users might be compensated for modifications made to current use. **Aboriginal Health:** Effects on Aboriginal Health are considered only relative to changes in air quality, quality and quantity of marine foods, and acoustic environment. Key health risks and impacts for Gitxaala as identified by Shandro et al., 2016 (discussed in detail in comments on Section 6.6 Community Health), are not considered here. The proponent should consider implementing an Aboriginal health monitoring system (as part of a broader community health monitoring system) as well as sharing routine environmental monitoring data with Gitxaala members in a timely and culturally appropriate manner to reduce perceived uncertainty. **Socioeconomic Conditions:** Similar to our comments on Current Use. Effects on socioeconomic conditions are assessed as insignificant, but may not be perceived or experienced as such by some Gitxaala members. The proponent should propose ways in which users might be compensated for modifications made to current use. See Memo "0217_AGIforGitxaala_Social Impacts" for further details.	In November 2016, Gitxaala Nation provided Aurora LNG with a study entitled Potential Risks, Impacts and Opportunities of the Aurora LNG Project for Gitxaala Nation (Shandro et al., 2016) (the "Gitxaala Nation Report"). As Aurora LNG had completed the analysis and writing for its Application for Environmental Assessment Certificate (the "Application") at the time the Gitxaala Nation Report was received, information contained in the report had not been reviewed or directly incorporated into the Application which was submitted to the BC EAO in November, 2016. Aurora LNG responded to the Gitxaala Nation Report in its technical memo entitled "Aurora LNG's Response to the 'Potential Risks, Impacts and Opportunities of the Aurora LNG Project for Gitxaala Nation'". A draft of this memo was shared with Gitxaala Nation on May 11, 2017 for their comment and will be filed with the BC EAO. Aurora LNG acknowledges the mitigation recommendations suggested by Gitxaala Nation. In addition, Aurora LNG is currently reviewing specific feedback on proposed mitigation measures received from Aboriginal Groups during Technical Workshops #4 and #5 and any revised or new mitigation measures proposed will be included as part of an updated Table 16-1 and 16-2 to be submitted to the BC EAO on Day 90.
1992.1	round 1	Gitxaala Nation	12.5.6.5	Aboriginal Consultation	**Assessment of Effects on Gitxaala:** The assessment of effects on Gitxaala's exercise of Aboriginal Interests does not reference Shandro et al., 2016. The Application takes into consideration "the relative importance of the Project vicinity...and the availability of other areas within the traditional territory where the meaningful exercise of the Aboriginal Interest could reasonably occur" (p. 12-156). Even if the exercise of an Aboriginal Interest "could reasonably occur" elsewhere, Gitxaala people should not be subjected to (further) environmental dispossession or economic displacement. If this cannot be avoided, then Gitxaala people should be appropriately compensated. The Application also states that "this interference [with aspects of Aboriginal title] is restricted to the PDA, which comprises 0.03% of Gitxaala Nation's traditional territory. The Project would not interfere with title rights in other areas of the traditional territory" (p. 12-159). This is not accurate, as inability to access the PDA could affect patterns of land use and marine activity outside of the PDA, thus affecting traditional territory outside of the PDA. In addition, this section identifies the Proponent's commitment to continue to consult with Gitxaala to develop appropriate mitigation measures. We propose that the Proponent seek to not only consult and accommodate, but moreover to obtain the Free, Prior and Informed Consent of Gitxaala and other Aboriginal Groups as per the IFC Performance Standards.	Please refer to Aurora LNG's technical memo entitled: Aurora LNG's response to the "Potential Risks, Impacts and Opportunities of the Aurora LNG Project for Gitxaala Nation". In addition, please refer to the technical memo entitled: "Additional Information Regarding CEAA 5(1)(c) and Part C Assessment Methodologies and the Consideration of Traditional Use Information in the Assessment". Finally, Aurora LNG requested specific feedback on proposed mitigation measures from Gitxaala Nation during Technical Workshops #4 and #5. Aurora LNG is currently reviewing feedback received to date on mitigation measures (including comments received in the 2016 Shandro Report) and any revised or new mitigation measures proposed will be included as part of an updated Table 16-1 and 16-2 to be submitted to the EAO on Day 90.
1993.1	round 1	Gitxaala Nation	12.5.6.6	Aboriginal Consultation	**Assessment of Effects on Gitxaala:** The assessment of effects on Gitxaala's exercise of Aboriginal Interests does not reference Shandro et al., 2016. The Application takes into consideration "the relative importance of the Project vicinity...and the availability of other areas within the traditional territory where the meaningful exercise of the Aboriginal Interest could reasonably occur" (p. 12-156). Even if the exercise of an Aboriginal Interest "could reasonably occur" elsewhere, Gitxaala people should not be subjected to (further) environmental dispossession or economic displacement. If this cannot be avoided, then Gitxaala people should be appropriately compensated. The Application also states that "this interference [with aspects of Aboriginal title] is restricted to the PDA, which comprises 0.03% of Gitxaala Nation's traditional territory. The Project would not interfere with title rights in other areas of the traditional territory" (p. 12-159). This is not accurate, as inability to access the PDA could affect patterns of land use and marine activity outside of the PDA, thus affecting traditional territory outside of the PDA. In addition, this section identifies the Proponent's commitment to continue to consult with Gitxaala to develop appropriate mitigation measures. We propose that the Proponent seek to not only consult and accommodate, but moreover to obtain the Free, Prior and Informed Consent of Gitxaala and other Aboriginal Groups as per the IFC Performance Standards.	Please refer to Aurora LNG's technical memo entitled: Aurora LNG's response to the "Potential Risks, Impacts and Opportunities of the Aurora LNG Project for Gitxaala Nation". In addition, please refer to the technical memo entitled: "Additional Information Regarding CEAA 5(1)(c) and Part C Assessment Methodologies and the Consideration of Traditional Use Information in the Assessment". Finally, Aurora LNG requested specific feedback on proposed mitigation measures from Gitxaala Nation during Technical Workshops #4 and #5. Aurora LNG is currently reviewing feedback received to date on mitigation measures (including comments received in the 2016 Shandro Report) and any revised or new mitigation measures proposed will be included as part of an updated Table 16-1 and 16-2 to be submitted to the EAO on Day 90.
1994.1	round 1	Gitxaala Nation	12.5.6.7	Aboriginal Consultation	**Assessment of Effects on Gitxaala:** The assessment of effects on Gitxaala's exercise of Aboriginal Interests does not reference Shandro et al., 2016. The Application takes into consideration "the relative importance of the Project vicinity...and the availability of other areas within the traditional territory where the meaningful exercise of the Aboriginal Interest could reasonably occur" (p. 12-156). Even if the exercise of an Aboriginal Interest "could reasonably occur" elsewhere, Gitxaala people should not be subjected to (further) environmental dispossession or economic displacement. If this cannot be avoided, then Gitxaala people should be appropriately compensated. The Application also states that "this interference [with aspects of Aboriginal title] is restricted to the PDA, which comprises 0.03% of Gitxaala Nation's traditional territory. The Project would not interfere with title rights in other areas of the traditional territory" (p. 12-159). This is not accurate, as inability to access the PDA could affect patterns of land use and marine activity outside of the PDA, thus affecting traditional territory outside of the PDA. In addition, this section identifies the Proponent's commitment to continue to consult with Gitxaala to develop appropriate mitigation measures. We propose that the Proponent seek to not only consult and accommodate, but moreover to obtain the Free, Prior and Informed Consent of Gitxaala and other Aboriginal Groups as per the IFC Performance Standards.	Please refer to Aurora LNG's technical memo entitled: Aurora LNG's response to the "Potential Risks, Impacts and Opportunities of the Aurora LNG Project for Gitxaala Nation". 1999.1	round 1	Gitxaala Nation	12.6	Aboriginal Consultation	Although this section identifies the potential for adverse effects on Aboriginal Groups due to accident or malfunction, it does not outline corresponding mitigation measures to ensure the exercise of Aboriginal Interests and cultural continuity. See comments on Section 9 for further recommendations.	The assessment of effects of Accidents or Malfunctions (Section 9) includes Preventative and Response Measures for each potential accident or malfunction. These measures will, by extension, reduce or avoid effects from an accident or malfunction on the exercise of Aboriginal Interests, including cultural wellbeing.
2000.1	round 1	Gitxaala Nation	14.12	Environmental and Operational Management Plans	A community health monitoring system should be included as part of the Social Management Plan. A local employment and procurement management plan should be included as part of the Social Management Plan. A formal grievance mechanism (unclear if this is covered under "community feedback processes") should be included as part of the Community Engagement Plan. See Memo "0217_AGIforGitxaala_Social Impacts" for further details on management plans.	Mitigation Measures 6.3.1 (Social Management Plan [SMP]) requires Aurora LNG to engage with regulators, Aboriginal Groups, and interested stakeholders to develop metrics used to monitor changes in demand on infrastructure and services (e.g., health care infrastructure and services). On-going monitoring of changes in health status is completed at the federal and provincial level. Federally, Health Canada, Statistics Canada and the Canadian Institute for Health Information monitor and report on various measures of health status. Provincially, BC Stats, the Provincial Health Services Authority, Local Health Authorities (e.g., Northern Health) and the Aboriginal Health Authority monitor and report on various measures of health status. Mitigation 6.4.8 (community grievance process) will be included under the Community Engagement Plan (mitigation 6.3.4) as part of the overall Social Management Plan (mitigation 6.3.1). Also see the "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment" technical memo for consideration of the referenced memo '0217_AGIforGitxaala_Social Impacts'. The technical memo will be filed with the BC EAO.

2001.1	round 1	Gitxaala Nation	14.12.1	Environmental and Operational Management Plans	A community health monitoring system should be included as part of the Social Management Plan. A local employment and procurement management plan should be included as part of the Social Management Plan. A formal grievance mechanism (unclear if this is covered under "community feedback processes") should be included as part of the Community Engagement Plan. See Memo "0217_AGIforGitxaala_Social Impacts" for further details on management plans.	Mitigation Measures 6.3.1 (Social Management Plan [SMP]) requires Aurora LNG to engage with regulators, Aboriginal Groups, and interested stakeholders to develop metrics used to monitor changes in demand on infrastructure and services (e.g., health care infrastructure and services). On-going monitoring of changes in health status is completed at the federal and provincial level. Mitigation 6.4.8 (community grievance process) will be included under the Community Engagement Plan (mitigation 6.3.4) as part of the overall Social Management Plan (mitigation 6.3.1). Also see the "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment" technical memo for consideration of the referenced memo '0217_AGIforGitxaala_Social Impacts'. The technical memo will be filed with the BC EAO.
2004.1	round 1	Gitxaala Nation	14.12.4	Environmental and Operational Management Plans	A community health monitoring system should be included as part of the Social Management Plan. A local employment and procurement management plan should be included as part of the Social Management Plan. A formal grievance mechanism (unclear if this is covered under "community feedback processes") should be included as part of the Community Engagement Plan. See Memo "0217_AGIforGitxaala_Social Impacts" for further details on management plans.	Mitigation Measures 6.3.1 (Social Management Plan [SMP]) requires Aurora LNG to engage with regulators, Aboriginal Groups, and interested stakeholders to develop metrics used to monitor changes in demand on infrastructure and services (e.g., health care infrastructure and services). On-going monitoring of changes in health status is completed at the federal and provincial level. Federally, Health Canada, Statistics Canada and the Canadian Institute for Health Information monitor and report on various measures of health status. Provincially, BC Stats, the Provincial Health Services Authority, Local Health Authorities (e.g., Northern Health) and the Aboriginal Health Authority monitor and report on various measures of health status. Mitigation 6.4.8 (community grievance process) will be included under the Community Engagement Plan (mitigation 6.3.4) as part of the overall Social Management Plan (mitigation 6.3.1). Also see the "Response to Gitxaala Nation Review of the Aurora LNG Environmental Assessment" technical memo for consideration of the referenced memo '0217_AGIforGitxaala_Social Impacts'. The technical memo will be filed with the BC EAO.
2005.1	round 1	Gitxaala Nation	1.2.10	Proposed Project Overview	Commitment stated to undertake adaptive management as "best in class" for "HSE&SR Management System... ...Throughout the Application process, Aurora LNG will continue to consider results of environmental surveys and will adopt an adaptive management approach." Specific reference made to Section 14 of EA application for "series of EMPs based on industry best management practices and standards, applicable regulations, commitments made during the Application process, and EAC and permit condition, to protect specific components of the environment, Project personnel, and the public by reducing or avoiding potential adverse effects from Project activities." Adaptive managment has been stated as a commitment for EMPs developed during all phases. Observation has been noted and will be referred to throughout EA application review.	Aurora LNG acknowledges the comment from Gitxaala Nation. Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended).
2006.1	round 1	Gitxaala Nation	1.3.1	Proposed Project Overview	Re: PNCIMA - statement to monitor with adaptive management and implement goals for "integrity of marine ecosystems, human wellbeing, governance, and improving the understanding of complex marine ecosystems", as it pertains to "risk assessment tools and cumulative effects". Observation has been noted and will be referred to throughout EA application review.	Aurora LNG acknowledges this comment.
2007.1	round 1	Gitxaala Nation	1.5.1.1	Proposed Project Overview	LNG from the Western Sedimentary Basin, as the upstream gas supply, currently uses a great deal of hydraulic fracturing in the extraction process and relies on off-grid technologies in the natural gas procurement process, which principally involves use of fossil fuels as an energy source (e.g., off-grid diesel generation). The extraction process is prone to fugitive emissions of methane (25+ times more effective of a GHG than carbon dioxide in the short term), which cannot be reliably factored into a carbon lifecycle assessment using current quantification methods. This has been acknowledged and accepted as problematic by the Parliamentary Secretary for ECCC and the Government of Canada and is a major source of uncertainty surrounding the Proponent's claim, but necessarily results in a more carbon intensive fossil fuel than conventional natural gas. It is also a major source of uncertainty underestimating overall GHG accounting for LNG production and export. The principal objective of adaptive management is to address such uncertainties and meaningfully inform the resource development process over time, particularly with respect to the risks to values held by all interests in the decision-making process. Management actions are an outcome of open and participatory consultation, where individual values and interests are given credible consideration in a formal consultative process (i.e., through workshops). How does the Proponent justify the production and export of LNG as a less "carbon intensive" supply to foreign markets, given these uncertainties and limitations, and how does its commitment to adaptive management factor into the decision making process for excluding upstream sources in the effects assessment of GHGs as a VC?	In fulfillment of Environment and Climate Change Canada (ECCC) requirements, Aurora LNG prepared a technical report titled: "Aurora LNG: Review of Upstream Greenhouse Gas Emissions Report." This document, provides an estimate of upstream GHG emissions associated with the Project. It is stated in Section 1.5.1.1 that the "Environmental benefits of the proposed Project include lessening dependence of foreign market on more carbon intensive fossil fuels through the production and export of LNG." This statement refers to the far lower GHG intensity of LNG as an energy source, compared to oil or coal, on a life-cycle basis.
2008.1	round 1	Gitxaala Nation	1.7.1.1	Proposed Project Overview	The Province is building the Site C dam as a major component of its "hydrolelectric backbone for storage capacity capable of meeting future demand" according to BC Hydro President Jessica Lewis, yet there is currently no economic case for Site C according to Harry Swain, Site C Joint Review Panel Chair, because demand for energy has been flat for the past twenty years. This Project represents a substantive demand centre for up to 250 MW of power that could draw from Site C power supply, if not making use of the local resource potential from local clean energy development interests. Grid-connected power should be given more serious consideration, either as a complete energy source or as a component of an electric drive liquefaction process.	As noted in Section 1.7.1.1 of the Application, BC Hydro will be evaluating the feasibility of providing additional power from the existing hydro grid to Digby Island, which is expected to require various infrastructure upgrades including the installation of a new transmission line to the island. Engagement to date with BC Hydro has indicated that it is unlikely that the existing grid can supply all of the power to operate the Project. Given the uncertainty surrounding the technical feasibility, power sourced from the BC Hydro grid is not identified as a preferred alternative.
2009.1	round 1	Gitxaala Nation	1.7.1.1	Proposed Project Overview	The outcome of BC Hydro's evaluation is a critical factor in the Project from an environmental and economic perspective that would reduce the Project's carbon footprint. The Project is expected to have significant cumulative adverse environmental effects based on the GHG VC assessment (See Section 4.3). What is the outcome of BC Hydro's evaluation? Can available local clean energy (especially onshore and offshore wind) also be supplied, possibly in combination with Site C power and feed gas as firm and stable energy sources for ancillary needs and liquefaction process?	As noted in Section 1.7.1.1 of the Application, engagement to date with BC Hydro has indicated it is unlikely that the existing grid can supply all of the power to operate the Project. BC Hydro is continuing to investigate options to supply power but this is expected to require various infrastructure upgrades including a new power line to the island. Given the uncertainty surrounding the technical feasibility of this option, it is not identified as a preferred alternative. Aurora LNG is not aware of any local energy projects that could reliably supply power to the Project, and has therefore not considered their feasibility as part of the assessment of alternative power supply options.
2010.1	round 1	Gitxaala Nation	1.7.1.2	Proposed Project Overview	The Proponent has not seriously considered the prospect of integrating local power supplied with either BC Hydro grid or micro-grid connectivity that could use reliable supply of feed gas along with available clean energy (particularly onshore and offshore wind resources) to be jointly developed by local interests? Such an energy supply could provide local economic benefits and would work to meaningfully reduce the overall GHG emissions expected to have significant adverse environmental effects based on the GHG VC assessment (Section 4.3) relative to natural gas. Incredibly, this conclusion does not even consider the upstream sources of emissions, LNG shipping-related emissions, or the product's end use (which is iteself a fossil fuel). This does not accord with Canada's binding commitments to the Paris Agreement and the BC Clean Energy Plan, neither of which are on course to meet their intended GHG reduction targets according to an analysis provided in the GHG VC effects assessment (refer to Section 4.3.3.2 on p. 4.3-11, paragraph 5).	Section 1.7.1 of the Application (Proposed Project Overview) includes an analysis of technically and economically feasible alternative options to supply power to the proposed Project. This includes power coming from the the existing BC Hydro grid, and onsite natural gas plants. Aurora LNG is not aware of any micro-grid projects that could reliably provide energy to the Project, and does not consider this a technically or economically feasible option to include in the assessment of alternatives.
2011.1	round 1	Gitxaala Nation	1.7.2	Proposed Project Overview	Prince Rupert and region is the wettest area in Canada with over 3000 mm of annual rainfall on average. Why have alternatives like the collection and storage of rainwater not been given meaningful consideration as a potential source of this process water? What kind of desalination method is being proposed and how can this be economically justified given the local environmental context?	The assessment of alternatives water supply options in section 1.7.2 considers the three options Aurora LNG considers technically and economically feasible for the Project, given that the Project water requirements (9,955 m3/day during operations). Given the seasonality of precipitation in the region, this source is not considered feasible to address the Project requirement for a consistent year round water supply.
2012.1	round 1	Gitxaala Nation	1.7.2.1	Proposed Project Overview	Desalination is likely to be much more expensive than the alternative options, especially given the local environmental context and energetic demands, which are preferred to be supplied by fossil fuel sources (i.e., feedstock gas). Please justify the economic criteria (i.e., high costs for all three alternative options), especially given the expected capital and operational costs for desalination, treatment, and disposal of waste products from the desalination process.	The preliminary evaluation conducted by Aurora LNG indicates that all three water supply options will have high costs when considering the volume of water required for the Project during operations which is anticipated to be approximately 9,855 m3/day.
2013.1	round 1	Gitxaala Nation	1.7.5.1	Proposed Project Overview	Why has the disposal of wastewater from the desalination process not been considered as a potential effect on "marine fish and fish habitat and aquatic species" in the summary table? The conceptual layout of the Project on Figure 1-2 shows the desalination plant footprint is located within the PDA, as well as its incurrent and excurrent water lines. A wastewater line exits the plant and leads directly to the deep outfall at Charles Point. There is no indication in the figure that wastewater from the desalination process will be effectively treated at the Wastewater Treatment Plant and Stormwater Retention Ponds located further south in the PDA. Effective wastewater treatment will be necessary prior to disposal at the outfall to avoid environmental effects, given the elevated concentration of solutes, including metals and other contaminants likely to be in the seawater from surrounding industrial activities (i.e., the "long history of industrial activity noted in Section 4.5.13.2, p. 4.5-53 of the Application, which references a "complete list of potential contaminant sources in the Prince Rupert Harbour area" in Appendix F), and especially because the location of te seawater intake will be in Casey Cove where the MOF will essentially serve as an industrial port with its "historical marine waste dump". This stands to be an obvious source of potential effects, with effluent discharge at the deep outfall as a pathway of effects to "marine fish and fish habitat and aquatic species" as the receptors in the marine receiving environment at Chrles Point. Please justify the exclusion and clarify if/how desalination wastewater will be treated prior to disposal? Where will any solids be disposed of?	The intent of Table 1-28 in Section 1.7 (Alternative Means of Undertaking the Proposed Project, Project Overview Chapter) was to evaluate options for disposing of material dredged from the dredge pockets associated with construction of the MOF and the LNG jetty. The intent was not to identify options around the release of wastewater into the marine environment. As described in the Project Overview Chapter, based on preliminary engineering and design, wastewater (warm brine with elevated salinity) from the desalination plant is expected to be combined with the power plant cooling tower blowdown, tested and treated to meet regulatory requirements, if required prior to being discharged to the marine environment through a deep water marine outfall (likely the deep water marine outfall off Charles Point, but to be determined during final engineering and design). Additional details on wastewater treatment for the Project is provided in the memo "Discharges to the Marine Environment" which will be filed with the BC EAO.Solids resulting from the wastewater treatment will be transported offsite for disposal at a licensed facility (see Section 1.2.5.3 of the Application). The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting. Potential effects to marine fish and fish habitat associated with the discharge of wastewater (including wastewater from the desalination process) out of the Charles Point outfall are assessed and characterized in the Marine Fish and Fish Habitat VC under the 'change in health' effect (Section 4.9.5.5). This assessment relies heavily on the results of the Water Quality VC (Section 4.5), which assessed potential changes to marine water quality associated with wastewater discharges. With respect to the comment ", ...given the elevated concentration of solutes, including metals and other contaminants likely to be in the seawater from surrounding industrial activities...", while there is a long history of industrial activities in the region, as described in Appendix F, the results of the water quality monitoring program indicate that metal concentrations in seawater are generally well below BC MOE water quality guidelines. Of the 41 metals analyzed, 23 were below detection limits in all samples analyzed, and only boron and copper exceeded guidelines. These results suggest that seawater chemistry in the area in the LAA is typical for the region, and does not show evidence of metal contamination. Please see Section 5.8.1 of Appendix F, Marine Sediment and Water Quality TDR for further discussion.
2014.1	round 1	Gitxaala Nation	1.7.5.1	Proposed Project Overview	What was the outcome of consultation with ECCC and why has Proponent decided not to pursue the Coast Island Disposal Site?	Aurora LNG met with ECCC on April 29, 2016 to discuss the Coast Island Disposal Site. During the meeting, ECCC informed Aurora LNG that the Coast Island Disposal Site would not be considered for future Disposal at Sea permits as the site was not suitable for multiple projects (i.e., projects other than the proposed Canpotex Potash Export Terminal). Based on this feedback, Aurora LNG removed the Coast Island Disposal Site from its DAS site alternatives.
2015.1	round 1	Gitxaala Nation	1.7.5.1	Proposed Project Overview	What are the applicable regulations and associated permitting requirements for each scenario and why has the regulatory burden of each alternative not been directly factored into the evaluation criterion for "Regulatory Requirements"?	Section 1.7.5.1 of the Application provides the applicable regulatory context for each scenario, specifying that the deep water disposal site at the Brown Passage site is regulated by ECCC under Section 127 of the Canadian Environmental Protection Act, 1999, and requires application for a Disposal at Sea Permit, while on-land disposal in BC must comply with the Environmental Management Act and its regulations, including contaminated sites and hazardous waste regulations, administered by BC MOE. The hybrid option is subject to both of these regulatory requirements. The regulatory requirements of each option were factored into the evaluation, as reflected in the text of this section.
2016.1	round 1	Gitxaala Nation	1.7.5.1	Proposed Project Overview	Disposal at sea is likely to have much less of a degree of land disturbance compared to the other options, especially given the local environmental context, yet all scenarios have been ranked as having a "moderate" effect. Please justify the rating and clarify how and why the evaluation criterion for "Land Disturbance" factored into this result.	Disposal at Sea at the proposed Brown Passage site will not result in land disturbance. An errata document is being created that will capture this correction and it will be filed with the BC EAO.
2017.1	round 1	Gitxaala Nation	2.4.1	Environmental Assessment Process	Water quality concerns acknowledged in summary table relate solely to water quality effects from LNG carriers and export tugs, but how does the response address Gitxaala's concerns about operational discharge?	Operational discharges to the marine environment are acknowledged as a potential Project interaction, under waste management, in Table 4.5-25, Section 4.5.14. Potential waste discharge effects are characterized in Section 4.5.15, with associated mitigation measures 4.5.8, and 4.5.9 listed in Table 4.5-26. Further details on Project waste discharges are provided in the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.

2018.1	round 1	Gitxaala Nation	2.4.1	Environmental Assessment Process	Potential marine fish and fish habitat effects have not considered the discharge of operational wastewater and effluent from the desalination process into the marine receiving environment.	Potential effects to marine fish and fish habitat associated with the discharge of wastewater during Project operations are assessed and characterized in the Marine Fish and Fish Habitat VC under the 'change in health' effect (Section 4.9.5.5). Effluent discharges will be tested and treated, if required, prior to being discharged to the marine environment. Project-related effluent discharges to the marine environment will comply with the BC Environmental Management Act regulations (i.e., Waste Discharge Regulation, Petroleum Storage and Distribution Facilities Storm Water Regulation), and will meet the CCME and BC water quality guidelines (which are designed to protect aquatic life) in the receiving environment outside of a defined mixing zone. For additional information on effluent treatment and permit requirements, please see the "Discharges to the Marine Environment" memo, which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2019.1	round 1	Gitxaala Nation	2.4.2	Environmental Assessment Process	Potential marine fish and fish habitat effects have not considered the discharge of operational wastewater and effluent from the desalination process into the marine receiving environment. In terms of the effluent plume, it will immediately impart a continuous and persistent effect to an unknown volume of marine fish habitat. There is no indication of how the effluent will disperse in the water column or the direction of dispersion and these represent critical deficiencies in the baseline data requirements for a credible effects assessment.	Project wastewater (including Desalination waste discharge) will meet CCME and BC water quality guidelines (WQG) for temperature and salinity, outside of the initial dilution zone. These guidelines allow a maximum change of ±1^{0}C from ambient at any time, location, or depth and a maximum rate of change <0.5^{0}C per hour. The CCME interim WQG for salinity limits the change of salinity to 10% from background conditions for a given time and depth. The residual chlorine concentration at the edge of the initial dilution zone, will be below the CCME WQG (0.5 µg/L). The exact size of the initial dilution zone is not yet known, and will be determined through modelling in the permitting phase. However, under the Fisheries Act, waste discharges within and outside the initial dilution zone, cannot be acutely toxic to fish. The effect of desalination waste discharge was assessed based on adherence to legally-binding legislation, designed to protect aquatic life. Further details on Project waste discharges are provided in the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2020.1	round 1	Gitxaala Nation	4.3.2.2	Greenhouse Gases	Upstream sources of GHG emissions represent a key uncertainty with respect to the potential for GHG VC effects to occur. A results-based adaptive environmental management plan can be implemented through the stated commitment if the goals and values of all interests are given credible consideration in the consultation process. It is a necessary condition of the formal adaptive management process. Why has this uncertainty not been considered in the Project's GHG managment and emissions reduction plan and directly tied to the commitment to undertake an adaptive management approach, as stated in Section 1.2.10, page 1-43 of Part A of the Application?	Upstream GHG emissions will be emitted by other operators and not Aurora LNG. The management of upstream emissions are not controlled by this Project. Direct emissions from the Project will be managed through the GHG Management Plan identified in Section 4.3.5.2 of the Application. Following receipt of a letter from ECCC to the EAO (dated December 1, 2016) regarding the requirement for an Aurora LNG Project Upstream Greenhouse Gas Assessment, Aurora LNG and the EAO agreed on the delivery date of Feb 22, 2017 for the upstream assessment report. The Aurora LNG Project Upstream Greenhouse Gas Assessment has been completed and delivered to the EAO.
2021.1	round 1	Gitxaala Nation	4.3.5.1	Greenhouse Gases	Appendix B was completed by Sana Talebi and Sandra Banholzer with a quality review by Daniel Hegg. Michael Murphy conducted the "independent" review; however, all of these individuals, including Murphy, work for Stantec, so how is the review considered to be independent? Is it not a conflict of interest?	The designated roles of Author, Discipline Lead, Quality Reviewer, and Independent Reviewer refer to the internal quality review processes undertaken as part of document development and completion. It is not intended to indicate that an independent third-party review was completed.
2022.1	round 1	Gitxaala Nation	4.3.4	Greenhouse Gases	Presumably any and all GHG emissions represent a measurable form of waste that warrants direct consideration as a Project interaction. Explain how the exclusion of treated and disposed of sewage and wastewater (especially from the desalination process) can be justified as not applicable to the effects assessment for the GHG VC?	The treatment of sanitary, stormwater, and wastewater were excluded from the GHG assessment due to the expected minimal concentration of GHGs entrained in the liquids. The handling of these liquids was assumed to not generate predictable or substantive volumes of GHG emissions.
2023.1	round 1	Gitxaala Nation	4.3.5.1	Greenhouse Gases	The expectation of negligible fugitive emissions with the stated mitigation is not a fair assumption. Numerous sources of fugitive emissions potentially exist apart from the few examples listed in the assessment. The Proponent identifies in its VC assessment scope and selection of GHGs that "[methane] is the main component of natural gas... produced by human activities, including the burning of fossil fuels, fugitive sources, and venting activities" (Section 4.3.2.4, p. 4.3-6). There is clear potential for fugitive emissions to result as a VC effect because it is present in all phases of the industry as a whole and is conventionally known and understood to be a problem in other phases. It is also a source of uncertainty that cannot be factored into GHG emissions reporting and this must not be overlooked. Fugitive emissions should not be assumed as negligible in the LNG production process. Rather, the problem represents a key uncertainty with respect to GHGs effects and should be managed through a credible operational monitoring program in the very least, and directly tied to the commitment to undertake an adaptive management approach, as stated in Section 1.2.10, page 1-43 of Part A of the Application.	As identified in Section 4.3.5.2 of the Application, "A GHG Management Plan will be prepared to identify the requirements of relevant GHG reporting legislations and will contain continuous assessment of monitoring and management requirements applicable to the mitigations listed in Table 4.3-12". Mitigation 4.3.5 states a fugitive emission detection program will be implemented with the aim to detect and repair fugitive leaks.
2024.1	round 1	Gitxaala Nation	4.3.5.1	Greenhouse Gases	Presence of international LNG carriers is a necessary outcome of this Project. The analysis warrants better justification for excluding LNG shipping from the Project's operational total for GHGs emissions, especially if this is already known (or assumed to be known) based on a previous assessment completed by the same consultancy (i.e., PNW 2014).	Shipping activities have been quantified and presented in Table 4.3-14 of Section 4.3 of the Application. These totals include emissions from LNG carriers (international) and domestic boats. In the GHG assessment, Project operation emissions are compared to PIR and NIR totals to determine the impact or percent contribution. However, the PIR and NIR totals do not include international shipping activities so they were excluded in this comparison. The GHG emission intensity presented in the Application also does not include international shipping emissions as these would not be included in future compliance reporting obligations and would not be included in annual operation GHG intensity calculations.
2025.1	round 1	Gitxaala Nation	4.3.5.2	Greenhouse Gases	Please explain and provide more details to justify this conclusion that GHG emissions from the dismantling of LNG facility during the decommissioning phase is expected to result in less GHG emissions in comparison to the construction phase.	Given the nature of the activity, it is expected that equipment usage will be for a shorter period and less intensive than the construction phase (i.e. no land clearing during decommissioning), and future mobile equipment (i.e., 30 years in the future) will likely consume fuel more efficiently. These factors suggest that during the decommissioning phase of the Project, GHG emissions are predicted to be less than the construction phase.
2026.1	round 1	Gitxaala Nation	4.3.5.2	Greenhouse Gases	A rationale has been provided for the mitigation, but not for the conclusions around likelihood and uncertainty. This is not meaningful as rationale and should not be considered acceptable. If the need has been identified for mitigation in the effects assessment, the rationale should not be limited to a response for selecting a specific mitigation measure. It should be provided in response to the actual assessment of the mitigation measure (i.e., determining that the mitigation will be successful, given the uncertainty it proffers). By the current logic, a reviewer has no choice but to accept all statements re: success and uncertainty of mitigation without any rationale provided. This is a critical element of any credible effects assessment, otherwise how can the assessment of the success of mitigation be meaningfully justified?	The majority of the mitigations presented in the GHG Assessment have been proposed with the understanding that there is a high degree of certainty that they will reduce the amount of GHG emissions released to the atmosphere. These mitigations relate to the removal or reduction of the source of GHG emissions (i.e. reduction in fuel consumption reduces the source of GHG emissions).
2027.1	round 1	Gitxaala Nation	4.3.5.2	Greenhouse Gases	How does "project design" constitute acceptable rationale for selecting a mitigation measure? The reviewer is supposed to just accept statements re: success and uncertainty of mitigation without a rationale, but this is a critical element of any credible effects assessment. Furthermore, stating that an "industry standard" is appropriate rationale for selecting a mitigation measure is quite meaningless. it does not indicate any interest by the Proponent to innovate or work to assist the Province and federal government in achieving legally binding GHG reduction targets. The Proponent already indicated in the GHG VC assessment that targets will not be met based on an analysis previously provided in the effects assessment (refer to Section 4.3.3.2 on p. 4.3-11, paragraph 5).	Project design refers to mitigations that are project specific and have historically been demonstrated to reduce GHG emission with a high degree of certainty. For instance, the use of efficient natural gas turbine technology to drive the refrigeration compressors in the liquefaction process will reduce fuel consumption. A reduction of fuel consumption is known (to a high degree of certainty) to reduce GHG emissions from combustion. Industry standard mitigations are those that were considered to be commonly adopted by proponents in the LNG industry and in other sectors. For instance, conducting scheduled preventative maintenance of facility and equipment as per the maintenance management system, will aim to avoid instances where GHG emissions are unintentionally released or where equipment is not operated at its most efficient state.
2028.1	round 1	Gitxaala Nation	4.3.5.2	Greenhouse Gases	A fugitive emissions detection program (Mitigation No. 4.3.5) is considered to have "a high likelihood of success" with a "high degree of certainty", yet there is no mention of the program in any other part of the VC assessment or in Part E. The Proponent has previously excluded the contribution of upstream GHG emissions in the VC assessment, claiming it cannot conclusively factor upstream GHGs into the assessment due to the high degree of uncertainty around the methods for quantification (Table 4.3-3, p. 4.3-4). This uncertainty is principally due to the problem of fugitive emissions, so clearly this will be a challenge and the conclusion about the success of the measure is not valid. More details should be provided to justify this conclusion, especially given the current uncertainty around the ability to detect and account for fugitive emissions in the industry as a whole, including the upstream phase that has been excluded from the assessment despite the stated directive from CEA Agency to include it.	A fugitive emission detection program has been identified as a mitigation for Project direct (onsite) GHG emissions. Upstream activities may also release fugitive GHG emissions; however, these emissions will need to be addressed by the proponent who owns/operates the upstream operations. The Project specific fugitive emission detection program identified in Mitigation 4.3.5 will be discussed in further detail in the GHG Management Plan. The proposed Project fugitive emission detection program is not related to the upstream assessment requested by the CEA Agency. The Upstream GHG Assessment identified in Table 4.3-3 of the Application was delivered, as request by the EAO, in February 2017.
2029.1	round 1	Gitxaala Nation	4.3.5.2	Greenhouse Gases	Please provide rationale for including the following mitigations in both the GHG Management and Air Quality Management plans: Mitigation Nos. 4.2.1, 4.2.3 to 4.2.6, and 4.2.11 to 4.2.13. Explain how they are intended to apply to each specific plan.	The rationale for including Mitigation 4.2.1, 4.2.3 to 4.2.6, and 4.2.11 to 4.2.13 in the GHG Assessment and Air Quality Assessment are identified in Table 4.3-12 and Table 4.2.10, respectively . These mitigations are either recognized as industry best practice, a project specific design element, or required by a policy/regulation/guideline.
2030.1	round 1	Gitxaala Nation	4.3.5.2	Greenhouse Gases	Explain the logic behind a "moderate" likelihood of success and certainty of the GHG Management Plan when all other mitigation measures associated with it, excluding Mitigation No. 4.2.1, have been considered to have a high likelihood of success with a high degree of certainty. This is untenable.	The majority of the mitigations presented in the GHG Assessment have been proposed with the understanding that there is a high degree of certainty that they will reduce the amount of Project GHG emissions released to the atmosphere. These mitigations relate to the removal or reduction of the source of GHG emissions (i.e. reduction in fuel consumption reduces the source of GHG emissions). The GHG Management Plan does not directly reduce GHG emissions, but instead it is used to understand and identify activities that should or could be taken to reduce GHG emissions. Therefore, implementation of the Plan and the reduction activities are required to realize the benefits. Without all the details of the Plan finalized, slightly more uncertainty (around success of the proposed mitigations) was conservatively factored in to the assessment characterizations.
2031.1	round 1	Gitxaala Nation	4.3.6	Greenhouse Gases	The Proponent has determined the Project to have a high likelihood of residual effects that are indicative of a long-term disturbance that is irreversible during all phases. This represents among the worst of possible outcomes in terms of characterizing a residual effect, yet a cumulative effects assessment is allegedly not possible according to the assessment methods developed? The assessment methods are weak and inappropriate for this VC in particular. For example, the Project's operational carbon footprint alone is estimated at 6.7 Mt/year continually, which is approximately 10.6% of the entire Province's GHG emissions and 0.9% of the GHGs for all of Canada (based on the 2014 NIR provided in Table 4.3-6, p 4.3-11). This is a substantive increase in GHG emissions and is directly cumulative to current known GHG emissions for provincial and federal jurisdictions. A jurisdictional assessment alone is indicative of the cumulative impact from a single project. This cumulative effects assessment requires more direct consideration of other projects in BC and Canada of similar economic magnitude and for all industry sectors, many of which currently use clean power sources in BC. In light of BC's and Canada's annual contributions to global GHGs and the legislated commitments for GHG emissions reduction (Table 4.3-2; pp. 4.3-2 for Canada and 4.3-3 for BC), this should be the benchmark for assessing cumulative risk. The Proponent should revise its cumulative effects assessment methodology to be more credible and efficacious, since GHG emissions represent among the most contentious of VCs identified for this project with respect to human values at this point in history.	As outlined in the approved AIR, the cumulative environmental effect related to GHGs is measured at the global level by international bodies such as the Intergovernmental Panel on Climate Change (IPCC) and is associated with global climate change. Thereby, the evaluation of cumulative effects to the degree outlined in this comment is outside of the scope of this assessment. Conclusions of the GHG assessment (Section 4.3.6 and 4.3.7 of the Application) acknowledge that GHG emissions from anthropogenic sources are extremely likely (as defined by IPCC) to be altering the global climate (IPCC 2013). Since the Project is contributing GHG emissions to an already significant cumulative effect of global GHG levels on climate change, the Project's GHG emissions are considered significant in the CEA case.
2032.1	round 1	Gitxaala Nation	4.3.6	Greenhouse Gases	This statement that "LNG would displace higher carbon intensity fuels (such as oil and coal)" is inappropriate and out of context, given the uncertainty and underestimation of the overall GHG intensity for BC's natural gas industry. Such language ignores the current carbon footprint associated with the upstream extraction phase of the industry in BC, upon which it inextricably depends and much of which is now largely sourced through hydraulic fracturing. This is a well known source of fugitive methane emissions that cannot reliably be measured and factored into the current accounting system of GHG emissions for the industry in BC (see previous comment in response to Part A, Section 1.5.1.1, p. 1-73). The statement should be removed from the assessment.	The sentence following the statement quoted in this comment provides additional context. It states "if the LNG exported from BC manages to reach a lower life cycle intensity than other fuel sources around the world, then exporting BC LNG could have an overall positive effect on global GHG levels." In this respect, it is acknowledged that the benefits are dependent on the life cycle intensity of the LNG compared with the fuel it is displacing.
2033.1	round 1	Gitxaala Nation	4.3.8	Greenhouse Gases	High onfidence based on "Scientific certainty relative to the effectiveness of the proposed mitigation measures", among other measures is untenable if the likelihood of success and certainty of the GHG Management Plan (i.e., Mitigation No. 4.3.6) has been considered as "moderate". Moreover, all other mitigation measures associated with the GHG Management Plan have been considered to have a "high" likelihood of success with a "high" degree of certainty, except Mitigation No. 4.2.1. This represents 8 of 12 or 75% of all mitigation proposed for the VC, so the conclusion is illogical. It either ignores additional, less certain mitigation measures that have not been listed or it fails to effectively weigh the individual value of the listed mitigation measures in the proposed GHG Management Plan. Please explain this conclusion.	The majority of the mitigations presented in the GHG Assessment have been proposed with the understanding that there is a high degree of certainty that they will reduce the amount of GHG emissions released to the atmosphere. These mitigations relate to the removal or reduction of the source of GHG emissions (i.e. reduction in fuel consumption reduces the source of GHG emissions). The GHG Management Plan does not directly reduce GHG emissions, but instead it is used to understand and identify further activities that should or could be taken to reduce GHG emissions. Until all details of the Plan have been finalized and implemented, a lower level of certainty has been conservatively applied. The calculation of 8 of 12 or 75% is not clearly described in the comment and the request to explain a conclusion is not understood.
2034.1	round 1	Gitxaala Nation	4.5.13.1	Water Quality	Appendix F was completed by Pola Wojnarowicz with contributions by Molly Brewis and a quality review by Karen Munro. Janine Beckett conducted the "independent" review; however, all of these individuals, including Beckett, work for Stantec, so how is the review considered to be independent? Is it not a conflict of interest?	Author, discipline lead, quality reviewer, and independent reviewer designations refer to the internal quality review processes undertaken as part of document development and completion. It is not intended to indicate that an independent third-party review was completed.
2035.1	round 1	Gitxaala Nation	4.5.5.3	Water Quality	Explain the logic behind the "moderate" likelihood of success and certainty of the Air Quality Management Plan. Measures associated with the plan, excluding Mitigation No. 4.2.10, represent >75% of all mitigation proposed for the VC and are considered to have a "high" likelihood of success with a high degree of certainty. The conclusion is illogical and either ignores additional, less certain mitigation measures that have not been listed or fails to effectively weigh the individual value of the listed mitigation measures in the proposed Air Quality Management Plan. Please explain this conclusion.	Mitigations with a "high" likelihood of success (4.1.1, 4.2.2, 4.1.3, 4.2.4, 4.1.5, 4.2.6, 4.1.7, 4.2.9, 4.1.11, 4.1.12, 4.2.13) will highly control or eliminate specific types of air emissions (e.g. avoid or eliminate burning). As such they are rated "high". Mitigations with a "moderate" likelihood of success (4.1.8, 4.2.10) will reduce emissions but cannot completely eliminate other types of air emissions (e.g. adopting BAT for gas turbines, implementing an AQMP with a mix of actions rated "high" and "moderate"). To be conservative, they are rated "moderate". Certainty relates to the expected degree of success. Not burning will be 100% successful in eliminating emissions from burning; hence the high degree of certainty. Gas turbine emission controls are proven, effective, measurable, and can be improved upon through mitigation measures. But they cannot be completely eliminated; hence the moderate uncertainty.
2036.1	round 1	Gitxaala Nation	4.5.8	Water Quality	There is a "high degree of confidence" that residual and cumulative effects will not be significant and the Air Quality Management Plan (i.e., Mitigation No. 4.2.8) is the principal mitigation measure for this VC effect. It has been considered as "moderate". Conclusions on prediction confidence and effectiveness of mitigation are illogical and either ignore additional, less certain mitigation measures that have not been listed or the conclusion has failed to effectively weigh the individual value of the listed mitigation measures in the proposed for the Air Quality Management Plan. Please explain this conclusion.	The significance of adverse residual effects to freshwater ecosystems from acidification and eutrophication is based on a review of existing conditions, and consideration of predicted pH changes and critical load exceedances. The degree of confidence is based on the quality of the baseline data, understanding of project effect mechanisms, effectiveness of mitigation measures, and by using conservative assumptions and thresholds throughout the assessment. Because facility emissions are predicted to result in deposition of acid and nutrient inputs into the aquatic ecosystems, air quality mitigation measures are expected to manage and reduce the overall air emissions, which will in turn reduce the predicted effects to aquatic ecosystems.

2037.1	round 1	Gitxaala Nation	4.5.14	Water Quality	How has wastewater discharge at the deep outfall from the desalination process been factored into the project interactions table? The desalination process will lead to wastewater disposal at Charles Point withough any clear demonstaration that it will be treated prior to dispoal based on the conceptual layout provided in Figure 1-2 of Part A, Section 1. Effluent will be highly concentrated in ambient solutes including salts and metals, among other contaminants that are likely to be present in seawater from the surrounding industrial activities.	Desalination waste water will meet CCME and BC water quality guidelines (WQG) for temperature and salinity, outside of the initial dilution zone. These guidelines allow a maximum change of ±1^{0}C from ambient at any time, location, or depth and a maximum rate of change <0.5^{0}C per hour. The CCME interim WQG for salinity limits the change of salinity to 10% from background conditions for a given time and depth. The residual chlorine concentration at the edge of the initial dilution zone, will be below the CCME WQG (0.5 µg/L). Results of the baseline water quality monitoring program indicate that metal concentrations in seawater in the Local Assessment Area, are generally well below BC MOE water quality guidelines. Of the 41 metals analyzed, 23 were below detection limits in all samples analyzed, and only boron and copper, which are naturally elevated in the area, exceeded guidelines (see Section 5.8.1 of Appendix F, Marine Sediment and Water Quality TDR). Metal contamination is therefore not predicted to be an issue in desalination waste water. The exact size of the initial dilution zone at the discharge site is not yet known, and will be determined through modelling in the permitting phase. However, under the Fisheries Act, waste discharges within and outside the initial dilution zone, cannot be acutely toxic to fish. The effect of desalination waste discharge was assessed based on adherence to legally-binding legislation, designed to protect aquatic life. Further details on Project waste discharges are provided in the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2038.1	round 1	Gitxaala Nation	4.5.15.3	Water Quality	The Proponent has previously acknowledged the potential effect from desalinated water, but there is no indication that the disposal of wastewater from the desalination process itself, an apparent requirement for hydrostatic testing during the construction and commissioning phase, will affect marine sediment and water quality or the associated marine biota. Also, the conceptual layout of the Project on Figure 1-2 of Section 1 shows the desalination plant footprint with a single excurrent water line leading to the deep outfall at Charles Point. There is no indication that any sanitary or treated wastewater from the construction camp or other sources will interact with this single pipe leading to the deep outfall. Please explain the inconsistency.	As stated in Section 4.5.15.3 of the Application (Project Mechanisms for a Change in the Physical or Chemical Composition of Marine Waters): "Desalinated seawater is anticipated to be used for hydrostatic testing of the LNG storage tanks and associated piping. Because discharge of test water will comply with the regulations and guidelines listed in Mitigation 4.5.9, the discharged water will not contain contaminants or “deleterious substances” (as defined in section 36 of the Fisheries Act). The test water will be released in a controlled manner to limit changes in general chemistry (e.g., temperature, salinity, pH) of the receiving marine waters. Therefore, no adverse effect on marine water quality is predicted due to hydrostatic testing." Mitigation 4.5.9, Table 4.5-26 states: "Hydrostatic testing will comply with the Canadian Association of Petroleum Producers Hydrostatic Test Water Management Guidelines (CAPP 1996), and discharged water will meet CCME Water Quality Guidelines for the Protection of Aquatic Life. If biocides are used, the test water will be neutralized prior to discharge" Figure 1-2 is a high-level conceptual layout, intended to show approximate locations of major Project components. Full details of the waste water management system will be developed during Front End Engineering Design. As stated in Mitigation 4.5.8, Table 4.5-26 "Waste discharges to the marine environment will comply with the Fisheries Act, CEPA, CSA 2001, BC Environmental Management Act, Waste Discharge Regulation, the Petroleum Storage and Distribution Facilities Storm Water Regulation, and the CCME Water Quality Guidelines for the Protection of Aquatic Life." Further details on Project waste discharges are provided in the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2039.1	round 1	Gitxaala Nation	4.5.15.3	Water Quality	The conceptual layout on Figure 1-2 of Part A, Section 1 shows the desalination plant footprint located within the PDA, as well as its incurrent and excurrent water lines. A single wastewater line exits the plant and leads directly to the deep outfall at Charles Point. There is no indication that wastewater from the desalination process will be effectively treated at the Wastewater Treatment Plant and Stormwater Retention Ponds located further south in the PDA. There is also no indication that any sanitary or treated wastewater from the construction camp or other sources will be connected to the deep outfall based on this conceptual layout. Please justify the exclusion and clarify if/how desalination wastewater will be treated prior to disposal?	Figure 1-2 is a high-level conceptual layout, intended to show approximate locations of major Project components. Full details of the wastewater management system will be developed during Front End Engineering Design. As stated in Mitigation 4.5.8, Table 4.5-26 "Waste discharges to the marine environment will comply with the Fisheries Act, CEPA, CSA 2001, BC Environmental Management Act, Waste Discharge Regulation, the Petroleum Storage and Distribution Facilities Storm Water Regulation, and the CCME Water Quality Guidelines for the Protection of Aquatic Life." Desalination wastewater will meet CCME and BC regulatory water quality guidelines (WQG) for temperature and salinity, outside of the initial dilution zone. These guidelines allow a maximum change of ±1^{0}C from ambient at any time, location, or depth and a maximum rate of change <0.5^{0}C per hour. The CCME interim WQG for salinity limits the change of salinity to 10% from background conditions for a given time and depth. The residual chlorine concentration at the edge of the initial dilution zone, will be below the CCME WQG (0.5 µg/L). The exact size of the initial dilution zone is not yet known, and will be determined through modelling in the permitting phase. However, under the Fisheries Act, waste discharges within and outside the initial dilution zone, cannot be acutely toxic to fish. The effect of desalination waste discharge was assessed based on adherence to legally-binding legislation, designed to protect aquatic life. Further details on Project waste discharges are provided in the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2040.1	round 1	Gitxaala Nation	4.5.15.3	Water Quality	The expected "high" success and "no expected risk" in terms of the uncertainty of Mitigation No. 4.5.8 are not justifiable with respect to the possible disposal of disharge cooling water from the power station and desalination plant effluent. The mechanism has not even been finalized according to the Proponent (see p. 4.5-62, paragraph 3). Clearly it cannot be credibly factored into the effects assessment for wastewater disposal. It also represents a key uncertainty that has been irresponsibly ignored such that the Proponent has not adequately considered the risks to marine sediment and water quality, as well as "marine fish and fish habitat and aquatic species". Therefore, this conclusion is untenable and should be re-evaluated.	Please see the "Discharges to the Marine Environment" technical memo for more details on how waste discharges to the marine environment are managed and how their potential effects were assessed. The technical memo will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2041.1	round 1	Gitxaala Nation	4.5.15.3	Water Quality	The expected "high" success and "no expected risk" in terms of the uncertainty of Mitigation No. 4.5.9 are not justifiable with respect to the possible disposal of wastewater from hydrostatic testing and desalination plant effluent. The mechanism has not even been finalized according to the Proponent (see p. 4.5-62, paragraph 3), although the desalination process has been stated as a necessary condition since hydrostatic testing involves desalinated water (see p. 4.5-60, final bulleted statement). The effect has not has not been credibly factored into the effects assessment for wastewater disposal and represents a key uncertainty that the Proponent has not adequately considered as a risk to marine sediment and water quality, as well as "marine fish and fish habitat and aquatic species". Therefore, this conclusion is untenable and should be re-evaluated.	Please see the "Discharges to the Marine Environment" technical memo for more details on how waste discharges to the marine environment are managed and how their potential effects were assessed. The technical memo will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2042.1	round 1	Gitxaala Nation	4.5.15.3	Water Quality	This is not sufficient waste management information to credibly undertake an effects assessment of discharge at the deep outfall and its impact on marine sediment and water quality and "marine fish and fish habitat and aquatic species" . Therefore the conclusions for Mitigation Nos. 4.5.8 and 4.5.9 are unjustiable and should be re-evaluated to acknowledge the high uncertainty with respect to potential effects..	Please see the "Discharges to the Marine Environment" technical memo for more details on how waste discharges to the marine environment are managed and how their potential effects were assessed. The technical memo will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2043.1	round 1	Gitxaala Nation	4.5.15.3	Water Quality	The Proponent states on p. 4.5-79 that "with mitigation, the receiving marine waters will meet CCME and BC water quality guidelines (mitigation 4.5.8). How is this commitment considered mitigation? There is no indication of what specific processes will be required to achieve this commitment such that it mitigates effects to marine sediment and water quality, as well as "marine fish and fish habitat and aquatic species", should they occur. Mitigation 4.5.8 has been determined by the Proponent to have "high" success such that "there are no expected risks with this mitigation measure" during the construction phase of the Project, yet there is no description provided about the mitigation itself. This conclusion is untenable and should be re-evaluated.	Please see the "Discharges to the Marine Environment" technical memo for more details on how waste discharges to the marine environment are managed and how their potential effects were assessed. The technical memo will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2044.1	round 1	Gitxaala Nation	4.5.15.3	Water Quality	This is a vague statement with respect to managing "power station cooling water". How exactly will the temperature and volume be "managed"? Is the desalination process expected lead to temperature changes that must be similarly "managed"?	Project waste water (including Desalination and cooling waste water) will meet CCME and BC water quality guidelines (WQG) for temperature and salinity, outside of the initial dilution zone. These guidelines allow a maximum change of ±1^{0}C from ambient at any time, location, or depth and a maximum rate of change <0.5^{0}C per hour. The CCME interim WQG for salinity limits the change of salinity to 10% from background conditions for a given time and depth. The residual chlorine concentration at the edge of the initial dilution zone, will be below the CCME WQG (0.5 µg/L). The exact size of the initial dilution zone is not yet known, and will be determined through modelling in the permitting phase. However, under the Fisheries Act, waste discharges within and outside the initial dilution zone, cannot be acutely toxic to fish. The effect of desalination waste discharge was assessed based on adherence to legally-binding legislation, designed to protect aquatic life. Further details on Project waste discharges are provided in the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2045.1	round 1	Gitxaala Nation	4.5.15.3	Water Quality	What about the treatment of other water quality parameters in the desalination effluent? Desalination will likely lead to wastewater that is highly concentrated in ambient solutes including salts and dissolved metals, among other contaminants that are likely to be present n seawater from the surrounding industrial activities near Prince Rupert (i.e., the "long history of industrial activity noted in Section 4.5.13.2, p. 4.5-53 of the Application, which references a "complete list of potential contaminant sources in the Prince Rupert Harbour area" in Appendix F), and especially because the location of te seawater intake will be in Casey Cove where the MOF will essentially serve as an industrial port with its "historical marine waste dump". Other parameters, such as temperature, have not be adequately considered. No treatment mechanisms have been proposed for the desalination effluent, apart from a stated potential need for dechlorination of any wastewater, presumably because initial chlorination would be intended as a biocide? This is a deficiency of the effects assesment on marine sediment and water quality, as well as "marine fish and fish habitat and aquatic species" and should be re-evaluated.	Project waste water (including Desalination waste water) will meet CCME and BC water quality guidelines (WQG) for temperature and salinity, outside of the initial dilution zone. These guidelines allow a maximum change of ±1^{0}C from ambient at any time, location, or depth and a maximum rate of change <0.5^{0}C per hour. The CCME interim WQG for salinity limits the change of salinity to 10% from background conditions for a given time and depth. The residual chlorine concentration at the edge of the initial dilution zone, will be below the CCME WQG (0.5 µg/L). Results of the baseline water quality monitoring program indicate that metal concentrations in seawater in the Local Assessment Area, are generally well below BC MOE water quality guidelines. Of the 41 metals analyzed, 23 were below detection limits in all samples analyzed, and only boron and copper, which are naturally elevated in the area, exceeded guidelines (see Section 5.8.1 of Appendix F, Marine Sediment and Water Quality TDR). Metal contamination is therefore not predicted to be an issue in desalination waste water. The exact size of the initial dilution zone at the discharge site is not yet known, and will be determined through modelling in the permitting phase. However, under the Fisheries Act, waste discharges within and outside the initial dilution zone, cannot be acutely toxic to fish. The effect of desalination waste discharge was assessed based on adherence to legally-binding legislation, designed to protect aquatic life. Further details on Project waste discharges are provided in the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2046.1	round 1	Gitxaala Nation	4.5.15.3	Water Quality	It is not possible to determine that the "likelihood of residual effects will be low during the operations phase because of the effectiveness of the mitigation measures" on marine sediment and water quality, as well as "marine fish and fish habitat and aquatic species" at this stage. There is not enough information about the Project design to provide specific and meaningful mitigation measures. It is also irresponsible to make likelihood statements at this stage of the Project and in terms of uncertainty and the effectiveness of mitigation, which has not been articulated with any degree of certainty. The statements favour the Proponent's interest over the interests the public and the potential risks posed to the marine environment.	The primary mitigation measures to protect marine water during operations, are treatment and monitoring of waste discharges. Waste discharges are subject to regulatory and permit constraints, designed to protect the marine environment. Aurora LNG will be legally obliged to adhere to these regulatory and permit constraints. The likelihood of residual effects under normal operations is therefore low. Further details on Project waste discharges are provided in the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2047.1	round 1	Gitxaala Nation	4.5.15.3	Water Quality	It is not possible to determine the likelihood of the mitigation measures for the effects on marine sediment and water quality, as well as "marine fish and fish habitat and aquatic species" at this stage. There is not enough information about the Project design to provide specific and meaningful mitigation measures. It is also irresponsible to make likelihood statements at this stage of the Project and in terms of uncertainty and the effectiveness of mitigation. The statements favour the Proponent's interest over the interests the public and the potential risks posed to the marine environment.	The mitigation measures proposed for marine water and sediment quality are based on well-understood, established practices. While not all details of the Project design are available at this stage, mitigation measures such as those pertaining to Project waste discharges to the marine environment are regulated, permitted activities. As such, the Project must be designed in a manner that adheres to these regulations and permits. The likelihood of success of mitigation measures was determined based on this rationale. Further details on Project waste discharges are provided in the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2048.1	round 1	Gitxaala Nation	4.5.16	Water Quality	Please correct the Table of Contents document of the EA application for this subsection. It is on p. 4.5-82, not p. 4.5-79.	Aurora LNG acknowledges the error in the Table of Contents. An errata document is being compiled that captures these corrections and it will be filed with the BC EAO.

2049.1	round 1	Gitxaala Nation	4.5.16.2	Water Quality	The Proponent states "the scale and type of effects to water quality are similar for the Project and for other activities and projects in the RAA". How many proposed LNG projects in the RAA will contain desalination plants for operational water supply with a plan to take in enough seawater in an area of a former marine waste dump to supply approxiamtely 9500 cubic metres of desalinated process water daily, then discharge all wastewater into the marine receiving environment? The conceptual layout (Figure 1-2 in Section 1, Part A) has no apparent linkage to the expected water treatment areas in the PDA. Although other LNG terminals proposed in the RAA may discharge effluent from cooling towers, how many other non-LNG industrial projects in the RAA currently discharge cooling tower effluent or desalination wastewater into the marine receiving environment? This is not a credible statement, given the lack of information on the Project and deficiencies in the residual effects assessment for wastewater and effluent discharge. How is the anticipated "ongoing releases of wastewater (treated and untreated, as applicable) to the marine environment during construction, operations, and decommissioning" similar for other activities and projects in the RAA?	The cumulative effects assessment takes into consideration that all other projects must abide by the same waste discharge regulations and permits that the Project will be subject to. For example, under the Fisheries Act, no project can discharge waste to fish habitat that is acutely toxic to fish; waste discharges are subject to permit conditions that limit the quantity and quality of waste and impose monitoring requirements. Therefore, the scale and type of effects to water quality will be similar for the Project and all other projects in the RAA. As acknowledged in Section 4.516.3 of the Application, several existing facilities have existing or historical effluent discharges to the marine environment, the effects of which are recognized in the existing baseline water quality conditions. Operating facilities require discharge permits, with associated effluent criteria, and typically produce a small mixing zone around the discharge point. These facilities are not near the proposed Project location (see Appendix F Marine Sediment and Water Quality TDR). The Project's contributions to cumulative effects on marine water quality are not expected to result in a health risk to a local or regional population of marine biota.
2050.1	round 1	Gitxaala Nation	4.5.16.3	Water Quality	In the likelihood statement no consideration has been given to the potential for cumulative effects due to discharge from effluent and wastewater in the marine receiving environment. The statement on p. 4.5-88 should be re-evaluated to acknowledge the uncertainty in wastewater discharge given the lack of baseline water quality information and lack of description of specific mitigation measures attributable to Mitigation Nos. 4.5.8 and 4.5.9 in terms of the means of treatment by which regulatory compliance will occur for marine water quality.	The likelihood of residual cumulative effects statement focused on dredging, because sediment dispersion associated with this activity has the potential for site-specific effects, and is not subject to dedicated legislation. As stated in Section 4.5.15.3, Characterization of Residual Effects, waste discharges are subject to legislation designed to protect marine life, so adverse effects to water quality from waste discharges under normal operations are therefore not predicted.
2051.1	round 1	Gitxaala Nation	4.5.18	Water Quality	In this likelihood statement no consideration has been given to the potential for cumulative effects due to discharge from effluent and wastewater in the marine receiving environment. The statement on p. 4.5-90 should be re-evaluated to acknowledge the uncertainty in wastewater discharge given the lack of baseline water quality information and lack of description of specific mitigation measures attributable to Mitigation Nos. 4.5.8 and 4.5.9 in terms of the means of treatment by which regulatory compliance will occur for marine water quality.	As noted in Section 4.5.18 of the Application, "The mechanisms for effects and the mitigation measures are well understood. Furthermore, the predicted effects to marine water quality were compared to conservative regulatory guidelines". This statement applies to waste discharges, which are stringently regulated, and will be subject to well-established treatment methods. Further details on Project waste discharges are provided in the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2052.1	round 1	Gitxaala Nation	4.5.19	Water Quality	Incredibly, no follow-up programs are proposed even though there are no baseline sediment or water quality data in the area of the deep outfall and only limited baseline fisheries data exist, which indicate the area of the outfall to be relatively high risk due to the diversity of marine species observed during the ROV surveys? This should be unacceptable.	A follow-up program is not proposed because dredging and marine construction activities are short term effects and not expected to affect water quality during operations or subsequent decommissioning. Waste discharge from the deep outfall will be subject to end-of-pipe monitoring in accordance with waste discharge permit requirements. These permit requirements are designed to protect marine life. Additional monitoring of the receiving marine environment is not proposed but the need for such monitoring will be re-assessed based on permit requirements. Further details on Project waste discharges are provided in the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2053.1	round 1	Gitxaala Nation	4.5.20	Water Quality	The Proponent states "with mitigation, the Project residual effects on marine water quality are predicted to be not significant because the significance threshold (risk to the health of marine organisms) will not be exceeded". For all the reasons previously stated in the commentary for Section 4.5, this statement is irresponsible, illogical, and should be unacceptable.	Aurora LNG acknowledges that Gitxaala Nation disagrees with the conclusions of the assessment. However, the conclusions were developed in accordance with the requirements of the AIR. The rationale supporting the residual effect conclusion noted above is provided in Section 4.5.20, Marine Water - Conclusions. Please see the "Discharges to the Marine Environment" technical memo, which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2054.1	round 1	Gitxaala Nation	4.6.3.1	Vegetation and Wetland Resources	Appendix I was completed by Christine Lion and Nicole Tennant asa discipline lead and quality reviewer. Matthew Ramsay conducted the "independent" review; however, all of these individuals, including Ramsay, work for Stantec, so how is the review considered to be independent? Is it not a conflict of interest?	The designated roles of Author, Discipline Lead, Quality Reviewer, and Independent Reviewer refer to the internal quality review processes undertaken as part of document development and completion. It is not intended to indicate that an independent third-party review was completed.
2055.1	round 1	Gitxaala Nation	4.6.5.2	Vegetation and Wetland Resources	An Invasive Species Management Plan and/or Inveasive Plant Management Plan is not listed among the "Management and/or Compensation Plans" of the mitigation summary table for this Mitigation No. 4.6.4. Please include it.	An Invasive Plant Management Plan is referenced in Table 4.6-10 for mitigation measure 4.6.4 in the column labelled "Expected Success/Risks and Uncertainty". This plan further mitigates the risk of adverse effects from invasive plant species that could occur while stockpiling the organic layer of soil for future use during reclamation.
2056.1	round 1	Gitxaala Nation	4.6.5.3	Vegetation and Wetland Resources	No reference is given for Mitigation No. 4.6.10 among the "Management and/or Component Plans". How will the BC MOE vegetation and soils monitoring request be tracked and what are the terms of reference to "monitor for changes in vegetation and soils, and provide adaptive management if necessary"?	Section 15.2.2 of the Application describes the proposed acidification and eutrophication follow-up program, which corresponds with mitigation measure 4.6.10. Monitoring in accordance with mitigation measure 4.6.10 will likely be among the EA Conditions issued by regulators if the Project is approved. Through the EA Conditions, it is anticipated that Aurora LNG will be directed to develop the monitoring plan in consultation with the Ministry of Environment and Aboriginal Groups. The Condition is also expected to outline any periodic reporting requirements. The resulting plan is expected to include the terms of reference for monitoring, detail reporting requirements, and include an adaptive management framework and criteria for selecting the management option during the course of the monitoring period. Aurora LNG's framework for adaptive management is as follows: Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended).
2057.1	round 1	Gitxaala Nation	4.6.6.2	Vegetation and Wetland Resources	The field sampling methodology applied in the Appendix I study is not appropriate to reliably detect invasive plant presence in the PDA. Invasive plants are more likely to be found at or near disturbed sites that have not been identified in the survey sampling protocol. Results are limited to more generalized vegetation plots for all plant species of interest. This is relevant to the vegetation program, but the lack of observation of invasive plants among veg plots should not be so heavily relied upon in making likelihood statements about the risk of invasive species. The assumption that the PDA overall lacks invasive plant species solely based on general veg plot observations in Appendix I is unjustified. The assessment should be re-evaluated, given the limitations posed by the results in Appendix I with respect to invasive plant species presence in the PDA.	The conclusions of the assessment are not based solely on the absence of invasive species within the PDA, but also the implementation of Best Management Practices in the Invasive Plant Management Plan (the reasoning is the same as that described for residual project effects in Section 4.6.5.2 of the Application), and the fact that none of the reasonably foreseeable future projects overlap spatially with the LAA. It is the opinion of Aurora LNG that the conclusion of no residual cumulative effects on plant species of interest due to the introduction or spread of invasive plants is sound, regardless of a lack of baseline surveys focused exclusively on detecting invasive plant species within the PDA.
2058.1	round 1	Gitxaala Nation	4.6.6.3	Vegetation and Wetland Resources	There is no mention of the cumulative risk of invasive plants for "Change in Abundance of Plant Species of Interest". Given the limitations of the survey methods applied in Appendix I, in terms of the ability to credibly examine and verify the presence of invasive plants in the PDA, the cumulative effects assessment needs to be re-evaluated.	No residual project effects are predicted on plant species of interest by invasive plants (in Section 4.6.5.2 of the Application). Additionally, none of the reasonably foreseeable future projects overlap spatially with the LAA; therefore there are no cumulative interactions that may introduce invasive plant species. It is the opinion of Aurora LNG that there is no need to re-evaluate the cumulative effects assessment to include invasive plants.
2059.1	round 1	Gitxaala Nation	4.7.3.1	Wildlife Resources (Terrestrial)	Appendix J was completed by Eloise Rowland and Jayme Brooks with Megan Willie as a discipline lead and quality reviewer. Colleen Bryden conducted the "independent" review; however, all of these individuals, including Bryden, work for Stantec, so how is the review considered to be independent? Is it not a conflict of interest?	Author, discipline lead, quality reviewer, and independent reviewer designations refer to the internal quality review processes undertaken as part of document development and completion. It is not intended to indicate that an independent third-party review was completed.
2060.1	round 1	Gitxaala Nation	4.7.5.3	Wildlife Resources (Terrestrial)	With respect to Mitigation No. 4.7.14 and "the extent to which marine birds are susceptible to light-induced mortality", how will monitoring and adaptive management occur if there are no follow-up programs proposed for marine birds in the Wildlife Management Plan, apart from the Marbled Murrelet Management Plan?	Mitigation 4.7.14 is inclusive of all bird species, and is listed in Sections 4.7 and 4.11 of the Application. The Wildlife Management Plan will provide a description of the procedures for searching, documenting, and reporting bird injuries and mortalities and will be consistent with applicable Environmental Assessment Certificate conditions. Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended).
2061.1	round 1	Gitxaala Nation	4.7.5.3	Wildlife Resources (Terrestrial)	With respect to Mitigation No. 4.7.16 and "the extent to which migratory birds are susceptible to light-induced mortality", how will monitoring and adaptive management occur if there are no follow-up programs proposed for migratory birds in the Wildlife Management Plan, apart from the Marbled Murrelet Management Plan?	Mitigation measure 4.7.16 is inclusive of all bird species, and is listed in Sections 4.7 and 4.11. The Wildlife Management Plan will provide a description of the procedures for searching, documenting, and reporting bird injuries and mortalities and will be consistent with applicable Environmental Assessment Certificate conditions. Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended).
2062.1	round 1	Gitxaala Nation	4.9.2.4	Marine Fish and Fish Habitat	Table 4.9-3 effect mechanisms for changes in mortality risk and health do not acknowledge effluent discharge from the desalination process or desalinated LNG processing water at the deep outfall. The seawater intake has been acknowledged as a mechanism for mortality risk, but nowhere in the table are marine sediment and water quality, as well as "marine fish and fish habitat and aquatic species" listed as measureable parameters for effect mechanisms at the deep outfall for any of the project effects identified. The potential effects should be re-evaluated to reflect this, otherwise a residual effects assessment cannot be credibly conducted.	Potential effects to fish and fish habitat resulting from waste discharges to the marine environment are assessed in the Marine Fish and Fish Habitat assessment under Project Mechanisms for Change in Health, Section 4.9.5 of the Application. This section details the mechanisms for change in fish health due to waste discharges during construction, operation, and decommissioning. The assessment identifies waste discharges during construction and operations, including power generation cooling water and treated sanitary wastewater (which may include chlorine content). Mitigation 4.5.8 in Table 4.9-20 covers waste discharges to the marine environment. Potential residual effects are assessed in the Characterization of Residual Effects for Change in Fish Health, under Construction – Waste Management, and Operations – Waste Management. The fish and fish habitat assessment did not assess waste discharge characteristics (e.g. temperature, chlorine concentration) individually. Instead, the potential for all waste discharges to affect fish health was assessed. Waste discharges, regardless of make up, are managed in the same manner; permit conditions limit the quality and quantity of the waste discharged and impose monitoring requirements. Aurora LNG is legally-obliged to abide by permit conditions, which are designed to protect marine life. Therefore, waste discharge effects to fish and fish habitat were considered not significant. The assessment of potential effects to fish and fish habitat resulting from waste discharges is supported by information from the Marine Water Quality assessment (Section 4.5.11 of the Application). A significant residual adverse environmental effect on marine water quality is one that is predicted to result in a change in sediment or water quality that would result in a health risk to a local population of marine biota. The marine water quality assessment therefore covers changes in water quality that may significantly affect fish and fish habitat. Table 4.5-19 in the Marine Water Quality section lists Project-related wastewater inputs to the marine environment as a project effect mechanism, and potential effects of this mechanism are assessed in Section 4.5.15. Mitigations 4.5.8 and 4.8.9 in Table 4.5-26 cover waste discharges to the marine environment. Potential residual effects to marine water quality related to waste management are characterized in the Characterization of Residual Effects component of Section 4.5.15.3. Further details on project waste discharges and associated regulations, are provided in the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.

2063.1	round 1	Gitxaala Nation	4.9.3.1	Marine Fish and Fish Habitat	Results of algae, marine vegetation and sessile species for CRA marine invertebrates in Appendix L showed the highest community diversity at sites CC07 (10 species present) and CC08 (9 species present) in the Casey Cove study area, which are the closest to the location of the deep outfall at Charles Point . Similarly for the East Digby Island study area, the highest diversity was observed at sites ED01 (22 species present) and ED04 (29 species present) with Site ED1 being the closest to the deep outfallof all nine study area transects during November 2015. Why has this location been selected given the results from these surveys?	Species richness in the marine environment is driven by a variety of physical and biological factors. Principal among these is substrate type. For algae and sessile invertebrates, which require hard substrate for attachment, species richness is almost always higher on rocky substrates than on soft sediment substrates. Of the eight ROV transects surveyed in Casey Cove, CC07 and CC08 are the only two that overlapped areas where the dominant substrate type was rocky (see Figure 16 in the Marine Fish and Fish Habitat Technical Data Report, Appendix L). All other transects overlapped soft bottom substrates or mixed substrates. Hence, the relatively higher species richness on transects CC07 and CC08 is likely due to the presence of rocky substrates around Charles Point. Substrates along the east side of Digby Island are primarily rocky, with cobble/gravel being dominant (see Figure 18 in Appendix L). Differences in species richness among East Digby Island ROV transects are likely due to site-specific conditions, such as slope, depth, substrate type distribution, and exposure. The proposed location of the outfall pipe to the south of Charles Point considered a number of ecological and engineering factors. First, the location was selected to minimize the distance between water use and treatment areas (located near Casey Cove) and the point of discharge. Second, the location capitalizes on the steep slope of the seabed off Charles Point in order to minimize the length of submarine pipe required to discharge at depth. This reduces the marine footprint of the pipe. Third, the location avoids areas of eelgrass identified in Casey Cove, and delivers the effluent to a location far enough away from the intake to avoid interaction between the outfall and the intake. Fourth, the outfall point is located in the channel between Digby and Kaien Islands, where strong currents will effectively disperse the effluent stream. It is important to note that the outfall pipe has a relatively small footprint in the marine environment, and will therefore have limited interaction with marine species. Based on preliminary design the pipe itself is anticipated to have an outside diameter of 0.76 m. It will be trenched through the intertidal zone (approximately 100 m distance), and will lie on the seafloor in the subtidal zone (approximately 130 m distance). Following trenching and backfilling in the intertidal zone, substrates will be returned to conditions similar to those prior to construction (i.e., boulder, cobble, gravel). This will expedite the recolonization of the affected habitat by algae and invertebrates. Furthermore, Aurora LNG will implement habitat offsetting measures for the permanent alteration of rocky habitat that results from installation of the outfall pipe. For further discussion on the proposed offsetting measures, please see the Conceptual Fish Habitat Offsetting Plan (Appendix V).
2064.1	round 1	Gitxaala Nation	4.9.3.1	Marine Fish and Fish Habitat	Results of marine fish and motile invertebrates summarized in Appendix L do indicate the presence of taxa among sites, but the data summary does not meaningfully indicate either mean or total abundance of taxa per site as a meaningful indication of the spatial distribution and relative abundance of taxa within the individual study areas. Tabulatng means per taxon within study areas gives no understanding of community structure within study areas and in relation to project mechanisms, such as the location of the deep outfall. Data should be properly summarized and re-interpreted to be meaningful to the residual effects assessment.	Determination of total abundance of taxa in a given study area is impractical; the dynamic, variable, and open nature of marine environments mean that an exhaustive amount of effort would need to be expended to try wo capture or sample all organisms. Instead, by subsampling within each study area using different methods (e.g., intertidal transects, ROV video, beach seines) over time, we can obtain an estimate of the typical relative abundance of each taxon observed (e.g., mean or median) and the typical variability of relative abundance (e.g., standard deviation or inter-quartile range). This comment refers to marine fish and motile invertebrates. Even if all of these organisms could be sampled in order to tabulate total abundance, daily, seasonal, and inter-annual movement of organisms mean that the specific location of capture in a study area would be of questionable relevance to the assessment of interaction with Project mechanisms. Understanding of community structure within a study area can be gained by interpreting patterns in relative abundance and variability of taxa over time.
2065.1	round 1	Gitxaala Nation	4.9.3.1	Marine Fish and Fish Habitat	Why do the survey methods in Table 4.9-16 not mention the crab trapping surveys by Triton/Khtada (Aug. 2014 and Mar. 2015) and Stantec (Aug. 2015 and May 2016)? Have these data not been factored into the effects assessment?	The collection of crab presence information through opportunistic trap sampling is described in the paragraph above Table 4.9-6. Full crab trapping methods are described in Section 5.3.1 and 5.3.2 of Appendix L of the Application. Results of these trapping efforts are reported in Section 5.3.3 of Appendix L and were used, together with other data reported in Appendix L, to inform the effects assessments.
2066.1	round 1	Gitxaala Nation	4.9.3.1	Marine Fish and Fish Habitat	According to Appendix L, no crab trapping baseline data exist in the East Digby study area near Charles Point where the deep outfall location is proposed. It is also unclear from the results how the distribution and abundance of marine crustaceans account specifically for this potentially affected location due to the physical presence of the discharge pipe and deep outfall. This represents a seasonal and spatial data deficiency and a source of uncertainty with respect to "marine fish and fish habitat and aquatic species" in subtidal marine habitats.	Crab and shrimp observations made during the ROV survey of the area near Charles Point are shown in Figure 20 of Appendix L of the Application. Crab and shrimp observed within the East Digby Island study area are described o p. 48 of Appendix L. These observations are used, along with the scientific literature described in Appendix L, to inform the assessment of effects relating to the discharge pipe and deep outfall.Characterization of residual effects resulting from the physical effects of the outfall pipe is found on p. 4.9-75 of the Application. The likelihood of residual effects for change in behaviour from the physical presence of the outfall is assessed on p. 4.9-78 of the Application. Aurora LNG believes that the field data and scientific information available are sufficient to support this assessment.
2067.1	round 1	Gitxaala Nation	4.9.3.1	Marine Fish and Fish Habitat	According to Appendix L, no baseline data exist for marine fish in the area directly south of Charles Point where the deep outfall location is proposed. It is unclear from the results how the distribution and abundance of marine fishes account specifically for this potentially affected area due to the discharge pipe and outfall, effluent discharge from the desalination process or desalinated LNG process water at the deep outfall. This data should be considered measureable parameters, given the effects potential identified. This represents a seasonal and spatial data deficiency and a source of uncertainty with respect to "marine fish and fish habitat and aquatic species" in subtidal marine habitats.	Marine fish observations made during the ROV survey of the area near Charles Point are shown in Figure 19 of Appendix L of the Application. Marine fish observed within the East Digby Island study area are described o p. 47 of Appendix L. These observations are used, along with the scientific literature described in Appendix L, to inform the assessment of effects relating to the discharge pipe and deep outfall. Characterization of residual effects as a result of the physical effects of the outfall pipe is found on p. 4.9-75 of the Application. The likelihood of residual effects for change in behaviour from the physical presence of the outfall is assessed on p. 4.9-78 of the Application. Aurora LNG believes that the field data and scientific information available are sufficient to support this assessment.
2068.1	round 1	Gitxaala Nation	4.9.3.1	Marine Fish and Fish Habitat	According to Appendix L, no 2014 baseline data exist for intertidal or subtidal habitats in Casey Cove, the MOF location where dredging is expected, or the area directly south of Charles Point where the deep outfall location is proposed. March 2015 trawls (Triton) cover part of the outfall area during the day (i.e., transects DT3 and DT4) and at night (i.e., transect NT2), but the transect lengths extend south to Emmerson and Phillips points, which are well beyond the potentially affected area. It is unclear from the results how the distribution and abundance of individual trawl data account specifically for the abundance in potentially affected areas, such as the deep outfall, where discharge from the desalination process or desalinated LNG processing water is expected. This represents a seasonal and spatial data deficiency and a source of uncertainty with respect to "marine fish and fish habitat and aquatic species" in subtidal and benthic marine habitats.	Baseline data characterizing intertidal and subtidal habitats in Casey Cove, including the MOF location where dredging is expected, are presented in Appendix L (intertidal: Section 5.1.3.1, Figure 9; subtidal: Section 5.2.3.1, Figures 14-17; eelgrass: Section 5.4.3.1, Figure 32, and marine fish: beginning on p. 79). Baseline data characterizing intertidal and subtidal habitats along East Digby Island, including the area south of Charles Point where the deep outfall is proposed, are presented in Appendix L (intertidal: Section 5.1.3.2, Figure 10; subtidal: Section 5.2.3.2, Figures 18-2; eelgrass: Section 5.4.3.2, Figure 33; and marine fish: beginning on p. 86). The trawl segments referred to in this comment and reported in Appendix 5 of Appendix L were exploratory in nature and were intended to inform a broad characterization of the Project LAA. The baseline observations referred to above are used, along with the scientific literature described in Appendix L, to inform the assessment of effects relating to the discharge pipe and deep outfall. Characterization of residual effects as a result of the physical effects of the outfall pipe is found on p. 4.9-75 of the Application. The likelihood of residual effects for change in behaviour from the physical presence of the outfall is assessed on p. 4.9-78 of the Application. Aurora LNG believes that the field data and scientific information available are sufficient to support this assessment.
2069.1	round 1	Gitxaala Nation	4.9.3.1	Marine Fish and Fish Habitat	With respect to marine sediment and water quality sampling (Appendix F), no baseline data exist for the area directly south of Charles Point where the deep outfall location is proposed. Without an understanding of baseline conditions, it is unclear from the results how marine sediment and water quality will potentially be affected by persistent and continual effluent discharge from the desalination process or desalinated LNG processing water at the deep outfall. These should be considered important indicators for determining measureable parameters, given the effects potential from sustained effluent discharge. This represents a data deficiency and a source of uncertainty with respect to marine sediment and water quality and "marine fish and fish habitat and aquatic species" in subtidal marine habitats.	Although no marine sediment or water quality samples were collected specifically at the location of the proposed Charles Point outfall, water quality and sediment samples collected in other areas of the LAA are expected to be representative of conditions at the Charles Point outfall (i.e., conditions at the location of the Charles Point outfall are not expected to differ substantially from other areas in the LAA). Appendix F (Marine Sediment and Water Quality Technical Data Report) describes the methods and results of the water quality and sediment sampling programs. A total of 227 marine sediment samples were collected from 57 sites in December 2014 (surface grabs only) and January 2016 (surface grabs and cores). Sediment sampling locations are identified in Figure 1 and Figure 2 of Appendix F. Water quality monitoring was conducted during the December 2014 sediment sampling field program at a location within each of the three proposed Project dredge footprints. These data were supplemented with water quality monitoring data collected quarterly (from 2013 through 2015) by the Prince Rupert Port Authority at six nearby sites. Figure 5 of Appendix F identifies the location of the water quality monitoring sites. The potential parameters of concern for the sanitary treatment plant, desalination plant, and cooling-water blowdown are total suspended solids, biological oxygen demand, nutrients, temperature, salinity, and (to a lesser degree) chlorine, which are not expected to affect water quality (outside a defined initial dilution/mixing zone) or sediment quality. Please also see the "Discharges to the Marine Environment" memo , which was developed in response to several comments. This technical memo will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting. The need for additional information to characterize existing conditions for marine water and sediment quality will be discussed with appropriate regulators (e.g., Ministry of Environment) during permitting for the Charles Point outfall. Aurora LNG is committed to completing a Marine Water Quality Monitoring Program to monitor water quality parameters in effluent discharges according to permitting requirements (see Section 15.3.6 of the Summary of Follow-Up Programs and Compliance Reporting Chapter). Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Marine Water Quality Monitoring Program prior to use to the outfall.
2070.1	round 1	Gitxaala Nation	4.9.3.1	Marine Fish and Fish Habitat	Appendix L was completed by Sandra Warren and Stefan Dick with a quality review by Tim Edgell. Karen Munro conducted the "independent" review; however, all of these individuals, including Munro, work for Stantec, so how is the review considered to be independent? Is it not a conflict of interest?	The designated roles of Author, Discipline Lead, Quality Reviewer, and Independent Reviewer refer to the internal quality review processes undertaken as part of document development and completion. It is not intended to indicate that an independent third-party review was completed.
2071.1	round 1	Gitxaala Nation	4.9.4	Marine Fish and Fish Habitat	Potential effects exist for the seawater intake and discharge of wastewater at the deep outfall, due to desalination processes during commissioning and start-up. Effects would lead to changes in mortality risk and behavioural changes in marine fish through entrainment and impingement at the seawater intake, behavioural avoidance the seawater intake, behavioural disturbance at physically altered habitats at the intake and outfall pipes, and chemically altered habitats at the outfall. The determination on Table 4.9-8 is inappropriate and should be re-evaluated.	The assessment of potential injury or mortality of marine fish due to impingement/entrainment in the seawater intake pipe focused on the operations phase of the Project because this phase is of much longer duration (25+ years) than the commissioning and startup phase (1 year). However, Aurora LNG acknowledges that, if the desalination system is operational during commissioning(i.e., to withdraw water for hydrostatic testing), there is potential for impingement/entrainment of marine fish and invertebrates. The mitigation measure is the same as for operations (specifically, the implementation of DFO's guidelines for minimizing the entrainment and impingement of aquatic organisms; Mitigation number 4.9.15 in Table 4.9-19). The effect mechanism is the same as that described for the operations phase (see page 4.9-82, Operations - Waste Management: Seawater Intake). The effect characterization is also the same as that described for the operations phase, with the exception that frequency would be 'multiple irregular events' (i.e., whenthe water is drawn for hydrostatic testing purposes), as opposed to 'continuous' for operations. The remainder of the effect characterization criteria are the same: magnitude = moderate; geographic extent = LAA; duration = medium- to long-term; reversibility = reversible; context = disturbed. With the implementation of mitigation measures to reduce potential effects on marine fish and fish habitat associated with effluent discharge, such as commitments that all effluent discharges to the marine environment will comply with the BC Environmental Management Act regulations (i.e., Waste Discharge Regulation, Petroleum Storage and Distribution Facilities Storm Water Regulation), and will meet the CCME and BC water quality guidelines (which are designed to protect aquatic life) in the receiving environment outside of a defined mixing zone, Project-related discharges are not expected to result in residual adverse effects to marine fish habitat or marine fish behaviour.
2072.1	round 1	Gitxaala Nation	4.9.5.3	Marine Fish and Fish Habitat	The Project has indicated use of the seawater intake and outfall and the intent to treat at least some of the wastewater, such that is meets all jurisdictional guidelines, yet there is no mention of the need to treat wasterwater prior to disposal at sea to avoid changes in water quality that influence the behaviour of "marine fish and fish habitat and aquatic species" in subtidal marine habitats. The conceptual layout on Figure 1-2 of Part A, Section 1 shows the desalination plant footprint located within the PDA, as well as its incurrent and excurrent water lines. A single wastewater line exits the plant and leads directly to the deep outfall at Charles Point. There is no indication that wastewater from the desalination process will be effectively treated at the Wastewater Treatment Plant and Stormwater Retention Ponds located further south in the PDA and there is also no indication that any sanitary or treated wastewater from the construction camp or other sources will be connected to the deep outfall based on this conceptual layout. Effects related to the use and disposal of seawater have not been mentioned so the assessment is deficient and needs to be re-assessed.	Effluent discharges will be tested and treated, if required, prior to being discharged to the marine environment. Project-related effluent discharges to the marine environment will comply with the BC Environmental Management Act regulations (i.e., Waste Discharge Regulation, Petroleum Storage and Distribution Facilities Storm Water Regulation), and will meet the CCME and BC water quality guidelines (which are designed to protect aquatic life) in the receiving environment outside of a defined mixing zone. With adherence to these regulations and guidelines, Project-related discharges are not expected to result in residual adverse effects to marine fish behaviour. For further details, please see the "Discharges to the Marine Environment" technical memo, which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2073.1	round 1	Gitxaala Nation	4.9.5.3	Marine Fish and Fish Habitat	There is no mention in Table 4.9-15 of the need to mitigate the effect related to the physical presence of seawater intake and outfall as it influences the behaviour of marine fish and aquatic species in subtidal marine habitats. The assessment acknowledges the intake pipe (minimum 30 inch diameter) and outfall pipe (minimum 12 inch diameter) will sit "unburied and unprotected" on the seafloor and has based its results from a laboratory study with a protected (concrete-weight coated) pipe as is "unlikely to be insurmountable" to Dungeness and several other crab species (Section 4.9.5.3, p. 4.9-76), but "may be limited" to "smaller, less motile species", which have to migrate around the pipe and be put in direct exposure to effluent at the outfall and entrainment and impingement at the intake, both of which may also lead to mortality and health risks as a direct result of a changein behaviour. Please revise the mitigation table to address the effect.	Table 4.9-15 of the Application specifically describes measures to avoid or reduce changes in marine fish behaviour. Mitigation measure No. 4.9.15, provided in the Application, Table 4.9-18, describes measures to reduce mortality risk associated with entrainment and impingement of aquatic organisms at the seawater intake pipe. Mitigation measure No. 4.5.8, provided in the Application, Table 4.9-20, describes adherence to regulations and guidelines for wastewater discharges into the marine environment (i.e., via the outfall pipe) relevant to limiting adverse effects on marine fish health.
2074.1	round 1	Gitxaala Nation	4.9.5.3	Marine Fish and Fish Habitat	There is no mention in Table 4.9-15 of the effect related to the use and disposal of seawater at the deep outfall and a need to mitigate the effect as it influences the behaviour of marine fish and aquatic species in subtidal marine habitats. Please revise the mitigation table to address the effect.	Table 4.9-15 of the Application specifically describes measures to avoid or reduce changes in marine fish behaviour. The intake of seawater and outflow of wastewater discharge are considered within the Application, in Tables 4.9-19 and 4.9-20, which apply to mitigation measures for avoiding or reducing change in mortality risk and change in health of marine fish, respectively. Mitigation measure No. 4.9.15, provided in the Application, Table 4.9-18, describes measures to reduce mortality risk associated with entrainment and impingement of aquatic organisms at the seawater intake pipe. Mitigation No. 4.5.8, provided in the Application, Table 4.9-20, describes adherence to regulations and guidelines for wastewater discharges into the marine environment (i.e., via the outfall pipe) relevant to limiting adverse effects on marine fish health. For further details, please see the "Discharges to the Marine Environment" technical memo, which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2075.1	round 1	Gitxaala Nation	4.9.5.3	Marine Fish and Fish Habitat	Characterization of negligible "residual changes in the behaviour of marine fish caused by the physical presence of the marine water intake and outfall pipes on the seabed" is illogical - it is "continuous and permanent", indicating the pipes will not be removed, yet it is expected to be "reversible following the removal of the pipe structures"? Moreover, there are no baseline data to verify the presence of crustaceans in the affected area, since crab trapping surveys were neither conducted in the area of the deep outfall pipe according to Appendix L, nor have they crab trapping surveys been mentioned in the effects assessment methods for existig condiitons. It is therefore not possible to make statements about an effect as negligible if no baseline data exist upon which to make such a determination. Assuming crustaceans are present along with "smaller, less motile" invertebrate species, the assessment acknowledges at least portions of the intake pipe (minimum 30 inch diameter) and outfall pipe (minimum 12 inch diameter) will sit "unburied and unprotected" on the seafloor. The Proponent has based its determination on a laboratory study that used a protected (concrete-weight coated) pipe, which is not directly comparable as a surface, and deemed the pipe "unlikely to be insurmountable" to Dungeness and several other crab species (see Section 4.9.5.3, p. 4.9-76), but "may be limited" to "smaller, less motile species". These species would have to migrate around the pipe and be put in direct exposure to the effluent discharge plume that has not been modeled or estimated by volume at the outfall where is may or may not even be treated according to Figure 1-2 in Section 1 of Part A. This will also lead to potential mortality and health risks as a direct result of the change in behaviour. The assessment is deficient and needs to be re-evaluated.	The presence of unburied portions of the intake and outfall pipes on the seabed is considered of negligible magnitude for change in behaviour of marine fish because of the expected ability of highly motile species that undertake nearshore migrations (e.g., Dungeness crab) to cross unburied portions and the ability of less motile species to move around the edge of the unburied portions of pipe. The expected ability of highly motile invertebrate species to cross the intake and outflow pipes is supported by both field and laboratory studies (Glaholt 2008). Mitigation measure No. 4.5.8, provided in the Application, Table 4.9-20, describes adherence to regulations and guidelines for wastewater discharges into the marine environment (i.e., via the outfall pipe) relevant to limiting adverse effects on marine fish health. Reference Glaholt, R. D. 2008. Environment Concerns in Rights-of-Way Management. 8th International Symposium. Investigation of the Potential Effects of Marine Pipelines on Dungeness Crab Movement and Benthic Ecology.. J. W. Goodrich-Mahoney, L. P. Abrahamson, J. L. Ballard and S. M. Tikalsky. Amsterdam, Elsevier: 679-692.

2076.1	round 1	Gitxaala Nation	4.9.5.4	Marine Fish and Fish Habitat	The construction phase does not acknowledge mortality risk due to the operation of the seawater intake and outfall pipes and associated effect mechanisms during commissioning ans start-up. Hydrostatic testing for commissioning will make use of desalinated seawater, which indicates that the desalination plant and associated water use must be present as a mechanism in the construction phase, therefore the risk of impingement and entrainment is also present. The assessment is deficient and needs to be re-evaluated.	The assessment of potential injury or mortality of marine fish due to impingement/entrainment in the seawater intake pipe focused on the operations phase of the Project because this phase is of much longer duration (25+ years) than the commissioning and startup phase (1 year). However, Aurora LNG acknowledges that, if the desalination system is operational during commissioning (i.e., to withdraw water for hydrostatic testing), there is potential for impingement/entrainment of marine fish and invertebrates. The mitigation measure is the same as for operations (specifically, the implementation of DFO's guidelines for minimizing the entrainment and impingement of aquatic organisms; Mitigation number 4.9.15 in Table 4.9-19). The effect mechanism is the same as that described for the operations phase (see page 4.9-82, Operations - Waste Management: Seawater Intake). The effect charactrization is also the same as that described for the operations phase, with the exception that frequency would be 'multiple irregular events' (i.e., when the water is drawn for hydrostatic testing purposes), as opposed to 'continuous' for operations. The remainder of the effect characterization criteria are the same: magnitude = moderate; geographic extent = LAA; duration = medium- to long-term; reversibility = reversible; context = disturbed. For further details, please see the "Discharges to the Marine Environment" technical memo, which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2077.1	round 1	Gitxaala Nation	4.9.5.4	Marine Fish and Fish Habitat	The assessment acknowledges the intake pipe (minimum 30 inch diameter) and outfall pipe (minimum 12 inch diameter) will sit on "unburied and unprotected" on the seafloor and has based its results from a laboratory study with a protected (concrete-weight coated) pipe as is "unlikely to be insurmountable" to Dungeness and several other crab species (Section 4.9.5.3, p. 4.9-76), but "may be limited" to "smaller, less motile species", which have to migrate around the pipe and be put in direct exposure to effluent at the outfall and entrainment and impingement at the intake . How can this change in subtidal substrate be considered similar to "prior to construction" for Mitigation No. 4.9.7? There is not even a "low" likelihood of success with this mitigation as a "mechanism of recovery", since it is not even comparable to "perfect restoration of surface conditions" as stated in terms of expected success in the assessment. The assessment is deficient and needs to be re-evaluated.	This comment includes two points, which are addressed in turn below. -- Point 1: small, less motile species will have to migrate around the pipe and be put in direct exposure to effluent at the outfall and entrainment and impingement at the intake -- It is anticipated that most species (even "small, less motile species" whose movement "may be limited" by the pipeline) will be able to move across the infrastructure - an expectation based on field observations reported in Glahold (2008). "Smaller, less motile species" generally means infaunal (i.e. sediment dwelling) and demersal/epibenthic (i.e. on or near the seafloor) invertebrates. Glaholt (2008) complements his laboratory results with numerous field-based results, including many that relate to these species. Field observations come from (1) an outfall pipe (76 centimetres outer diameter [cm OD]) located in Bazan Bay, BC, and (2) a time series video, spanning ten years, of twin 25.4 cm OD pipelines crossing the Straight of Georgia, BC. Key conclusions from these field-based observations are summarised below: ___Bazan Bay___ 1. When community assemblages around the pipe were compared using standard statistical methods (i.e. Bray Curtis dissimilarity indices), the only major differences identified were between shallow eelgrass habitats and deep mud/silt habitats: "Other differences in community composition were not apparent using the analytical techniques employed". 2. Relationships between invertebrate abundance and increased distance from the pipeline depended on taxonomic group and side of the pipeline (north vs south), which (Glaholt postulates) could be due to differences in sediment composition. 3. Effects on benthic infaunal communities were highly localized and "non-pipeline related phenomena are likely at least as important as pipeline presence in determining patterns of species diversity and abundance in soft-bottom communities". 4. Observations from underwater video of the pipeline showed use of the infrastructure by demersal and epibenthic invertebrates, including many "small, less motile species", e.g. crabs (8 species, including Dungeness crab), shrimp (4 species), spot prawn, kelp fleas, nudibranchs (4 species), and "starfish" (2 species) were seen on the pipeline "suggesting that the pipeline was being traversed by these species". __Straight of Georgia___ 5. Crustaceans (box crab, red rock crab, california sea cucumber) actively crossed the pipelines. 6. There was a notable increase in abundances and diversity of species associated with the pipe infrastructure and protective concrete mattresses. Based on these observations, Aurora LNG does not expect seawater cooling system pipes to impede movement, except in rare circumstances, where individuals may have to circumnavigate the infrastructure via one end of the pipe. Regardless, if individuals do have to circumnavigate the infrastructure, they will not be impinged/entrained in the intake pipe because the mouth of the intake pipe will be elevated above the seafloor. Likewise, the end of the outfall pipe will be oriented upwards to promote mixing with the receiving environment and reduce exposure to benthic organisms. -- Point 2: How can this change in subtidal substrate be considered similar to "prior to construction" for Mitigation No. 4.9.7? There is not even a "low" likelihood of success with this mitigation as a "mechanism of recovery", since it is not even comparable to "perfect restoration of surface conditions" -- Please note that this section of the chapter relates to mortality risk; habitat effects are considered separately in Section 4.9.5.2, and in particular pages 4.9-55 (Installation of Seawater-System Pipes: Alteration of Substrate) and 4.9-64 (Physical Presence of Marine Water Intake and Outfall Pipes), where the substrate changes mentioned are fully assessed. The mitigation measures described in Table 4.9-18 pertain specifically to their capacity to avoid or reduce mortality risk. Even with the uncertainty relating to success as described in the table, the mitigation is expected to reduce mortality risk of 'fish' in the medium term.
2078.1	round 1	Gitxaala Nation	4.9.5.5	Marine Fish and Fish Habitat	With respect to waste management on p. 4.9-96, the Proponent states that "treated sanitary wastewater released from the land-based construction camp will be discharged into the marine environment through a deepwater outfall located off of Charles Point (near Casey Cove)". The conceptual layout on Figure 1-2 of Part A, Section 1 shows the desalination plant footprint located within the PDA, as well as its incurrent and excurrent water lines. A single wastewater line exits the plant and leads directly to the deep outfall at Charles Point. There is no indication that sanitary wastewater will be effectively treated from the construction camp or other sources and connect with the line leading to the deep outfall from the desalination plant. The statement needs to be corrected and the effects require re-assessment.	Figure 1-2 is a high-level conceptual layout, intended to show approximate locations of major Project components. Full details of the waste water management system will be developed during Front End Engineering Design. As stated in Section 4.5.15.3, Characterization of Residual Effects – Waste Management: waste water outfall designs and locations will comply with federal and provincial legislation designed to protect water quality. Sanitary wastewater will meet permit requirements, including dechlorination of any chlorinated wastewater. Mitigation 4.5.8, Table 4.5-26 also states that Project waste discharges to the marine environment will comply with the Fisheries Act, CEPA, CSA 2001, and the BC Environmental Management Act, Waste Discharge Regulation. Specific details on waste volumes and contaminant concentrations are not yet available and will be determined during Front End Engineering Design. However, Aurora LNG is legally obliged to abide by waste discharge regulations, designed to protect the marine environment. Environmental effects from waste discharge are therefore predicted to be not significant. Further details on Project waste discharges are provided in the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2079.1	round 1	Gitxaala Nation	4.9.5.5	Marine Fish and Fish Habitat	Statements pertaining to waste management on p. 4.9-97 confirm the preliminary state of the wastewater management system's design. Given this uncertainty, risk to marine sediments, water quality, and fish and aquatic species, cannot be evaluated with high confidence, as proclaimed in the mitigation measures. These statements are unfounded and misleading. The risks should be re-evaluated to admit these uncertainities and the Proponent should admit the uncertainty and frame mitigation in the context of adaptive management as a a commitment to address the potential effects.	All discharges to the marine environment, as a result of waste management, will comply with the Fisheries Act, Canadian Environmental Protection Act, the Canada Shipping Act (2001), the BC Environmental Management Act (i.e., Waste Discharge Regulations, Petroleum Storage and Distribution Facilities Storm Water Regulations), and will meet the CCME and BC water quality guidelines, which were specifically designed for the protection of aquatic life, and in consideration of health effects. Adherence with these regulations is a legislated requirement of all proponents, including Aurora LNG, and failure to adhere to them can have serious ramifications. Aurora LNG is committed to complying with these regulations and, hence, the mitigation measure assumes adherence will be achieved. See the "Discharges to the Marine Environment" technical memo which provides additional information and will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting. Details on the mitigation objectives, approach and field protocols will be developed and formalized in the Marine and Freshwater Resources Management Plan. This plan will include "water quality monitoring programs that will be implemented, including water quality thresholds, monitoring frequency and specific monitoring location". It is standard practice for management plans of this nature to include an adaptive management framework. Aurora LNG's framework for adaptive management is as follows: Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended). Aurora LNG will engage with the appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of environmental management plans.
2080.1	round 1	Gitxaala Nation	4.9.5.5	Marine Fish and Fish Habitat	There is no indication of what measures will be required to achieve Mitigation No. 4.5.8 to avoid potential effects to fish health, should changes occur in marine sediment and water quality, as well as "marine fish and fish habitat and aquatic species". Expected "high likelihood of success" and "no expected risks" are not justifiable with respect to waste discharge effects to fish health at the deep outfall because the design is preliminary and the deep outfall location at Charles Point is only one possible location (see p. 4.9-97, paragraph 3). The mechanism has also not been finalized according to the Proponent (see p. 4.5-62, paragraph 3). To declare the commitment as mitigative with a "high likelihood of success" is not credible as an effects assessment for wastewater disposal, given such high uncertainty. The Proponent has neither considered the risks to fish health nor the potential cost of adequately meeting the mitigation measure, which may not even be economically feasible given the magnitude of wastewater generated, so the conclusion is untenable and should be re-evaluated.	All discharges to the marine environment, as a result of waste management, will comply with the Fisheries Act, Canadian Environmental Protection Act, the Canada Shipping Act (2001), the BC Environmental Management Act (i.e., Waste Discharge Regulations, Petroleum Storage and Distribution Facilities Storm Water Regulations), and will meet the CCME and BC water quality guidelines, which were specifically designed for the protection of aquatic life, and in consideration of health effects. Adherence with these regulations is a legislated requirement of all proponents, including Aurora LNG, and failure to adhere to them can have serious ramifications. Aurora LNG is committed to complying with these regulations and, hence, the mitigation measure assumes adherence will be achieved. See the "Discharges to the Marine Environment" technical memo which provides additional information and will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting. Details on the mitigation objectives, approach and field protocols will be developed and formalized in the Marine and Freshwater Resources Management Plan. This plan will include "water quality monitoring programs that will be implemented, including water quality thresholds, monitoring frequency and specific monitoring location". It is standard practice for management plans of this nature to include an adaptive management framework. Aurora LNG's framework for adaptive management is as follows: Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended). Aurora LNG will engage with the appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of environmental management plans.
2081.1	round 1	Gitxaala Nation	4.9.5.5	Marine Fish and Fish Habitat	Why has Mitigation No. 4.5.9 been referenced in the waste management characterization on p. 4.9-104, but is not included in the mitigation summary table (Table 4.9-20) on p. 4.9-100? Please update the summary table to consider the potential for effects from desalinated water used for hydrostatic testing and associated discharge into the marine receiving environment (i.e., waste management).	Page 4.9-104 should say "Mitigation 4.5-8 [not 9]", which is included in Table 4.9-20. An errata document is being developed that will capture these corrections and it will be filed with the BC EAO.
2082.1	round 1	Gitxaala Nation	4.9.5.5	Marine Fish and Fish Habitat	This statement is inappropriate for characterizing residual effects potential, given the uncertainty in the deep outfall design and location and baseline information provided on the appropriate VCs. Lack of baseline data on marine water and sediment quality near Charles Point also indicate high uncertainty and and potentially high risk with respect to wastewater discharge effects on fish health. In either case, this effects determination is not appropriate and inconclusive.	Aurora LNG acknowledges that details around the design and operation of the Charles Point outfall are preliminary and will be refined during final engineering and design; however, Aurora LNG is of the opinion that characterization of potential effects on marine fish health associated with effluent discharges at the Charles Point outfall is adequate. The assessment considered information on marine fish and fish habitat collected from scientific literature and Project-specific studies (see Appendix L, Marine Fish and Fish Habitat TDR). The following sections in Appendix L provide information to characterize intertidal and subtidal fish and fish habitats along East Digby Island, including the area south of Charles Point where the deep outfall is proposed: Section 5.1.3.2, Figure 10 (intertidal); Section 5.2.3.2, Figure 18, Figure 19, Figure 20, and Figure 21 (subtidal); Section 5.4.3.2, Figure 33 (eelgrass); and Section 5.5.6, Figure 42 and Figure 43 (marine fish). With the implementation of mitigation measures to reduce potential effects on marine fish and fish habitat associated with effluent discharge, such as commitments that all effluent discharges to the marine environment will comply with the BC Environmental Management Act regulations (i.e., Waste Discharge Regulation, Petroleum Storage and Distribution Facilities Storm Water Regulation), and will meet the CCME and BC water quality guidelines (which are designed to protect aquatic life) in the receiving environment outside of a defined mixing zone, Project-related discharges are not expected to result in residual adverse effects to marine fish health. Aurora LNG is committed to conducting a Marine Water Quality Monitoring Program, which will include monitoring effluent discharges and the receiving environment as per permitting requirements (see Section 15.3.6 of the Summary of Follow-up Programs and Compliance Reporting). Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Marine Water Quality Monitoring Program. The technical memo "Discharges to the Marine Environment" provides additional information. This technical memo will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.

2083.1	round 1	Gitxaala Nation	4.9.5.5	Marine Fish and Fish Habitat	Declaring that no measurable changes to marine fish health will be expected to occur due to waste management or commissioning and start-up is inappropriate for characterizing the residual effects potential, given the uncertainty in the deep outfall design and location and baseline information provided on the VC. There is a lack of baseline data on marine fish (i.e., no crab trapping, beach seining, or tangle netting conducted in the affected area), site-specific limitations on the quality of the mid-water trawling data in the affected area, and the relatively high diversity of marine species have been observed from existing baseline subtidal ROV data obtained near Charles Point (i.e., sites ED01, CC07, and CC08). All of these factors indicate high uncertainty and potentially high risk with respect to the ROV data in particular; however, because the ROV data have not been effectively organized to undersand the spatial distribution and abundance within individual study areas, there is more uncertainty than risk. In either case, this effects determination is inconclusive and inappropriate. The assessment should be re-evaluated.	Aurora LNG acknowledges that details around the design and operation of the Charles Point outfall are preliminary and will be refined during final engineering and design; however, Aurora LNG is of the opinion that characterization of potential effects on marine fish health associated with effluent discharges at the Charles Point outfall is adequate. The assessment considered information on marine fish and fish habitat collected from scientific literature and Project-specific studies (see Appendix L, Marine Fish and Fish Habitat TDR). For further details, please see the "Discharges to the Marine Environment" technical memo, which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting. The following sections provide information to characterize intertidal and subtidal fish and fish habitats along East Digby Island, including the area south of Charles Point where the deep outfall is proposed: Section 5.1.3.2, Figure 10 (intertidal); Section 5.2.3.2, Figure 18, Figure 19, Figure 20, and Figure 21 (subtidal); Section 5.4.3.2, Figure 33 (eelgrass); and Section 5.5.6, Figure 42 and Figure 43 (marine fish). With the implementation of mitigation measures to reduce potential effects on marine fish and fish habitat associated with effluent discharge, such as commitments that all effluent discharges to the marine environment will comply with the BC Environmental Management Act regulations (i.e., Waste Discharge Regulation, Petroleum Storage and Distribution Facilities Storm Water Regulation), and will meet the CCME and BC water quality guidelines (which are designed to protect aquatic life) in the receiving environment outside of a defined mixing zone, Project-related discharges are not expected to result in residual adverse effects to marine fish health. Aurora LNG is committed to conducting a Marine Water Quality Monitoring Program, which will include monitoring effluent discharges as per permitting requirements (see Section 15.3.6 of the Summary of Follow-up Programs and Compliance Reporting). Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Marine Water Quality Monitoring Program. With respect to the organization of subtidal ROV data, observations of CRA fish species along each transect are shown on Figures 15 through 25 in Appendix L to visualize the spatial distribution of CRA fish observations within each study area. Furthermore, relative abundances of marine fish and invertebrates were calculated across transects, for each study area, and are presented in Appendix 2 of Appendix L.
2084.1	round 1	Gitxaala Nation	4.9.5.5	Marine Fish and Fish Habitat	There is not enough information about the preliminary project design to provide credible statements on the effectiveness of mitigation, given a lack of baseline data collected to understand the current environmental conditions (i.e., no sediment or water quality data and limited marine fish data in the area of the proposed deep outfall at Charles Point). Given the uncertainty in the deep outfall design, location, and limited baseline information provided on the VCs, a "negligible" residual effects determination (p. 4.9-105) is inappropriate. The assessment should be re-evaluated.	Aurora LNG acknowledges that details around the design and operation of the Charles Point outfall are preliminary and will be refined during final engineering and design; however, Aurora LNG is of the opinion that the characterization of potential effects on marine fish health associated with effluent discharges at the Charles Point outfall is appropriate. The assessment considered information on marine fish and fish habitat collected from scientific literature and Project-specific studies (see Appendix L, Marine Fish and Fish Habitat TDR). The following sections provide information to characterize intertidal and subtidal fish and fish habitats along East Digby Island, including the area south of Charles Point where the deep outfall is proposed: Section 5.1.3.2, Figure 10 (intertidal); Section 5.2.3.2, Figure 18, Figure 19, Figure 20, and Figure 21 (subtidal); Section 5.4.3.2, Figure 33 (eelgrass); and Section 5.5.6, Figure 42 and Figure 43 (marine fish). Furthermore, although no marine sediment or water quality samples were collected specifically at the location of the proposed Charles Point outfall, water quality and sediment samples collected in other areas of the LAA are expected to be representative of conditions at the Charles Point outfall (i.e., conditions at the location of the Charles Point outfall are not expected to differ substantially from other areas in the LAA). Appendix F (Marine Sediment and Water Quality Technical Data Report) describes the methods and results of the water quality and sediment sampling programs. A total of 227 marine sediment samples were collected from 57 sites in December 2014 (surface grabs only) and January 2016 (surface grabs and cores). Sediment sampling locations are identified in Figure 1 and Figure 2 of Appendix F. Water quality monitoring was conducted during the December 2014 sediment sampling field program at a location within each of the three proposed Project dredge footprints. These data were supplemented with water quality monitoring data collected quarterly (from 2013 through 2015) by the Prince Rupert Port Authority at six nearby sites. Figure 5 of Appendix F identifies the locations of the water quality monitoring sites. With the implementation of mitigation measures to reduce potential effects on marine fish health associated with effluent discharge, such as commitments that all effluent discharges to the marine environment will comply with the BC Environmental Management Act regulations (i.e., Waste Discharge Regulation, Petroleum Storage and Distribution Facilities Storm Water Regulation), and will meet the CCME and BC water quality guidelines (which are designed to protect aquatic life) in the receiving environment outside of a defined mixing zone, Project-related discharges are not expected to result in residual adverse effects to marine fish health. Aurora LNG is committed to conducting a Marine Water Quality Monitoring Program, which will include monitoring effluent discharges as per permitting requirements (see Section 15.3.6 of the Summary of Follow-up Programs and Compliance Reporting). Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Marine Water Quality Monitoring Program. With respect to the mitigation measures identified in the Marine Fish and Fish Habitat VC (Section 4.9), these measures are based on an understanding of existing conditions (characterized through scientific literature and extensive Project-specific field studies, see Appendix L), expected construction methods, timing, and Project design, professional experience with similar projects in the Pacific North Coast of BC, and industry-accepted best management practices. In most cases, mitigation measures proposed for marine fish and fish habitat are standard and have been proven to be effective at reducing effects to the marine environment. Additional details on the mitigation measures will be provided in the Marine and Freshwater Resources Management Plan. Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the marine and Freshwater Resources Management Plan.
2085.1	round 1	Gitxaala Nation	4.9.5.5	Marine Fish and Fish Habitat	It is irresponsible to make any likelihood statements (p. 4.9-106) at this stage of the project and in terms of the effectiveness of mitigation, especially since the statements are in favour of the Proponent's interest over the interests the public and the potential risks posed to the marine environment. Given the uncertainty in the deep outfall design, location, and baseline information provided on the VCs, the likelihood statement is not appropriate and should be re-evaluated.	Aurora LNG was required to provide a likelihood determination for each effect in the Marine Fish and Fish Habitat assessment (Section 4.9), as per the Environmental Assessment (EA) methods. The EA methods were outlined in the final Application Information Requirement document for the Aurora LNG Project and approved by the EAO. Aurora LNG acknowledges that there is uncertainty in the assessment of residual effects and this uncertainty is captured under Section 4.9.8 (Prediction Confidence) of the Marine Fish and Fish Habitat assessment. Follow up programs will be implemented to assess the accuracy of the predictions made in the EA and the effectiveness of the mitigation measures. These programs will include a Marine Water Quality Monitoring Program to characterize water quality parameters in effluent discharges as per permitting requirements (see Section 15.3.6 of the Summary of Follow-up Programs and Compliance Reporting). Aurora LNG is of the opinion that the level of information provided in the assessment of potential effects on marine fish and fish habitat (Section 4.9) is sufficient to evaluate the likelihood of residual effects.
2086.1	round 1	Gitxaala Nation	4.9.6	Marine Fish and Fish Habitat	This cumulative effects assessment is predicated on limited baseline data pertaining to VCs of interest, ignores uncertainty in risks, given the preliminary stage of the project design, flaws in logic and deficiencies in the effects assessment, and the wholly inconclusive characterization of residual effects. Based on this, a cumulative assessment cannot be credibly determined and should not be given further consideration until a more credible effects assessment is complete.	Aurora LNG acknowledges this comment but disagrees with the provided characterization of the cumulative effects assessment for Marine Fish and Fish Habitat.
2087.1	round 1	Gitxaala Nation	4.9.7.2	Marine Fish and Fish Habitat	The "residual effects" likelihood statement on p. 4.9-121 directly contradicts previous statements made on p. 4.9-112: "The likelihood of residual cumulative effects on marine fish habitat is considered high since, despite the widespread implementation of habitat compensation/offsetting, some adverse changes in habitat have occurred as a consequence of existing projects and activities and are expected to occur during construction of reasonably foreseeable future projects," as well as in Table 4.9-23 on p.4.9-118. The significance determination is inconclusive and inappropriate. The assessment should be re-evaluated.	Aurora LNG thanks you for highlighting this contradiction. The statement on page 4.9-121 (Section 4.9.7.2, first paragraph, first sentence) should read: "The likelihood of residual cumulative effects on marine fish habitat is considered high since, despite the widespread implementation of habitat compensation/offsetting, some adverse changes in habitat have occurred as a consequence of existing projects and activities and are expected to occur during construction of reasonably foreseeable future projects." An errata document is being compiled that will capture this correction and it will be filed with the BC EAO.
2088.1	round 1	Gitxaala Nation	4.9.7.2	Marine Fish and Fish Habitat	Explain how "the combined residual cumulative effects on marine fish and fish habitat are predicted to be not significant"? How can this be a logical conclusion if three of the four effects identified (i.e., habitat, behaviour, and mortality) have all been considered as having a high likelihood of occurrence, are either long-term or permanent, and with all habitat effects being irreversible? Moreover, the conclusion of a "low" likelihood of changes in fish health is inappropriate due to myriad reasons in previously stated comments, sources of uncertainty related to the deep outfall design and location, lack of baseline information provided on the VCs of interest (i.e., marine sediment, water quality, and fish and fish habitat and aquatic species), and the faulty logic behind the mitigation proposed. This all indicates more uncertainty than risk. This determination is inconclusive and inappropriate. The assessment should be re-evaluated.	The statement referenced in Section 4.9.7.2 (page 4.9-122) refers to the significance of the combined residual cumulative effects, not the likelihood of those effects. While there is a high likelihood of residual cumulative effects for changes in fish habitat, behaviour, and mortality risk, all four of the effects assessed are predicted to be not significant (see page 4.9-121). As there are no individually-significant residual cumulative effects, the combined residual cumulative effects are also predicted to be not significant. The rationale for the characterization of residual cumulative effects on marine fish health as 'low likelihood' is provided in Section 4.9.6.6 (page 4.9-118).
2089.1	round 1	Gitxaala Nation	4.10.5.2	Marine Wildlife - Marine Mammals	There is no mention of adaptive management to assist the Proponent in the development of effective monitoring programs that address the uncertainties in Mitigation Nos. 4.10.1 and 4.10.2. Reference is made to the Marine and Freshwater Resources Management. Plan. If not through adaptive management, how with the Proponent address the risks and uncertainties?	The Marine and Freshwater Resources Management Plan will be developed through engagement with regulators (i.e., DFO, the BC Oil and Gas Commission) and Aboriginal Groups. This plan will describe BMPs and mitigation measures that will be implemented during construction and operation of the LNG facility to avoid or reduce potential adverse effects of Project activities on marine mammals. The plan will include details on the following: Prior to the start of marine construction, acoustic modelling of in-water blasting will be done to verify assumptions and predictions made in this assessment and refine mitigation measures, as necessary.Field verification will be undertaken at multiple locations to confirm predicted extents of underwater noise levels over the full range of predicted values for in-water blasting and impact pile driving.A marine mammal monitoring program will be developed and implemented to enforce an exclusion zone during in-water impact pile driving and around the in-water blasting area.Aurora LNG is willing to collaborate in regional programs planned and developed by government and in conjunction with other proponents, regarding regional management of effects of underwater noise and vessel strikes on marine mammals in the RAA. Aurora LNG's framework for adaptive management is as follows: Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended).
2090.1	round 1	Gitxaala Nation	4.10.5.3	Marine Wildlife - Marine Mammals	There is no mention of adaptive management to assist the Proponent in the development of effective monitoring programs that address the uncertainties in Mitigation Nos. 4.10.1 and 4.10.2. Reference is made to the Marine and Freshwater Resources Management Plan. If not through adaptive management, how with the Proponent address the risks and uncertainties?	The Marine and Freshwater Resources Management Plan will be developed through engagement with regulators (i.e., DFO, the BC Oil and Gas Commission) and Aboriginal Groups. This plan will describe BMPs and mitigation measures that will be implemented during construction and operation of the LNG facility to avoid or reduce potential adverse effects of Project activities on marine mammals. The plan will include details on the following: Prior to the start of marine construction, acoustic modelling of in-water blasting will be done to verify assumptions and predictions made in this assessment and refine mitigation measures, as necessary.Field verification will be undertaken at multiple locations to confirm predicted extents of underwater noise levels over the full range of predicted values for in-water blasting and impact pile driving.A marine mammal monitoring program will be developed and implemented to enforce an exclusion zone during in-water impact pile driving and around the in-water blasting area.Aurora LNG is willing to collaborate in regional programs planned and developed by government and in conjunction with other proponents, regarding regional management of effects of underwater noise and vessel strikes on marine mammals in the RAA.
2091.1	round 1	Gitxaala Nation	4.10.5.4	Marine Wildlife - Marine Mammals	There is no mention of adaptive management to assist the Proponent in the development of effective monitoring programs that address the uncertainty in Mitigation No. 4.10.3. Reference is made to the Marine and Freshwater Resources Management Plan. If not through adaptive management, how with the Proponent address the risks and uncertainties?	The Marine and Freshwater Resources Management Plan will be developed through engagement with regulators (i.e., DFO, the BC Oil and Gas Commission) and Aboriginal Groups. This plan will describe BMPs and mitigation measures that will be implemented during construction and operation of the LNG facility to avoid or reduce potential adverse effects of Project activities on marine mammals. The plan will include details on the following: Prior to the start of marine construction, acoustic modelling of in-water blasting will be done to verify assumptions and predictions made in this assessment and refine mitigation measures, as necessary.Field verification will be undertaken at multiple locations to confirm predicted extents of underwater noise levels over the full range of predicted values for in-water blasting and impact pile driving.A marine mammal monitoring program will be developed and implemented to enforce an exclusion zone during in-water impact pile driving and around the in-water blasting area.Aurora LNG is willing to collaborate in regional programs planned and developed by government and in conjunction with other proponents, regarding regional management of effects of underwater noise and vessel strikes on marine mammals in the RAA.
2092.1	round 1	Gitxaala Nation	4.10.5.5	Marine Wildlife - Marine Mammals	Please explain why the operations phase was not included in the residual effects assessment in Table 4.10-11 (p. 4.10-71).	The potential for residual effects of change in health to marine mammals during routine operations, or from Project-related vessel traffic during any phase, is considered low and the potential interaction was not carried further into the assessment of change in health (see Section 4.10.5.2 of the Application). As a result, the operations phase was not included in the summary of Project residual effects on marine mammals (Table 4.10-11) for change in health. The summary of potential residual effects on change in behaviour and change in mortality risk during the operations phase are summarized in Table 4.10-11.
2093.1	round 1	Gitxaala Nation	4.10.5.5	Marine Wildlife - Marine Mammals	Table 4.10-12 gives no indication of specific mitigation measures that may be necessary for individual species, given the uncertainties. Blanket mitigation measures generally applied for all marine mammal species are not sufficient to address residual cumulative effects across auch a range of individual species with unique life histories and habitats, and especially for harbour porpoises if the effects are considered to be significant for this species.	The mitigation measures proposed are consistent with recovery strategies and action plans, where such documents exist. The suite of mitigation measures proposed are expected to be effective at achieving their primary objectives (i.e., to reduce potential for changes in health and behaviour during in-water blasting; to reduce potential for changes in health and behaviour during impact pile driving; and to to reduce potential changes in marine mammal mortality risk from increased risk of vessel strikes) regardless of the species of marine mammal under consideration. While each species may exhibit individual and unique life histories and habitats, the mechanisms for potential effects are common to all species.
2094.1	round 1	Gitxaala Nation	4.10.8	Marine Wildlife - Marine Mammals	Despite the uncertainties listed to arrive at the conclusion, there is no mention of adaptive mangment to assist the Proponent in the development of effective monitoring programs that can meaningfully address this uncertainty. If not through adaptive management, how with the Proponent address the risks and uncertainties?	The Marine and Freshwater Resources Management Plan will be developed through engagement with regulators (i.e., DFO, the BC Oil and Gas Commission) and Aboriginal Groups. The plan will include details on the following: Prior to the start of marine construction, acoustic modelling of in-water blasting will be done to verify assumptions and predictions made in this assessment and refine mitigation measures, as necessary.Field verification will be undertaken at multiple locations to confirm predicted extents of underwater noise levels over the full range of predicted values for in-water blasting and impact pile driving.A marine mammal monitoring program will be developed and implemented to enforce an exclusion zone during in-water impact pile driving and around the in-water blasting area.Aurora LNG is willing to collaborate in regional programs planned and developed by government and in conjunction with other proponents, regarding regional management of effects of underwater noise and vessel strikes on marine mammals in the RAA.

2095.1	round 1	Gitxaala Nation	4.10.9	Marine Wildlife - Marine Mammals	Acceptance of siginificant cumulative adverse effects to harbour porpoise without any follow-up or monitoring programs is untenable. If the Proponent is committed to adaptive management for the Project and PNCIMA in general, the stated acknowledgement of uncertainities in the risk assessment necessarily involves follow-up programs if adaptive management is to be effectively implemented. Reference is solely made to the Marine and Freshwater Resources Management Plan, which does not further discuss any intent to invoke adaptive management as part of its implementation (Part E, Section 14.9).	Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Marine and Freshwater Resources Management Plan. The plan will include details on the following: Prior to the start of marine construction, acoustic modelling of in-water blasting will be completed to verify assumptions and predictions made in the assessment (Application) and to refine mitigation measures, as necessary.Field verification will be undertaken at multiple locations to confirm predicted extents of underwater noise levels over the full range of predicted values for in-water blasting and in--water impact pile driving.A marine mammal monitoring program will be developed and implemented to enforce an exclusion zone during in-water impact pile driving and around the in-water blasting area.Aurora LNG is willing to collaborate in regional programs planned and developed by government and in conjunction with other proponents, regarding regional management of effects of underwater noise and vessel strikes on marine mammals in the RAA. Additional mitigation measures will be assessed and implemented, as required, based on results from the field verification that will occur.
2096.1	round 1	Gitxaala Nation	6.4	Land and Resource Use	PNCIMA goal implementation cites monitoring with adaptive management largely related to "marine environments and marine use" (p. 6.4-16). Reference to adaptive management in the mitigation measure deals almost exclusively with land use activities for terrestrial wildlife (Mitigation No. 4.7.15), vegetation (Mitigation No. 4.6.10), wetlands (Mitigation 4.6.14 and 4.6.15), with the exception of marine birds (Mitigation Nos. 4.7.13) in terms of lighting-induced effects to migration (presumably this includes both onshore and offshore lighting). How is monitoring with adaptive management intended to address all the risk uncertainties associated with the marine environment specifically?	Aurora LNG have proposed multiple mitigation measures to reduce potential effects on Marine Use and Navigable Waters, only one of which focuses on adaptive management. The other mitigation measures are based on industry standards and proven techniques used at other federal ports. In consideration of all proposed mitigation measures, Aurora LNG is confident in the conclusions made in the Application. Aurora LNG's framework for adaptive management is as follows: Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended). The creation of a Marine Activities Plan (Mitigation 6.5.2) will further describe how the Project's marine activities can be managed to avoid or reduce effects on current marine users and other stakeholders. Aurora LNG proposes to develop this plan through engagement with the appropriate regulatory agencies, Schedule B Aboriginal Groups, marine users, and other relevant stakeholders. Other inputs to the planning process will be derived from the TERMPOL study, and Aurora LNG's participation on the PRPA's Marine Construction and Coordination Committee (e.g., they could lead to recommendations regarding such issues as ship design/operation, terminal design, navigational routes, risks and accident avoidance, and pollution prevention). Additional information on the nature of the Marine Activities Plan will be shared as the plan is developed.
2097.1	round 1	Gitxaala Nation	6.5.6.4	Marine Use and Navigable Waters	How will an adaptive management strategy be applied as an approach to addressing the impacts from inceremental increases in shipping traffic "where needed"?	Aurora LNG's framework for adaptive management is as follows: Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended). The use of adaptive management framework, as suggested for the Marine Activities Plan, provides flexibility to address changing conditions like increased shipping. It also provides a pathway for modifications and improvements to be made to Project-related shipping practices. This could include modifications to port practices and terminal operations.
2098.1	round 1	Gitxaala Nation	6.5.7.1	Marine Use and Navigable Waters	How will an adaptive management strategy be applied as a approach to addressing the impacts from increaseed vessel traffic, "if needed"?	Aurora LNG's framework for adaptive management is as follows: Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended). The use of adaptive management framework, as suggested for the Marine Activities Plan, provides flexibility to address changing conditions like increased shipping. It also provides a pathway for modifications and improvements to be made to Project-related shipping practices. This could include modifications to port practices and terminal operations.
2099.1	round 1	Gitxaala Nation	6.6.5.3	Community Health	How can Mitigation No. 6.3.3 specifically be refined and developed over time, as part of an adaptive management process in the Health and Medical Services Plan to reduce adverse effects on social environments and social support networks for staff and contractors in the workplace?	Mitigation No. 6.3.3 is proposed to be included as part of the Health and Medical Services Plan. Under the Northern Health's Health and Medical Services Plan Best Management Guide for Industrial Camps (March 2015), a section of the plan must allow for quality improvement, recognizing that conditions can be subject to ongoing change. The requirement for cultural awareness of staff and contractors is one such example of conditions that may be subject to change, given that the culture of staff is a constantly evolving medium. Mitigation 6.3.3 can be refined and developed over time to accommodate cultural awareness by offering associated training to promote continued growth and knowledge of all staff and contractors. Information provided at cultural awareness training would evolve, as required, to incorporate new cultural information.
2100.1	round 1	Gitxaala Nation	11	CEAA 2012	Why is there no mention of the adaptive management commitments to assist the Proponent in its compliance with federal statutory requirements?	Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended).
2101.1	round 1	Gitxaala Nation	12.5.6.3	Aboriginal Consultation	Why has the consultation process neither acknowledged nor considered Gitxaala Nation's interest in participating in an adaptive management framework for ongoing environmental effects monitoring and management, as a stated commitment by the Proponent (see Part A, Section 1, pp. 1-43 and 1-48 of the Application)?	Aurora LNG understands that Gitxaala Nation is referring to Section 12.5.6.3, Summary of Past, Present, and Anticipated Future Use of the Project Vicinity in this comment. That section is a description of Aurora LNG's understanding of Gitxaala Nation's use of the area without the presence of the Project. This includes the "Future Use" section. Aurora LNG sought information from Gitxaala Nation regarding how it would use the Project Vicinity in the future if the Project were not present. Gitxaala Nation's interest in being part of future monitoring discussions is acknowledged in Table 12.9-1 (page 12-325). Aurora LNG is in the process to developing management plans and monitoring programs. Aurora LNG will continue to consult with Aboriginal Groups in the development of those plans. Aurora LNG's framework for adaptive management is as follows: Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended).
2102.1	round 1	Gitxaala Nation	12.5.6.6	Aboriginal Consultation	Gitxaala cites the importance of echinoderms, crustaceans, cephalopods and other molluscs, halibut and other benthic fishes, which are listed on p. 12-160 as harvested marine resources in Casey Cove, where dredging and placement of the seawater intake are expected. There is a lack of baseline data to effectively understand the current state of the populations of these traditional marine resouces in the study areas, which stand to be adversely affected by the mechanisms for water use and wastewater disposal the project. This reprsents a key ucertainty in the Project that will require direct consultation and involvment of Gitxaala Nation in the monitoring and management process.	Aurora LNG conducted extensive field studies to characterize marine fish habitats and associated fish and invertebrate species occurring in Casey Cove. These studies include; an intertidal survey, a subtidal remotely operated vehicle (ROV) survey, crab trapping, and marine fish surveys (using beach seines and tangle nets). For a detailed discussion on the methods used and results of these studies, please refer to the Marine Fish and Fish Habitat TDR (Appendix L). Information gathered from the Project-specific field studies was supplemented with information obtained through a review of available technical reports and scientific literature. The results of this literature review are also presented in the Marine Fish and Fish Habitat TDR (Appendix L).
2103.1	round 1	Gitxaala Nation	12.5.6.6	Aboriginal Consultation	The loss of access along east shore of Digby Island for traditional harvest of marine resources identified on p. 12-160 represents an issue that will require direct consultation and involvment of Gitxaala Nation in the monitoring and management process.	Aurora LNG would be pleased to discuss this matter with Gitxaala Nation during the development of management plans and monitoring programs.
2104.1	round 1	Gitxaala Nation	12.5.6.6	Aboriginal Consultation	Continual consultation with Aboriginal Groups to develop processes to monitor the implementation and evaluate the effectiveness of mitigation measures (p. 12-173) is critical step in the adaptive management process. The Proponent needs to clarify what "consultation" with Gitxaala Nation looks like in terms of the decision-making process and involvement in monitoring to mitigate any potential effects. This has not been adequately identified in the component environmental management plans that have been included as commitments of the Proponent.	Prior to the start of construction, Aurora LNG will develop environmental management plans and monitoring programs for the Project. Aurora LNG will engage with the appropriate regulatory agencies and Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) in the development of those plans. Aurora LNG's framework for adaptive management is as follows: Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended).
2105.1	round 1	Gitxaala Nation	12.5.6.7	Aboriginal Consultation	Significant effects on harbour porpoise, which are important as a VC of interest to Gitxaala Nation, require that the Proponent identify how it intends to engage Gitxaala in the monitoring and management of project activities that have high potential for residual adverse effects. This has not been adequately identified in the component environmental management plans that have been included as commitments of the Proponent.	Prior to the start of construction, Aurora LNG will develop environmental management plans and monitoring programs for the Project. Aurora LNG will engage with the appropriate regulatory agencies and Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) in the development of those plans. Aurora LNG's framework for adaptive management is as follows: Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended). Potential effects to harbour porpoise as a culturally-important species to Gitxaala Nation are described in Section 12.5.6.7 (starting on page 12-177).
2106.1	round 1	Gitxaala Nation	12.5.6.12	Aboriginal Consultation	Why has the consultation process neither acknowledged nor considered Gitxaala Nation's (or any Aboriginal interest included in Part C) in participating in an adaptive management framework for ongoing environmental effects monitoring and management, as a stated commitment by the Proponent (see Part A, Section 1, pp. 1-43 and 1-48 of the Application)?	Gitxaala Nation's interest in being part of future monitoring discussions is acknowledged in Table 12.9-1 (page 12-325). Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended). Aurora LNG would be pleased to discuss this matter with Gitxaala Nation during the development of management plans and monitoring programs.
2107.1	round 1	Gitxaala Nation	12.5.6.13	Aboriginal Consultation	The consultation process has not expressly stated a commitment to uphold Gitxaala Nation's (or any Aboriginal interest included in Part C) in participating in the adaptive management framework for ongoing environmental effects monitoring and management, as a stated commitment by the Proponent (see Part A, Section 1, pp. 1-43 and 1-48 of the Application). This should be included in the summary as a key conclusion for addressing the uncertainty in residual effects.	Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended). Aurora LNG would be pleased to discuss this matter with Gitxaala Nation during the development of management plans and monitoring programs.
2108.1	round 1	Gitxaala Nation	12.8	Aboriginal Consultation	Why have the issues identified in Table 12.8-1 come after the assessment has been conducted? Concerns should be presented in Part C prior to conducting an effects assessment in order to adequately contextualize and validate the assessment. It provides the reviewer witha *priori* knowledge of Aboriginal concerns, since these concerns are precisely the basis of this section. The methodology is illogical in terms of the structure in which information has been presented.	Table 12.8-1 is a summary table, as per the requirement of the AIR. The structure of Part C mirrors the structure of the AIR. Aurora LNG included much of the information in Table 12.8-1 in the Key Findings table at the start of Part C (see Table 12.1-4) to address the point raised by Gitxaala Nation in this comment.
2109.1	round 1	Gitxaala Nation	12.9	Aboriginal Consultation	Why have the pre-application views in Table 12.9-1 come after the assessment has been conducted? Concerns should be presented in Part C prior to conducting an effects assessment in order to adequately contextualize and validate the assessment. It provides the reviewer witha *priori* knowledge of Aboriginal concerns, since these concerns are precisely the basis of this section. The methodology is illogical in terms of the structure in which information has been presented.	Table 12.9-1 is a summary table. The structure of Part C mirrors the structure of the AIR. Aurora LNG also included a table of Key Concerns for Gitxaala Nation in Section 12.3.3 (Table 12.3-3) prior to the assessment of effects on Aboriginal Interests.
2110.1	round 1	Gitxaala Nation	12.9	Aboriginal Consultation	Inclusion of Gitxaala Nation's cultural understanding of the VCs of interest will be necessary to reduce the uncertainty around VC effects and to effectively develop mitigation that includes Gitxaala's concerns. Although there is a stated commitment by Aurora LNG to use adaptive management, (see Part A, Section 1, pp. 1-43 and 1-48 of the Application), Gitxaala involvement in the adaptive management decision process has neither been identified nor described in any meaningful detail in any of the component environmental management plans. It has also not been described in Part B as part of the commitments of the Proponent and with respect to Gitxaala Nation.	Prior to the start of construction, Aurora LNG will develop environmental management plans and monitoring programs for the Project. Aurora LNG will engage with the appropriate regulatory agencies and Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) in the development of those plans. Aurora LNG's framework for adaptive management is as follows: Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended).

2111.1	round 1	Gitxaala Nation	12.9	Aboriginal Consultation	Table 12.9-1 states, "Gitxaala Nation has the view that Fish Mortality or Fish Health are secondary considerations when assessing Gitxaala Harvesting. Instead, Gitxaala access to the fish should be the main concern", which then refers to specific VC assessment sections in Part B as a boiler plate response. These sections have very little to do with Gitxaala Nation and the VC assessments give no mention of effects related to access to the fishery by Gitxaala Nation. Therefore the effect of a change in access to the fishery has not been meaningfully factored into the VC assessment methodology, which is formatted differently in Part C compared to Part B.	Section 11.3.9.5 (Assessment of CEAA 5(1)(c) i--Aboriginal Socio-Economic Conditions) includes a specific consideration of "socio-economic barriers to increased participation in the fishing sector and the sensitivity of the practices to change" (page 11-204) that affect Gitxaala Nation's fishing practices beyond the effects assessed in Section 6.5 (Marine Use and Navigable Waters). The assessment of effects on CEAA 5(1)(c) factors is structured in the same way as Part B VC assessments.
2112.1	round 1	Gitxaala Nation	12.9	Aboriginal Consultation	Gitxaala Nation did not receive the full Application prior to submission, as the intent was to capture views on the draft Part C (Section 12) of the Application in accordance with the AIR. The lack of consultation in the steps leading up to submission has not effectively demonstrated the stated commitment to invoke adaptive management. This is particularly obvious with respect to insufficient VC baseline data describing existing conditions, ineffectively summarized results of data collected from baseline studies, overall lack of consideration about VC effects in Part B that are specific to Gitxaala Nation, illogical conclusions about likelihood and certainty of the success for proposed mitigation, irresponsible statements about significance despite certain residual and cumulative effects characterizations made, and most importantly, the high confidence in predictions given with respect to statements on likelihood and significance, despite clear uncertainties identified in the preliminary Project design, effect mechanisms, and numerous mitigation measures proposed. How does the Proponent intend to meaningfully adjust the consultation process undertaken to date to be more inclusive and participatory if it is truly committed to adaptive management? Given the relevance of this point to the EA process, please do not limit the response to a list of boiler plate statements.	Aurora LNG has been committed to ongoing consultation with Gitxaala Nation throughout the Application Review phase to discuss issues and concerns related to the Application. Aurora LNG was disappointed that Gitxaala Nation made the decision not to fully participate in Technical Workshop #4 held on January 25th and 26th in Prince Rupert. This workshop provided a meaningful opportunity to discuss concerns and issues associated with the assessment of VCs in Part B of the Application, and to explore new mitigation ideas. Aurora LNG offered Gitxaala Nation another opportunity to meet regarding the remaining material from Workshop #4, which occurred on March 28, 2017. On March 27, 2017, Aurora LNG held Technical Workshop #5 with Gitxaala Nation to further discuss the characterization of effects and significance conclusions outlined in the CEAA 2012 Section 5(1)(c) assessment, and the assessment of Project effects related to Aboriginal Interests in Part C. Technical Workshops #4 and #5 were also an opportunity to discuss feedback on mitigation measures, proposed management plans and follow-up programs. Throughout Technical Workshops #4 and #5, Aurora LNG documented Gitxaala Nation opinions, concerns and feedback. Aurora LNG was also disappointed that Gitxaala Nation chose not to participate at the EAO's Working Group session held on February 6th and 7th in Prince Rupert. A key purpose of these sessions was to facilitate a discussion of issues and concerns with the Application. Aurora LNG also invited Gitxaala Nation to participate in a Field Review (in March 2017), in response to Gitxaala Nation's desire to conduct a "Field Audit". While Aurora LNG understands that Gitxaala Nation wishes to conduct a full audit of the field work, Aurora LNG has outlined for Gitxaala Nation an approach designed to achieve a common understanding of the baseline study findings and how these findings were incorporated into the Application. Gitxaala Nation declined to participate in the Field Review. Aurora LNG will be providing a draft of Aboriginal Consultation Report #3 (i.e. the interim consultation report) at day 90 of the 180 day Application-review period (as per the EAO's letter of December 14, 2016). As part of the draft Aboriginal Consultation Report #3, Aurora LNG will report on its understanding of the status of issues/concerns resolution with Gitxaala Nation for the issues/concerns recorded during all phases of the EA (in table format), including those identified in Aboriginal Consultation Report #2 and recorded as part of Technical Workshops #4 and #5. The final version of Aboriginal Consultation Report #3 will be submitted at day 120 of the 180 day Application-review period (as per the section 11 Order). Aurora LNG's framework for adaptive management is in relation to environmental management plans and is as follows: Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended). Prior to the start of construction, Aurora LNG will develop environmental management plans and monitoring programs for the Project. Aurora LNG will engage with the appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the plans.
2113.1	round 1	Gitxaala Nation	14.3	Environmental and Operational Management Plans	No mention of the use of adaptive management in its description. How is adaptive management being proposed if it is necessary for Mitigation No. 4.6.10: monitoring for effects to "vegetation from SO2 and NO2 atmospheric concentrations, soil acidification or soil eutrophication" in Section 4.6 (p. 4.6-35, Table 4.6-11)? Why has there been no mention of Gitxaala Nation involvement or the role of adaptive management?	For clarification purposes: the Air Quality Management Plan identified in section 14.3 of the Application is different than the proposed acidification and eutrophication follow-up monitoring program which relates to mitigation number 4.6.10 and is summarized in section 15.2.2 of the Application. The former plan will describe BMPs and mitigation measures that will be implemented to avoid or reduce potential effects to air quality from Project activities. The latter is a follow-up program designed to assess the modeled (predicted) effects of acidification and eutrophication on soils and ecological communities. The proposed acidification and eutrophication follow-up monitoring program, which relates to mitigation number 4.6.10, is summarized in section 15.2.2 (not section 14.3) of the Application. This follow-up program will entail the following steps: monitoring baseline conditions, monitoring conditions during operations, designating management thresholds (i.e., indicators of measurable changes in soils or ecological communities that warrant a mitigation-response), and implementing mitigation measures if management thresholds are exceeded. It is expected that the monitoring effort will be regionally focused to encompass all of the potential airshed contributors and coordinated through the BC Ministry of Environment. In establishing that regional monitoring effort, it is assumed that the Ministry will determine the monitoring criteria and outline a suite of potential mitigation measures to address expected outcomes based on the monitoring results It is expected that the proposed acidification and eutrophication follow-up monitoring program will be developed under direction of Ministry of Environment and through engagement with Schedule B Aboriginal Groups and key stakeholders. Aurora LNG's framework for adaptive management is as follows: Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended).
2114.1	round 1	Gitxaala Nation	14.4	Environmental and Operational Management Plans	How is the plan, which is expected to be moderately successful, going to be implemented to address VC-specific issues using adaptive management principles, especially with respect to waste products, the Project's overall carbon footprint, and the issue of fugitive emissions?	The GHG Management Plan will be prepared to identify all the activities that are being taken to address GHG emissions, including reporting to regulators. As activities are adapted to updated technologies, techniques, or regulations, the Plan will be updated. As part of annual compliance reporting under the BC Greenhouse Gas Industrial Reporting and Control Act, total Project emissions (including fugitive emissions) will need to be evaluated and reported. These emissions would also be verified by a 3rd party before submission to regulators.
2115.1	round 1	Gitxaala Nation	14.6	Environmental and Operational Management Plans	An "Invasive Species Management Plan" was proposed for Mitigation No. 4.6.4 in Section 4.6 (p. 4.6-29, Table 4.6-10), but has not been mentioned in this section, unless it is the same thing as the Invasive Plant Management Plan, which gives no mention of the use of adaptive management in its description.	The "Invasive Plant Management Plan" is referenced in Table 4.6-10, Mitigation No. 4.6.6 and in Section 14 of the Application. and is the same as the "Invasive Species Management Plan" referenced in Mitigation No. 4.6.4. While the process of adaptive management may not be explicitly listed among the elements of the Invasive Plant Management Plan, it is included among the Best Management Practices that are referred to and will be included as part of the monitoring and management response of the Invasive Plant Management Plan when it is developed.
2116.1	round 1	Gitxaala Nation	14.7	Environmental and Operational Management Plans	Although a form of consultation has been acknowledged, it is not as an explicit statement to undertake adaptive management to implement the plan; however, the VC assessment stated adaptive management as the principal means for monitoring wetland function with reference given to the Wetland Compensation Plan. Why has there been no mention of Gitxaala Nation involvement or the role of adaptive management? More details are needed here about the process for implementing the plan to address the uncertainties.	Section 14 of the Application provides a summary of the proposed environmental and operational management plans, in accordance with the Application Information Requirements. Section 14.7 states that the Wetland Compensation Plan will be developed in consultation with Aboriginal Groups. Section 5.3 of the Wetland Compensation Plan (Appendix U of the Application) states that the details of the monitoring program for the Wetland Compensation Plan will be determined through engagement with appropriate regulatory agencies and with Schedule B Aboriginal Groups. Effectiveness monitoring will be a component of the monitoring program, to confirm that wetland functions are performing as intended. Mitigation measures 4.6.14 and 4.6.15 in Table 4.6-13 of the Application identify that adaptive management will be applied as needed in response to wetland monitoring results. Aurora LNG's framework for adaptive management is as follows: Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended).
2117.1	round 1	Gitxaala Nation	14.8	Environmental and Operational Management Plans	How is the plan, which is expected to be moderately successful, going to be implemented to address VC-specific issues using adaptive management principles, especially with respect to Mitigation Nos. 4.7.14 for marine birds (i.e., MAMU) and 4.7.16 (i.e., migratory birds and bats)? Why has there been no mention of Gitxaala Nation involvement or the role of adaptive management? More details are needed here about the process for implementing the plan to address the uncertainties.	To support mitigation measures 4.7.14 and 4.7.16, the Wildlife Management Plan will provide a description of the procedures for searching, documenting, and reporting bird, bat and wildlife injuries and mortalities and will be consistent with applicable Environmental Assessment Certificate conditions. The Marbled Murrelet Management and Bat Management Plans will also include a description of activities to support these mitigation measures for targets species (or species groups) applicable to each. Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of these plans.
2118.1	round 1	Gitxaala Nation	14.8.1	Environmental and Operational Management Plans	How is the plan going to be implemented to address specific issues pertaining to MAMU using adaptive management principles and why has there been no mention of Gitxaala Nation involvement or the role of adaptive management? More details are needed here about the process for implementing the plan to address the uncertainties.	The Marbled Murrelet Management Plan will specifically outline avoidance, reduction, mitigation, and monitoring measures to effects from change in habitat or mortality risk from Project construction and operation activities. The Marbled Murrelet Management Plan will include an adaptive management component to manage potential project effects in that it will be updated as the Project progresses and monitoring results are analyzed. Scheduled reviews will be undertaken annually,subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modifications to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended).
2119.1	round 1	Gitxaala Nation	14.8.2	Environmental and Operational Management Plans	How is the plan going to be implemented to address specific issues pertaining to *Myotis lucifugus* and *M. septrentrionalis* using adaptive management principles and why has there been no mention of Gitxaala Nation involvement or the role of adaptive management? More details are needed here about the process for implementing the plan to address the uncertainties.	The Bat Management Plan will specifically outline avoidance, reduction, mitigation, and monitoring measures to limit potential effects to bats from change in habitat or mortality risk from Project construction and operation activities. Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of this plan. Regarding planning related to northern myotis (Myotis septentrionalis), Aurora LNG notes that the Bat Management Plan will focus on potentially occurring species and that the northern myotis (Myotis septentrionalis) is not expected to occur in the RAA (Environment Canada 2015) and has not been observed as part of the field programs related to the Application. The Bat Management Plan will include an adaptive management component to manage potential project effects in that it will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended). Reference: Environment Canada. 2015. Recovery Strategy for Little Brown Myotis (Myotis lucifugus), Northern Myotis (Myotis septentrionalis), and Tri-colored Bat (Perimyotis subflavus) in Canada [Proposed]. Species at Risk Act Recovery Strategy Series. Environment Canada, Ottawa. ix + 110 pp.
2120.1	round 1	Gitxaala Nation	14.9	Environmental and Operational Management Plans	Of all management plans proposed, this plan is of the greatest importance in the context of adaptive management. This is largely due to the high degree of uncertainty associated with the preliminary design of the water management system, including the seawater intake, desalination, and deep outfall associated with desalination. Remaining disposal of LNG process water and sanitary wastewater has also not been adequately addressed by the conceptual layout in Figure 1-2 and the assessment gives an untold amount of unresolved statements in the body of the EA regarding the combined treatments and disposal of all waste in the marine receiving environment to more than one possible outfall. Why has there been no mention of Gitxaala Nation involvement or the role of adaptive management with respect to PNCIMA and as a commitment stated to undertake adaptive management as "best in class" for "HSE&SR Management System" (i.e., see p. 1-43 of Section 1.2.10 of Part A)? More details are needed here about the process, given the lack of baseline data and deficiencies in the effects assessment for this VC.	Aurora LNG recognizes the importance of adaptive management in guiding the development and implementation of the Marine and Freshwater Resources Management Plan. The plan will include details related to implementing water quality monitoring programs, and will identify water quality thresholds, monitoring frequency, and water quality monitoring locations (Section 14, Summary of Proposed Environmental and Operational Management Plans). As described in Section 15, Aurora LNG has committed to developing and implementing a Marine Water Quality Monitoring Program to confirm, among other aspects, effluent quality parameters prior to discharging to the marine environment. The Marine and Freshwater Resources Management Plan (and other environmental management plans, where appropriate) will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended).
2121.1	round 1	Gitxaala Nation	14.9	Environmental and Operational Management Plans	Page 4.9-80 of Part B, Section 4.9.5.4 of the application states that "the risk of injury or mortality associated with operation of the intake is difficult to quantify because it depends on a variety of factors relating to the intake design, fish species and life stage, and environmental conditions (e.g., time of year). The final design of the marine intake will be confirmed through final engineering design." Given the uncertainty with respect to mortality risk due to this Project mechanism, why has there been no mention of Gitxaala Nation involvement or the role of adaptive management with respect to PNCIMA and as a commitment stated to undertake adaptive management as "best in class" for "HSE&SR Management System" (i.e., see p. 1-43 of Section 1.2.10 of Part A)? More details are needed here about the process, given the lack of baseline data and deficiencies in the effects assessment for this VC.	As discussed on page 4.9-93 of Section 4.9.5.4 (Marine Fish and Fish Habitat VC), the proposed seawater intake will be designed following DFO guidance for marine intakes (Fedorenko 1991) to reduce the potential for injury or mortality of marine organisms through impingement and entrainment. Specifically, the intake will be:Located to avoid areas of known Pacific herring spawning. The nearest documented area of herring spawning is located to the north of Dodge Cove, on the east side of Digby Island (Hay and McCarter 2013) Located to avoid topographical features that promote eddies, which may cause the retainment of planktonic organisms and larvae, which are most at risk of becoming entrained in intakes Located to avoid subtidal rock reefs, which support macroalgal communities (e.g., kelps) that serve as nursery habitats to juvenile fish and invertebrates; the intake terminus is located over soft sediment habitat near the mouth of Casey Cove Located at a depth of -25 m CD, which is below the layer where marine organisms are found in greatest numbers (e.g., juvenile salmon, larval eulachon, larval/juvenile Pacific herring) Elevated 2 m above the seabed, which helps to avoid entrainment of epibenthic plankton living near, and associated with, the seafloor substrate (e.g., mysids, prawn larvae, and larvae of various demersal fish species). In addition to these siting criteria, the intake terminus is proposed to be fitted with a “velocity cap”, which has been shown to induce an avoidance response in fish, reducing impingement and entrainment (Missimer et al. 2015). Seawater drawn into the intake will be conveyed to a screening and pump station located near the MOF, where it will pass through travelling screens designed in accordance with the guidelines developed by DFO (Fedorenko 1991). Screens will be sprayed from the inside and any marine organisms that have become impinged will be returned to the ocean through a wash water return line. With adherence to these design criteria, Aurora LNG believes that the risk of impingement and entrainment will be reduced to an acceptable level. As such, Aurora LNG is not proposing a follow-up monitoring program for the seawater intake. These measures (i.e., adherence to design criteria outlined above) and other mitigation measures developed during FEED will be included in the Marine and Freshwater Resources Management Plan. Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of this plan.
2122.1	round 1	Gitxaala Nation	14.9	Environmental and Operational Management Plans	Page 4.9-85 of Part B, Section 4.9.5.4 of the application states that "onsite monitoring will allow for the temporary suspension of activities should they result in the mortality of fish. This will limit the extent of impacts, and allow for adaptive management of mitigation measures to avoid or reduce the likelihood of further impacts." Given the uncertainty with respect to mortality risk due to Project activities, why has there been no mention of Gitxaala Nation involvement or the role of adaptive management with respect to PNCIMA and as a commitment stated to undertake adaptive management as "best in class" for "HSE&SR Management System" (i.e., see p. 1-43 of Section 1.2.10 of Part A)? More details are needed here about the process, given the lack of baseline data and deficiencies in the effects assessment for this VC.	Aurora LNG recognizes the importance of adaptive management in guiding the development and implementation of the Marine and Freshwater Resources Management Plan. The plan will include details related to implementing water quality monitoring programs, and will identify water quality thresholds, monitoring frequency, and water quality monitoring locations (Section 14, Summary of Proposed Environmental and Operational Management Plans). As described in Section 15, Aurora LNG has committed to developing and implementing a Marine Water Quality Monitoring Program to confirm, among other aspects, effluent quality parameters prior to discharging to the marine environment. The Marine and Freshwater Resources Management Plan (and other environmental management plans, where appropriate) will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended).

2123.1	round 1	Gitxaala Nation	14.9	Environmental and Operational Management Plans	The marine mammal monitoring program is listed as a component of Mitigation No. 4.10.2 with reference to this plan, but is not mentioned in Sections 14 or 15 of Part E. Please discuss how the marine mammal monitoring program will be implemented as a follow-up rpogram.	As noted in Section 14 of the Application, no follow-up programs for marine mammals are being proposed. To verify compliance of the Project with commitments presented in the Application and conditions of an Environmental Assessment Certificate, mitigation 4.10.2 will be implemented via the Marine and Freshwater Resources Management Plan. This mitigation measure is captured in the third bullet of Section 14.9 of the Application (i.e., the Marine and Freshwater Resources Management Plan will include specific procedures and policies related to in-water pile driving). Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Marine and Freshwater Resources Management Plan. This plan will describe BMPs and mitigation measures that will be implemented during construction and operation of the LNG facility to avoid or reduce potential adverse effects of Project activities on marine mammals. Details of this Plan will be developed prior to commencement of Project construction, and will be consistent with requirements outlined in Environmental Assessment Certificate Conditions.
2124.1	round 1	Gitxaala Nation	14.10	Environmental and Operational Management Plans	Although a form of consultation has been acknowledged, there is no explicit statement to undertake adaptive management to implement the plan, despite the uncertainty with respect to fisheries productivity losses due to the Project. Why has there been no mention of Gitxaala Nation involvement or the role of adaptive management with respect to PNCIMA and as a commitment stated to undertake adaptive management as "best in class" for "HSE&SR Management System" (i.e., see p. 1-43 of Section 1.2.10 of Part A)? More details are needed here about the process, given the lack of baseline data and deficiencies in the effects assessment for this VC.	The conceptual fish habitat offsetting plan is just the first step in the process of developing an effective, final habitat offsetting plan that would be submitted to DFO as part of a Fisheries Act authorization application. The intentions of this conceptual plan include (but are not limited to): 1) outline the structure of the habitat offsetting plan to show what components will be considered (including an adaptive management plan in the event that habitat offsetting does not perform as expected) 2) outline Aurora LNG's philosophy and approach to habitat offsetting to demonstrate that it aligns with DFO's guidance 3) identify potential offsets that could counterbalance serious harm to fish incurred by the project Aurora LNG is fully committed to fulfilling the legal obligation to effectively offset all Project-driven serious harm to fish, we see this conceptual plan as a starting point in the development of effective habitat offsetting. Through collaborative engagement with regulatory agencies (primarily DFO) and consultation with Aboriginal Groups during the Fisheries Act authorization application process, Aurora LNG fully anticipates being able to find adequate and appropriate locations, and develop suitable designs, for effective offsets.
2125.1	round 1	Gitxaala Nation	14.12.1	Environmental and Operational Management Plans	This is the sole reference made to adaptive management for all proposed EMPs and OMPs listed in this section, which seems to indicates that consultation will drive a formal adaptive management process; however, all specified management plans referenced throughout the EA as part of the mitigation require a process to address uncertainties. The process should be expounded upon for its intended application in each component plan in this section.	Aurora LNG's framework for adaptive management is as follows: Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended).
2126.1	round 1	Gitxaala Nation	14.12.4	Environmental and Operational Management Plans	Mitigation No. 6.3.3 is listed and is specifically intended to indicate refinement over time and as part of an adaptive management process in the Health and Medical Services Plan. Why has there been no indication stated that the plan will undertake adaptive management such that Gitxaala Nation, or any other interests outside of Northern Health, are involved in a meaningfully consultative approach?	The Health and Medical Services Plan (HMSP) will be developed with reference to Northern Health's "Health and Medical Services Plan Best Management Guide for Industrial Camps" (March 2015). The HMSP will complement the Social Management Plan (mitigation 6.3.1) by outlining health and medical policies, services and protocols to be implemented at the worker accommodation camp. The HMSP is an internal shared document between Aurora LNG and Northern Health. Development of the Social Management Plan, which includes consideration of health care infrastructure and services (the subject matter mitigated through the HMSP), will be informed through engagement with concerned stakeholders, appropriate regulatory agencies and Schedule B Aboriginal Groups. Aurora LNG's framework for adaptive management is as follows: the social management plan, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plan will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plan will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended).
2127.1	round 1	Gitxaala Nation	14.14	Environmental and Operational Management Plans	In order for these mitigation measures to be effective, some form of wastewater treatment and management will be necessary, especially for the desalination process to be in compliance with all provincial and federal regulatory requirements that have been acknowledged and listed in the associated mitigation descriptions. Given the uncertainty with respect to this Project mechanism, why has there been no mention of Gitxaala Nation involvement or the role of adaptive management with respect to PNCIMA and as a commitment stated to undertake adaptive management as "best in class" for "HSE&SR Management System" (i.e., see p. 1-43 of Section 1.2.10 of Part A)? More details are needed here about the process, given the lack of baseline data and deficiencies in the effects assessment for this VC.	Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Waste Disposal Management Plan. Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended).
2128.1	round 1	Gitxaala Nation	15.2	Follow-up Programs and Compliance Reporting	Although programs will be used to "support the implementation of adaptive management measures to address any previously unanticipated adverse effects" is a valid statement on p. 15-1 regarding the management of unforeseen risks, it does not acknowledge the uncertainty around those risks that have been identified and assessed as a part of the methodology. Numerous determinations have been made in Part B of the EA that are based on questionable assumptions and limited information. They are therefore unjustifiable, given the inherent uncertainty, and should be managed in such a manner to improve the understanding of effects potential and to implement appropriate measures proven to most effectively mitigate risks. If the Proponent is truly committed to adaptive management, which has been repeatedly stated in the EA, then all of the existing risks identified, as well as any stated "previously unanticipated adverse effects", will require a formal consultative process for arriving at the objective questions needed to set working hypothesis for experimental management and to derive agreed upon and focused monitoring programs that can be used to test these hypotheses and work to develop effective mitigation that appeases all interests in the consultative committee.	Aurora LNG is committed to implementing follow-up programs when there is a conclusion of potential residual adverse effect and either a low prediction confidence in that conclusion or uncertainty in a specific component of the assessment. In these cases, the follow-up program will be used to verify the accuracy of predictions. Aurora LNG has committed to a number of follow-up programs (see Section 15, Summary of Follow-up Programs and Compliance Reporting). VCs that concluded moderate to high prediction confidence will be managed through the development of Environmental and Operational Management Plans (Section 14) designed to verify compliance of the Project with commitments in the Application and conditions of the Environmental Assessment Certificate. Criteria for proposed inclusion of a follow-up program are consistent with the Considerations for Developing a Follow-up Program outlined in the Operational Policy Statement Follow-up Programs under the Canadian Environmental Assessment Act (Government of Canada, 2011).
2129.1	round 1	Gitxaala Nation	15.2	Follow-up Programs and Compliance Reporting	A follow-up program is necessary for GHG emissions, given the determination of significant cumulative adverse effects in the VC assessment. The high degree of uncertainty surrounding potential effects warrants a follow-up program that addresses questionable logic surrounding the decision to remove upstream sources (a CEAA requirement) and international shipping sources in the overall GHG assessment, unsubstantiated mitigation measures proposed as part of the GHG Management Plan, and the moderate degree of confidence in the GHG Management Plan as a whole. Statements about compliance monitoring contained in Section 15.3.4 are insufficient for understanding the how the Project will contribute to GHGs. This requires some evidence-based means for ascertaining whether mitigation measures contained in the GHG Management Plan will truly be effective.	As per CEA Agency (2003) guidance, a project that has been determined to have a high magnitude of GHG emissions should prepare a GHG Management Plan. Aurora LNG has committed to developing a GHG Management Plan (Mitigation 4.3.6) following Project approval. In Section 4.3.5.2 of the Application, "A GHG Management Plan will be prepared to identify the requirements of relevant GHG reporting legislation and will include a continuous assessment of monitoring and management requirements applicable to the mitigation listed in Table 4.3-12 (i.e., requirements of a fugitive emission survey program). The majority of the mitigation measures presented in the GHG Assessment have been proposed with the understanding that there is a high degree of certainty that they will reduce the amount of GHG emissions released to the atmosphere. These mitigation measures relate to the removal or reduction of the source of GHG emissions (i.e. reduction in fuel consumption reduces the source of GHG emissions). The GHG Management Plan does not directly reduce GHG emissions, but instead it is used to understand and identify activities that should be undertaken to reduce GHG emissions. Therefore, implementation of the Plan and the associated reduction activities are required to realize the benefits. Without all the details of the Plan finalized, slightly more uncertainty was conservatively factored in.
2130.1	round 1	Gitxaala Nation	15.2	Follow-up Programs and Compliance Reporting	The marine mammal monitoring program is listed as a component of Mitigation Nos. 4.10.1 and 4.10.2, but has not been mentioned in Sections 14 or 15 of Part E. Please include and discuss how the monitoring program will be implemented as a follow-up rpogram.	As noted in Section 14 of the Application, no follow-up programs for marine mammals are being proposed. To verify compliance of the Project with commitments presented in the Application and conditions of an Environmental Assessment Certificate, mitigation 4.10.2 will be implemented via the Marine and Freshwater Resources Management Plan. This mitigation measure is captured in the third bullet of Section 14.9 of the Application (i.e., the Marine and Freshwater Resources Management Plan will include specific procedures and policies related to in-water pile driving). Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Marine and Freshwater Resources Management Plan. This plan will describe BMPs and mitigation measures that will be implemented during construction and operation of the LNG facility to avoid or reduce potential adverse effects of Project activities on marine mammals. Details of this Plan will be developed prior to commencement of Project construction, and will be consistent with requirements outlined in Environmental Assessment Certificate Conditions.
2131.1	round 1	Gitxaala Nation	15.2	Follow-up Programs and Compliance Reporting	A follow-up program is necessary for the harbour porpoise, given the determination of significant cumulative adverse effects in the VC assessment. The high degree of uncertainty in the potential effects warrants a follow-up program due to unsubstantiated blanket mitigation measures proposed for all marine mammals with no specific mitigation afforded to harbour porpoise, despite the determination of significance.	The Marine and Freshwater Resources Management Plan will be developed in consultation with DFO and the BC Oil and Gas Commission. This plan will describe BMPs and mitigation measures that will be implemented during construction and operation of the LNG facility to avoid or reduce potential adverse effects of Project activities on marine mammals. The plan will include details on the following: Prior to the start of marine construction, acoustic modelling of in-water blasting will be done to verify assumptions and predictions made in this assessment and refine mitigation measures, as necessary.Field verification will be undertaken at multiple locations to confirm predicted extents of underwater noise levels over the full range of predicted values for in-water blasting and impact pile driving.A marine mammal monitoring program will be developed and implemented to enforce an exclusion zone during in-water impact pile driving and around the in-water blasting area.Aurora LNG is willing to collaborate in regional programs planned and developed by government and in conjunction with other proponents, regarding regional management of effects of underwater noise and vessel strikes on marine mammals in the RAA. The mitigation measures proposed are consistent with recovery strategies and action plans, where such documents exist. The suite of mitigation measures proposed are expected to be effective at achieving their primary objectives (i.e., to reduce potential for changes in health and behaviour during in-water blasting; to reduce potential for changes in health and behaviour during impact pile driving; and to reduce potential changes in marine mammal mortality risk from increased risk of vessel strikes) regardless of the species of marine mammal under consideration. While each species may exhibit individual and unique life histories and habitats, the mechanisms for potential effects are common to all species.
2132.1	round 1	Gitxaala Nation	15.2	Follow-up Programs and Compliance Reporting	Section 4.6.9 (p. 4.6-78) clearly identifies follow-up and monitoring that includes an "invasive species monitoring program". Please include a follow-up program that can provide the collection of more baseline information using appropriate sampling protocols in order to credibly assess the potential for invasive species to occur in the PDA. Statements about compliance monitoring contained in Section 15.3.2 are not sufficient to understand the how the Project itself will influence the spread of invasive plant species in the absence of meaningful baseline data.	The success of implemented Best Management Practices (BMPs) related to invasive plants are well understood, and Environmental Inspectors will be well qualified to identify and manage invasive plants. Aurora LNG does not consider a specific invasive plant survey necessary for this Environmental Assessment. An Invasive Plant Management Plan (IPMP; Mitigation 4.6.6) will be developed in consultation with regulators. The IPMP (described in Section 14.6 of the Application) will include best management practices which will meet the legal obligations under the Weed Control Act and Regulations, which prohibit the spread of noxious weeds on highways and prohibits using seeds with noxious weed seeds intermixed, and will meet the BC Oil and Gas Commission (BC OGC) Environmental Protection and Management Guideline (2015) requiring control of invasive species during all phases of a project. Best management practices will be included in the invasive plant management plan and will include those in the following references:Best Practices for Managing Invasive Plants on Roadsides. Published by BC Ministry of Transportation and Infrastructure; available as a pocket guide. Contains best practices for roadside workers that are equally applicable to road contractors in the oil and gas sector. http://www.th.gov.bc.ca/publications/eng_publications/environment/ManagingInvasivePlants.pdfThe Best Practices for Managing Invasive Plants on Oil and Gas Operations. Pocket guide developed for British Columbia's Oil and Gas workers. Contains information on key aquatic invasive species as well. http://prrd.bc.ca/services/environmental/weed_control/documents/PRINT-READY-OG-Guide_2013_FINAL.v2.pdfMinistry of Agriculture, Seven Steps to Managing Your Weeds. A Guide for Integrated Weed Management in British Columbia. http://www.agf.gov.bc.ca/weedsbc/pdf/7StepsToManagingYourWeeds.pdfMinistry of Forests, Lands and Natural Resource Operations, Invasive Alien Plant Program - Reference Guide Part 1 https://www.for.gov.bc.ca/hra/plants/RefGuide.htm Mitigation 4.6.5 will also be included in the Invasive Plant Management Plan. Mitigation: Temporary workspaces, reclaimed land, and other revegetation activities will be vegetated using certified weed-free native plant seed and traditional use species where practicable. Mitigation mechanism: Reclaiming temporary workspaces as soon as practicable reduces the chance that invasive species will grow and will minimize erosion and therefore soil loss.

2133.1	round 1	Gitxaala Nation	15.2	Follow-up Programs and Compliance Reporting	A follow-up program for improving the baseline understanding of marine sediment, water quality, and marine fisheries is necessary due to high uncertainty arising from the wastewater management system and preliminary Project design; data deficiencies for sediment, water quality, and fisheries; lack of clearly presented baseline fisheries data for individual study areas; unproven and unsubstantiated mitigation measures proposed; and high likelihood of residual cumulative effects determined for marine fish habitat, behaviour, and mortality risk with an overall moderate degree of confidence in the prediction of non-significance. All these factors indicate uncertainty around the effects potential such that statements about compliance and effectiveness monitoring contained in Section 15.3.6 are insufficient for understanding baseline conditions and ascertaining how the Project effect mechanisms, once finalized, will influence the marine habitat and marine fish and aquatic species due to waste disposal at the deep outfall.	Aurora LNG is committed to implementing follow-up programs when there is a conclusion of potential residual adverse effect and either a low prediction confidence in that conclusion or uncertainty in a specific component of the assessment. In these cases, the follow-up program will be used to verify the accuracy of predictions. Aurora LNG has committed to a number of follow-up programs specific to marine fish and fish habitat and marine water quality (see Section 15, Summary of Follow-up Programs and Compliance Reporting). VCs that concluded moderate to high prediction confidence will be managed through the development of Environmental and Operational Management Plans (Section 14) designed to verify compliance of the Project with commitments in the Application and conditions of the Environmental Assessment Certificate. Criteria for proposed inclusion of a follow-up program are consistent with the Considerations for Developing a Follow-up Program outlined in the Operational Policy Statement Follow-up Programs under the Canadian Environmental Assessment Act (Government of Canada, 2011). Aurora LNG is committed to developing and implementing a Marine and Freshwater Resources Management Plan. While Aurora LNG recognizes that some Project details are preliminary (e.g., around the design and operation of the Charles Point outfall - please see the technical memo "Discharges to the Marine Environment" for additional information about effluent discharges and marine outfalls), Aurora LNG is of the opinion that the level of detail and understanding of Project design and engineering, as well as the understanding of baseline conditions and effectiveness of mitigation measures, is sufficient to support the assessment of Project effects on marine fish and fish habitat, including effects associated with construction and operation of the Charles Point outfall (Section 4.9). This is based on the following:The assessment considered extensive baseline information collected from the scientific literature, information on TEK, and from field surveys (see Appendix L, Marine Fish and Fish Habitat TDR). This included baseline information specific to characterizing intertidal and subtidal fish and fish habitats along East Digby Island, including the area south of Charles Point where the deep outfall is proposed (Section 5.1.3.2, Figure 10 [intertidal]; Section 5.2.3.2, Figure 18, Figure 19, Figure 20, and Figure 21 [subtidal]; Section 5.4.3.2 Figure 33 [eelgrass]; and Section 5.5.6, Figure 42 and Figure 43 [marine fish]). Conservative assumptions and approaches were taken where uncertainties exist, to characterize potential effects associated with the most conservative scenario. A list of assumptions specific to the Marine Fish and Fish Habitat assessment is include in Section 4.9.5.1 (Methods). Mitigation measures identified in the Marine Fish and Fish Habitat VC (Section 4.9) are based on an understanding of existing conditions, expected construction methods, timing, and Project design, professional experience with similar projects in the Pacific North Coast of BC, and industry-accepted best management practices. In most cases, mitigation measures proposed for marine fish and fish habitat are standard and are proven to be effective at reducing effects to the marine environment. Additional details on the mitigation measures will be provided in the Marine and Freshwater Resources Management Plan. Aurora LNG acknowledges that mitigation measures are subject to refinement through consultation with appropriate regulators, and will reflect Environmental Assessment Certificate Conditions. Uncertainty in the assessment of residual effects is captured under Section 4.9.8 (Prediction Confidence) of the Marine Fish and Fish Habitat VC. Follow up programs will be implemented to assess the accuracy of the predictions made in the EA and the effectiveness of mitigation measures. A final version of the Fish Habitat Offsetting plan (conceptual plan provided in Appendix V) will be developed and implemented to offset serious harm to fish associated with the Project. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting. With respect to the comment regarding "…data deficiencies for sediment, water quality…", although no marine sediment or water quality samples were collected specifically at the location of the proposed Charles Point outfall, water quality and sediment samples collected in other areas of the LAA are expected to be representative of conditions at the Charles Point outfall (i.e., conditions at the location of the Charles Point outfall are not expected to differ substantially from other areas in the LAA). Appendix F (Marine Sediment and Water Quality Technical Data Report) describes the methods and results of the water quality and sediment sampling programs. The need for additional information to further characterize existing conditions will be discussed with appropriate regulators during permitting for the construction and operation of the Charles Point outfall. With respect to the comment regarding "…lack of clearly presented baseline fisheries data for individual study areas…", Appendix L (Marine Fish and Fish Habitat TDR) presents the data collected during each type of Project-specific field study (e.g., marine fish surveys) by study area. For the majority of studies, data were gathered from four study areas: Casey Cove, East Digby Island, South Digby Island, and Delusion Bay (see Figure 8). Aurora LNG is of the opinion that this structure provides a clear description of site conditions specific to areas potentially affected by Project infrastructure and activities.
2134.1	round 1	Gitxaala Nation	15.2	Follow-up Programs and Compliance Reporting	A follow-up program for improving the understanding of wastewater effluent dispersion through 3-D modelling of the dispersion plume and expected concentration of marine solutes at the deep outfall in absence of any clearly defined treatment mechanisms and incongruences in the effects assessment and the conceptual layout of the project provided in Figure 1-2 of Section 1, Part A. Myriad factors indicate uncertainty around the effects potential such that statements about compliance and effectiveness monitoring contained in Section 15.3.6 are insufficient for understanding baseline conditions and ascertaining how the Project effect mechanisms, once finalized, will influence the marine habitat and marine fish and aquatic species due to waste disposal at the deep outfall.	Wastewater effluent discharges will require permits under the Environmental Management Act. These permits mandate end-of-pipe and receiving environment monitoring, in addition to modeling of the dispersion plume at the outfall. Further details on waste discharges and associated monitoring are provided in the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2135.1	round 1	Gitxaala Nation	15.2.1	Follow-up Programs and Compliance Reporting	Please state how any objective questions for monitoring "that the colony will persist, continue to use this breeding location, and not be adversely affected by the Project" through adaptive management. Specifically, how will the proposed follow-up program address "key concerns raised by Aboriginal Groups, the public, and other stakeholders during the development of the Application", as well as any regulatory requirements?	Aurora LNG is committing to maintaining setbacks to decrease the extent of sensory disturbance in the vicinity of active nesting sites for great blue heron and to reduce the potential for flushing during the nesting and rearing period. Aurora LNG acknowledges that Develop with Care recommends as a best management practice that excessive noises should not occur within 1,000 m of a great blue heron colony during the nesting window (BC MOE 2014). As per mitigation 4.7.4, high-disturbance Project-related activities (e.g., blasting, pile driving) will be avoided where practicable during the breeding window (i.e., January 15 through September 15) within 500 m of the great blue heron rookery at Dodge Cove. To address the uncertainty over the degree to which high disturbance activities occurring within 1,000 m of the heron rookery may result in disturbance displays by nesting herons (as per provincial guidelines), Aurora LNG is committing to monitoring for changes in breeding activity at the rookery if high disturbance activities for Project construction occur within 1,000 m of the rookery during the breeding window (January 15 to September 15 for great blue heron). Given the geography of the area and the fact that there is a ridge of land that visually separates the rookery from proposed road corridor it is unlikely that road construction activities will cause a change in breeding activity. Monitoring protocols will follow the Survey Protocol for Measurement of Nesting Productivity at Pacific Great Blue Heron Nesting Colonies (Vennesland and Norman 2006). Monitoring and adaptive approaches will be described in detail in the Wildlife Management Plan. Aurora LNG will engage with the appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding development of the Wildlife Management Plan. Reference: British Columbia Ministry of Environment (BC MOE). 2014. Develop with Care 2014: Environmental Guidelines for Urban and Rural Land Development in British Columbia. Available at: http://www.env.gov.bc.ca/wld/documents/bmp/devwithcare/index.html#Main. Accessed: April 2016. Vennesland, R. G. and D. M. Norman, 2006. Survey Protocol for Measurement of Nesting Productivity at Pacific Great Blue Heron Nesting Colonies. The Heron Working Group.
2136.1	round 1	Gitxaala Nation	15.2.2	Follow-up Programs and Compliance Reporting	Please state how any objective questions for monitoring will determine "a response of waterbodies to Project emissions, compare to predictions made in the acidification and eutrophication assessment, and evaluate the effectiveness of proposed mitigation measures" through adaptive management. Specifically, how will the proposed follow-up program address "key concerns raised by Aboriginal Groups, the public, and other stakeholders during the development of the Application", as well as any regulatory requirements?	A key aspect of a monitoring program is to validate the predicted Project effects, particularly when scientific modelling approaches are used to estimate the effects. The Aurora LNG monitoring program is expected to include monitoring changes to water quality (before, during and following project operations) at select sites that include both waterbodies that are not predicted to have effects and those that are predicted to have effects (e.g. lakes with a critical load exceedance). Ongoing monitoring of water quality will identify changes to physical or chemical composition of water from baseline conditions or from expected project effects. Aurora LNG's framework for adaptive management is as follows: Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended).
2137.1	round 1	Gitxaala Nation	15.2.2	Follow-up Programs and Compliance Reporting	Please state how any objective questions for monitoring will "document any effects to vegetation and soils from increased atmospheric NO2 and SO2 concentrations, soil acidification, or soil eutrophication in areas where deposition is predicted to occur" through adaptive management. Specifically, how will the proposed follow-up program address "key concerns raised by Aboriginal Groups, the public, and other stakeholders during the development of the Application", as well as any regulatory requirements?	The details of this monitoring plan are still to be determined. However, examples of monitoring parameters could include sampling of soils within predicted exceedance areas to measure pH and Nitrogen (various forms), along with vegetation attributes such as species composition, cover, and health and vigor at each soil-sampling site. Sampling outside the modeled area of exceedance would likely be required for comparison. Aurora LNG's framework for adaptive management is as follows: Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended).
2138.1	round 1	Gitxaala Nation	15.2.3	Follow-up Programs and Compliance Reporting	Gitxaala Nation and other Aboriginal groups did not receive the full Application prior to submission, as the intent was "to capture views on the draft Part C (Section 12) of the Application in accordance with the AIR". This lack of consultation in the steps leading up to submission of the Application is not an effective demonstration of a stated commitment to invoke adaptive management. Please state how any objective questions for monitoring will be determined if "this [marine sediment deposition monitoring] program will not be developed or implemented if the pile-and-deck MOF option is selected". Specifically, how has this decision addressed "key concerns raised by Aboriginal Groups, the public, and other stakeholders during the development of the Application", as well as DFO regulatory requirements?	The objective of the Marine Sediment Deposition Monitoring Plan is "to monitor the potential accumulation of marine sediment along the shoreline at Charles Point". This accumulation is only predicted to occur under the concrete caisson MOF scenario. Please compare Figures 65c and 69b in Appendix M (Hydrodynamic Modelling of Changes in Sediment Erosion and Accretion due to Project Infrastructure). These figures show the difference between post-construction conditions and existing conditions in maximum bed thickness change for the two MOF scenarios. Red colours indicate that, after construction is complete, sediment accretion will be increased (or sediment scour will be reduced) "compared to existing conditions"; blue colours indicate the opposite - after construction is complete, sediment accretion will be reduced (or sediment scour will be increased) "compared to existing conditions". Note the area of deep red around Charles Point in the concrete caisson MOF scenario (Figure 69b), indicating the potential for an increase in sediment deposition approaching 4 cm per year. In contrast, the pile-and-deck MOF scenario (Figure 69c) shows only a small area of low-magnitude (predominantly < 1 cm per year) difference in sediment accretion compared to existing conditions. As such, the concern pertaining to ongoing effects from sediment accretion only applies to the concrete caisson MOF scenario; consequently, monitoring is not deemed necessary for the pile-and-deck MOF option. Nevertheless, Aurora LNG recognizes that (as stated in Section 15) "additional follow-up programs may be identified through further consultation and engagement". Aurora LNG welcomes further discussions with Gitxaala Nation on the Application and environmental management plans/programs during the workshops being held during the Application Review period.
2139.1	round 1	Gitxaala Nation	15.3.1	Vegetation and Wetland Resources	Please refer to and outline an adaptive management process for the Wetland Compensation Plan.	See Mitigation 4.6.15 in Table 4.6-13 of the Application which refers to monitoring the performance of restored, enhanced, or created wetlands that are established according to the Project's Wetland Compensation Plan. This effectiveness monitoring is intended to confirm that the ecological function of the compensatory habitat is performing as intended (See also Section 5.3 of Appendix U of the Application). In the event that restored, enhanced, or created wetland habitat is not functioning as intended, then adaptive management would be applied. Adaptive management measures cannot be defined in advance of knowing what the issue is, but could include such management measures as: adjustment to wetland hydrology through grading or channel design; replanting with more-suitable plant species; controlling herbivory; or removing invasive plant species. The precise measures would depend on the stressors and/or monitoring plan results.
2140.1	round 1	Gitxaala Nation	15.3.2	Follow-up Programs and Compliance Reporting	Please provide information about how the plan will address uncertainities in the presence and potential spread of invasive species. Given the deficiences in the survey sampling and data collection methodologies from Appendix I, lack of analysis undertaken to reliably assess the likelhood of invasive species due to Project activities, the current conclusions and prediction confidence are not justifiable.	TEM and rare plant field plots provide evidence that invasive species are not prevalent in undisturbed areas of the PDA. The Invasive Plant Management Plan will include industry Best Management Practices, which will meet legislated requirements and permit conditions related to invasive plants and invasive plant management. The management of invasive species in BC is well regulated. With the implementation of the Invasive Plant Management Plan, the potential introduction or spread of invasive plant species from disturbed areas of the PDA or off-site sources will be mitigated to acceptable levels.
2141.1	round 1	Gitxaala Nation	15.3.2	Follow-up Programs and Compliance Reporting	How will objective questions for monitoring be determined through adaptive management in the Invasive Species Management Plan, in terms of the spread of noxious weeds and the BC Oil and Gas Commission (2015) Environmental Protection and Management Guideline requirements for control of invasive species during all phases of projects. Specifically, how will the proposed follow-up program address "key concerns raised by Aboriginal Groups, the public, and other stakeholders during the development of the Application", as well as any regulatory requirements including the Weed Control Act?	As stated in Section 15.3.2 of the Application, an invasive species monitoring program will be included as part of the Invasive Plant Management Plan. Detection of noxious weeds or invasive plant species listed by the Northwest Invasive Species Council during monitoring would trigger the implementation of control methods in accordance with the BC Oil and Gas Commission Environmental Protection and Management Guide and the Weed Control Act. Controlling the establishment and spread of invasive plant species accordingly is expected to address concerns raised by Aboriginal Groups, the public, and other stakeholders, as well as meet regulatory requirements.
2142.1	round 1	Gitxaala Nation	15.3.3	Air Quality	How will SO2 and NO2 emissions also be considered in the monitoring of acidification and eutrophication effects to freshwater habitat, as well as Mitigation No. 4.6.10: to monitor effects to "vegetation from SO2 and NO2 atmospheric concentrations, soil acidification or soil eutrophication" in Section 4.6 (p. 4.6-35, Table 4.6-11)?	It is expected that commitments to monitor acidification and eutrophication will result in the collection of samples from the ambient environment (freshwater, vegetation, soil) to determine the potential increase in acidic and nitrogen deposition and the resultant changes in the biosphere. The scientists conducting this work will consider emissions of SO2 and NO2 in their interpretation of the results. For example, effects predicted in the Application can be compared to observed effects in the environment, given the actual vs. projected emissions. Monitoring may also allow an evaluation of how year-to-year changes in emissions are expressed in the environment.
2143.1	round 1	Gitxaala Nation	15.3.4	Greenhouse Gases	A commitment to monitoring and reporting of emissions discharge is not sufficient, given the determination of significant cumulative adverse effects in the VC assessment. There is a high degree of uncertainty in the potential for effects due to the removal of upstream sources as a CEAA requirement, as well as the shipping sources. There are unsubstantiated mitigation measures proposed in the GHG Management Plan, which has a moderate likelihood of success, despite an illogical claim that all of its component mitigation measures will have high likelihood of success. How will monitoring be undertaken in terms of the Project's contribution to GHGs? How will consultation with relevant interest groups be factored into this process if the Proponent is truly committed to the principles of adaptive management? What adjustments will be offered to improve on the uncertainty in the ability to reliably detect fugitive emissions since these represent additional methane sources potentially released in the production per tonne of LNG, apart from methane directly used to drive liquefaction. All methane releases should be accounted for in accordance with the Province's intensity-based metrics for LNG carbon pricing.	GHG emission monitoring during the operation phase will be completed through annual compliance reporting obligations. Following the quantification of project related GHG emissions, the Project will be able to monitor the effectiveness of any GHG mitigations that are implemented. Aurora LNG will have an open dialogue with regulators such as the BC Climate Action Secretariat in regards to annual GHG emissions and GHG management. Fugitive emissions released by the Project will be monitored in the Fugitive emission detection program. However, fugitive emissions from activities upstream of the Project will be the responsibility of the owner/operator of those upstream operations.
2144.1	round 1	Gitxaala Nation	15.3.5	Follow-up Programs and Compliance Reporting	Philip Molloy completed the plan and Karen Munro conducted the "independent" review for Appendix V; however, both of these individuals work for Stantec, so how is the review considered to be independent? Is it not a conflict of interest?	The term 'Independent Reviewer' is a Stantec internal term for a reviewer, who was not directly involved with the development of the report, but has expertise, or experience in the area, and can provide a review that focuses on the larger picture and presentation of the information in context of the project. The previous term for this was 'Senior Reviewer'. It is not meant to indicate that the person is independent of Stantec or the Project.
2145.1	round 1	Gitxaala Nation	15.3.5	Follow-up Programs and Compliance Reporting	Appendix V, Section 4.2.3.3, p.9 identifies "a sanitary wastewater treatment facility will be established for use during construction and operations within the camp system to treat wastewater prior to discharge through the outfall pipe located at Charles Point." The conceptual layout on Figure 1-2 of Part A, Section 1 shows the desalination plant footprint located within the PDA, as well as its incurrent and excurrent water lines. A single wastewater line exits the plant and leads directly to the deep outfall at Charles Point with no lines interconnecting with the sanitary wastewater treatment facility. Please explain how these two systems are expected to interact and state the implications for potential effects to fisheries productivity in the offsetting plan.	Figure 1-2 shows a conceptual layout of project infrastructure. Additional information will be provided during Front End Engineering and Design (FEED). Please see the memo "Discharges to the Marine Environment" for more discussion on this matter. This technical memo will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting. Any discharge into the marine environment from the combined outflow from the desalinization plant and sanitary wastewater treatment facility will meet water quality guidelines prescribed by the federal government outside of a defined mixing zone. This mixing zone will be determined during the permitting phase of the Project. Because of this, discharges to the marine environment from the desalinization plant and sanitary wastewater treatment plant are expected to have a negligible effect on the productivity of CRA fisheries in the RAA.

2146.1	round 1	Gitxaala Nation	15.3.5	Follow-up Programs and Compliance Reporting	Appendix V intends to derive a substantial amount of its productivity offsets from barrier removals; however, this measure was also proposed by Stantec for the offsetting plan for LNG Canada, which DFO ultimately did not accept. This conceptual plan was developed by the same consultancy and represents prior knowledge of the regulatory setting as weel as the conclusions anticipated by DFO for theregion. How can these measures be justified for the Project if they were not deemed to be acceptable for LNG Canada, which has not yet been granted a full Fisheries Act authorization?	The Conceptual Fish Habitat Offsetting Plan includes barrier removals as part of a suite of options available to compensate for the anticipated loss of freshwater habitat within the PDA. It does so because barrier removals, where they prevent fish from accessing high quality habitat or large amounts of habitat upstream, can provide large increases in fish production for perpetuity with very low risks of failure. Presence/absence of fish at the proposed barrier removal sites would need to be determined as part of development of the offsetting plan. The current offset plan included with the application is conceptual in nature.The offset plan will be refined through collaborative engagemen with regulatory agencies (primarily DFO) and Aboriginal Groups.
2147.1	round 1	Gitxaala Nation	15.3.5	Follow-up Programs and Compliance Reporting	Although Appendix V identifies the seawater desalination system as a "terrestrial component" that stands to affect fisheries productivity, it does not specifically identify how desalination and disposal of wastewater will affect marine fish and fish habitat. In its reference to the marine environment, "Project construction and operations could cause serious harm to fish either via death of fish or habitat effects. Specifically, death of fish could be caused via crushing, burial, entrainment or impingement; exposure to underwater noise or pressure waves; marine habitat change or loss could occur through: Removal of marine vegetation, including marine riparian vegetation, eelgrass and macroalgae; change in substrate shape, height or type; Removal of substrate". By this description and the estimate of losses provided (i.e., Table 16 of Appendix V on p. 46 states all project activities will amount to a total 130 square metres of marine habitat requiring offsetting due to the installatin of the pipes), potential effects due to effluent discharge in the marine environment have not been considered. Limited baseline data exist to indicate water quality conditions or marine fisheries productivity in the area of the deep outfall and no effects modelling has been undertaken in the environmentalassessment to determine effluent dispersion in the water column, given the estimated construction and operational volumes of daily discharge, as well as the proposed location of the deep outfall. There is a complete lack of information provided to indicate the prevailing ocean current system will influence dispersion. These are clear deficiencies in the overall assessment that requires baseline information and a more credible assessment of effects. These data are necessary for a more credible estimation of productivity losses, especially given the uncertainties surrounding the actual seawater desalination process and wholly unknown mechansisms for effective treatment of wastewater prior to disposal.	The release of wastewater at the deep water outfall near Charles Point is not expected to result in residual serious harm to fish. DFO (2013) defines serious harm to fish as: a) the death of fish; b) a permanent alteration to fish habitat of a spatial scale, duration or intensity that limits or diminishes the ability of fish to use such habitats as spawning grounds, or as nursery, rearing or food supply areas, or as a migration corridor, or any other area in order to carry out one or more of their life processes; o c) the destruction of fish habitat of a spatial scale, duration or intensity that fish can no longer rely upon such habitat for use as spawning grounds, or as nursery, rearing or food supply areas, or as a migration corridor, or any other area in order to carry out one or more of their life processes. All effluent discharges to the marine environment will comply with the BC Environmental Management Act regulations (i.e., Waste Discharge Regulation, Petroleum Storage and Distribution Facilities Storm Water Regulation), and will meet the CCME and BC water quality guidelines (which are designed to protect aquatic life) in receiving water outside of a defined mixing zone. Therefore, Project-related discharges are not expected to harm (or kill) marine fish or invertebrates, nor are they expected to result in habitat changes that affect the ability of marine fish or invertebrates to complete their life processes. Reference: Fisheries and Oceans Canada [DFO]. 2013. Fisheries Protection Policy Statement. Ecosystem Programs Policy. Ottawa, Ontario. 22 pp.
2148.1	round 1	Gitxaala Nation	15.3.5	Follow-up Programs and Compliance Reporting	Appendix V does not discuss the treatment and disposal of wastewater generated from the desalination process. Please explain how this wastewater will interact with any treatment and/or disposal systems and state the implications for potential effects to fisheries productivity in the offsetting plan.	Please refer to the "Discharges to the Marine Environment" technical memo for more information on how wastewater will be treated prior to discharge to the marine environment. This technical memo will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting. The release of wastewater at the deep water outfall near Charles Point is not expected to result in residual serious harm to fish. DFO (2013) defines serious harm to fish as: a) the death of fish; b) a permanent alteration to fish habitat of a spatial scale, duration or intensity that limits or diminishes the ability of fish to use such habitats as spawning grounds, or as nursery, rearing or food supply areas, or as a migration corridor, or any other area in order to carry out one or more of their life processes; o c) the destruction of fish habitat of a spatial scale, duration or intensity that fish can no longer rely upon such habitat for use as spawning grounds, or as nursery, rearing or food supply areas, or as a migration corridor, or any other area in order to carry out one or more of their life processes. All effluent discharges to the marine environment will comply with the CCME and BC water quality guidelines (which are designed to protect aquatic life) outside of a defined mixing zone. Therefore, Project-related discharges are not expected to harm (or kill) marine fish or invertebrates, nor are they expected to result in habitat changes that affect the ability of marine fish or invertebrates to complete their life processes. Reference: Fisheries and Oceans Canada [DFO]. 2013. Fisheries Protection Policy Statement. Ecosystem Programs Policy. Ottawa, Ontario. 22 pp.
2149.1	round 1	Gitxaala Nation	15.3.5	Follow-up Programs and Compliance Reporting	Appendix V (Section 5.2.1, pp.18-21) identifies Casey Cove and South Digby Island as the areas where marine fish habitat and species have been considered. Please include the area east of Digby Island in the plan, particulary the location of the deep outfall near Charles Point, as an area where marine fish habitat and aquatic species should be considered.	The outfall location at Charles Point falls within the spatial scope of the Casey Cove area and, hence, has already been considered in this section. For confirmation, please see Figures 14-17, in the Marine Fish and Fish Habitat Technical Data Report (Appendix L).
2150.1	round 1	Gitxaala Nation	15.3.5	Follow-up Programs and Compliance Reporting	The persistent release of wastewater in the area of the deep outfall has not been factored in as a mechanism of change leading to serious harm to fisheries productivity defined as "death of fish and permanent alteration or destruction of fish habitat" (Appendix V Section 7.2, Table 8 on p.28). Please factor this mechanisms into the evaluation of marine fish habitat offsetting requirements as it pertains to waste management during construction and operations.	The release of wastewater at the deep water outfall near Charles Point is not expected to result in residual serious harm to fish. DFO (2013) defines serious harm to fish as: a) the death of fish; b) a permanent alteration to fish habitat of a spatial scale, duration or intensity that limits or diminishes the ability of fish to use such habitats as spawning grounds, or as nursery, rearing or food supply areas, or as a migration corridor, or any other area in order to carry out one or more of their life processes; o c) the destruction of fish habitat of a spatial scale, duration or intensity that fish can no longer rely upon such habitat for use as spawning grounds, or as nursery, rearing or food supply areas, or as a migration corridor, or any other area in order to carry out one or more of their life processes. All effluent discharges to the marine environment will comply with the CCME and BC water quality guidelines (which are designed to protect aquatic life) outside of a defined mixing zone. Therefore, Project-related discharges are not expected to harm (or kill) marine fish or invertebrates, nor are they expected to result in habitat changes that affect the ability of marine fish or invertebrates to complete their life processes. Reference: Fisheries and Oceans Canada [DFO]. 2013. Fisheries Protection Policy Statement. Ecosystem Programs Policy. Ottawa, Ontario. 22 pp.
2151.1	round 1	Gitxaala Nation	15.3.6	Follow-up Programs and Compliance Reporting	This issue stands to be one of the greatest sources of uncertainty with respect to environmental effects, principally due to the lack of baseline data for marine sediment and water quality, preliminary Project design, and contradicting statements regarding overall wastewater treatment prior to disposal compared to the conceptual layout of the desalination plant and outfall pipe presented in Figure 1-2 in Section 1 of Part A. Of the limited marine fisheries baseline data that do exist , the indication is that the area of the outfall represents among the most productive habitats observed in the East Digby Island and Casey Cove study areas, yet this has not been acknowledged at any point in the entire assessment. The marine water quality monitoring program should be a principle element of the adaptive management strategy for assessing and mitigating risks beyond simply monitoring "parameters in effluent discharges according to permit requirements" with no specific details provided about mitigation measures or any reference made to the stated commitment of adaptive management.	Aurora LNG acknowledges that details around the design and operation of the Charles Point outfall are preliminary and will be refined during final engineering and design; however, Aurora LNG is of the opinion that characterization of potential effects on marine fish health associated with effluent discharges at the Charles Point outfall is adequate. The assessment considered information on marine fish and fish habitat collected from scientific literature and Project-specific studies (see Appendix L, Marine Fish and Fish Habitat TDR). The following sections provide information to characterize intertidal and subtidal fish and fish habitats along East Digby Island, including the area south of Charles Point where the deep outfall is proposed: Section 5.1.3.2, Figure 10 (intertidal); Section 5.2.3.2, Figure 18, Figure 19, Figure 20, and Figure 21 (subtidal); Section 5.4.3.2, Figure 33 (eelgrass); and Section 5.5.6, Figure 42 and Figure 43 (marine fish). With the implementation of mitigation measures to reduce potential effects on marine fish and fish habitat associated with effluent discharge, such as commitments that all effluent discharges to the marine environment will comply with the BC Environmental Management Act regulations (i.e., Waste Discharge Regulation, Petroleum Storage and Distribution Facilities Storm Water Regulation), and will meet the CCME and BC water quality guidelines (which are designed to protect aquatic life) in the receiving environment outside of a defined mixing zone, Project-related discharges are not expected to result in residual adverse effects to marine fish health. Aurora LNG is committed to conducting a Marine Water Quality Monitoring Program, which will include monitoring effluent discharges and the receiving environment as per permitting requirements (see Section 15.3.6 of the Summary of Follow-up Programs and Compliance Reporting). Details on the mitigation objectives, approach and field protocols will be developed and formalized in the Marine and Freshwater Resources Management Plan. This plan will include "water quality monitoring programs that will be implemented, including water quality thresholds, monitoring frequency and specific monitoring location". It is standard practice for management plans of this nature to include an adaptive management framework. Aurora LNG's framework for adaptive management is as follows: Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended). Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Marine Water Quality Monitoring Program and the Marine and Freshwater Resources Management Plan.
2152.1	round 1	Gitxaala Nation	7.2.1	Heritage	This section states that the assessment incorporates information gathered during consultation with Aboriginal Groups however the document does not make it clear exactly how Gitxaala TUS/TK from Calliou 2016 has been incorporated. Further, Gitxaala has repeatedly asked to be included in the archeaological field work in order to ensure that our TUS/TK information is being properly accounted for. Despite these requests, Gitxaala was been repeatedly excluded. In order to rectify this exclusion and ensure that all Gitxaala archaeological and heritage resources have been properly accounted for, Nexen had agreed to support Gitxaala in a field audit of all field work that had been performed. Nexen has failed to follow through with this agreement to date and as such, Gitxaala does not have any certainty that our archeaological and heritage resources have been properly characterized and assessed in the application.	The TK/TU studies that were available at the time of assessment are listed in Section 7.2.3.1 of the Application. These studies were reviewed for information that could inform the archaeological and heritage resources effects assessment, in particular, information regarding traditional land use sites, activity areas and place names in the LAA/RAA. The results of these studies are summarized in Appendix S.2. The public versions of these TK/TU studies are available from the BC EAO. The AIA permit report (Appendix W) describes the assessment of the PDA conducted in 2015, prior to completion of project-specific TK/TU studies. The AIA included a desktop review of publicly available ethnographic and ethno-historic sources, as well as TK/TU reports from other environmental assessments near the LAA/RAA. Gitxaala Nation's TK/TU study, Caillou Group 2016, is cited in section 7.2.2.2 and 7.2.3.1. Aurora LNG has also invited Gitxaala Nation to participate in a Field Review (in March 2017), in response to Gitxaala Nation's desire to conduct a "Field Audit". While Aurora LNG understands that Gitxaala Nation wishes to conduct a full audit of the field work, Aurora LNG has outlined for Gitxaala Nation an approach designed to achieve a common understanding of the baseline study findings and how these findings were incorporated into the Application. Aurora LNG communicated this in a letter dated February 14, 2017 from Jason Gouw to James Witzke. Ultimately Gitxaala Nation declined to participate in the proposed field review. Further information that provides context related to Aurora LNG's approach to consultation and fieldwork participation is provided in the technical memo entitled "Aurora LNG's Approach to Consultation with Aboriginal Groups" which will be filed with the EAO.
2153.1	round 1	Gitxaala Nation	7.2.2.2	Heritage	This section does not accurately capture the issues and concerns that Gitxaala has continually expressed with the archealogical and heritage program during consultation. No mention is made of the ongoing issue of Gitxaala being excluded from field work and therefore unable to verify the success and accuracy of the application in properly assessing effects to Gitxaala archaeological and heritage resources.	Aurora LNG acknowledges the concern of Gitxaala Nation regarding the archaeological and heritage sites in the PDA. Further information that provides context related to Aurora LNG's approach to consultation and fieldwork participation is provided in the technical memo entitled "Aurora LNG's Approach to Consultation with Aboriginal Groups" which will be filed with the EAO.
2154.1	round 1	Gitxaala Nation	7.2.2.3	Heritage	This section states that the assessment incorporates information gathered during consultation with Aboriginal Groups however the document does not make it clear exactly how Gitxaala TUS/TK from Calliou 2016 has been incorporated. Further, Gitxaala has repeatedly asked to be included in the archeaological field work in order to ensure that our TUS/TK information is being properly accounted for. Despite these requests, Gitxaala was been repeatedly excluded. In order to rectify this exclusion and ensure that all Gitxaala archaeological and heritage resources have been properly accounted for, Nexen had agreed to support Gitxaala in a field audit of all field work that had been performed. Nexen has failed to follow through with this agreement to date and as such, Gitxaala does not have any certainty that our archeaological and heritage resources have been properly characterized and assessed in the application.	The TK/TU studies that were available at the time of assessment are listed in Section 7.2.3.1 of the Application. These studies were reviewed for information that could inform the archaeological and heritage resources effects assessment, in particular, information regarding traditional land use sites, activity areas and place names in the LAA/RAA. The results of these studies are summarized in Appendix S.2. The public versions of these TK/TU studies are available from the BC EAO. The AIA permit report (Appendix W) describes the assessment of the PDA conducted in 2015, prior to completion of project-specific TK/TU studies. The AIA included a desktop review of publicly available ethnographic and ethno-historic sources, as well as TK/TU reports from other environmental assessments near the LAA/RAA. Gitxaala Nation's TK/TU study, Caillou Group 2016, is cited in section 7.2.2.2 and 7.2.3.1. Aurora LNG has also invited Gitxaala Nation to participate in a Field Review (in March 2017), in response to Gitxaala Nation's desire to conduct a "Field Audit". While Aurora LNG understands that Gitxaala Nation wishes to conduct a full audit of the field work, Aurora LNG has outlined for Gitxaala Nation an approach designed to achieve a common understanding of the baseline study findings and how these findings were incorporated into the Application. Aurora LNG communicated this in a letter dated February 14, 2017 from Jason Gouw to James Witzke. Ultimately Gitxaala Nation declined to participate in the proposed field review. Further information that provides context related to Aurora LNG's approach to consultation and fieldwork participation is provided in the technical memo entitled "Aurora LNG's Approach to Consultation with Aboriginal Groups" which will be filed with the EAO.
2155.1	round 1	Gitxaala Nation	7.2.3	Heritage	This section states that the details related to studies are outlined in Section 7.2.3 (Existing Conditions for Archaeological and Heritage Resources). In Section 7.2.3. they then write that the existing conditions are described in AIA report for permit 2015-0007. In our review of permit 2015-0007, there is no reference to TUS/TK studies, specifically Calliou 2016. Please clarify what Gitxaala specific TUS/TK information was used, how it was used and where these details are outlined.	The TK/TU studies that were available at the time of assessment are listed in Section 7.2.3.1 of the Application. This includes Gitxaala Nation's TK/TU study, Caillou Group 2016, which is cited in Sections 7.2.2.2 and 7.2.3.1. These studies were reviewed for information that could inform the archaeological and heritage resources effects assessment, in particular, information regarding traditional land use sites, activity areas and place names in the LAA/RAA. The results of these studies are summarized in Appendix S.2. The public versions of these TK/TU studies are available from the BC EAO. The AIA permit report (Appendix W) describes the assessment of the PDA conducted in 2015, prior to completion of project-specific TK/TU studies. The AIA included a desktop review of publicly available ethnographic and ethno-historic sources, as well as TK/TU reports from other environmental assessments near the LAA/RAA.
2156.1	round 1	Gitxaala Nation	7.2.3.2	Heritage	As noted before, without having been a part of the fieldwork or having had the opportunity to perform a field audit (as had been agreed on but not followed through with by Nexen), Gitxaala has been unable to verify the conclusion that certain sites, such as the two rock overhangs at Spire Island, are not of archaeological or cultural significance to the Nation.	Regarding the two rock overhangs on Spire Island, while visual examination of the areas did not identify any archaeological materials or remains, given the potentially sensitive nature of these features as potential burial places, intrusive subsurface inspection was not conducted. As per the AIA report (Appendix W), avoidance is recommended. If avoidance is not feasible, additional archaeological study should be undertaken prior to construction. Aurora LNG has invited Gitxaala Nation to participate in a Field Review (in March 2017), in response to Gitxaala Nation's desire to conduct a "Field Audit". While Aurora LNG understands that Gitxaala Nation wishes to conduct a full audit of the field work, Aurora LNG has outlined for Gitxaala Nation an approach designed to achieve a common understanding of the baseline study findings and how these findings were incorporated into the Application. Aurora LNG communicated this in a letter dated February 14, 2017 from Jason Gouw to James Witzke. Ultimately Gitxaala Nation declined to participate in the proposed field review. Further information that provides context related to Aurora LNG's approach to consultation and fieldwork participation is provided in the technical memo entitled "Aurora LNG's Approach to Consultation with Aboriginal Groups" which will be filed with the EAO.
2157.1	round 1	Gitxaala Nation	7.2.4	Heritage	Why doesn't this section include any mention to indirect impacts to sites situated adjacent to proposed project area?	Potential Project interactions with archaeological and heritage resources are only anticipated to occur from activities that result in tree removal or ground disturbance (including dredging) within the Project Development Area during the construction phase.

2158.1	round 1	Gitxaala Nation	7.2.5.2	Heritage	See technical memo 0217_Gitxaala_Archaeological and Heritage Impacts	Technical memo 217 from Gitxaala Nation Site avoidance Aurora LNG has incorporated a buffer that avoids some coastal and riparian areas within the PDA (Figures 7-1, 7-2). The adoption of this buffer zone results in avoidance of most of the significant archaeological and heritage resources in the PDA. Final project design may result in opportunities for further avoidance of sites, but for purposes of the application we have conservatively assumed that any sites within the PDA that are not in the buffer zone will be altered. Proposed buffer zone and indirect impacts The buffer zone is 30 metres wide. While this avoids most of the significant archaeological and heritage resources in the PDA, it is recognized that once final project design is complete, site-specific mitigation measures will be established so that measures designed to ensure site avoidance will be effective for both direct impact as well as potential for erosion. Site-specific mitigation plans are not yet provided nor evaluated as project engineering plans are not sufficiently advanced to determine the exact nature of potential Project impacts. However, as mitigation measures will be determined in consultation with appropriate regulatory agencies, and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended), the success of the measures that are currently included in the Application with the addition of site specific planning, is predicted to be high. SDR Aurora LNG acknowledges the importance of the archaeological and heritage sites in the PDA to the Gitxaala Nation. While the Archaeology Branch (FLNRO) will determine the mitigation measures for protected archaeological sites, Aurora LNG welcomes further discussion with Gitxaala Nation during preparation of the Archaeological and Heritage Resources Management Plan. Vessel wake The potential for wake effects from vessels was considered in this assessment (Section 7.2.5.2), and is not expected to have adverse effects on marine intertidal areas. TU/TK The TK/TU studies that were available at the time of assessment are listed in Section 7.2.3.1 of the Application. These studies were reviewed for information that could inform the archaeological and heritage resources effects assessment, in particular, information regarding traditional land use sites, activity areas and place names in the LAA/RAA. The results of these studies are summarized in Appendix S.2. The public versions of these TK/TU studies are available from the BC EAO. The AIA permit report (Appendix W) describes the assessment of the PDA conducted in 2015, prior to completion of project-specific TK/TU studies. The AIA included a desktop review of publicly available ethnographic and ethno-historic sources, as well as TK/TU reports from other environmental assessments near the LAA/RAA. Gitxaala Nation's TK/TU study, Caillou Group 2016, is cited in section 7.2.2.2 and 7.2.3.1.
2159.1	round 1	Gitxaala Nation	Table 7-7	Heritage	Very little effort has been made to change proposed project footprint so that sites are avoided, aside from the proposed buffer zone. The Project Development Area is essentially unchanged from the one proposed in original assessments, and though Aurora LNG states that avoidance is the preferred option for archaeological and heritage sites, it doesn't appear to be reflected in any meaningful project re-design. GEM would like to see further efforts to prioritize site avoidance over mitigative measures.	Aurora LNG acknowledges that the PDA boundary has remained consistent, however by incorporating the proposed buffer some coastal and riparian areas are retained within the PDA (Figures 7-1, 7-2). The adoption of this buffer zone results in avoidance of most of the significant archaeological and heritage resources in the PDA (Section 7.2.5.2). While Aurora LNG will look for further opportunities during construction to avoid sites within the PDA where feasible, for purposes of the application it is assumed that sites that are not within the buffer will be impacted by construction.
2160.1	round 1	Gitxaala Nation	Table 7-8	Heritage	See technical memo 0217_Gitxaala_Archaeological and Heritage Impacts	Technical memo 217from Gitxaala Nation Site avoidance Aurora LNG has incorporated a buffer that avoids some coastal and riparian areas within the PDA (Figures 7-1, 7-2). The adoption of this buffer zone results in avoidance of most of the significant archaeological and heritage resources in the PDA. Final project design may result in opportunities for further avoidance of sites, but for purposes of the application we have conservatively assumed that any sites within the PDA that are not in the buffer zone will be altered. Proposed buffer zone and indirect impacts The buffer zone is 30 metres wide. While this avoids most of the significant archaeological and heritage resources in the PDA, it is recognized that once final project design is complete, site-specific mitigation measures will be established so that measures designed to ensure site avoidance will be effective for both direct impact as well as potential for erosion. Site-specific mitigation plans are not yet provided nor evaluated as project engineering plans are not sufficiently advanced to determine the exact nature of potential Project impacts. However, as mitigation measures will be determined in consultation with appropriate regulatory agencies, and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended), the success of the measures that are currently included in the Application with the addition of site specific planning, is predicted to be high. SDR Aurora LNG acknowledges the importance of the archaeological and heritage sites in the PDA to the Gitxaala Nation. While the Archaeology Branch (FLNRO) will determine the mitigation measures for protected archaeological sites, Aurora LNG welcomes further discussion with Gitxaala Nation during preparation of the Archaeological and Heritage Resources Management Plan. Vessel wake The potential for wake effects from vessels was considered in this assessment (Section 7.2.5.2), and is not expected to have adverse effects on marine intertidal areas. TU/TK The TK/TU studies that were available at the time of assessment are listed in Section 7.2.3.1 of the Application. These studies were reviewed for information that could inform the archaeological and heritage resources effects assessment, in particular, information regarding traditional land use sites, activity areas and place names in the LAA/RAA. The results of these studies are summarized in Appendix S.2. The public versions of these TK/TU studies are available from the BC EAO. The AIA permit report (Appendix W) describes the assessment of the PDA conducted in 2015, prior to completion of project-specific TK/TU studies. The AIA included a desktop review of publicly available ethnographic and ethno-historic sources, as well as TK/TU reports from other environmental assessments near the LAA/RAA. Gitxaala Nation's TK/TU study, Caillou Group 2016, is cited in section 7.2.2.2 and 7.2.3.1.
2161.1	round 1	Gitxaala Nation	Section 2.4	Greenhouse Gases	Aurora LNG indicates that "inherent uncertainty in estimating emission rates from the Project…the emissions estimates are conservatively high to capture worst-case full build-out conditions." In Section 1.2, Proposed Project Description (page 1-3) ,the Project includes three LNG storage tanks and based on 4 production trains will produce 24 MTPA of LNG at full build-out. Although Aurora ackowledges that the Project's 4 trains may be built over two phases, Aurora is not asking for approval related to Phase 1 only, it is seeking approval for both Phases. As such, the suggestion that the GHG emissions estimate is conservatively high and represents worst-case, full build-out conditions is neither justified, nor supported. It represents a minimally reasonable approach. *Questions: Can Aurora describe why the GHG emission estimates for the two phases are conservatively high? Has Aurora committed to GHG emission intensity < 0.28 tCO2e/tCO2e LNG produced?*	The Project GHG emission estimates are conservative due to the assumed conditions that have been included in the worst-case, full build-out scenario. Conservative conditions include the following:Main gas supply is assumed to have a conservative 1.82% mol CO2 content. Other projects have used lower values for estimated C02 content. The entire facility power demand is expected to be produced onsite, including the power for the compressor gas turbines. It has been conservatively assumed that the Project will not consume electricity through BC Hydro. Aurora LNG is continuing discussions with BC Hydro to determine if electrical options may become available. The current facility design is based on simple cycle gas turbine power generation which is the least efficient and most expensive to operate. As the facility design progresses through its engineering design, Aurora LNG will be looking for opportunities to improve facility efficiency and minimize energy waste. This is expected to include consideration of combined cycle gas turbines and waste heat recovery for use in other processes which would be expected to help lower the overall emissions including GHGs. Based on the current Project design, the GHG emission intensity has been conservatively estimated to be 0.28t CO2e/t LNG produced. This emission intensity is expected to be much lower once actual data is available during the operation phase of the Project. The current Project design includes the operations of the full build-out scenario. This method was approved in the AIR and meets the objective to evaluate the reasonable worst case scenario. For further information, regarding how changes of mol CO2 % in the feed gas can affect the GHG emission intensity, please refer to the memo "Feed Gas Carbon Dioxide (CO2) content Impact on GHG Emissions for the Aurora LNG Application for an Environmental Assessment Certificate", which will be filed with the BC EAO.
2162.1	round 1	Gitxaala Nation	Section 4	Greenhouse Gases	As noted above, the suggestion that the GHG assessment is conservative based on go/no go decision with respect Phase 2 and market demand is irrelevant and not supported by the Project Application. This is not a conservative assumption - it is a minimally reasonable approach. *Question: Can Aurora describe why the GHG emission estimates for the two phases are conservatively high?*	The Project GHG emission estimates are conservative due to the assumed conditions that have been included in the worst-case, full build-out scenario. Conservative conditions include the following:Main gas supply is assumed to have a conservative 1.82% mol CO2 content. Other projects have used lower values for estimated C02 content. The entire facility power demand is expected to be produced onsite, including the power for the compressor gas turbines. It has been conservatively assumed that the Project will not consume electricity through BC Hydro. Aurora LNG is continuing discussions with BC Hydro to determine if electrical options may become available. The current facility design is based on simple cycle gas turbine power generation which is the least efficient and most expensive to operate. As the facility design progresses through its engineering design, Aurora LNG will be looking for opportunities to improve facility efficiency and minimize energy waste. This is expected to include consideration of combined cycle gas turbines and waste heat recovery for use in other processes which would be expected to help lower the overall emissions including GHGs. Based on the current Project design, the GHG emission intensity has been conservatively estimated to be 0.28t CO2e/t LNG produced. This emission intensity is expected to be much lower once actual data is available during the operation phase of the Project. The current Project design includes the operations of the full build-out scenario. This method was approved in the AIR and meets the objective to evaluate the reasonable worst case scenario. For further information, regarding how changes of mol CO2 % in the feed gas can affect the GHG emission intensity, please refer to the memo "Feed Gas Carbon Dioxide (CO2) content Impact on GHG Emissions for the Aurora LNG Application for an Environmental Assessment Certificate", which will be filed with the BC EAO.
2163.1	round 1	Gitxaala Nation	Section 5	Greenhouse Gases	"For the purpose of adhering to a conservative approach, the following assumptions apply: During operations, terminal liquefaction capacity is assumed to be 94.5%, which means that the facility is operating on average about 345 days a year at maximum capacity. Power for the entire facility is conservatively assumed to be produced onsite, including the power for the compressor gas turbines. There is no electricity consumption through BC Hydro. Therefore, emission estimates are conservative as GHG emissions from power generation onsite are included in the assessment, compared to when lower GHG intensity grid power is imported from BC Hydro." Section 1.2.5.3 Power Supply of the Proposed Project Overview (page 1-29) indicates that a ~250 MW power generation facility will be installed onsite and the preliminary design indicates that it will be a combined cycle natural gas power plant. The power plant will operate 24/7/365 and the liquefaction trains will operate 345 out of 365 days at maximum capacity. The proponent again suggests that the GHG assessment is conservative and may be over-estimating GHG emissions but fails to acknowledge the Project description that forms the basis for the Application. These are not conservative assumptions - they appear to be based on a minimally reasonable approach. Q*uestion: Can Aurora describe why the GHG emission estimates for the two phases are conservatively high?*	The Project GHG emission estimates are conservative due to the assumed conditions that have been included in the worst-case, full build-out scenario. Conservative conditions include the following:Main gas supply is assumed to have a conservative 1.82% mol CO2 content. Other projects have used lower values for estimated C02 content. The entire facility power demand is expected to be produced onsite, including the power for the compressor gas turbines. It has been conservatively assumed that the Project will not consume electricity through BC Hydro. Aurora LNG is continuing discussions with BC Hydro to determine if electrical options may become available. The current facility design is based on simple cycle gas turbine power generation which is the least efficient and most expensive to operate. As the facility design progresses through its engineering design, Aurora LNG will be looking for opportunities to improve facility efficiency and minimize energy waste. This is expected to include consideration of combined cycle gas turbines and waste heat recovery for use in other processes which would be expected to help lower the overall emissions including GHGs. Based on the current Project design, the GHG emission intensity has been conservatively estimated to be 0.28t CO2e/t LNG produced. This emission intensity is expected to be much lower once actual data is available during the operation phase of the Project. The current Project design includes the operations of the full build-out scenario. This method was approved in the AIR and meets the objective to evaluate the reasonable worst case scenario. For further information, regarding how changes of mol CO2 % in the feed gas can affect the GHG emission intensity, please refer to the memo "Feed Gas Carbon Dioxide (CO2) content Impact on GHG Emissions for the Aurora LNG Application for an Environmental Assessment Certificate", which will be filed with the BC EAO.
2164.1	round 1	Gitxaala Nation	Section 5.1	Greenhouse Gases	As noted above, the suggestion that the GHG assessment is conservative based on onsite power generation and not grid power reflects the preliminary design philosophy in the Application and would be mis-stated as an over-estimation of effects. *Questions: Can Aurora describe why the GHG emission estimates for the power generation are conservatively high? Is Aurora committing to using grid power from BC Hydro, and if so, to what extent?*	The Project GHG emission estimates are conservative due to the assumed conditions that have been included in the worst-case, full build-out scenario. Conservative conditions include the following:Main gas supply is assumed to have a conservative 1.82% mol CO2 content. Other projects have used lower values for estimated C02 content. The entire facility power demand is expected to be produced onsite, including the power for the compressor gas turbines. It has been conservatively assumed that the Project will not consume electricity through BC Hydro. Aurora LNG is continuing discussions with BC Hydro to determine if electrical options may become available. The current facility design is based on simple cycle gas turbine power generation which is the least efficient and most expensive to operate. As the facility design progresses through its engineering design, Aurora LNG will be looking for opportunities to improve facility efficiency and minimize energy waste. This is expected to include consideration of combined cycle gas turbines and waste heat recovery for use in other processes which would be expected to help lower the overall emissions including GHGs. Based on the current Project design, the GHG emission intensity has been conservatively estimated to be 0.28t CO2e/t LNG produced. This emission intensity is expected to be much lower once actual data is available during the operation phase of the Project. The current Project design includes the operations of the full build-out scenario. This method was approved in the AIR and meets the objective to evaluate the reasonable worst case scenario. For further information, regarding how changes of mol CO2 % in the feed gas can affect the GHG emission intensity, please refer to the memo "Feed Gas Carbon Dioxide (CO2) content Impact on GHG Emissions for the Aurora LNG Application for an Environmental Assessment Certificate", which will be filed with the BC EAO.

2165.1	round 1	Gitxaala Nation	Section 6	Greenhouse Gases	As noted above, the suggestion that the GHG assessment is conservative yet reflects the preliminary design philosophy in the Application cannot be characterised as an over-estimation of effects. Aurora has not committed to emit fewer GHG emissions through FEED design so the GHG assessment represents a minimally acceptable and non-conservative approach. *Questions: Can Aurora describe why the GHG emission estimates for the two phases are conservatively high? Has Aurora committed to GHG emission intensity < 0.28 tCO2e/tCO2e LNG produced?*	The Project GHG emission estimates are conservative due to the assumed conditions that have been included in the worst-case, full build-out scenario. Conservative conditions include the following:Main gas supply is assumed to have a conservative 1.82% mol CO2 content. Other projects have used lower values for estimated C02 content. The entire facility power demand is expected to be produced onsite, including the power for the compressor gas turbines. It has been conservatively assumed that the Project will not consume electricity through BC Hydro. Aurora LNG is continuing discussions with BC Hydro to determine if electrical options may become available. The current facility design is based on simple cycle gas turbine power generation which is the least efficient and most expensive to operate. As the facility design progresses through its engineering design, Aurora LNG will be looking for opportunities to improve facility efficiency and minimize energy waste. This is expected to include consideration of combined cycle gas turbines and waste heat recovery for use in other processes which would be expected to help lower the overall emissions including GHGs. Based on the current Project design, the GHG emission intensity has been conservatively estimated to be 0.28t CO2e/t LNG produced. This emission intensity is expected to be much lower once actual data is available during the operation phase of the Project. The current Project design includes the operations of the full build-out scenario. This method was approved in the AIR and meets the objective to evaluate the reasonable worst case scenario. For further information, regarding how changes of mol CO2 % in the feed gas can affect the GHG emission intensity, please refer to the memo “Feed Gas Carbon Dioxide (CO2) content Impact on GHG Emissions for the Aurora LNG Application for an Environmental Assessment Certificate”, which will be filed with the BC EAO.
2166.1	round 1	Gitxaala Nation	Section 4.3.2.4	Greenhouse Gases	"As stated in the CEA Agency (2003) document, GHG assessments cannot address the significance of a single project’s potential effect on climate change, as the effect on climate change cannot be accurately quantified or measured. Although it is understood that there is a relationship between GHG emissions from anthropogenic sources over the past 100+ years and a changing climate as an effect thereof, effects on climate change cannot be addressed in this GHG assessment. The science of climate change has not advanced to the point where a clear cause and effect relationship can be established between Project specific releases and measurable changes to global climate." This CEAA document is out of date with respect to the advancement of our our knowledge of the the effects of humans on climate change. It is not uncommon in EA's in Canada to assess Project effects on climate change. For example, Sections 6.4 (Project Effects) and 8.2 (Cumulative Effects) Assessment of GHG's of the Air Quality and Greenhouse Gas technical Report for the TransMountain Pipeline Project included a asummary of the Projects effect on climate change. https://transmountain.s3.amazonaws.com/application14/V5C_TECH_REPS/0730.html. Aurora LNG should undertake a similar assessment to report the effects of the Project's GHG emissions (i.e., construction, operations and marine) and cumulative effects on climate change. *Question: What are the quantified effects of the Project on climate change and the cumulative effect of the proposed LNG plants in BC on climate change?*	In relation to guidance on how Canadian projects are to evaluate their potential impact on climate change, CEA Agency 2003 is still the most current guidance from the relevant regulatory authorities. As outlined in the approved AIR, the cumulative environmental effect related to GHGs is measured at the global level by international bodies such as the Intergovernmental Panel on Climate Change (IPCC) and is associated with global climate change. Thereby, the evaluation of cumulative effects of proposed LNG facilities in BC to global climate change is not within the scope of the assessment.
2167.1	round 1	Gitxaala Nation	Section 4.3.2.8	Greenhouse Gases	See above comment.	In relation to guidance on how Canadian projects are to evaluate their potential impact on climate change, CEA Agency 2003 is still the most current guidance from the relevant regulatory authorities. As outlined in the approved AIR, the cumulative environmental effect related to GHGs is measured at the global level by international bodies such as the Intergovernmental Panel on Climate Change (IPCC) and is associated with global climate change. Thereby, the evaluation of cumulative effects of proposed LNG facilities in BC to global climate change is not within the scope of the assessment.
2168.1	round 1	Gitxaala Nation	Section 4.3.2.5	Greenhouse Gases	Aurora LNG indicates that "inherent uncertainty in estimating emission rates from the Project…the emissions estimates are conservatively high to capture worst-case full build-out conditions." In Section 1.2, Proposed Project Description (page 1-3) ,the Project includes three LNG storage tanks and based on 4 production trains will produce 24 MTPA of LNG at full build-out. Although Aurora ackowledges that the Project's 4 trains may be built over two phases, Aurora is not asking for approval related to Phase 1 only, it is seeking approval for both Phases. As such, the suggestion that the GHG emissions estimate is conservatively high and represents worst-case, full build-out conditions is neither justified, nor supported. It represents a minimally reasonable approach. *Questions: Can Aurora describe why the GHG emission estimates for the two phases are conservatively high? Has Aurora committed to GHG emission intensity < 0.28 tCO2e/tCO2e LNG produced? In the evcent that Phase Two does not proceed, what are the total GHG emissions for Phase One and the GHG intensity?*	The Project GHG emission estimates are conservative due to the assumed conditions that have been included in the worst-case, full build-out scenario. Conservative conditions include the following:Main gas supply is assumed to have a conservative 1.82% mol CO2 content. Other projects have used lower values for estimated C02 content. The entire facility power demand is expected to be produced onsite, including the power for the compressor gas turbines. It has been conservatively assumed that the Project will not consume electricity through BC Hydro. Aurora LNG is continuing discussions with BC Hydro to determine if electrical options may become available. The current facility design is based on simple cycle gas turbine power generation which is the least efficient and most expensive to operate. As the facility design progresses through its engineering design, Aurora LNG will be looking for opportunities to improve facility efficiency and minimize energy waste. This is expected to include consideration of combined cycle gas turbines and waste heat recovery for use in other processes which would be expected to help lower the overall emissions including GHGs. Based on the current Project design, the GHG emission intensity has been conservatively estimated to be 0.28t CO2e/t LNG produced. This emission intensity is expected to be much lower once actual data is available during the operation phase of the Project. The current Project design includes the operations of the full build-out scenario. This method was approved in the AIR and meets the objective to evaluate the reasonable worst case scenario. For further information, regarding how changes of mol CO2 % in the feed gas can affect the GHG emission intensity, please refer to the memo “Feed Gas Carbon Dioxide (CO2) content Impact on GHG Emissions for the Aurora LNG Application for an Environmental Assessment Certificate”, which will be filed with the BC EAO.
2169.1	round 1	Gitxaala Nation	Section 4.3.5.2	Greenhouse Gases	"The GHG Management Plan will also contain a Best Achievable Technology analysis." Table 28 on page 38 of the TDR indicates that 99% of the GHG emissions from operations will be discharged by stationary combustion sources and thermal oxidizers for acid gas. *Questions: Explain what is meant by 'Best Achievable Technology' analysis? Does Aurora mean Best Available Control Technology? What opportunities does Aurora currently understand are available to control GHG emissions and what level of reduction is Aurora committed to achieve?*	The GHG Management Plan will contain discussion that aligns with guidance from the BC Ministry of Environment on " Best Achievable Technology" (BC MOE 2015) and guidance from the Ministry of Natural Gas Development (MNGD) entitled "Best Available Techniques Economically Achievable (MNGD 2014). As the facility design advances through detailed engineering, efficiencies and optimum equipment selections are expected to result in reduced overall project operation emissions. Commitments cannot be made at this time, but these Best Achievable Technologies will be identified and discussed in the GHG Management Plan. British Columbia Ministry of Environment (BC MOE). 2015. Ministry of Environment FactSheet – Waste Discharges. Best Achievable Technology. Ministry of Natural Gas Development (MNGD). 2014. Best Available Techniques Economically Achievable Guideline.
2170.1	round 1	Gitxaala Nation	Section 4.3.5.2	Greenhouse Gases	"Further, if future technology advancements in GHG emission reductions become available and are considered economically feasible, a reduced GHG intensity is expected." *Question: What reduced level of GHG emission intensity is Aurora committed to for Phases one and two?*	Commitments cannot be made at this time as to the level of reduction expected from future technology advancements. The statement quoted in this comment aligns with one of the intents of the BC Ministry of Natural Gas Developments (MNGD) guidance entitled "Best Available Techniques Economically Achievable" (MNGD 2014) and the Air Quality Mitigation #4.2.10 noted in the Application. Ministry of Natural Gas Development (MNGD). 2014. Best Available Techniques Economically Achievable Guideline.
2171.1	round 1	Gitxaala Nation	Section 4.3.5.3	Greenhouse Gases	In Table 4.3-13, Aurora reports that the estimated GHG emissions for the Project will total 925,970 t CO2e which as avery large amount of emissions. In Table 4.3-15 on page 4.2-28, Aurora ranks these GHG construction emissions to be "Low" in terms of magnitude. *Question, what metric is Aurora comparing these construction GHG emissions to arrive at this determination? How does Aurora define the magnitude of Low, Medium and High GHG emissions in terms of values and what is the basis for these values?*	In the absence of provincial and federal GHG policy and legislation related to a quantitative definition of magnitude in environmental assessments, the construction GHG emissions were evaluated in the context of the provincial and national inventory reports (PIR and NIR, respectively). The Project, under the full build-out scenario, which includes four trains, will release approximately 925,970 tonnes of CO2e into the atmosphere over the entire construction period. Approximately 46% of the Project’s GHG emissions are estimated to come from land clearing activities, 48% are from site preparation (fleet emissions) and on-shore construction, and 1% and 5% are from marine construction and vehicle traffic respectively. Construction emissions are not captured in the PIR and NIR. However, land clearing emissions are included. Land clearing makes up 46% (419,345 tonnes of CO2e) of the total construction emissions. Site preparation, which includes land clearing and decay, will take place over four years. Therefore, if assumed to be evenly distributed, emissions impacting the PIR and NIR would be approximately 104,836 tonnes of CO2e/year. Compared against the PIR and NIR totals, it is estimated that site preparation (land clearing and decay) activities would increase 2014 PIR and NIR totals by 0.17% and 0.01%, respectively. Therefore, the magnitude has been considered to be low. This assessment considers a low magnitude to be a measurable change from the existing conditions (i.e. increase 2014 PIR and NIR totals by 0.17% and 0.01%, respectively). However based on CEA Agency guidance (2003) and professional judgment the change is considered small in comparison to PIR and NIR totals.
2172.1	round 1	Gitxaala Nation	Section 4.3.6	Greenhouse Gases	Aurora cites a report from Global Advisors that exporting BC LNG is expected to have an overall positive effect on global GHG levels as LNG fuel would displace coal and oil as fuel, which emit higher GHG's, Whereas, combustion of LNG may have this desirable outcome, it is not clear whether this statement is true if the LNG plant GHG operational emissions from cooling, compression and liquefaction, and acid gas incineration and power generation are accounted for. *Question: Confirm the global benefit of using BC LNG still exists if proper accounting of operational GHG emissions includes those related to producing the LNG at Aurora.*	The Global Advisors Report can't be directly connected with Aurora LNG as it was published before the submission of this Application. The Application limited its reference to the Global Advisors Report as it was only known that "if LNG exported from BC manages to reach a lower life cycle intensity than other fuel sources around the world, then exporting BC LNG could have an overall positive effect on global GHG levels." The Project's GHG intensity (0.28 t CO2e/t LNG produced) closely reflects the Global Advisors GHG intensity for BC "Clean" LNG with no carbon capture and storage (0.27 t CO2e/ t LNG produced). Conclusions of the Global Advisor Report "shows that 'clean' natural gas from BC could result in significantly reduced global GHG emissions depending on which scenario is achieved. " (Globe Advisors. 2014)
2173.1	round 1	Gitxaala Nation	Section 4.3.7.1	Greenhouse Gases	Lost in the discussion is the fact that as AB is trying to reduce GHG emissions from the early retirement of its coal fired power plants, BC may potentially approve several LNG plants that create as much as or more GHG emissions that are being retired in AB. The outcome of this could be either no change in GHG emissions in AB and BC when Canadian commitments in international agreements were to reduce GHG emissions.	It is outside of the scope of this assessment to provide commentary on provincial and/or national policy or targets.
2174.1	round 1	Gitxaala Nation	3.6.6	Assessment Methods	The proponent describes thresholds as "the limits of an acceptable change in measurable parameter or state" (p.3-17). This establishes a reasonable expectation that the threshold should be indicated by a numerical or detailed qualitative value that can be used as a metric for establishing significance. In many cases throughout the application, however, the threshold provided is insufficiently defined to allow a clear statement about predicted effects being below or above the threshold, leaving determination of significance in the realm of opinion. Specific examples of this concern with threshold establishment are identified in relation to specific VC assessments, below.	Consistent with EAO guidelines (2013), the Application uses both quantitative and qualitative thresholds in the determination of significance. Per Section 3.6.6 of the AIR and Section 3.6.6 of the Application, threshold criteria were developed for each potential effect. Where thresholds were not set by guidelines, management standards or regulations, a qualitative threshold was developed to present the limits of an acceptable change. Other factors used to derive thresholds for significance include resource management objectives, community standards, scientific literature or ecological processes (e.g., desired states for fish or wildlife habitats or populations) and professional judgement. Reference: Environmental Assessment Office (EAO) 2013. Guideline for the Selection of Valued Components and Assessment of Potential Effects. Available at: http://www.eao.gov.bc.ca/pdf/EAO_Valued_Components_Guideline_2013_09_09.pdf
2175.1	round 1	Gitxaala Nation	Table 3-4	Assessment Methods	Please indicate which of these projects will supply gas to the Aurora Project.	As outlined in Section 1.2.7 of the Application, the natural gas supply for the Project (also known as feed gas) will be sourced from within the Western Canadian Sedimentary Basin including the Horn River and the Liard and Cordova basins, as well as from market hubs. Natural gas will be delivered to the Project via a third party-owned pipeline which is yet to be determined and, consistent with the Section 11 Order and the final Application Information Requirements for the Project, not within the scope of this Project assessment.

2176.1	round 1	Gitxaala Nation	4.2.2.2	Air Quality	Rationale for exclusion of ozone due in part to thick cloud cover is not sufficient to preclude it from the air quality assessment, especially under a climate change scenario. Ozone should be included in the air quality assessment, especially given its potential impact on vegetation	Early in the EA process it was determined that the addition of precursor emissions from the Project is unlikely to alter the existing concentrations of ozone meaningfully. Consistent with the final Application Information Requirements (AIR), secondary ozone formation was therefore not pursued for the air quality assessment. None of the LNG assessments performed in BC has considered secondary ozone formation. It is not an issue associated with LNG facilities located in rural/remote regions
2177.1	round 1	Gitxaala Nation	4.2.2.4	Air Quality	Primary pollutants expected from the construction phase include coarse particulate matter such as TSP and PM10. TSP should also be included as a substance of concern.	Measures are proposed to reduce, avoid, or mitigate coarse fugitive particulate emissions from construction. They are contained in Table 4.2-10 of part 4.2 of the Application (Mitigation Measures Proposed to Avoid or Reduce Air Emissions). Measures are proposed such as limiting vehicle speed, and dust suppression. Coarse particulate matter emissions are easily managed in this setting, and are generally not an issue. The assessment focuses instead on fine particulate matter (PM2.5) from combustion sources
2178.1	round 1	Gitxaala Nation	4.2.4	Air Quality	Burning of biomass during land clearing is not identified as a project interaction. Can Aurora confirm that no burning activities will occur as part of the construction activities? If burning is to occur, it needs to be included as a project interaction.	Measures are proposed to reduce, avoid, or mitigate emissions from the burning of biomass. They are contained in Table 4.2-10 of part 4.2 of the Application (Mitigation Measures Proposed to Avoid or Reduce Air Emissions). Measures are proposed such as salvaging timber, avoiding biomass burning, and reducing or postponing biomass burning consistent with the Open Burning Smoke Control Regulation (BC Reg. 145/93 and BC Reg. 41/2016 amendments). Air curtain burners are an effective technology and will be considered during the FEED process as part of the land clearing procurement process.
2179.1	round 1	Gitxaala Nation	4.2.4	Air Quality	Exclusion of possible venting sources in the air quality assessment is not discussed. Exclusion requires a rationale.	Facility equipment associated with natural gas liquids (NGL) will be a closed system. There will not be any significant continuous venting of hydrocarbon emissions. Boil off gas will be recovered during storage and loading processes and re-injected into the fuel and feed gas systems. Piping, vessels, pumps and tanks will be designed to minimize potential for fugitive hydrocarbons by using best practices such as the Best Management Practice Report published by the Canadian Association of Petroleum Producers Management for Fugitive Emissions at Upstream Oil and Gas Facilities (January 2007). The design strategy to minimize fugitive emissions for each valve, seal, pump, and tank in hydrocarbon service will be determined during detailed design. Aurora LNG will also implement a Directed Inspection & Maintenance (DI&M) Program to routinely inspect and repair leaking components (Table 4.3-12, Mitigation No. 4.3.5)
2180.1	round 1	Gitxaala Nation	4.2.5.2	Air Quality	Aurora has not provided a description of potential effects from shipping traffic along the shipping route. Marine-based emission sources only include maneuvering and berthing activities by LNG carriers and tugs.	The approved Application Information Requirements (AIR: Sect 4.2.2) notes that air quality will be assessed through dispersion modeling to determine the potential effects of Project marine vessels on air quality for activities near the LNG facility. This includes the LNG and support vessels when maneuvering and at berth. The AIR notes that potential effects from shipping traffic associated with Project vessels are excluded from the dispersion modelling assessment based on experience with recent projects. More specifically, the Kitimat LNG project was approved and the dispersion modelling completed for the EA only assessed vessels at berth. The LNG Canada project dispersion modelling assessed vessels at berth and shipping traffic and that assessment clearly demonstrated that effects on air quality associated with marine shipping were not significant. The BC MOE approved the final Detailed Model Plan (Appendix 1, Air Quality - TDR) which excluded modelling of Project LNG vessels when underway.
2181.1	round 1	Gitxaala Nation	4.2.2.5	Air Quality	Sensitive receptors identified during the First Nations consultation process in addition to community receptors should be identified and provided on a figure.	Figure 3-2 from Appendix 4 (Air Quality Technical Data Report) has been revised to more clearly show the sensitive receptors identified during First Nation consultation and included in the air quality and human health risk assessments. An errata document is being created that will capture these corrections and it will be filed with the BC EAO.
2182.1	round 1	Gitxaala Nation	4.3.5.2	Greenhouse Gases	The proponent has indicated that a GHG Management Plan will be prepared. The GHG Management Plan should be prepared as part of the application and address all project phases	As per CEA Agency (2003) guidance, a project that has been determined to have a high magnitude of GHG emissions should prepare a GHG Management Plan. The Aurora LNG has committed to developing a GHG Management Plan (Mitigation 4.3.6) upon Project approval. In Section 4.3.5.2 of the Application, "A GHG Management Plan will be prepared to identify the requirements of relevant GHG reporting legislation and will contain continuous assessment of monitoring and management requirements applicable to the mitigation listed in Table 4.3-12 (i.e., requirements of a fugitive emission survey program). The management plan will also contain a Best Achievable Technology analysis." This Plan will consider all phases of the project
2183.1	round 1	Gitxaala Nation	4.3.5.2	Greenhouse Gases	The proponent states that the management plan will contain a Best Achievable Technology analysis. Given the proponents experience, an analysis would be expected as part of the application, which can be updated during each phase of the project.	A GHG Management Plan will be prepared to assess monitoring and management requirements applicable to all phases of the Project. The Plan will include discussion that aligns with guidance from the BC Ministry of the Environment on " Best Achievable Technology" (BC MOE 2015) and guidance from the Ministry of Natural Gas Development (MNGD) entitled "Best Available Techniques Economically Achievable" (MNGD 2014). British Columbia Ministry of Environment (BC MOE). 2015. Ministry of Environment FactSheet – Waste Discharges. Best Achievable Technology. Ministry of Natural Gas Development(MNGD). 2014. Best Available Techniques Economically Achievable Guideline.
2184.1	round 1	Gitxaala Nation	4.3.2.4	Greenhouse Gases	Greenhouse gases assessment does not assess whether the emissions from project will affect climate change and how potential changes in climate may affect infrastructure associated with the project as laid out by the Federal-Provincial-Territorial Committee on Climate Change and Environmental Assessment (FPTCCCEA) 2003 federal guidance document. A review of historical climate data and the analysis of future climate projections follows accepted practices for conducting EAs. Some of this information is provided in the "Effects of the Environment on the Project" section but needs to be referenced here for completeness.	As outlined in the AIR, the Greenhouse Gas (GHG) assessment does not include an evaluation of Project impacts on climate change. Canadian Environmental Assessment (CEA) Agency (2003) guidance states GHG assessments cannot address the significance of a single project's potential effect on climate change. As identified in Section 4.3.1 of the Application, the effect of climate change on the Project are addressed in the Effects of the Environment on the Proposed Project (Section 10.0) Historical climate trends can be found in the Air Quality TDR (Appendix A of the Application). Future climate projections can be found in Section 10.2.8 of the Application.
2185.1	round 1	Gitxaala Nation	4.3.2.5	Greenhouse Gases	The assessment should describe the historical climate trends and the future climate projections across spatial boundaries used across all disciplines.	Historical climate trends can be found in the Air Quality TDR (Appendix A of the Application). Future climate projections can be found in Section 10.2.8 of the Application.
2186.1	round 1	Gitxaala Nation	4.3.2.8	Greenhouse Gases	While the contribution of an individual project to climate change may not be easily measured, Project GHG emissions on climate change should be included and adequately assessed as a potential residual effect.	As outlined in the AIR, the GHG assessment evaluates the direct emissions from the Project. Climate change is studied at the global scale; its relation to global GHGs is evaluated by international bodies such as the Intergovernmental Panel on Climate Change (IPCC). The study of climate change is outside the scope of this assessment. IPCC conclusions applicable to this assessment are identified in Section 4.3.6 of the Application.
2187.1	round 1	Gitxaala Nation	4.3.4	Greenhouse Gases	Burning of biomass will result in GHG emissions. If burning is to occur, it needs to be included as a physical activity. If burning is not to be included, a commitment is required that it will not occur as part of construction or operations activities	Mitigation 4.2.5 states the Project will "Avoid burning of biomass." The construction GHG inventory conservatively includes burning of biomass to account for debris, stumps, and unused portions of the salvaged timber. However, the Project intends to avoid the burning of biomass.
2188.1	round 1	Gitxaala Nation	4.3.4	Greenhouse Gases	Vehicle traffic is not listed as an activity under Operations and needs to be assessed as a potential effect.	As per the WCI quantification methods used by the Greenhouse Gas Industrial Reporting and Control Act: Reporting Regulation, mobile equipment at facilities that are required to report GHG emissions include: -on-site transportation or movement of substances, materials or products, and -other mobile equipment such as tractors, mobile cranes, log transfer equipment, mining machinery, graders, backhoes and bulldozers, and other industrial equipment. These types of operations do not apply to the Project. The WCI quantification methods further states that on-road vehicles are not included. On-road vehicles would be the only types of vehicle traffic during Project operation.
2189.1	round 1	Gitxaala Nation	4.3.4	Greenhouse Gases	Given the duration of operations, how can waste management (including collection and treatment) not be considered to require GHGs and result in potential effects? Please include a description of waste management during the Project life-cycle on GHGs.	As indicated in the Application, it is not anticipated that waste management will contribute to GHGs in a substantial manner. Aurora LNG intends to avoid open burning of accumulated waste during construction and operation of the Project. These activities will be managed through a Solid Waste Management Plan. Activities in support of waste management at the site, such as handling and transport, will not be large GHG sources. Further, as per WCI guidance, the mobile equipment used for handling waste is not required to be reported to the BC GHG Industrial Reporting Regulation (refer to WCI.280 in guidance document). For a more detailed discussion on waste management, see Section 6.3.5.2 of the Application.
2190.1	round 1	Gitxaala Nation	4.3.10	Greenhouse Gases	Proponent already determined that GHG emissions during operations are considered to have a high magnitude and indicate that a detailed GHG Management Plan will be completed upon project approval. Given the magnitude, a management plan should be completed as part of the application	As per CEA Agency (2003) guidance, a project that has been determined to have a high magnitude of GHG emissions should prepare a GHG Management Plan. The Aurora LNG has committed to developing a GHG Management Plan (Mitigation 4.3.6) upon Project approval.
2191.1	round 1	Gitxaala Nation	Table 4.4-3 and Figure 4.4-1	Acoustic Environment	Port Edward does not appear to be included in the RAA. Given the projects proposed for Ridley and Lelu Islands, the potential for cumulative effects on Port Edward, and the high percentage of Nation members residing in Port Edward, it should be included in the RAA and effects assessed.	Please refer to the technical memo "Cumulative Noise Assessment" for the cumulative noise assessment at two additional Port Edward receptors. The technical memo will be filed with the BC EAO. The "Cumulative Noise Assessment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2192.1	round 1	Gitxaala Nation	Figure 4.4-1 and Table 4.4-4	Acoustic Environment	While the prevailing wind in the Prince Rupert region is from the south-east year round, winds in winter are considerably higher, suggesting that noise may be travel farther in winter. Please indicate how data from summer only stations (M1, in particular) have been used and the model ling based on it corrected to account for higher winter noise carriage. Please indicate where (which sections) winter predictions are presented in the relevant TDRs.	The ambient sound levels are higher during high wind and rainy weather conditions. For baseline monitoring, data collected during high wind events (exceeding 15 km/hr) and rain events is not included in the determination of baseline sound level. If the wind is higher during the winter period, the ambient sound level collected at receptor M1 during the summer season is likely to be lower. This is considered a conservative approach as the use of a lower ambient sound level (i.e. during summer and excluding high wind and rain events) will result in a higher predicted impact from the Project noise effect in the assessment. The noise model considered wind speed up to 5 m/s (or 18 km/hr) when the receptor is downwind of the noise source. The wind speed was based on ISO 9613-2 standard, which assumes 1 to 5 m/s downwind condition from the source to the receptor in the sound propagation calculation.
2193.1	round 1	Gitxaala Nation	4.4.3	Acoustic Environment	the Application notes that "the acoustic environment is characterized primarily by sounds from nature, such as those originating from bids, insects, wind-generated noise…" Noting that natural and anthropogenic noises can have similar noise levels but be perceived differently, how is the addition of anthropogenic noise distinguished as an effect. If distinguished through the metric of "annoyance" (%HA), have annoyance levels been disaggregated by receptor community to address the potential for first nations communities to be more highly annoyed by additional anthropogenic noise? If not, what is the rationale for not doing so? Failure to do so prevents a complete assessment of effects on TU.	Natural and anthropogenic noise effects may be perceived differently. The %HA metric does not separate the sound quality between anthropogenic noise and sounds from nature. While First Nations communities have indicated that anthropogenic noise may have different effects, the effects are in part, perceptually based values, which vary from one person to another. Also, there is no available literature that quantifies the potential annoyance of First Nations communities due to the difference in sound quality between anthropogenic noise and sounds from nature. In addition to sounds from nature, the acoustic environment is also influenced by noise effects from marine traffic (Section 4.4.3, page 4.4-13 of Application).
2194.1	round 1	Gitxaala Nation	4.4.4	Acoustic Environment	Environmental Assessment of LNG facilities in Australia indicate the potential for low frequency noise (LFN) and vibration to be generated from vehicles used during construction, and from both facility and vessel activity during operations. What is the rationale for excluding these from consideration and assessment, particularly given the proximity of flare stacks (which contribute LFN in the form of pressure waves) to Delusion Bay? Delusion Bay is presently home to large populations of birds which are known to be sensitive to LFN/vibration.	LFN analysis results during both construction and operation phases are included in Section 4.4.5.2 of the Application. The LFN analysis for Year 1 construction, Year 5 construction, and operations phase are presented in Table 4.4-17, Table 4.4-18, and Table 4.4-19 of the Application, respectively. The results are presented for both the daytime and nighttime period.
2195.1	round 1	Gitxaala Nation	Table 4.4-19	Acoustic Environment	dBA weighted noise is used because it is considered a better tool for measuring injury to human hearing in workplace exposure. dBC is a better metric for capturing LFN, particularly at night when sleep may be disturbed by LNF, experiences as hum or vibration. Some literature (e.g. Berglund and Lindvall, 1995, WHO) indicates that 30dB should be considered the maximum nighttime noise limit where significant portions of noise are derived from LFN. Given exceedances of OGC limits for dBC-dBA, what is the rationale for using the ANSI guidance rather than a more conservative value?	The BC OGC Noise Guideline uses a cautionary limit (e.g., 20 dB) on the difference between the C-weighted and the A-weighted levels. When the actual difference exceeds the cautionary limit, further evaluation is recommended. Under the BC OGC noise guideline, the evaluation considers low frequency tones. If no low frequency tonality is present, potential adverse LFN effects are deemed as acceptable even if the cautionary limit is exceeded. In order to identify tonal component at a receptor, the sound pressure level must be in one-third octave band center frequency. This low frequency tonality is commonly identified from measurements instead of prediction modelling because equipment noise emission information in one-third octave band center frequency is typically not available from the manufacturer. When there is no available information to confirm the low frequency tonality, the ANSI 12.9 standard is used in addition to the BC OGC Noise Guideline to assess potential LFN effects. Low frequency noise effect is addressed in the technical memo "Low Frequency Noise Assessment ". The "Low Frequency Noise Assessment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting. The sleep disturbance effect is address in the technical memo "Sleep Disturbance and Speech Interference" based on the WHO noise guidance. The "Sleep Disturbance and Speech Interference" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting. These documents will be filed with the BC EAO.
2196.1	round 1	Gitxaala Nation	Table 4.4-20, 4.4-21, and 4.4-22	Acoustic Environment	please provide additional columns for each of these tables that indicate Ld(dBC) and Ln(dBC) for Existing, Year 1 Construction, Year 5 Construction, and Operations time periods to allow a better understanding of nighttime effects on sleeping in sensitive areas including Kinehan Islands (where sleeping campers may be present)	The sleep disturbance effect is addressed in the "Sleep Disturbance and Speech Interference" technical memo based on the WHO noise guidance. The WHO noise guidance uses A-weighting decibel sound level for sleep disturbance threshold. The "Sleep Disturbance and Speech Interference" technical memo was presented to the Working Group in draft for pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting. Existing Ld and Ln in C-weighting decibel is not available from the monitoring program. Prediction C-weighting decibel results for Year 1 Construction, Year 5 Construction, and Operation phases are presented in Table 4.4-17, Table 4.4-18, and Table 4.4-19 of the Application. The C-weighting decibel results were used to assess low frequency noise effect. Additional information on low frequency noise effect is also provided in the "Low Frequency Noise Assessment technical memo. The technical memos will be filed with the BC EAO. The "Low Frequency Noise Assessment" technical memo was presented to the Working Group in draft for pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2197.1	round 1	Gitxaala Nation	4.4.5.3	Acoustic Environment	The Application states that "no mitigation is proposed during the operations phase as negligible effects are expected". The absence of data regarding dBC at night suggests that this statement cannot be fully supported. LFN and vibration remain a concern for the community and, at a minimum, an ongoing monitoring and adaptive management plan must be developed to confirm predictions and respond if LFN/vibration result in community annoyance or adverse health effects.	Mitigation for the predicted change in noise level is presented in Section 4.4.5.2 Table 4.4-9 of the Application. Details on a noise monitoring program will be included in the Noise Management Plan (per Section 14.5 of the Application) to confirm assessment predictions and provide information for corrective actions (continuous improvement programs), if required. The Noise Management Plan will also describe a process for outlining how complaints regarding noise, including LFN and vibration, will be addressed. LFN analysis results during both construction and operation phases are included in Section 4.4.5.2 of the Application. The LFN analysis for Year 1 construction, Year 5 construction, and operations phase are presented in Table 4.4-17, Table 4.4-18, and Table 4.4-19 of the Application, respectively. The results are presented for both the daytime and nighttime period.

2198.1	round 1	Gitxaala Nation	4.4.10	Acoustic Environment	The Assessment is not satisfactory in two regards: 1) the application has dismissed the potential for LFN during operations without adequate data and rationale to do so and (2) the almost exclusive focus on dBA renders the assessment sufficient only to assess effects of noise on humans. Please provide an additional discussion of bird sensitivity to noise (both dBA and dBC) and an assessment of the predictions for noise on birds. Particular emphasis must be paid in this discussion to the potential effects to birds of operational noise given the proximity of infrastructure that may cause significant noise immediately adjacent to Delusion Bay, currently a site of high bird density.	A discussion on potential noise-based effects (i.e., dBA and dBC) to human receptors is provided in Section 4.4 of the Application. The low frequency noise effect analyses for construction and operation are summarized in Table 4.4-17 to Table 4.4-18 of the Application . The results indicate no exceedance when compared to the ANSI 12.9 standard threshold for human receptors. Wildlife-related literature has primarily centered on A-weighted decibel noise effects, as it represents the most common weighting used in noise measurement. There is limited information available on the effects of C-weighted decibel noise to wildlife. Section 4.7.5 of the Application discusses indirect effects of change in habitat, incorporating available scientific literature, based on noise-based effects for species occurring within the LAA (or for similar species whose effects are expected to be representative).
2199.1	round 1	Gitxaala Nation	4.5.3	Water Quality	Each lake/stream appears to only be sampled once. Why was seasonality not addressed through field work?	There are no effluent discharges to lakes or streams planned, so for general assessment of freshwater quality, seasonal water quality data is not needed. For freshwater quality, related to the potential for acidification and eutrophication, it has been common practice in other regional assessments to sample lakes during fall turnover to capture fully mixed conditions that represent times of maximum nutrient concentrations. Seasonal data for identified areas of concern (e.g., lakes with predicted critical load exceedances) should be collected as part of future regional monitoring programs.
2200.1	round 1	Gitxaala Nation	4.5.3	Water Quality	How was the methodology changed for LAK03 (exhibiting a thermocline)? Sampled collected above and below thermocline?	For LAK03, a composite sample was collected to incorporate stratified layers.
2201.1	round 1	Gitxaala Nation	4.5.6.3	Water Quality	What are the direct effects of the nutrient-nitrogen critical load values being exceeded for LAK11? How will this impact the community?	Refer to the technical memorandum, "Additional Information about Eutrophication and Acidification in Freshwater" which will be filed with the BC EAO. The "Additional Information about Eutrophication and Acidification in Freshwater" technical memo was presented to the Working Group in draft for pre-read on April 17, 2017 under the title of "Nutrient Nitrogen in Lakes." The memo was updated as a result of the discussion during the Working Group meeting.
2202.1	round 1	Gitxaala Nation	Table 4.5-26	Water Quality	The use of tugs equipped with propulsion systems that reduce sediment scour will be considered.' Considered is a weak word that should not be given a high likelihood of success expectation.	This mitigation was rated as having a high likelihood of success because tugs equipped with propulsion systems that reduce sediment scour are widely used in industry, and their limitations are well-understood. Aurora LNG will make a final decision on tug propulsion type when Project detailed design is complete.
2203.1	round 1	Gitxaala Nation	Appendix E-Water Quality	Water Quality	Concentrations of TOC were not available for the historical datasets; therefore, DOC concentrations were used in the calculation.' Was the calculation modified to account for DOC being used instead of TOC?	Concentrations of TOC and DOC were often similar in waterbodies where both parameters were sampled. For the sites sampled on Digby Island and the Tsimpsean Peninsula, no change in the calculation was required, as TOC was measured. For the Environment Canada dataset only DOC was measured, therefore this value was supplemented into the calculation in place of TOC to calculate acid neutralizing capacity. Typically, dissolved concentrations are less than total concentrations and therefore the use of DOC will give a more conservative estimate (i.e., lower ANC value). There is no adjustment to the calculation required.
2204.1	round 1	Gitxaala Nation	Appendix I	Vegetation and Wetland Resources	Provide information why an invasive species specific survey wasn't conducted within the PDA and Terrestrial LAA? I.e. focus on roadways, cleared areas, corridors.	The success of implemented Best Management Practices (BMPs) related to invasive plants are well understood, and Environmental Inspectors will be well qualified to identify and manage invasive plants. Aurora LNG does not consider a specific invasive plant survey necessary for this Environmental Assessment. An Invasive Plant Management Plan (IPMP; Mitigation 4.6.6) will be developed in consultation with regulators. The IPMP (described in Section 14.6 of the Application) will describe BMPs which will meet legislated requirements and permit conditions related to invasive plants and invasive plant management.
2205.1	round 1	Gitxaala Nation	Appendix I	Vegetation and Wetland Resources	In addition to the Weeds Act and NWIPC invasive species list, were any other invasive species lists (additional unregulated invasive plants of concern in BC ISCBC) consulted?	No. The Northwest Invasive Species Council is the relevant regional partner to the broader BC ISCBC.
2206.1	round 1	Gitxaala Nation	4.6-10	Vegetation and Wetland Resources	Pre-construction rare plant surveys will be conducted in the PDA, near know locations of rare plants.' Define "near".	"Near" in this context means: within the spatial extent of contiguous suitable habitat for the known occurrence of a given species.
2207.1	round 1	Gitxaala Nation	4.6.3	Vegetation and Wetland Resources	The red-listed non-vascular plant, Sphagnum major (no common name) and blue-listed non-vascular plant, Sphagnum centrale (no common name) will be translocated from the known locations within the PDA. This mitigation measure involves salvaging the species from the PDA and transplanting it outside of the PDA so that it may persist within the RAA. How will compensation be achieved if transplants do not succeed?	An example of possible compensation, should translocation fail, could be securing, restoring, or enhancing populations of Sphagnum majus and Sphagnum centrale in a nearby area. There are several populations in the vicinity of the Project, including one on Kaien Island, east of Digby Island.
2208.1	round 1	Gitxaala Nation	4.6-31	Vegetation and Wetland Resources	4 TU species were identified in the PDA but not elsewhere in the terrestrial LAA. Are the locations of these recorded occurrences mapped?	Yes, spatial data for each record exists, though it is not presented graphically in the Application. This information can be made available to Metlakatla First Nation if interested.
2209.1	round 1	Gitxaala Nation	4.6.5.2	Vegetation and Wetland Resources	TU species commonly occur elsewhere in the RAA. Has the accessibility of these TU species by local FN groups been considered? Has compensation, transplanting TU species to be destroyed in the PDA to other FN accessible areas on Digby Island?	Yes, access to TU species has been considered in the assessment. Effects on the changes in consumptive and non-consumptive land and resource use for traditional purposes are presented in Section 11.3 and 11.4 of the Application, and include an assessment on vegetation gathering. Effects on First Nation harvesting-related Aboriginal interest are presented in Part C, Section 12 of the Application. Together these sections address site-specific loss of vegetation resources for traditional use within the PDA. Also see the technical memo titled, "Assumptions Regarding Availability of Harvested Resources and Importance of PDA and Surrounding Area" prepared by Aurora LNG in response to comments pertaining to concerns about access and availability of traditional use species. Transplanting TU plant species from within the PDA to areas outside the PDA has not been considered among the mitigation measures for the Project.
2210.1	round 1	Gitxaala Nation	4.6	Vegetation and Wetland Resources	Please provide a figure showing rare plant survey locations	Rare Plant Survey locations are shown in Figure 3 of the Vegetation and Wetlands Resources Technical Data Report in Appendix I of the Application.
2211.1	round 1	Gitxaala Nation	Table 4.6-11, 4.6-10	Vegetation and Wetland Resources	Where effects to vegetation from NO2 and SO2 atmospheric concentrations, soil acidification or soil eutrophication are predicted to occur through modelling, vegetation and soils will be periodically monitored as necessary in consultation with the BC MOE. This mitigation measure will monitor for changes in vegetation and soils, and provide adaptive management if necessary. Provide details on the monitoring program expectations likely to be requested by MOE	The details of this monitoring plan are still to be determined. However, examples of monitoring parameters could include sampling of soils within predicted exceedance areas to measure pH and Nitrogen (various forms), along with vegetation attributes such as species composition, cover, and health and vigor at each soil-sampling site. Sampling outside the modeled area of exceedance would likely be required for comparison.
2212.1	round 1	Gitxaala Nation	4.6.5.4	Vegetation and Wetland Resources	Will there be any compensation for TU important wetlands destroyed by the project?	The Wetland Compensation Plan aims to achieve no net loss of wetland functions for wetlands that are designated as 'ecologically or socio-economically important to a region in BC, as defined by regional guidance issued by the Canadian Wildlife Service/Environment Canada (2014), which does not necessarily include wetlands that may be of importance to First Nations for traditional use purposes.
2213.1	round 1	Gitxaala Nation	4.6.5.4	Vegetation and Wetland Resources	Project is expected to destroy +450ha of wetlands, the majority which are bogs. Has carbon sequestration offsetting been considered? What are the mitigation methods to deal with the reduction in carbon storage?	The Project would affect 370 ha of wetlands within the PDA, the majority of which are bogs. The carbon sequestration function of wetlands within the PDA has been considered in Section 4.6.5.4 of the Application and Section 3.3.2.2 of the conceptual Wetland Compensation Plan. Table 4 of the Wetland Compensation Plan identifies the functions and wetland area that will be replaced through compensation, and it includes carbon sequestration. The details of the Wetland Compensation Plan, such as methods of replacing the carbon sequestration function, will be determined in consultation with the Canadian Wildlife Service/ Environment and Climate Change Canada, the Prince Rupert Port Authority (where relevant, as a federal lands manager), and potentially affected Aboriginal groups, following issuance of the Environmental Assessment Certificate. Examples of methods that could be considered to compensate for the loss of the carbon sequestration function include restoration, enhancement, or creation of swamp-class wetlands, or contributions to a carbon credit program.
2214.1	round 1	Gitxaala Nation	4.6.6.2	Vegetation and Wetland Resources	Why is the loss of red- and blue-l listed ecological communities from the PDA not being compensated? Their occurrence within the RAA does to seem like a sufficient answer	For regulatory guidance on this topic, the Application relies on the Objectives set for red- and blue-listed plant communities within the Great Bear Rainforest Order (GBRO), which is a Ministerial order that provides land use objectives according to ecosystem-based management principles for the region where the Project is located. The GBRO objectives for red- and blue-listed plant communities allow up to 5% of a red-listed community to be disturbed and 30% of a blue-listed community within a landscape unit to be disturbed, where there is no practicable alternative for avoidance. See Table 4 in Appendix I, Vegetation and Wetlands Resources Technical Data Report, for the proportions of each occurrence and regional extent that would be disturbed. All instances are below the allowable thresholds stated in the GBRO objectives. Other than the regulatory guidance provided by the GBRO objectives, Aurora LNG is not aware of any legislation or regulations that require compensation for the loss of red- or blue-listed communities.
2215.1	round 1	Gitxaala Nation	Appendix I	Vegetation and Wetland Resources	Why were seaweed and fungi not included in the TU study?	Seaweed were not included among Traditional Use Plants in the RAA, because the RAA for Vegetation and Wetland Resources is defined as the terrestrial portion of the Tuck and Kaien Landscape Units; terrestrial in this context refers to the area above the high tide/high water mark of the coast.Fungi were not included among Traditional Use Plants in the RAA, because plant species in the TDR and Application were limited to vascular and non-vascular plants and lichens.
2216.1	round 1	Gitxaala Nation	Appendix I	Vegetation and Wetland Resources	Figures are not included in the appendix	The figures for Appendix I of the Application are located within the PDF version of the Appendix. Please refer to BC EAO EPIC: https://projects.eao.gov.bc.ca/p/aurora-lng-digby-island/docs
2217.1	round 1	Gitxaala Nation	4.7.3.1	Wildlife Resources (Terrestrial)	Timing of surveys were inconsistent from year to year and many surveys only conducted once per year or season. Please explain the rationale for this approach.	Field studies for wildlife resources were completed to provide a record of occurrence and patterns in habitat use within the PDA and LAA. The scope and timing of field studies were consistent with recommendations within applicable Resource Inventory Standards Committee Standards. Although some surveys were in a single season, survey effort was replicated across and within habitat types in the PDA and LAA. To provide greater regional context, results of field studies were evaluated in consideration of regional datasets and information sources.
2218.1	round 1	Gitxaala Nation		Wildlife Resources (Terrestrial)	Traditional ecological knowledge should include which animal species are important, used or harvested, what times of year harvesting takes place, and areas within the RAA (if available).	Section 3.3.1 of Appendix J, informed by traditional ecological knowledge studies available at the time of Application submission (see references therein), outlines terrestrial wildlife species identified as being important for harvesting or cultural importance. Additional details on the timing and location of different harvesting practices are provided in Appendix S.2. Information on harvesting practices was used to support Section 4.7, Section 11, and Part C of the Application. Available information related to the referenced areas was compiled in Appendix S.2 (Aboriginal Consultation TDR) of the Application. In particular, Aurora LNG notes the information compiled for Metlakatla First Nation in Tables 6-11 to 6-16 (pg. 89 to 116). Section 4.7.2.3 (Traditional Knowledge and Traditional Use Incorporation) of the Application and Section 3.1.1 (Traditional Ecological Knowledge) of the associated Appendix J (Wildlife Resources (Terrestrial) TDR) indicate that available Traditional Knowledge /Traditional Use information (i.e. the information compiled in Appendix S.2) was reviewed, considered and, where appropriate, incorporated into Section 4.7 of the Application.
2219.1	round 1	Gitxaala Nation	4.7.3.2	Wildlife Resources (Terrestrial)	Wildlife species of management concern - there are 19 listed in the table, not 18, as indicated in the text.	Aurora LNG acknowledges the error. The sentence preceding Table 4.7-7 should indicate 19 terrestrial wildlife species of management concern have potential to occur within the LAA or RAA. An errata document is being compiled that captures these corrections and it will be filed with the BC EAO.

2220.1	round 1	Gitxaala Nation	4.7.3.2	Wildlife Resources (Terrestrial)	Wildlife habitat suitability modelling: Were other habitat suitability models available for species that reside in the LAA? Why were these four species chosen for habitat modelling?	The assessment for wildlife resources uses two modelling approaches to evaluate change in habitat for species known or potentially occurring within the PDA and LAA. Wildlife habitat community modelling was developed to provide an assessment of potential effects on habitat availability for 15 wildlife habitat communities within the LAA. These wildlife habitat communities provide coverage for all habitat types that occur within the LAA and are used to assess effects of change in habitat to a wider suite of wildlife species assemblages that occupy them. Methods and findings of the wildlife habitat community models are provided in Section 4.1 of Appendix J and carried forward in Section 4.7.5.2 of the Application. These sections provide a detailed description of each of the 15 communities, describes wildlife species that are expected to occur within each, and discusses potential effects to species assemblages due to construction and operation of the Project. Four terrestrial wildlife species were selected for wildlife habitat suitability modelling (i.e., marbled murrelet, western screech-owl kennicottii subspecies, little brown myotis, and western toad) based on the following suite of criteria (also described in Sections 4.7.3 of the Application and Section 4 of Appendix J): (1) likelihood of occurrence or documented use of habitats within the LAA and RAA; (2) potential interaction with Project activities; (3) conservation status; (4) ecological importance; (5) established base of information, knowledge, or data; and, (6) cultural or traditional value. The four selected species were considered to best represent the criteria listed above, given consideration of the primary habitats available within the LAA and the likelihood of occurrence based on Project and regional datasets and known habitat requirements. In addition, the four selected species were determined to be good candidates for species-specific habitat suitability models because they each require a suite of habitat features that are best assessed at the species-level (rather than at the community-level). Provincial standards advise planners to select species for suitability modelling where there is a strong understanding of the relationship between habitat characteristics and species whose life requisites (e.g., breeding, feeding) compare well with terrestrial ecosystem map units (RIC 1999). Specifically, marbled murrelet requires old to mature coniferous forests with specific tree-level characteristics for nesting (e.g., large branches, high epiphyte cover); western screech owl requires open mixedwood forest with large diameter trees for nesting and roosting; little brown myotis requires mature and old growth forests with cavities and snags for male and maternal roosting; and western toad requires shallow wetlands with fine sediments that retain open water throughout the breeding season. Collectively, the habitat requirements of the four selected species are complementary and serve to evaluate a range of habitat types within the LAA. References: Resource Inventory Committee (RIC). 1999. Wildlife Habitat Rating Standards, Version 2. Ministry of Environment, Lands and Parks. Victoria, BC. 98 pp.
2221.1	round 1	Gitxaala Nation	4.7.3.2	Wildlife Resources (Terrestrial)	Please show map of survey locations rather than referencing the appendix.	For brevity, figures of survey locations were only provided in Appendix J. To facilitate the assessment of change in habitat availability and for ease of comparison of habitat community and suitability models at full Project build-out, the habitat community and suitability models under existing conditions presented in Appendix J were carried forward into Section 4.7 of the Application.
2222.1	round 1	Gitxaala Nation	4.7.3.2	Wildlife Resources (Terrestrial)	Where were marbled murrelet audiovisual surveys conducted? Were these located in "critical habitat" or high suitability habitat?	The locations of marbled murrelet audiovisual surveys are shown in Figure 9 of Appendix J. Survey locations were selected to provide survey coverage within or adjacent to critical or preferred breeding habitat (including areas of overlap), with individual stations positioned to provide optimal audio or visual detection.
2223.1	round 1	Gitxaala Nation	4.7.3.2	Wildlife Resources (Terrestrial)	Species listed as important for local FNs should be considered as species of concern for the Project and the effects assessment.	Sections 4.7.2.2 and 4.7.2.3 describe the Aboriginal Groups from which traditional knowledge and traditional use information was gathered, and how the information was incorporated into the assessment. Table 4.7-2 outlines key information and concerns raised by Aboriginal Groups and how that information influenced the assessment for wildlife resources. Section 4.7.3.2 provides a summary of findings of traditional ecological knowledge for wildlife resources, including identified species and areas of importance for harvesting by Aboriginal Groups; these details are also described in Appendix J. Species identified therein are discussed throughout Sections 4.7.5 and 4.7.6 where there was an identified mechanism for interaction with Project activities and infrastructure.
2224.1	round 1	Gitxaala Nation	Table 4.7-9	Wildlife Resources (Terrestrial)	Waste management should be included in Change in Habitat (change in nutrients/contaminants) for all phases. Remediation and reclamation should be included as a change in habitat (even if change is positive).	On-site waste management includes temporary container storage to contain waste materials as a means to limit environmental releases, and subsequent effects on environmental valued components. Contaminant storage and disposal is subject to regulatory requirements, but will also be contained to prevent environmental releases. Accordingly, waste management was not considered a mechanism for interaction with change in habitat. However, the potential for waste management to serve as an attractant for some terrestrial wildlife (e.g., bears, wolves) increases the potential for human-wildlife conflict, and was carried forward in the assessment of change in mortality risk for wildlife resources (see Section 4.7.5.3 of the Application). Aurora LNG recognizes that decommissioning activities may result in a positive change in habitat availability and quality for wildlife resources. Table 4.7-9 indicates that dismantling of land-based and marine infrastructure is the primary mechanism in which that change will occur.
2225.1	round 1	Gitxaala Nation	4.7	Wildlife Resources (Terrestrial)	Mitigation measures in the tables (4.7-10, 4.7-14 and 4.7-15) consistently refer to implementing measures "as soon as practicable" or "where practicable". For the reviewer to have any faith in the assessment, stronger commitments are required. Precise language should be used. For example: What is the maximum length of time between clearing and revegetation? Where would measures not be practicable? Wording must leave no room for non-compliance.	Aurora LNG is committed to following a mitigation hierarchy to avoid, limit, and mitigate for potential effects to wildlife resources and will implement options that result in avoiding or reducing effects to wildlife resources. Some Project activities (e.g., vegetation clearing within the PDA) will result in direct and indirect loss of habitat, however, these activities will be scheduled to occur outside of restricted activity periods to avoid effects on wildlife (as per mitigation 4.7.17). In cases where Project activities or infrastructure cannot avoid effects to wildlife resources, Aurora LNG has proposed alternative mitigation measures to reduce and mitigate those effects. For example, if vegetation clearing is required during breeding bird and amphibian periods, pre-clearing surveys will be completed (as per mitigation measures 4.7.18 and 4.7.19). Applicable management plans will provide detail on timelines for implementing Project mitigation measures, and will describe monitoring and reporting requirements, as appropriate, to support compliance monitoring.
2226.1	round 1	Gitxaala Nation	4.7	Wildlife Resources (Terrestrial)	The Wetland Compensation Plan is only compensating for a very small fraction of wetlands to be disturbed or removed through the Project. Please see comments in the Vegetation and Wetland Resources section.	The Wetland Compensation Plan was prepared according to regional guidance issued by the Canadian Wildlife Service of Environment Canada (2014), which stipulates which wetlands are subject to the no-net-loss goal of the Federal Policy on Wetland Compensation. Offsetting for estuarine wetlands will occur through the Fish Habitat Offsetting Plan. Reference: Environment Canada. 2014. Federal Policy on Wetland Conservation – Guidance for Application and Implementation in Environmental Assessment. Available at: https://a100.gov.bc.ca/appsdata/epic/documents/p403/d37786/1404937173815_193684738c554031afd3fe7a5b3bf6196c13620cba3241eac8c3f318682e8f7f.pdf. Accessed: March 2017.
2227.1	round 1	Gitxaala Nation	4.7.5	Wildlife Resources (Terrestrial)	Revegetating temporary work spaces is assumed to have a high success rate but some uncertainty as regeneration may take longer than expect or have lower productivity. It should also be noted that mature forests cannot be "replaced". The assumption that the success rate is high is false. From a habitat perspective, areas of forest cannot be replaced, or at the very least, take generations to replace. This timeframe is too long to be of value.	Revegetating temporary workspaces and reclaimed land (Mitigation 4.6.5) is considered to be effective during the construction phase of the Project (i.e., short-term) and therefore expected success was evaluated for the construction phase only. The goal of this mitigation measure is to establish functional habitat to promote wildlife use after temporary spaces are no longer needed. For example, regenerating vegetation will provide security cover to support wildlife movement. To reduce the extent of necessary vegetation clearing, including clearing of mature or old forests, temporary workspaces will be limited to within the PDA boundaries to the extent practical (as per mitigation 4.7.1). Revegetation activities for temporary workspace will be provided in the Invasive Plant Management Plan. Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development ofthis plan.
2228.1	round 1	Gitxaala Nation	4.7.5	Wildlife Resources (Terrestrial)	When will a bat management plan be developed, and by whom?	Management plans will be developed by Aurora LNG prior to the commencement of construction. The Bat Management Plan will specifically outline avoidance, reduction, mitigation, and monitoring measures to limit potential effects from change in habitat or mortality risk from Project construction and operation activities. Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of this plan.
2229.1	round 1	Gitxaala Nation	4.7.5	Wildlife Resources (Terrestrial)	High-disturbance project related activities are to be avoided within 300m of occupied bald eagle nests. This language leaves too much room for uncertainty. Use stronger language than "avoid". In addition, helicopter distances of greater than 500m from bald eagle nests and heron rookeries has been proposed. While both these measures are good mitigation practices (with stronger language for the 300m distance), there should be monitoring that goes along with these measures to confirm that bald eagle and heron are not disturbed from nests. At least at the beginning stages of the work. In addition, heron nests/rookery should be added to the 300m buffer for high-disturbance activities.	High-disturbance Project-related activities (e.g., blasting, pile driving) will be avoided where practicable within 500 m of occupied nest locations for great blue heron (i.e., the rookery at Dodge Cove) and within 300 m of occupied nest locations for bald eagles during the breeding windows for either species. Helicopter flights will be a minimum of 500 m from known locations of great blue heron and bald eagle nests. The setback distances are based on prescribed setbacks provided in A Compendium of Wildlife Guidelines for Industrial Development Projects in the North Area, British Columbia, Interim Guidance, North Area (BC MFLNRO 2014), the Environmental Protection and Management Guideline (BC OGC 2016) and Develop with Care 2014: Environmental Guidelines for Urban and Rural Land Development in British Columbia (BC MOE 2014). As per Mitigation 4.7.18, setbacks will be established around active nests to limit disturbance or displacement. The on-site Environmental Monitor will be responsible for monitoring the effectiveness of no-disturbance setbacks for all active nests within or adjacent to the PDA (including bald eagle nests), and to modify disturbance buffers as necessary to maintain effectiveness. Details for active nest setbacks will be described in the Wildlife Management Plan. Aurora LNG has further committed to monitoring the rookery for changes in breeding activity if vegetation clearing for Project construction overlaps with the breeding window for great blue heron. Environmental Protection and Management Guideline. Version 2.2. Available at: http://www.bcogc.ca/node/5899/download. Accessed: February 2017.
2230.1	round 1	Gitxaala Nation	4.7.5	Wildlife Resources (Terrestrial)	Please provide details for marbled murrelet management plan. Who will be responsible for this? When will it be prepared? What will it include? Same for Wildlife Management Plan and Bat Management Plan.	The Marbled Murrelet, Wildlife, and Bat Management Plans will specifically outline avoidance, reduction, mitigation, and monitoring measures to limit potential effects from change in habitat, mortality risk, or movement (as applicable) from Project construction and operation activities. Management plans will be developed by Aurora LNG prior to commencement of construction. Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of this plan.
2231.1	round 1	Gitxaala Nation	4.7.5	Wildlife Resources (Terrestrial)	Will management plans be prepared for other species of concern, such as great blue heron or western toad?	There are no species-specific management plans currently proposed for great blue heron or western toad. The Wildlife Management Plan will outline measures to avoid, reduce, mitigate, and monitor for breeding birds and amphibians, and will include direction on mitigation measures specific to great blue heron and western toad (e.g., Mitigation measures 4.7.4, 4.7.6, 4.7.10, 4.7.12, 4.7.16, 4.7.17, and 4.7.19).
2232.1	round 1	Gitxaala Nation	4.7.5	Wildlife Resources (Terrestrial)	"Proposed clearing for the entire PDA footprint is estimated to result in the removal of 19ha of marbled murrelet critical habitat and 77ha of preferred habitat for marbled murrelet. Project specific studies indicate that areas outside of the PDA, specifically on the north side of Casey Cove and Metford Island, represent high-suitability with a moderate likelihood to support nesting activities." Is this statement supposed to justify the loss of critical habitat?	This statement is intended to provide context for the extent and distribution of critical and preferred breeding habitat for marbled murrelet within the PDA or LAA, and provides context for characterizing the effects of change in habitat availability for the species. Please refer to Figure 9 in the Wildlife Resources (Terrestrial) Technical Data Report for the distribution of critical and preferred habitat.
2233.1	round 1	Gitxaala Nation	Table 4.7-12	Wildlife Resources (Terrestrial)	Table only includes four of the 19 species of management concern that may occur in the LAA or RAA. Of those, it is known that great blue heron, band-tailed pigeon, and barn-swallow are known to occur in the PDA. Why have these species not been included in the assessment?	The assessment of Project effects on wildlife resources considers effects on great blue heron, band-tailed pigeon, and barn swallow in consideration of documented or potential occurrence within the PDA and LAA, how habitats within these boundaries support life history requirements, and the mechanisms for interaction with Project activities and infrastructure. Section 4.7.5 discusses potential effects of change in habitat, mortality risk, or movement as applicable to each species. Field studies and the wildlife habitat community model (existing condition and full Project build-out scenarios) are used to support the characterization of effects for each.
2234.1	round 1	Gitxaala Nation	4.7.5.2	Wildlife Resources (Terrestrial)	Indirect change in habitat: Only a brief discussion of acoustic emissions or in-air noise has been included. However, this discussion is based on A-weighted decibels. Where is the discussion of C-weighted decibels? The C-weighted dBs have a lower frequency sound and produce a stronger pressure wave. These waves could have a greater effect on birds, and should be considered in the assessment. How will the vibration cavity of birds be affected by the acoustic emissions? How will this relate to sudden pressure and sudden noise associated with flaring? Or with construction and operational noise?	Section 4.7.5.2 of the assessment considered indirect effects of change in habitat incorporated information on noise-based effects available in scientific literature, for species occurring within the LAA (or for similar species whose effects are expected to be representative). Available wildlife-related literature has centered on A-weighted decibel noise, as it represents the most common weighting used in noise measurement. Although there is limited information available on effects of C-weighted decibel noise to wildlife, a discussion on potential effects to human receptors is provided in Section 4.4of the Application. The low frequency noise effect analyses for construction and operation are summarized in Table 4.4-17 to Table 4.4-18. The results indicate no exceedance when compared to the ANSI 12.9 standard threshold for human receptors. Continuous flaring with high flow rate and no noise mitigation considerations can result in noise effects at nearby receptors. The LNG facility will be designed such that continuous flaring during operations will not result in regulatory exceedances. There will be flaring with higher flow rate during the startup phase; however, effects are expected to be temporary, short term, and intermittent. While flaring will affect noise production during Project operations, it is not expected to generate substantial vibration for wildlife receptors unless they are in the immediate vicinity of an active flare, in which case individuals are likely close enough to a heat source sufficient to cause injury or mortality (as assessed in Section 4.7.5.3). Aurora LNG has committed to mortality monitoring and reporting (mitigation 4.7.14). The Wildlife Management Plan will provide details on procedures for identifying, recording, and reporting on injury or mortality related to Project activities; where possible, Project personnel will be required to describe the cause of mortality (including pressure-based mortality [e.g., barotrauma]).
2235.1	round 1	Gitxaala Nation	4.7.5.2	Wildlife Resources (Terrestrial)	The habitat suitability models chosen (marbled murrelet, western toad, western screech-owl, and little brown myotis) do not represent a diverse range of wildlife habitat types. No medium or large mammals have been considered, no small terrestrial mammals (only bats for small mammals), no songbirds, no primary cavity nesters, no aerial foraging birds (swifts, swallows).	The assessment for wildlife resources uses two modelling approaches to evaluate change in habitat for species known or potentially occurring within the PDA and LAA. Wildlife habitat community modelling was developed to provide an assessment of potential effects on habitat availability for 15 wildlife habitat communities within the LAA. These wildlife habitat communities provide coverage for all habitat types that occur within the LAA and are used to assess effects of change in habitat to a wider suite of wildlife species assemblages that occupy them. Methods and findings of the wildlife habitat community models are provided in Section 4.1 of Appendix J and carried forward in Section 4.7.5.2 of the Application. These sections provide a detailed description of each of the 15 communities, describes wildlife species that are expected to occur within each, and discusses potential effects to species assemblages due to construction and operation of the Project. Habitat suitability models were developed for four terrestrial wildlife species (i.e., marbled murrelet, western screech-owl kennicottii subspecies, little brown myotis, and western toad) based on criteria described in Section 4.7.3 of the Application and Section 4 of Appendix J. Although these models were not specifically developed for large, medium, or small mammals (other than bats), songbirds, cavity nesting species, or aerial foragers, their habitat requirements are accounted for through the wildlife habitat community modelling approach.

2236.1	round 1	Gitxaala Nation	4.7.5.2	Wildlife Resources (Terrestrial)	What explanation is there for federally designated critical habitat for marbled murrelet being assessed as "low or moderate likelihood to support nesting activity and were generally ranked as moderately suitable based on habitat attributes described…"? These critical habitat features were added to the recovery strategy in 2014, thus they should be up to date and accurate. Furthermore, while retention objectives for suitable habitat on the northern mainland coast are currently being achieved, cumulative effects of additional losses in the region are not advised. These are minimum amounts.	Environment Canada (2014) acknowledges that their current identification of marbled murrelet critical habitat "constitutes a partial identification of nesting critical habitat". The current extent of mapped critical habitat represents areas "within which nesting critical habitat is found for marbled murrelet is delineated by a set of geographic location polygons". The recovery strategy provides a set of polygons representing the largest extent of areas thought to contain suitable nesting habitat, using the best available information. Although the recovery strategy was released in 2014, it incorporates several different mapping approaches, some of which have incorporated older datasets and may not accurately reflect current conditions at individual sites (see Environment Canada 2014 for full details on methods). As a result of this mapping approach, identified polygons represent areas where the biophysical attributes for marbled murrelet nesting habitat are found but it does not necessarily mean that the entire extent of an identified critical habitat polygon meets the attributes necessary to support nesting activities. Aurora LNG used a combination of wildlife habitat assessments (i.e., desktop mapping verified by ground plots), detailed habitat assessments focused on preferred suitability habitat and identified critical habitat, and audio-visual surveys to provide a detailed, ground-truthed, assessment and verification of the availability and quality of nesting habitat on Digby Island (see Appendix J for details). Given that these field studies reflect current existing conditions and are comprehensive and site-specific, Aurora LNG expects some discrepancy between the extent of potential critical habitat identified in Environment Canada (2014) and that which has been verified through site-specific field assessments completed for the Project. For the purpose of comparison, Figure 9 of Appendix J provides an overview of the spatial extent of Project-specific habitat data superimposed with identified critical habitat polygons. In Section 4.7 of the Application, the net change in identified critical habitat was estimated to be 14 ha, accounting for less than 0.0001% of the habitat supply target for the Northern Mainland Coast population. The Project's contribution to cumulative effects is considered a conservative estimate given that: (a) the full extent of identified critical habitat polygons were used to estimate direct effects, (b) the majority of habitat is located within 500 m of shoreline and is therefore only 'moderately likely' to support nesting (Environment Canada 2014), and (c) Aurora LNG is committed to implementing a Marbled Murrelet Management Plan to avoid or reduce potential Project effects to changes in nesting habitat. Accordingly, the Project's contribution to cumulative effects of change in nesting habitat is not expected to affect the ability to achieve short and long-term regional population and habitat objectives as per the recovery strategy (Environment Canada 2014). References: Environment Canada. 2014. Recovery Strategy for the Marbled Murrelet (Brachyramphus marmoratus) in Canada. Species at Risk Act Recovery Strategy Series. Environment Canada, Ottawa. v + 49 pp.
2237.1	round 1	Gitxaala Nation	4.7.5.2	Wildlife Resources (Terrestrial)	"Direct habitat removal will occur once during vegetation clearing and will persist until the PDA is reclaimed following decommissioning of the Project." Revegetation may take generations to be fully functional when replacing mature forests. Ecosystem functions will not be the equivalent of existing conditions for potentially a hundred years, if possible to recover at all.	The statement quoted is meant to confirm that vegetation in the PDA will remain cleared until decommissioning and reclamation - not that the effect on habitat will only last until decommissioning and reclamation. Duration of effects to direct habitat removal is characterized as long-term, which is defined in Section 4.7.2.6, as "Residual effect occurs across multiple breeding seasons or generations".
2238.1	round 1	Gitxaala Nation	4.7.5.3	Wildlife Resources (Terrestrial)	Table 4.7-14: Mitigation 4.7.9 includes measures for reducing the risk of lighting to "marine birds". Should include terrestrial birds and bats.	Aurora LNG acknowledges the comment from Metlakatla First Nation. To clarify, mitigation measure 4.7.9 is applicable to terrestrial and marine birds, as well as bats and is carried forward in Sections 4.7 and 4.11. An errata documentis being compiled that captures these corrections and it will be filed with the BC EAO.
2239.1	round 1	Gitxaala Nation	4.7.5.3	Wildlife Resources (Terrestrial)	Table 4.7-14: Mitigation 4.7.20 should include shielding to prevent birds and bats from injury or death during flaring events.	Section 1.2.5.1 describes the proposed flare system design and does not include a shielding mechanism, due to infrastructure constraints. Aurora LNG considered placement options of the flare system within the PDA to reduce potential interaction with environmental valued components and to limit the amount of light dispersal (Table 1-26). As per mitigation measure 4.7.20, maintenance flaring events will be scheduled during daylight hours to the extent practicable to further reduce attraction by birds and bats to flare system infrastructure during nocturnal migration or foraging. This is expected to reduce potential effects of injury or mortality to birds and bats; however, Aurora LNG is committed to monitoring the effectiveness of this mitigation measure through the reporting of injuries and mortalities (mitigation measures 4.7.14 and 4.7.16).
2240.1	round 1	Gitxaala Nation	4.7.5.3	Wildlife Resources (Terrestrial)	Table 4.7-14: Mitigation 4.7.12 includes mitigation measures to reduce injuries and mortalities to amphibians and other wildlife. How will this be monitored? Who is responsible? Who decides when temporary drift fencing needs to be installed? These details are important in determining the efficacy of the mitigation strategies. Furthermore, it would be advisable to develop strategies to allow amphibians and other small wildlife to cross roads in areas where migration between wetlands or other features is observed. This could include the installation of small underpasses with drift fences leading to the underpasses at key locations. This has the potential to significantly reduce road mortalities for migrating western toad.	Aurora LNG has committed to developing a Wildlife Management Plan and Transportation Management Plan (see Section 14 of the Application), both of which will include a description of activities to meet the commitment for Mitigation 4.7.12. These plans will outline detailed mitigation activities (e.g., instructions for timing, locations, and procedures for drift fence installation), effectiveness monitoring, and education and training requirements for Project personnel. The need, locations, and extent of drift fencing installation will be determined by a Qualified Environmental Professional in consultation with the on-site Environmental Monitor.
2241.1	round 1	Gitxaala Nation	4.7.5.3	Wildlife Resources (Terrestrial)	Table 4.7-14: Mitigation 4.7.14 includes the reporting of bird injuries or fatalities related to Project activities. This should also include any other wildlife injuries or fatalities. In addition, the mitigation mechanism should include birds, bats and other wildlife, and an Adaptive Management plan to be developed (identify when this will be prepared and by whom).	Aurora LNG acknowledges the comment and will amend Mitigation 4.7.14 to include bat and wildlife injury and fatality reporting. An errata document is being compiled that captures these corrections and it will be filed with the BC EAO. The Wildlife Management Plan will include reporting requirements of wildlife sightings and is inclusive of detections of wildlife injuries or fatalities, as a means to evaluate patterns in use, potential mortality, and for monitoring the effectiveness of mitigation measures. Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Wildlife Management Plan. An errata document is being compiled that captures this additional commitment and it will be filed with the BC EAO.
2242.1	round 1	Gitxaala Nation	4.7.5.3	Wildlife Resources (Terrestrial)	Characterization of Residual Effects for Change in Mortality Risk: How does having the PDA on an island affect the ability of local populations to recruit to offset losses? This is a limited resource if populations are restricted by waterbodies. Are there unique genetic populations on the island, specifically for non-flying wildlife such as terrestrial mammals and amphibians? If wildlife is salvaged during the construction phase, what is the risk of breaching the carrying capacity of populations on the rest of Digby Island?	Natural recruitment (e.g., through reproduction and immigration) is expected to offset potential Project effects to a regional population, accounting for individuals located within the LAA and RAA (including areas of Digby Island, other coastal islands, and the mainland). The area in which recruitment can occur depends on the mobility of organisms, with less mobile species (e.g., amphibians) restricted to recruitment from regional populations elsewhere on Digby Island, while mobile species (e.g., songbirds) having broader capacity. Although individual distribution for some species may be restricted to Digby Island, the Island is not known to support genetically distinct populations. If salvage is required, preference will be to relocate individuals to adjacent suitable habitats present on Digby Island to support maintenance of the overall viability of Island populations. However, the extent of salvage (e.g., the number of individuals) and the size, suitability, and access to relocation sites will inform the inclusion of alternate sites for relocation to maintain viable populations at each. Relocation sites are subject to review and approval through application for wildlife salvage under the BC Wildlife Act, and will be developed in consultation with the Ministry of Forest, Lands, and Natural Resource Operations.
2243.1	round 1	Gitxaala Nation	4.7.4	Wildlife Resources (Terrestrial)	Table 4.7-15: See comments from previous tables (4.7-10 and 4.7-14).	Clarifications to mitigation measures presented in Tables 4.7.10 or 4.7.14 also apply to those mitigation measures that have been carried forward in Table 4.7-15.
2244.1	round 1	Gitxaala Nation	4.7	Wildlife Resources (Terrestrial)	While a vegetated buffer around the PDA has been proposed as mitigation, this narrow strip of mature and old growth forest (30m in most parts) is inadequate to prevent losses of marbled murrelet habitat. The critical habitat within the vegetated buffer strips should also be considered effectively lost and calculated in the total losses. This is fragmentation of critical habitat. Furthermore, removing forested areas beyond 30m leaves trees exposed to wind damage and creates edge habitat. How is this useful to marbled murrelet? What is the viability of this vegetated buffer? Areas designated as "high suitability" during Project surveys should also be included in losses. These statements are based on the recovery strategy that states that the most likely suitable sites for nest habitat are 0.5 to 30km from saltwater habitat. Leaving 30m adjacent to saltwater with nothing left behind provides unsuitable habitat for marbled murrelet. Please also discuss the effectiveness of these thin vegetated buffers with respect to bat habitat.	Section 4.7.5.2 of the Application provides an estimate of direct and indirect loss of preferred breeding habitat and identified critical habitat for marbled murrelet within the LAA, after accounting for the riparian buffer. The Project is estimated to result in the direct removal of 61 ha of preferred and 14 ha of identified critical habitat (with overlap in extent between those two classifications; see Figure 9 of Appendix J). The majority of preferred and identified critical habitat is located in stands of old-growth forests located on the perimeter of Digby Island. Environment Canada (2014) identifies marbled murrelet critical habitat as "a set of polygons representing the largest extent of areas thought to contain suitable nesting habitat, using the best available information". The entire extent of an identified polygon does not necessarily meet the attributes for critical habitat. In absence of more detailed mapping information in the recovery strategy, the Application used a conservative estimate of potential effects to identified critical habitat, including: (a) using full extent of identified critical habitat polygons to estimate direct effects, (b) qualifying habitat within 500 m of shoreline although it is only 'moderately likely' to support nesting (Environment Canada 2014). Habitat suitability models were supplemented with audio-visual surveys and detailed habitat assessments to refine the prediction of potential effects on marbled murrelet habitat. Baseline data was used to determine evidence of breeding (i.e., marbled murrelets seen or heard landing, perching, or flying through or out of the forest canopy) and to refine habitat attributes within preferred or identified critical habitat polygons (see Section 5.7.2 of Appendix J for details). To reduce potential effects on marbled murrelet nesting habitat, Aurora LNG will retain a marine riparian disturbance buffer. The riparian buffer will be a minimum of 30 m wide, but may extend beyond 30 m in some areas on the east side of Digby Island (see Figure 4.7-7). Given the proximity of these habitats to salt water, they are only "moderately likely" to support nesting habitat under existing conditions but given the width of the riparian buffer on the east side of Digby Island, they are expected to retain habitat function during construction and operation by reducing noise and light transmission to interior forested habitats remaining. To further address direct loss of nesting habitat, Aurora LNG has committed to developing a Marbled Murrelet Management Plan that will outline avoidance, reduction, mitigation, and monitoring measures to effects from Project construction and operation activities. Based on the information provided in the recovery strategy and the potential effects on marbled murrelet terrestrial nesting habitat, marbled murrelet use of the local assessment area is not expected to change as a result of the Project. The Project's residual effects and its contribution to cumulative effects on marbled murrelet are not expected to influence the long-term viability of regional murrelet populations and are therefore considered not significant. With respect to bats, the riparian buffer will be a minimum of 30 m wide, but extend beyond 30 m in some areas on the east side of Digby Island resulting in greater retention of mature and old-growth forest habitat to support roosting opportunities for local bat species. Given the width of the riparian buffer on the east side of Digby Island, this area is expected to retain habitat function during Project construction and operation. Aurora LNG has also committed to developing a Bat Management Plan that will outline avoidance, reduction, mitigation, and monitoring measures to effects from change in habitat or mortality risk for bats from Project construction and operation activities. References: Environment Canada. 2014. Recovery Strategy for the Marbled Murrelet (Brachyramphus marmoratus) in Canada. Species at Risk Act Recovery Strategy Series. Environment Canada, Ottawa. v + 49 pp.
2245.1	round 1	Gitxaala Nation	4.7	Wildlife Resources (Terrestrial)	There has been absolutely no mention of white-nose syndrome in bats in this assessment. This is a major oversight, as bat populations in BC are on the verge of a potential devastating collapse. Please revise assessment to include cumulative impacts of white-nose syndrome.	The assessment for wildlife resources recognizes that little brown myotis is a species designated as Endangered on Schedule 1 of SARA, due in part to rapid declines in eastern populations as a result of the spread of white-nose syndrome (WNS; Environment Canada 2015). Although there have been no confirmed records of white-nose syndrome (WNS) in British Columbia, Aurora LNG is aware that the Washington State Department of Fish and Wildlife confirmed that WNS was identified in a single little brown myotis in March 2016. Recovery objectives for populations of little brown myotis in non-affected areas of western Canada are to maintain current population levels (Environment Canada 2015). Accordingly, Aurora LNG has committed to several bat-specific mitigation measures, including the development of a Bat Management Plan, which will outline measures to avoid, reduce, and mitigate for potential effects from Project infrastructure and activities. Mitigation measures applicable to little brown myotis (and other bat species) are listed in Table 4.7-17. Collectively, these measures are expected to limit the Project's contribution to cumulative effects on little brown myotis and supports the current objective to maintain current population levels in western Canada. Reference: Environment Canada. 2015. Recovery Strategy for Little Brown Myotis (Myotis lucifugus), Northern Myotis (Myotis septentrionalis), and Tri-colored Bat (Perimyotis subflavus) in Canada [Proposed]. Species at Risk Act Recovery Strategy Series. Environment Canada, Ottawa. ix + 110 pp.
2246.1	round 1	Gitxaala Nation	4.7	Wildlife Resources (Terrestrial)	How will anthropogenic structures within the PDA influence bats and bat mortality? Little brown myotis are known to use anthropogenic structures, and may be drawn to the PDA with the loss of forest habitat. As such, this may increase the likelihood of accidental mortality (collisions, flaring, etc.).	Species of bats with potential to occur in the PDA may use anthropogenic structures to various degrees for roosting and foraging. The extent to which bats may attempt to roost in buildings within the PDA is unknown, but is expected to be low given that building maintenance will limit access opportunities, and presence of operational noise and light will decrease the suitability of roosting structures. Section 4.7.5.3 of the Application describes the influence of anthropogenic light on disruptions to roosting and foraging behaviour, and the associated mortality risk. Facility staff will document and report bat injuries or fatalities related to Project activities, alongside birds (as per Mitigation 4.7.14).
2247.1	round 1	Gitxaala Nation	4.7.6.4	Wildlife Resources (Terrestrial)	Please see comments on Vegetation and Wetland Resources regarding soil acidification. Given that amphibians are particularly sensitive to changes in pH, what are the calculated impacts on western toad?	Acidification and eutrophication could reduce survival and reproductive success of amphibians in the RAA. Section 4.7 of the Application acknowledges that there is some uncertainty in the response of freshwater systems and, in turn, the health of aquatic wildlife, as a result of acidification and eutrophication that may occur due to Project emissions. To address this uncertainty, Aurora LNG has committed to developing an Acidification and Eutrophication Follow-up Program in consultation with BC MOE (see Section 15: Summary of Follow-up Programs and Compliance Reporting). The follow-up program will include freshwater, soil, and vegetation monitoring that will together provide a measure of change in wetland functions, such as the ability of wetlands to support amphibian breeding.

2248.1	round 1	Gitxaala Nation	4.7	Wildlife Resources (Terrestrial)	This assessment of wildlife resources (terrestrial) is incomplete. As such, a result of non-significant adverse effects has been determined. We disagree with this conclusion. See comments above for additional discussions required to complete the assessment. Currently, the assessment's conclusion of non-significant effects is inappropriate given the loss of critical habitat and high suitability habitat for marbled murrelet and little brown myotis. In addition, FNs interests have not been considered in the impacts, therefore impacts to harvestable species have not been addressed.	Aurora LNG acknowledges the comment from Gitxaala Nation. The assessment of wildlife resources (terrestrial) was completed following the framework outlined in the Project's Application Information Requirements and Valued Components Selection document. Significance thresholds for wildlife resources (terrestrial) present the limits of an acceptable change in a measurable parameter or state of regional wildlife populations and are based on applicable legislation, regulatory guidance documents, or other management standards (including cultural use). Where thresholds are not set by legislation, policy, and regulatory guidance documents, a threshold has been developed based on scientific literature and professional judgement, and with the incorporation of available traditional ecological knowledge. Significance thresholds vary between species or species groups and potential effects. As described in Section 4.7.2.8 of the Application, a residual effect is considered significant if it affects the viability of local or regional terrestrial wildlife populations. The viability of species can be affected by several factors, including reproduction, mortality, immigration, emigration, and habitat availability, where viability was defined in the Application as the long-term maintenance in abundance, diversity, or distribution of wildlife through natural recruitment. Viability is inclusive of maintaining sustainable wildlife populations from both a conservation status and cultural use perspective. Aurora LNG has determined that residual effects of the Project on preferred and critical habitat for marbled murrelet is not significant, based on it's evaluation of the extent of effects in combination with proposed mitigation measures (including the Marbled Murrelet Management Plan). Mitigation measures applicable to marbled murrelet are listed in Table 4.7-17. Please see responses to responses to comments #2236.1 and #2244.1 for further information. Residual effects of the Project on preferred habitat for little brown myotis is also expected to be not significant. As with marbled murrelet, Aurora LNG has committed to several bat-specific mitigation measures, including the development of a Bat Management Plan, which will outline measures to avoid, reduce, and mitigate for potential effects from Project infrastructure and activities. Mitigation measures applicable to little brown myotis (and other bat species) are listed in Table 4.7-17. Collectively, these measures are expected to limit the Project's contribution to cumulative effects on little brown myotis. Aurora LNG's proposed mitigation measures for change in habitat have incorporated federal and provincial regulations and guidelines as well as measures that have been recommended or proven effective on similar projects within the RAA with associated marine terminals. With the implementation of mitigation measures, the partial loss of habitats expected to support breeding or roosting by marbled murrelet and little brown myotis (respectively), will be offset for the Project and will reduce the net effect of change in habitat removed by construction of the LNG facility and associated infrastructure. Information on harvested species presented in traditional ecological knowledge studies from Aboriginal groups informed the assessment and characterization of residual Project effects, and is described in Section 4.7.2.2 and 4.7.2.3.
2249.1	round 1	Gitxaala Nation	4.8	Freshwater Fish and Fish Habitat	Please include benthic and macro invertebrates in the assessment of freshwater fish and fish habitat. How will water quality affect the benthic and macro invertebrates? How will this in turn affect food sources for fish? How will removal of instream habitat affect recruitment of benthic and macro invertebrates. How will this be monitored? This assessment is incomplete without the inclusion of this information.	Freshwater benthic and macro invertebrates were not included in the baseline surveys of Freshwater Fish and Fish Habitat for the Project as the assessment of Freshwater Fish and Fish Habitat focusses on CRA fisheries, as defined in the Fisheries Act. By identifying important fish that might be affected by the Project (CRA fish species) and developing mitigation measures to protect these resources, which includes protecting their habitat and the fish and invertebrate communities that live in it, the overall effects on the ecological function of the aquatic ecosystems can be reduced or avoided. Invertebrates and other aquatic life in the freshwater environment are considered as part of the freshwater habitat ecosystem and are not defined individually in the assessment. There are no predicted residual effects to water quality in watercourses retained within and around the project footprint, and therefore no predicted effects on the benthic invertebrate communities within those watercourses.
2250.1	round 1	Gitxaala Nation	Appendix K	Freshwater Fish and Fish Habitat	Some watercourses that were investigated for fish presence were only assessed during summer months. How did low seasonal water levels affect fish habitat sampling and assessment? Some watercourses may only provide habitat for overwintering, and thus would not have had CRA fish present in the summer.	Watercourse reaches identified as not fish-bearing (i.e., reaches above a known permanent barrier to fish passage) were sampled for fish presence in two or three seasons to confirm fish presence/absence. If all sections of a watercourse above a known barrier were determined to be dry or not have the minimum water depths to support fish at the same time, the reaches above the barrier were designated as not fish-bearing. Reaches where only one season of sampling occurred, but no barrier was present, were conservatively identified as suspected fish-bearing even though no fish were caught during sampling. A second season of sampling should be completed to confirm fish presence/absence. The majority of these watercourses are outside of the PDA, and will not be removed or modified due to Project construction (J watercourse system).
2251.1	round 1	Gitxaala Nation	Appendix K	Freshwater Fish and Fish Habitat	What was the criteria for selecting the 60 watercourse reaches, of 106 within or connected to the PDA? What assumption has been made about the 46 watercourse reaches not surveyed? Is it assumed that these watercourses do not have CRA fish species present? Or no fish at all present?	A desktop review was completed for Digby Island and identified 106 reaches on the island. Fish presence and habitat surveys were conducted in the watercourse reaches that are within, or directly connected to the PDA, including the reference reaches. This totalled 60 reaches. Sampling locations were systematically selected to provide adequate representation of the freshwater communities within, and in the vicinity of, the Project area. Data from fish presence and habitat surveys were used to complement and verify results of the desktop review.
2252.1	round 1	Gitxaala Nation	4.8.3.2	Freshwater Fish and Fish Habitat	Please confirm whether the 32,752m2 of fish habitat identified within 39,356m2 of instream area includes all 106 watercourses or just the 60 watercourses investigated.	The 32,752 m2 of fish habitat identified in the environmental assessment is part of the 39,356 m2of instream area represents the watercourses located in, or connected to the PDA. The 106 watercourse reaches represent all watercourse reaches on Digby island, only 60 of which connect directly to, or are within, the PDA. It is these 60 watercourse reaches that were surveyed for fish presence and habitat, and from these area calculations were generated.
2253.1	round 1	Gitxaala Nation	4.8.3.2	Freshwater Fish and Fish Habitat	"Instream and riparian areas of watercourses determined to be non-fish-bearing are not considered fish habitat". Please explain this statement given that suspected non-classified drainages (NCDs) connected upstream of some of the most valuable fish habitat (J1.1.1, J2.1.2L and J2.1.1.1L) would fall into this category. These reaches provide food and nutrients, and contribute to water quality and water quantity in the downstream fish-bearing reaches.	Instream and riparian areas of watercourses determined to be not fish-bearing are not considered fish habitat for the purposes of habitat loss calculations in the assessment and fish habitat offsetting plan. While these areas support and maintain the quality of existing fish habitat through the contributions of water, food, and nutrients, they do not represent direct loss of instream habitat utilized by CRA fish. The final agreed to gain-to-loss ratio will provide, at a minimum, enough habitat creation, enhancement, or restoration to offset the CRA fish production lost due to habitat losses caused by the project as required by the Fisheries Protection Policy Statement..
2254.1	round 1	Gitxaala Nation	4.8.3.2	Freshwater Fish and Fish Habitat	If only 60 watercourses were surveyed, please explain how 97 watercourse reaches were assigned a fish bearing status, and how 70 watercourse reaches were found to be CRA fish-bearing.	A desktop review was completed for all 106 reaches identified on Digby Island. Sample locations (60) were identified in the known or suspected fish-bearing reaches and suspected not fish-bearing reaches within or connected to the PDA. These sample locations were selected to characterize the freshwater fish communities within, and in the vicinity of, the Project area. Data from the ground surveys were used to complement or verify results of the desktop review. Fish-bearing reaches were proven by the capture of fish in the field or assumed based on information found in the desk-top review. Fish-bearing reaches supporting CRA fish species were similarly proven by the capture of salmon, trout, or charr or assumed based on access to this habitat by these species (i.e., no barriers to fish migrations). Fish-bearing reaches not supporting CRA fish species were those where no salmon, trout, or charr were captured in the field and where barriers to fish migrations existed or where habitat conditions (e.g., low pH) were unsuitable for CRA fish. Those unsurveyed reaches outside of the PDA where no barriers were known to exist, or those reaches connected to known fish bearing reaches were considered fish-bearing by default. Of the 106 reaches that were mapped on Digby Island, 97 are thought to be fish bearing and/or a classified stream. There are a total of 24 streams that are thought to be fish bearing, including those in the reference stream (S), and these 24 streams have 70 reaches. The total of 97 fish-bearing reaches included those that were confirmed fish bearing, and those that were connected to fish-bearing watercourses and by default were classified as streams and considered fish bearing. This includes reaches inside, and outside of the PDA.
2255.1	round 1	Gitxaala Nation	4.8.3.2	Freshwater Fish and Fish Habitat	Why was dissolved oxygen only measured for 23 of the watercourse reaches?	In situ dissolved oxygen (DO) was measured at a sub-sample of fish-bearing reaches where water depths and conditions were sufficient to do so. While in situ DO was not measured at all sampling locations, it should be noted that at locations where it was measured, the value represents an isolated, single snapshot in time of DO levels within any given section of stream, and the value was not used to infer the fish-bearing status of sampled stream reaches.
2256.1	round 1	Gitxaala Nation	4.8.3.2	Freshwater Fish and Fish Habitat	Where were instances of turbidity that were not low? Why was turbidity not measured but only visually assessed? Were background metals sampled? If so, please provide results.	Turbidity was assessed as a qualitative visual estimate, as an indication of what stream conditions were like at the time of sampling. Measurements of turbidity (NTUs) were not taken at the time of habitat surveys, as each measurement would represent only an isolated, single event, snapshot in time of turbidity levels at the time of sampling. Specific measurements of turbidity will be used during construction monitoring to maintain levels of suspended sediments within guidelines for the protection of aquatic life. For streams in BC, section 4.2.5.7 of the Reconnaissance (1:20 000) Fish and Fish Habitat Inventory Standards and Procedures(as were used during the baseline data collection - see Appendix K), only requires the visual estimation of turbidity. Background metals were not sampled as there are no predicted effects on metal levels resulting from the project.
2257.1	round 1	Gitxaala Nation	4.8.3.3	Vegetation and Wetland Resources	"There are 60 watercourse reaches within, or adjacent to the PDA, and from these 60 reaches, 54 were sampled for fish." This statement is inconsistent with the information provided above.	Aurora LNG acknowledges that this is an error. The statement in Section 4.8.3.2 which reads "Of the 106 freshwater watercourse reaches within, or adjacent to, the PDA, 60 watercourse reaches were surveyed for fish presence. " should be changed to "Of the 106 freshwater watercourse reaches within, or adjacent to, the PDA, 60 watercourse reaches were surveyed for fish or fish habitat." Fish habitat assessments were completed in 60 reaches and fish sampling was conducted at 54 of the 60 reaches. An errata document is being compiled that captures these corrections and it will be filed with the BC EAO.
2258.1	round 1	Gitxaala Nation	4.8.3.3	Freshwater Fish and Fish Habitat	"There are no known traditional use sites, or harvest locations, of freshwater fish within the PDA." However, discussion mentions importance of Pacific salmon, trout and char to FNs. Given the anadromous nature of these species, the freshwater environment is of importance to FNs whether they specifically harvested at the freshwater locations within the PDA, or not.	Aurora LNG acknowledges and agrees with the comment. While there are no specific harvest locations or traditional use sites identified in the freshwater areas within the PDA, it is recognized that the fish that inhabit or temporarily make use of these areas are fish that may be important to First Nations at locations outside of the PDA.
2259.1	round 1	Gitxaala Nation	4.8.4	Freshwater Fish and Fish Habitat	Please describe how waste management will not interact with change in fish habitat, but will interact with fish mortality and health and fish abundance. Please describe whether LNG production will require the transportation of materials over any watercourses.	Waste management is not expected to interact with change in fish habitat during the decommissioning phase of the project (as indicated in Table 4.8-9), as the fish habitat in areas near the infrastructure will have already been removed. As part of the facility construction, bridges are expected to be built over the retained watercourses to facilitate transportation of personnel, vehicles, and materials throughout the site. The potential for interaction with change in fish health and fish abundance exists through all phases of the Project as transportation of waste materials within and away from the site will occur in construction through operations and decommissioning.
2260.1	round 1	Gitxaala Nation	4.8.5	Freshwater Fish and Fish Habitat	"All watercourses in the LAA were assumed to be fish-bearing, unless proven otherwise by field assessment." Please explain how this was determined based on a few field surveys? What about watercourse reaches not sampled? How was fish status confirmed in those reaches? How much sampling effort was required to "prove" no fish present? Was seasonal habitat use taken into consideration?	Watercourse reaches were identified as not fish-bearing if they were located upstream of a known permanent barrier to fish passage and no fish were captured during sampling over two or three seasons to confirm fish presence/absence. Reaches above a known barrier for which only one season of sampling was completed were identified as "suspected" not fish-bearing, acknowledging that a second season of sampling should be completed to confirm fish presence/absence. Once a second season of sampling was completed, reaches were designated as fish-bearing or not fish-bearing according to results of the surveys. All assessed reaches were eventually given one of the following designations: "fish-bearing", "suspected fish-bearing", or "not fish-bearing". All fish-bearing and suspected fish-bearing reaches were considered fish habitat for the purposes of the assessment. If all sections of a watercourse above a known barrier were determined to be dry or not have the minimum water depths to support fish at the same time, the reaches above the barrier were designated as not fish-bearing. Seasonal habitat use was considered, as baseline sampling occurred throughout the year.
2261.1	round 1	Gitxaala Nation	4.8.5.2	Freshwater Fish and Fish Habitat	Table 4.8-10 Potential effects on fish habitat should include change in food and nutrients supplies/concentrations for grading and use of industrial equipment under construction, and waste management under operations. Vehicle traffic and Organic debris management should include change in food availability and nutrients.	Potential changes in food and nutrient supply are assessed under vegetation clearing during the construction phase of the project (Section 4.8.5.2) as the majority of allochthonous food and nutrient inputs in project area watercourses are afforded by insect and leaf litter drop from stream side vegetation.
2262.1	round 1	Gitxaala Nation	4.8.5.2	Freshwater Fish and Fish Habitat	Table 4.8-11: Exclusion fencing is to be installed - how far from habitat will fencing be installed? Please describe which BMPs will be used. Will there be the creation of a Construction Environmental Management Plan? Who is responsible for this? What permits will be required? How has water quality been included in the mitigation measures to avoid or reduce change in fish habitat? How will water quality be monitored and measured, and what parameters? Metals, oil & grease, PAHs, pH, temperature, dissolved oxygen? Where will water be discharged from and where will it be discharged to?	Further details on construction and operations monitoring, mitigation measures, best management practices, erosion and sediment control, wastewater management, and compliance monitoring, etc. will be provided in the Marine and Freshwater Resources Management Plan (equivalent to the construction environmental management plan) developed for the project. The plan will be developed prior to the phase of the Project for which is required. Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of this plan. Storm or wastewater will not be discharged from the site until it has been tested and confirmed that it meets regulatory requirements.
2263.1	round 1	Gitxaala Nation	4.8.5.2	Freshwater Fish and Fish Habitat	Please explain the difference between "important spawning habitat" and "spawning habitat".	For the purpose of this section of the assessment, spawning habitat refers to instream areas of project area watercourses where conditions (e.g., substrates, depths, water velocity) are sufficient to provide the potential for spawning activity to occur, whereas important spawning habitat refers to instream areas with ideal spawning habitat characteristics (e.g,. redds, observed spawners)for a species observed using, or known to use, the specific location for spawning activity.
2264.1	round 1	Gitxaala Nation	4.8.5.2	Freshwater Fish and Fish Habitat	Please describe how the non-CRA fish bearing watercourses in the PDA contribute to food, nutrients, water quality and water quantity in the downstream fish-bearing reaches. The removal of all the non-CRA fish bearing watercourse reaches within the PDA represents an impact on fish habitat downstream, and potentially fish abundance.	Watercourses in the PDA that are being retained will have an intact 30 m vegetated riparian buffer, and their upstream watershed will remain intact. Aurora LNG is aware of the hydrological conditions associated with the PDA and surrounding area and recognizes that upstream areas of fish-bearing waters support and maintain the quality of existing fish habitat through the contributions of water, food, and nutrients; as such there will be detailed water management, erosion and sediment control plans in place and approved by regulators in advance of Project construction.
2265.1	round 1	Gitxaala Nation	4.8.5.2	Freshwater Fish and Fish Habitat	Quantification of fish habitat loss only includes fish-bearing watercourses. The loss of suspected non-fish bearing watercourses equals a degradation of fish habitat downstream. Impacts to food, nutrients, water quality and quantity.	Instream and riparian areas of watercourses determined to be not fish-bearing are not considered fish habitat for the purposes of habitat loss calculations in the assessment and fish habitat offsetting plan. While these areas support and maintain the quality existing fish habitat through the contributions of water, food, and nutrients, they do not represent direct loss of instream habitat utilized by CRA fish. The final agreed to gain-to-loss ratio for offsets will provide, at a minimum, enough habitat creation, enhancement, or restoration to offset the CRA fish production lost due to habitat losses caused by the project as required by the Fisheries Protection Policy Statement and therefore overall productivity of the fishery will be maintained.

2266.1	round 1	Gitxaala Nation	4.8.5.2	Freshwater Fish and Fish Habitat	Why has the Riparian Reserve Zone (RRZ) been used in the calculation of riparian losses when the text says the losses are based on the Riparian Management Area (RMA)? Please show RRZ widths used for the watercourse calculations.	The sentence referenced in the Application states: "Riparian losses are based on the RMA, which consists of the Riparian Management Zone and the Riparian Reserve Zone (RRZ) (BC MOF 1995; BC OGC 2016). The potentially affected riparian area is based on the width of the RRZ for the application of the watercourse classification (S1 – S6)." The first sentence is meant to be an introduction to the components of the RMA (two components, RRZ and RMZ) and the second sentence defines which component is being used to calculate riparian losses. The RRZ is chosen as the width to be used in calculating riparian losses, as this is the riparian buffer that should be retained in all cases (except where watercourses are crossed by a linear development) according to the OGC's Environmental Protection and Management Regulation. The RRZ used for calculating riparian habitat losses varies between 0 and 30 m within the PDA, depending upon the riparian class of the stream. Aurora LNG used a conservative approach and assumed a minimum 15 m RRZ on all riparian stream classes, including non-fish bearing (S5-6). Streams that were fish bearing had a RRZ of between 20 and 30 m on each side of the watercourse.
2267.1	round 1	Gitxaala Nation	4.8.5.2	Freshwater Fish and Fish Habitat	"The five most important watercourse reaches (J5, J1.1, TT1, K2 and J2) with the most observed fish habitat…" Why have TT1 and K2 not been discussed until this point? K2 is also shown on the maps as a suspected non-fish bearing (CRA) watercourse. Does this mean K2 may contain other fish species other than CRA species? Why is K2 considered one of the most important? "Four of these reaches will retained, or will remain accessible after Project completion." Which four? J1.1, J5 and J2 will be retained, so between K2 and TT1, which one will remain accessible? By Project completion, does this mean construction phase or after decommissioning?	The statement "five most important watercourse reaches" was determined by the area available for fish, and J5, J2, J1.1, TT1 and K2 provided the most area of fish habitat. Of these five watercourse reaches, J5, J1.1, TT1, and J2, will remain accessible after Project construction and during operations. Watercourse TT1, in the northern part of the PDA, will not be removed, but will have a culvert or bridge installed that will maintain fish access and passage through that area. All applicable provincial and federal permitting will be completed prior to instream works in TT1. After the baseline study was completed, watercourse reach K2 was suspected to be non-fish bearing; access may currently be limited by a cascade barrier at the downstream end of the reach. No fish were captured in this reach during the baseline studies (see Appendix K - Technical Report); however, the reach was observed to contain habitat that would be suitable for spawning and rearing salmonids, if accessible. The description of the K2 fish habitat will be updated. An errata document is being compiled that captures these corrections and it will be filed with the BC EAO. "By Project completion" was meant to indicate the completion of Project construction and the start of operation of the facility.
2268.1	round 1	Gitxaala Nation	4.8.5.2	Freshwater Fish and Fish Habitat	How is a loss of 10,000m2 of instream habitat and 218,000m2 of riparian habitat considered a moderate magnitude residual effect, but with offsetting these are considered negligible? Compensation habitat is only being considered for fish-bearing watercourses that are to be lost, not the other 6,600m2 instream and 140,300m2 riparian habitat. In adition, habitat offsetting is not equivalent to retaining existing habitat. It can take generations for fish habitat to function as intended or equivalently to existing habitat. Furthermore, offsetting habitat must be in place and functioning before the loss of existing habitat, otherwise there is most certainly a negative impact on fish habitat.	Fish habitat losses associated with the project will be counterbalanced by offset measures that will be determined in a detailed fish habitat offset plan for the project. The plan will be part of an authorization application under the Fisheries Act, which stipulates that all "serious harm" to fish (which includes both permanent alteration of habitat and the death of fish), which cannot be mitigated or avoided, must be counterbalanced by appropriate offset measures. As effective offsetting is federally legislated, by law, any losses of productivity to fisheries will be balanced by productivity associated with offset measures, and the net residual effect to fisheries productivity will be negligible. Instream and riparian areas of watercourses determined to be not fish-bearing are not considered fish habitat for the purposes of habitat loss calculations in the assessment and fish habitat offsetting plan. While these areas support and maintain the quality of existing fish habitat through the contributions of water, food, and nutrients, they do not represent direct loss of instream habitat utilized by CRA fish. Within the detailed offset plan for the project, any time lags in the function of offset habitats will be considered in habitat balance calculations. Ratios of offset habitat to impacted habitat will be established that will account for any time lags.
2269.1	round 1	Gitxaala Nation	4.8.5.3	Freshwater Fish and Fish Habitat	Table 4.8-14: See comments to Table 4.8-10.	Potential changes in food and nutrient supply are assessed under vegetation clearing during the construction phase of the project (Section 4.8.5.2) because this is the Project phase and activity during which the majority, if not all, of the allochthonous food and nutrient inputs provided by riparian vegetation to project area watercourses will be altered. Once this riparian vegetation is removed during construction, no additional effect from changes in food and nutrient concentrations are expected during subsequent phases.
2270.1	round 1	Gitxaala Nation	4.8.5.3	Freshwater Fish and Fish Habitat	Structures or materials placed in water may also reduce complexity and cover if surfaces are smooth, such as a culvert or bridge abutment.	Aurora LNG agrees with the comment. Potential effects of structures or materials placed below the high water mark of a stream has been considered in the assessment.
2271.1	round 1	Gitxaala Nation	4.8	Freshwater Fish and Fish Habitat	How has change in water quantity/base flows due to infilling of watercourse reaches upstream of fish habitat been considered? This needs to be modelled. How will these changes be monitored? This assessment is not complete without the inclusion of effects of changes to water flows.	No effect on water quantity/base flows is expected as flows will be maintained within watercourses that will remain in the PDA (J1-5 and J1.1). Runoff from areas within the PDA will be collected, diverted around project infrastructure, and returned to the same drainage downstream, if possible; otherwise it will be directed through a storm water system and released into the marine environment. Storm water or wastewater from the site will be tested and treated, if required, to meet regulatory requirements prior to being discharged.
2272.1	round 1	Gitxaala Nation	4.8.5.3	Freshwater Fish and Fish Habitat	Table 4.8-15: See comments to Table 4.8-11. Mitigation No 4.8.9 mentions a concrete wastewater plan. Who is responsible for this? Mitigation No 4.8.10 should include the preparation of a Construction Environmental Management Plan, training for employees, and a spill response plan. Responsible parties should also be identified. Mitigation measures should also include water quality monitoring during operations, fish sampling and monitoring plans, fish offsetting monitoring, fish tissues for contaminants if water quality is an issue, water flow monitoring and an adaptive management plan.	Details on measures pertaining to fish and fish habitat such as construction monitoring, additional construction mitigation measures, best management practices, wastewater treatment, erosion and sediment control, and compliance monitoring will be provided in the Marine and Freshwater Resources Management Plan developed for the project. Requirements for both effectiveness and compliance monitoring for project related fish habitat offsets will be described in the Fish Habitat Offsetting Plan for the project.
2273.1	round 1	Gitxaala Nation	4.8.5.3	Freshwater Fish and Fish Habitat	Acidification and Eutrophication: "Acidification is not expected in 92% of lakes and streams in the LAA assessed for three of the four case scenarios…" Which three scenarios? And what happens in the fourth? "Overall, no changes in pH above the biological limit are anticipated, and no fish mortality is anticipated as a result of acidification." What about pH below the lower threshold of 6.5? This is acidification, and many watercourses are already well below this. J7 is expected to receive above the critical threshold for Nitrogen. While no CRA fish species were present (three spine stickleback were), what will this do to the stickleback, and the downstream CRA fish-bearing watercourse reaches including J5 and associated reaches?	The four emissions cases that were modelled are the Base case, Application case, Project case and Cumulative effects assessment (CEA) case. Under the Base case, three lakes (ADSW9, LAK12, LAK13) show a predicted critical load exceedance indicating that at baseline conditions these lakes are acid sensitive. Zero depositional input would result in a modelled critical load exceedance for these lakes due to low acid neutralizing capacity, low pH and alkalinity. Therefore, for the Project and Application case (which incorporate estimated deposition from project and background emissions) these three lakes also indicate a modelled exceedance to the critical load. For the CEA case, (which incorporates estimated deposition from project, background and future regional industrial emissions) two additional lakes (NC309 and NC366) show a predicted critical load exceedance. For the CEA case, three streams have also been predicted to have a pH change above 0.3 units (conservative biological threshold). The model used to predict pH changes relates pH to acid neutralizing capacity which was based on lake systems as there isn't an applicable stream system. The model may overestimate effects to streams as streams have higher rates of water renewal due to water flow. Cumulative emissions can be considered conservative as they incorporate some regional projects that are not expected to be implemented. In addition, a more conservative threshold of 0.3 was chosen to align with previous regional studies, however pH changes of up to 0.4 are still considered protective of aquatic biota. Modelled pH changes for these three streams are at or below the 0.4 threshold. It is anticipated that lakes and streams that indicate predicted exceedances will be incorporated into the followup monitoring program for acidification and eutrophication.
2274.1	round 1	Gitxaala Nation	4.8.5.4	Freshwater Fish and Fish Habitat	Table 4.8-16: See comments from Table 4.8-10	Potential changes in food and nutrient supply are assessed in Section 4.8.5.2 under vegetation clearing during the construction phase of the project as the majority of allochthonous food and nutrient inputs in project area watercourses are afforded by insect and leaf litter drop from stream side vegetation.
2275.1	round 1	Gitxaala Nation	4.8.5.4	Freshwater Fish and Fish Habitat	Excavation: "Lower flows may limit access to upper reaches of watercourses, as well as cause increased water temperatures, changing the use of existing habitat." How will this be predicted (modelled?), monitored or mitigated?	No effect on water quantity/base flows is expected as flows will be maintained within watercourses that will remain in the PDA (J1-5 and J1.1). Runoff from areas within the PDA will be collected, diverted around project infrastructure, and returned to the same drainage downstream, if possible; otherwise it will be directed through a storm water system and released into the marine environment Delusion Bay. Storm water or wastewater from the site will be tested and treated, if required, to meet regulatory requirements prior to being discharged.
2276.1	round 1	Gitxaala Nation	4.8.5.4	Freshwater Fish and Fish Habitat	Avoidance: "Mitigation of serious harm to CRA fish under the Fisheries Act, through the loss of freshwater habitat, will be through the development and implementation of the fish and fish habitat offsetting plan, with the goal to achieve an overall no-net loss of the productive capacity of the freshwater environment on Digby Island." Productive capacity must include food, nutrients, water quality and quantity. Loss of upstream habitat will impact downstream reaches that are being retained, thus a decreasing productive capacity with changes in food, nutrients, water flows, temperature and other potential water quality parameters. In addition, offsetting habitat must be in place and functioning as intended prior to impacts for a "no-net loss".	There are no measurable changes to habitat productivity expected in the retained watercourses (J1.1 and J5). All offset habitat created for the project will be of similar or better quality to the habitat lost through project development, and therefore overall productivity of the fishery will be maintained. Within the detailed offset plan for the project, any time lags between loss of the original habitat and confirmed functionality of the offset habitats will be considered in habitat balance calculations, and additional offsets or mitigation measures may be required to account for these time lags.
2277.1	round 1	Gitxaala Nation	4.8.5.4	Freshwater Fish and Fish Habitat	CRA Fish Species Distribution and Abundance: Catch per unit effort measurements shown are only applicable for seine netting, and do not represent the fish sampling program as a whole.	The catch per unit effort (CPUE) results referenced in section 4.8.5.4 include electrofishing effort and seining. The range provided was to demonstrate that a wide range of fish densities were present in the project areas, but overall number of captured fish, per unit of effort, were not high. Additional details on CPUE are provided in Section 4.8.3.2 and in the technical report in Appendix K.
2278.1	round 1	Gitxaala Nation	4.8.5.4	Freshwater Fish and Fish Habitat	Summary: Negligible to low magnitude effects are only manageable if offsetting habitat is functioning as intended prior to impacts. See comment above regarding avoidance and productive capacity. Will lost habitat be re-opened during decommissioning?	Aurora LNG will conduct effectiveness monitoring on all offset habitat constructed. The effectiveness monitoring will assess the offset habitat against specific parameters to confirm that the habitat functions as proposed. In the event that offset habitat does not function as intended, Aurora LNG will be required to implement additional mitigation measures or create additional habitat so that there is no detrimental effect to the productivity of the local fisheries. Aurora LNG will revegetate the site and restore drainage patterns, where possible, as part of the decommissioning phase of the Project which will reconnect upstream habitats to downstream habitats. Aurora LNG will engage with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the Decommissioning and Abandonment Plans.
2279.1	round 1	Gitxaala Nation	4.8.5.4	Freshwater Fish and Fish Habitat	Likelihood of Residual Effects We disagree with the residual effects assessment. Only 60/106 watercourse reaches sampled. Loss of food, nutrients, and water flow. And loss of potential fish habitat - just because fish are not present currently (or not sampled), this does not mean the watercourse does not have the potential to have fish in the future.	While only a subsample of watercourse reaches identified on Digby Island were sampled (57%), the selected watercourse reaches included watercourse reaches that may be affected by the Project. The subsample was selected to provide a representation of the freshwater communities within, and in the vicinity of, the Project area. Data from ground surveys were used to complement and verify results of the desktop review. As the watercourses being retained within the PDA will have undisturbed riparian buffers and mostly undisturbed upstream areas there are no measurable changes to habitat productivity due to loss of food, nutrients, or flow expected in these watercourses.
2280.1	round 1	Gitxaala Nation	4.8.6.1	Freshwater Fish and Fish Habitat	Please describe how a loss of 1/3 of the available fish habitat in the LAA is considered a "relatively small area of the available fish habitat".	The description of the loss of fish habitat was meant only as a frame of reference to the scale of habitat available in the LAA; the loss of approximately 33% of the available habitat within the LAA means that 67% of the habitat would be retained. These losses would be mitigated by offsetting such that the productivity of the local fishery would be maintained or potentially improved. The loss of habitat is smaller when compared to the remaining habitat within a 10 km radius of the PDA (i.e., within the RAA) which also contributed to the productivity of the fishery.
2281.1	round 1	Gitxaala Nation	4.8.6.3	Freshwater Fish and Fish Habitat	Cumulative Effects Mechanisms: "Important habitats within fish-bearing watercourses in the LAA that are permanently altered or destroyed by Project activities, that overlap spatially and temporally with effects from other projects, can affect overall productivity of the fishery before disturbed habitats can recover or offset habitats become fully functional." Offset habitat must be functional before impacts take place.	The detailed offset plan will consider time lags in the function of offset habitats when calculating the Project's offsetting habitat balance. Typically, additional offsets or mitigation measures may be required to account for an increased time lag between habitat changes and offsetting. Offsetting requirements will be determined during the permitting phase of the Project.
2282.1	round 1	Gitxaala Nation	4.8.6.3	Freshwater Fish and Fish Habitat	Cumulative Effects Mitigation: "With the application of mitigation identified in Section 4.8.5.2, along with the offsetting measures described in the Project specific CFHOP, the losses of fish habitat productivity, due to Project construction and operational activities, will be effectively counterbalanced." We disagree with this statement. Effects have not fully been described or considered and productivity will most certainly be affected.	Aurora LNG acknowledges the comment from Gitxaala Nation. Fish habitat impacts resulting in serious harm to fish (which includes both permanent alteration of habitat and the death of fish) associated with the project will be counterbalanced by offset measures that will be determined in a detailed fish habitat offset plan for the project. The plan will be part of an authorization application under the Fisheries Act. As effective offsetting is federally legislated, by law, any losses of productivity to fisheries will be balanced by productivity increases associated with offset measures, and the net residual effect to fisheries productivity will be negligible.
2283.1	round 1	Gitxaala Nation	4.8.6.3	Freshwater Fish and Fish Habitat	Residual Cumulative Effects: "The area of instream fish habitat affected by the Project represents 33% of the available fish habitat in the PDA/LAA." The PDA and the LAA are not the same. Please fix. What is the fate of the watercourse reaches not surveyed? "No loss of spawning habitat is predicted due to the development of the Project." This statement is simply not true. J2.1, J3.1 are reaches that contain spawning habitat that will not be retained.	Agreed, the LAA and the PDA do not represent the same area. This should have been written as only the PDA ("The area of instream fish habitat affected by the Project represents 33% of the available fish habitat in the PDA"). An errata document is being compiled that captures these corrections and it will be filed with the BC EAO. Watercourse reaches that have not been surveyed for fish presence or habitat are outside of the PDA, and do not have a direction connection to the PDA. These watercoursesand will be retained and no habitat removal or clearing will occur in these areas; therefore, not all watercourse were ground-truthed in these areas. All watercourses within the PDA that will be removed for project development have been surveyed for fish presence or habitat, with the exception of those streams that were identified by LiDAR only and could not be ground-truthed (identified by a 'L' at the end of the watercourse identifier). Additionally, watercourse reaches or are upstream of a known not fish-bearing reach, with a confirmed barrier to fish passage, were not all sampled for fish presence. The basis of the serious harm for fish habitat accounted for all fish habitat within the PDA to be infilled with the exception of J5 and J1.1. Fish habitat losses associated with the project will be counterbalanced by offset measures that will be determined in a detailed fish habitat offset plan for the project. The plan will be part of an authorization application under the Fisheries Act, which stipulates that all "serious harm" to fish (which includes both permanent alteration of habitat and the death of fish), which cannot be mitigated or avoided, must be counterbalanced by appropriate offset measures. As effective offsetting is federally legislated, by law, any losses of productivity to fisheries will be balanced by productivity associated with offset measures, and the net residual effect to fisheries productivity will be negligible.
2284.1	round 1	Gitxaala Nation	4.8.6.3	Freshwater Fish and Fish Habitat	Residual Cumulative Effects: Consistent argument that the Project effects represent a "relatively small area" of the available fish habitat. This is meaningless argument unless it can be backed up with numbers and facts stating this loss is not significant. "…the fish habitat offsetting plan will be designed to achieve an overall net gain in fish productivity, and there is no predicted population-level effects to anadromous fish species in the RAA." This is the first mention of the offsetting plan having a "net gain". Why has this only been mentioned at this point in the assessment?	Use of the term "relatively small area" was used as a frame of reference to indicate that the area of loss (10,857 m2 or 33% of the total available habitat) was relatively small in comparison to the amount of available fish habitat in the LAA (32,752 m2) and the amount of fish habitat that would remain in the LAA (21,895 m2 or 67% of the total available habitat). The final offset plan (as approved by DFO) will provide more habitat and/or higher quality habitat than will be lost due to construction of the project. The offset ratio will take in to account any uncertainties in fish production and any time lags that may result. The final agreed to gain-to-loss ratio will provide, at a minimum, enough habitat creation, enhancement, or restoration to offset the CRA fish production lost due to habitat losses caused by the project as required by the Fisheries Protection Policy Statement.
2285.1	round 1	Gitxaala Nation	4.8.6.3	Freshwater Fish and Fish Habitat	Summary: "This cumulative effect is anticipated to be reversible immediately after reclamation of the site." This statement is simply false. Restoring filled in watercourses that have been buried for approximately 30 years will take time to become functional. How long will reclamation take? How long until the watercourses are functional?	There will be no net cumulative effect on change in fish habitat as all adverse effects on fish habitat will be offset as legislated under the federal Fisheries Act. If there is a time lag between the time habitat is adversely affected and the time created offset habitat is completed and functional, there will be a temporal effect that will be reversed once offset habitats are functional. Any temporary loss of productivity will be accounted for in the habitat balance specified in the detailed habitat offset plan developed for the project. Fish habitat losses associated with the project will be counterbalanced by offset measures that will be determined in a detailed fish habitat offset plan for the project. The plan will be part of an authorization application under the Fisheries Act, which stipulates all "serious harm" to fish (which includes both permanent alteration of habitat and the death of fish), which cannot be mitigated or avoided, must be counterbalanced by appropriate offset measures. As effective offsetting is federally legislated, by law, any losses of productivity to fisheries will be balanced by productivity associated with offset measures, and the likelihood of a net residual effect is low. The statement in Section 4.8.6.3 will be revised to read: Residual effects are anticipated to be reversible once offset habitats are functional and consequently there are no predicted cumulative effects. An errata document is being compiled that captures these corrections and it will be filed with the BC EAO.

2286.1	round 1	Gitxaala Nation	4.8.6.3	Freshwater Fish and Fish Habitat	Likelihood of residual cumulative effects: Likelihood has been considered low. We disagree based on the arguments addressed above.	Fish habitat losses associated with the project will be counterbalanced by offset measures that will be determined in a detailed fish habitat offset plan for the project. The plan will be part of an authorization application under the Fisheries Act, which stipulates all "serious harm" to fish (which includes both permanent alteration of habitat and the death of fish), which cannot be mitigated or avoided, must be counterbalanced by appropriate offset measures. As effective offsetting is federally legislated, by law, any losses of productivity to fisheries will be balanced by productivity associated with offset measures, and the likelihood of a net residual effect is low. There will be no net cumulative effect on change in fish habitat as all adverse effects on fish habitat will be offset as legislated under the federal Fisheries Act. If there is a time lag between the time fish habitat is adversely affected and the time when created offset habitat is completed and functional, there will be a temporal effect which will be reversed once offset habitats are functional. Any temporary loss of productivity will be accounted for in the habitat balance specified in the detailed fish habitat offset plan developed for the project. A correction will be made to Section 4.8.6.3 so that the statement reads: Residual effects are anticipated to be reversible once offset habitats are functional and consequently there are no predicted cumulative effects. An errata document is being compiled that captures these corrections and it will be filed with the BC EAO.
2287.1	round 1	Gitxaala Nation	4.8.6.4	Freshwater Fish and Fish Habitat	Concerns re: acidification: Please explain how five lakes anticipated to exceed critical loads for acidification for the CEA case are not expected to have concerns for acidification. Please show, do not just reference. What about J7? This waterbody has not been mentioned in this section. Section also references the LAA, which should be the RAA for cumulative effects."Additional studies may be needed to determine the accuracy of the predictions and the potential effects of acidification on fish health on the Project area." Please indicate when these studies will be undertaken and when results will be incorporated.	The four emissions cases that were modelled are the Base case, Application case, Project case and Cumulative effects assessment (CEA) case. Under the Base case three lakes (ADSW9, LAK12, LAK13) (see Section 4.5) show a predicted critical load exceedance, indicating that at baseline conditions these lakes are acid sensitive. Zero depositional input would result in a modelled critical load exceedance for these lakes due to low acid neutralizing capacity, low pH and alkalinity. Therefore, for the Project and Application case (which incorporate estimated deposition from project and background emissions) these three lakes also indicate a modelled exceedance to the critical load. For the CEA case, (which incorporates estimated deposition from project, background and future regional industrial emissions) two additional lakes (NC309 and NC366) show a predicted critical load exceedance. For the CEA case, three watercourses (TT1, J6 and J1/2) have also been predicted to have a pH change above 0.3 units (conservative biological threshold). Watercourse J7 is not predicted to have this change. It is anticipated that lakes and streams that indicate predicted exceedances will be incorporated into future monitoring programs to monitor pH changes. Details of the proposed follow-up program on acidification and eutrophication (noted in Table 15-1 of the Application) will be determined in coordination with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended). Note that this program would be to monitor any changes that may occur during facility operations. LAA references are to provide details on the location of the modelled effects, the RAA is specifically indicated in the discussion on cumulative and residual effects in section 4.8.6.4.
2288.1	round 1	Gitxaala Nation	4.8.6.5	Freshwater Fish and Fish Habitat	CPUE numbers are only for seining results. Not representative of fish populations as a whole for the study.	The CPUE results referenced in section 4.8.6.5 include electrofishing effort and seining. The range provided was to demonstrate that a wide range of fish densities was present in the project areas, but overall number of captured fish, per unit of effort, was not high. Additional details on CPUE are provided in section 4.8.3.2 and in the technical report in Appendix K.
2289.1	round 1	Gitxaala Nation	4.8.6.5	Freshwater Fish and Fish Habitat	Assumption that the LAA supports only a small population of fish for a "portion of their life cycle" as justification for impacts is inappropriate. The portion of the life cycle within the LAA for CRA species is highly important. Overwintering habitat is generally considered a limiting factor for salmonid populations, and spawning habitat is critical.	The assumption will be revised as follows: The majority of watercourses in the LAA support a small population of CRA fish species for a portion of their life cycle. The project design has been modified to retain watercourses in which CRA populations carry out one or more critical life-stages. These watercourses include J1-5 and J1.1, which contain the highest quality, deep channel habitat in the LAA, and which provides fish opportunities to carry out critical stages in their life-cycle (e.g., spawning. overwintering). An errata document has been created that captures these corrections and it will be filed with the BC EAO.
2290.1	round 1	Gitxaala Nation	4.8.9	Freshwater Fish and Fish Habitat	Follow-up monitoring is absolutely necessary. Monitoring should include water quality, water/flow levels, fish abundance and distribution, benthic or macro invertebrates, and must include monitoring of the offsetting habitat. This is important to determine if impacts to watercourses are indeed negligible, or require further mitigation or adaptive management.	Compliance monitoring will occur to verify implementation of Project mitigation measures and adherence to regulatory requirements of permits, authorizations and EAC conditions (see Section 15.3 of the Application). Requirements for both effectiveness and compliance monitoring for project related habitat offsets will be described in the Project fish habitat offset plan, which will follow the Fisheries Productivity Investment Policy: A proponent's Guide to Offsetting, as required by DFO to meet the requirements for permitting and offsetting under the Fisheries Act.
2291.1	round 1	Gitxaala Nation	4.9.4	Marine Fish and Fish Habitat	During screening, the proponent responded to our comment (screening IR #112) with the answer found in column g (proponent response). We believe that there is still outstanding information and require the additional question(s) posed in column h be responded to. See screening comment #112: Information regarding potential effects of cooling tower effluent have not been identified Working Group Determination of Status column : Please indicate the size and extent of the mixing zone and the fisheries exclusions zone surrounding the outfall	Modelling will be conducted as part of Project design to determine the size and extent of the outfall effluent mixing zone and the results will inform the Project permitting stage. No fishery exclusions zones around the cooling water outfall are anticipated because there are no health or safety concerns associated with the effluent. See the "Discharge to the Marine Environment" technical memo for more details. The technical memo will be filed with the BC EAO.
2292.1	round 1	Gitxaala Nation	4.9.5	Marine Fish and Fish Habitat	During screening, the proponent responded to our comment (screening IR #116) with the answer found in column g (proponent response). We believe that there is still outstanding information and require the additional question(s) posed in column h be responded to. For as Gitxaala's excel of their IR comments: Screening comment IR 116 -In some cases, mitigation measures are not described in sufficient detail to evaluate their efficacy. This will be addressed further at review stage. Proponent Response - The mitigation measures identified in the Marine Fish and Fish Habitat VC are based on an understanding of existing conditions, expected construction methods and timing, professional experience with similar projects in the Pacific North Coast of BC, and industry-accepted best management practices. In most cases, mitigation measures proposed for marine fish and fish habitat are standard and have been proven to be effective. As per the Application Information Requirements, each mitigation measure was described in terms of how it will mitigate potential effects on marine fish and fish habitat (i.e., the mechanism), why it was chosen (i.e., rationale), its expected success, potential risks and uncertainties associated with the measure (if any), the time required for it to become effective, and the Project phase during which the measure will be implemented. Additional details on the mitigation measures will be provided in the Marine and Freshwater Resources Management Plan. WG determination status of Proponent Response column - The proponent indicates a methodology (mechanism, rationale, expected success, risks, uncertainties) in the response provided. It is Gitxaala's position that the details regarding mitigation (the "how") are insufficient to be able to evaluate the success of the measures proposed. In the absence of details regarding implementation, it is not possible for external reviewers to test the hypothesis that the mitigation will be sufficiently successful to justify a determination of "no significant effect following mitigation." Gitxaala therefore reiterates its request for a description of detailed mitigation measures that include, among other things, thresholds for adaptive management.	An understanding of the effectiveness of mitigation measures can be taken from their application on other projects. These past examples serve as 'field tests' of "the hypothesis" that the mitigation is effective. This consideration was given to all mitigation measures and is implicit in the development of best-management practices, which Aurora LNG has adopted wherever applicable. With regards to effectiveness of mitigation measures on the present Project specifically, the EA process accommodates for the fact that the only absolutely certain way to "test the hypothesis that the mitigation will be sufficiently successful to justify a determination of no significant effect following mitigation" is to monitor Project effects during and after construction. As such, Aurora LNG has committed to compliance monitoring and to a series of follow-up programs, while recognizing that additional follow-up programs may be identified through consultation and engagement. Finally, it is standard EA practice to provide the level of detail included in the present application regarding mitigation measures. Further details are refined and described in management plans and monitoring programs once Project design is completely finalized. To this end, Aurora LNG has committed to develop a suite of Environmental and Operational Management Plans. Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended).
2293.1	round 1	Gitxaala Nation	4.8.2.2 and Table 4.9-2	Freshwater Fish and Fish Habitat	Note that vessel wake is also a concern as it may affect safety of harvesters on shore or while fishing. Study designs need to consider this in order for the conclusions to be meaningful when carried forward to Part C.	The assessment of potential project effects on intertidal harvesters working on shore conservatively assumed that the harvesters are using both low tide periods in a day (this is unlikely, as the two low tides in a day are not often the same tidal height and, therefore, one is more suitable for harvesting than the other), and harvesting can be undertaken for two hours during each low tide (i.e., one hour on each side of each low), then approximately 17% (4/24 hours) of each day is available for intertidal harvesting. The potential for intertidal harvesters to interact with Project-related shipping is temporally restricted on a daily basis; for approximately 83% of each day, wake from Project-related shipping cannot interact with intertidal harvesters The potential for Project-related ship wake to interact with fishing vessels on the water is also temporally limited. Please refer to the "Effects of Lost Fishing Time" technical memo for a description of conditions that must be met for a fisher-LNG carrier interaction to occur. The rationale outlined in that memo also applies to wake effects. The technical memo will be filed with the BC EAO. Section 6.5.4.2 states that the mean monthly average natural wave height in the Project area is assumed to be between 0.14 m and 1.8 m. The potential maximum wave height (immediately adjacent to the source vessel) of 0.4 m produced by LNG carriers and escort vessels at 12 knots is within the range of anticipated mean monthly average wave height in the Project area. The modeled wake height of LNG carriers (and other vessel types) indicates that wake-related waves attenuate as they travel further from the source vessel (Oceanic Consulting Corporation 2014). This means that the actual wave height when it reaches the shoreline or a fishing vessel is expected to be lower than the original wake height at the source vessel, and within the natural wave height range currently experienced by shoreline harvesters and fishing vessels. Moreover, Project-related traffic will travel along the existing and established shipping route currently used by other marine traffic (e.g., container ships, cargo ships, breakbulk ships, ferries) to access the Port of Prince Rupert. The predicted wake-related wave height 300 m from the centreline of travel of a large loaded LNG carrier traveling at 12 knots (and that modeled for 14 knots) is similar to those predicted for ore carriers, cruise ships, and BC Ferries vessels (Oceanic Consulting Corporation 2014), all of which call at the Port of Prince Rupert. Project-related wake effects are not expected to differ from the variable wave heights and conditions already experienced by fishing vessels and shoreline harvesters, relating to natural weather patterns and existing shipping. Consequently, no significant effects from Project generated wake are predicted. Reference Oceanic Consulting Corporation. 2014. Kitimat Ship Wake Study. Prepared for: LNG Canada Development Inc.
2294.1	round 1	Gitxaala Nation	4.9.2.8	Marine Fish and Fish Habitat	The significance threshold is noted as an effect "that threatens the long-term persistence of a marine fish population." Please provide a definition of "persistence" as it relates to population numbers or percentage of population affected and the relationship to viability. Please also indicate whether salmon species have been assessed by river of origin as some populations may be disproportionately affected by impacts. This is relevant to First Nations harvesting, as harvest locations may be determined by cultural rules rather than by presence of alternative harvesting opportunities.	Population-level inference was determined based on existing information relating to (a) environmental and regulatory guidelines, and (b) the ecology of those species likely to be affected. Specifically, for (b), we focused on issues such as their use and dependency on the area being affected, the life stage affected, availability of similar habitat elsewhere, and the potential for that effect to interrupt a life process on a scale that could cause harm at the population level. This inference considers the biology and ecology of the taxa affected, such as (but not limited to) life-history, reproductive rate, feeding ecology, larval ecology (pelagic dispersal and resulting connectivity), and migratory behaviour. It also considers known information on environmental perturbations that those species are exposed to, and their resilience to those perturbations given their biology and ecology. With regards to the river of origin, it stands to reason that salmon from all salmon-bearing tributaries within the Skeena River must migrate through the river's mouth in order to reach the ocean or from the ocean to reach spawning tributaries. Since the Project lies within the Skeena estuary, Aurora LNG assumed that salmon from all salmon-bearing tributaries of the Skeena would be present within the area, and could therefore interact with the Project. Aurora LNG also assumed that salmon from other (non-Skeena) local and regional watersheds would be present in the marine area. Note that Aurora LNG will offset any residual serious harm to salmon resulting from changes to fish habitat or fish mortality resulting from the project.
2295.1	round 1	Gitxaala Nation	4.9.4	Marine Fish and Fish Habitat	The Application states that effects of plant operation "Are anticipated to primarily interact with the terrestrial environment…Therefore, potential effects associated with natural gas treatment and natural gas liquids extraction activities are not included in this assessment." This is an inappropriate approach to EA: cooling water from operations will be discharged to the marine environment so a potential pathway of effects exists. A defensible rationale for exclusion of this pathway of effects must be provided or the effect must be assessed. Please provide a rationale for the choice to exclude an effects assessment of cooling water release or assess this effect.	Potential effects to fish and fish habitat resulting from waste discharges to the marine environment are assessed in the Marine Fish and Fish Habitat assessment under Project Mechanisms for Change in Health, Section 4.9.5 of the Application. This section details the mechanisms for change in fish health due to waste discharges during construction, operation, and decommissioning. The assessment identifies waste discharges during construction and operations, including power generation cooling water and treated sanitary wastewater (which may include chlorine content). Mitigation 4.5.8 in Table 4.9-20 covers waste discharges to the marine environment. Potential residual effects are assessed in the Characterization of Residual Effects for Change in Fish Health, under Construction – Waste Management, and Operations – Waste Management. The fish and fish habitat assessment did not assess waste discharge characteristics (e.g. temperature, chlorine concentration) individually. Instead, the potential for all waste discharges to affect fish health was assessed. Waste discharges, regardless of make up, are managed in the same manner; permit conditions limit the quality and quantity of the waste discharged and impose monitoring requirements. Aurora LNG is legally-obliged to abide by permit conditions, which are designed to protect marine life. Therefore, waste discharge effects to fish and fish habitat were considered not significant. The assessment of potential effects to fish and fish habitat resulting from waste discharges is supported by information from the Marine Water Quality assessment (Section 4.5.11 of the Application). A significant residual adverse environmental effect on marine water quality is one that is predicted to result in a change in sediment or water quality that would result in a health risk to a local population of marine biota. The marine water quality assessment therefore covers changes in water quality that may significantly affect fish and fish habitat. Table 4.5-19 in the Marine Water Quality section lists Project-related wastewater inputs to the marine environment as a project effect mechanism, and potential effects of this mechanism are assessed in Section 4.5.15. Mitigations 4.5.8 and 4.8.9 in Table 4.5-26 cover waste discharges to the marine environment. Potential residual effects to marine water quality related to waste management are characterized in the Characterization of Residual Effects component of Section 4.5.15.3. Further details on project waste discharges and associated regulations, are provided in the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2296.1	round 1	Gitxaala Nation	4.9.5	Marine Fish and Fish Habitat	The Application notes that maintenance dredging may be required approximately once per decade. This represents and operational effect that must be considered. Please assess the effects of maintenance dredging.	The marine fish and fish habitat assessment considered potential effects associated with maintenance dredging under the 'change in habitat' effect (Section 4.9.5.2) and the 'change in mortality risk' effect (Section 4.9.5.4).
2297.1	round 1	Gitxaala Nation	4.9.5	Marine Fish and Fish Habitat	Were residual effects of sediment disposal on glass sponges and cold water sponges known to be present at the disposal location (ROV study results, PNLWLNG) assessed? Please indicate the sections in the relevant TDRs that include this discussion.	Please see the technical memo titled "Brown Passage: Characterization of Existing Conditions and Potential Effects associated with Disposal at Sea" which will be filed with the BC EAO.

2298.1	round 1	Gitxaala Nation	4.9.5	Marine Fish and Fish Habitat	A pathway of potential effects exists between liquid effluent and fish/fish habitat. A discussion of potential effects from cooling water release and/or release of residual chlorine in treated wastewater appears to be absent. Please indicate where these potential effects are discussed or provide a rationale for their exclusion.	Potential effects to fish and fish habitat resulting from waste discharges to the marine environment are assessed in the Marine Fish and Fish Habitat assessment under Project Mechanisms for Change in Health, Section 4.9.5 of the Application. This section details the mechanisms for change in fish health due to waste discharges during construction, operation, and decommissioning. The assessment identifies waste discharges during construction and operations, including power generation cooling water and treated sanitary wastewater (which may include chlorine content). Mitigation 4.5.8 in Table 4.9-20 covers waste discharges to the marine environment. Potential residual effects are assessed in the Characterization of Residual Effects for Change in Fish Health, under Construction – Waste Management, and Operations – Waste Management. The fish and fish habitat assessment did not assess waste discharge characteristics (e.g. temperature, chlorine concentration) individually. Instead, the potential for all waste discharges to affect fish health was assessed. Waste discharges, regardless of make up, are managed in the same manner; permit conditions limit the quality and quantity of the waste discharged and impose monitoring requirements. Aurora LNG is legally-obliged to abide by permit conditions, which are designed to protect marine life. Therefore, waste discharge effects to fish and fish habitat were considered not significant. The assessment of potential effects to fish and fish habitat resulting from waste discharges is supported by information from the Marine Water Quality assessment (Section 4.5.11 of the Application). A significant residual adverse environmental effect on marine water quality is one that is predicted to result in a change in sediment or water quality that would result in a health risk to a local population of marine biota. The marine water quality assessment therefore covers changes in water quality that may significantly affect fish and fish habitat. Table 4.5-19 in the Marine Water Quality section lists Project-related wastewater inputs to the marine environment as a project effect mechanism, and potential effects of this mechanism are assessed in Section 4.5.15. Mitigations 4.5.8 and 4.8.9 in Table 4.5-26 cover waste discharges to the marine environment. Potential residual effects to marine water quality related to waste management are characterized in the Characterization of Residual Effects component of Section 4.5.15.3. Further details on project waste discharges and associated regulations, are provided in the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2299.1	round 1	Gitxaala Nation	Table 4.9-11	Marine Fish and Fish Habitat	Please note that Mitigation respecting last risk window timing for blasting, dredging, and disposal needs to be added.	The intent of Table 4.9-11 was to identify mitigation measures that will be implemented during construction, operations, and decommissioning activities to avoid or reduce potential changes in habitat. Potential changes in habitat are not expected to be influenced by the timing of dredging, disposal at sea, and underwater blasting activities, and as a result, mitigation measures in 4.9.8 (related to restricting dredging and disposal at sea to the least risk timing window) and 4.9.9 (related to restricting underwater blasting to the least risk timing window) were not included in Table 4.9-11. Aurora LNG is committed to conducting dredging, disposal at sea, and underwater blasting activities within the least risk timing window (November 30 - February 15), unless otherwise approved by DFO.
2300.1	round 1	Gitxaala Nation	Table 4.9-11	Marine Fish and Fish Habitat	No mitigation is present to address potential temperature and chemistry effects (Cl) of cooling water release.	Cooling tower blowdown water will meet CCME and BC water quality guidelines for temperature, outside of the mixing zone. These guidelines allow a maximum change of ±1^{0}C from ambient at any time, location, or depth and a maximum rate of change <0.5^{0}C per hour. The exact size of the mixing zone is not yet known, and will be determined through modelling in the permitting phase. However, under the Fisheries Act, waste discharges within and outside the mixing zone, cannot be acutely toxic to fish. The effect of cooling tower blowdown waste discharge was assessed based on adherence to legally-binding legislation, designed to protect aquatic life. Further details on project waste discharges and associated regulations, are provided in the "Discharges to the Marine Environment" technical memo which will be filed with the BC EAO. The "Discharges to the Marine Environment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2301.1	round 1	Gitxaala Nation	page 4.9-48	Marine Fish and Fish Habitat	Typo. The area requiring offsetting should be in square metres (not metres).	Aurora LNG acknowledges the typing error. The reference to the amount of marine fish habitat that may require offsetting should have been expressed in metres squared (m2) and not in metres (m). An errata document is being compiled that captures these corrections and it will be filed with the BC EAO.
2302.1	round 1	Gitxaala Nation	page 4.9-49	Marine Fish and Fish Habitat	Please confirm that the regulatory guideline being used is the 24-hour guideline (5mg/L)	The regulatory guideline referred to in the following sentence "Given the expected requirement for offsetting, permanent alteration to substrate as a result of dredging is considered to exceed regulatory guidelines..." refers to the Fisheries Act which prohibits any work, undertaking, or activity that results in serious harm to fish.Aurora LNG will need to offset for any work that results in serious harm to fish. Serious harm to fish is defined by DFO (2013) as: a) the death of fish; b) a permanent alteration to fish habitat of a spatial scale, duration or intensity that limits or diminishes the ability of fish to use such habitats as spawning grounds, or as nursery, rearing or food supply areas, or as a migration corridor, or any other area in order to carr out one or more of their life processes; or c) the destruction of fish habitat of a spatial scale, duration or intensity that fish can no longer rely upon such habitat for use as spawning grounds, or as nursery, rearing or food supply areas, or as a migration corridor, or any other area in order to carry out one or more of their life processes. Although it is not relevant to the paragraph referenced, which discusses thresholds for serious harm to fish, elsewhere in the application the 24 hour (5 mg/L) threshold is used for purposes of water quality monitoring (e.g. 4.9.5.5, in particular page 4.9-103 "ANTICIPATED TSS LEVELS DURING DISPOSAL AT SEA"). Reference: Fisheries and Oceans Canada [DFO]. 2013. Fisheries Protection Policy Statement. Ecosystem Programs Policy. Ottawa, Ontario. 22 pp.
2303.1	round 1	Gitxaala Nation	page 4.9-52	Marine Fish and Fish Habitat	Please indicate the expected seasons/months in which the 4 referenced disposal periods will occur. Please also indicate the number of disposal events in each disposal period.	A sediment transport model was used to predict sediment dispersion and deposition associated with disposal at sea activities (Appendix H, Technical Memorandum – Aurora LNG: Disposal at Sea Modelling). The model assumed that dredged material destined for disposal at sea would be disposed of during the DFO least risk timing window (i.e., November 30-February 15) over the course of two years. Dredgeate removed from the MOF, Berth 1 North, and Berth 1 South would be disposed of in year 1, while dredgeate removed from Berth 2 would be disposed of in year 2. Each of the four dredge pockets is associated with a disposal period that is identified in the following tables in Appendix H: Table 4-1 (MOF), Table 4-2 (Berth 1 North), Table 4-3 (Berth 1 South) and Table 4-4 (Berth 2). These tables also indicate the total number of disposal events (or 'trips') within each disposal period.
2304.1	round 1	Gitxaala Nation	page 4.9-52	Marine Fish and Fish Habitat	The Application states that "communities in this area have been previously exposed to sediment deposition and are anticipated to recover to these baseline conditions within one to five years". Glas sponges and cold water corals are present in the disposal area. Recovery rates of these species are unknown but are likely to be longer given sensitivity to sediments and slow growth rates. Please indicate for the presence of sensitive, slow-growing species in the characterization of residual effect.	Please see the technical memo titled "Brown Passage: Characterization of Existing Conditions and Potential Effects associated with Disposal at Sea"which will be filed with the BC EAO.
2305.1	round 1	Gitxaala Nation	page 4.9-70	Marine Fish and Fish Habitat	The application notes literature that identifies 95dB as the threshold above which salmonids respond to sound and also that impulsive sound causes greater response than continuous sound. To better understand project effects, it would be useful to see a figure derived from modelling which identifies the 95dB contour for dredging. Please provide this figure to enable a better understanding of the geographic scope of potential behavioral disturbance to salmonids.	As stated in the Application, Section 4.9, pp. 4.9-69 to 4.9-70, lower frequency (< 380 Hz) underwater sounds with sound pressure levels above 95 dB are expected to be within the audible range of Pacific salmon. The cited literature (Feist et al. 1996; citing Hawkings and Johnstone 1978) does not, however, identify 95 dB as a threshold above which salmon respond to underwater sound. A figure showing the expected spatial extent of audible detection of a sound source by salmonids is therefore not considered a suitable proxy for the spatial extent of their potential behavioural disturbance. Reference Feist, B. E., J. J. Anderson and R. Miyamoto. 1996. Potential impacts of pile driving on juvenile pink (Oncorhynchus gorbuscha) and chum (O. keta) salmon behaviour and distribution. Fisheries Research Institute, School of Fisheries, University of Washington. FRI-UW-9603. pp. 58.
2306.1	round 1	Gitxaala Nation	page 4.9-76 AND	Marine Fish and Fish Habitat	The Application notes that herring are noted to reorient in response to vessel noise at a distance of up to 1000 m from the vessel in a 40-degree arc around the bow. What is the rationale for using a distance threshold of 400m as the distance from vessels within which fish will be disturbed rather than the more conservative value of 1000m?	Herring are able to detect underwater sounds over a broader frequency range than the majority of fish species and have the ability to determine the location of a sound source within a distance of at least 400 m (Schwarz and Greer 1984). As stated in the Application (Section 4.9 p. 4.9-77), although Misund et al. (1996) report individuals reorienting themselves to the path of approaching vessels at distances between 25 m and 1,000 m, the majority of individuals responded at a distance that aligned with the 400 m distance identified by Schwarz and Greer (1984). References: Misund, O.A., J.T. Øvredal and M.T. Hafsteinsson. 1996. Reactions of herring schools to the sound field of a survey vessel. Aquatic Living Resources 9: 5-11. Schwarz, A. L. and G. L. Greer. 1984. Responses of Pacific herring, Clupea harengus pallasi, to some underwater sounds. Canadian Journal of Fisheries and Aquatic Sciences 41: 1183-1192.
2307.1	round 1	Gitxaala Nation	Table 4.9-19	Marine Fish and Fish Habitat	The maximum distance at which injury threshold for type-3 fish is indicated to be 1,800m from the MOF. This is wider than the channel between Kaien and Digby Islands at the MOF location and therefore represents a complete sonic barrier to fish movement which will either require bahavioural change (avoidance) or lead to death. What is the rationale for characterizing this sound level effect on behaviour (as opposed to mortality) as low magnitude and assessing it as "not significant"?	The 1,800 m radius reported in Table 4.9-19 does not represent a 'sonic barrier', nor does it represent a zone of permanent injury or mortality. Rather, the 1,800 m radius is the maximum distance from impact pile driving at the MOF where type 2 and 3 fish (i.e., fish with swim bladders) may experience recoverable (i.e., non-lethal) injury. It is important to note that all thresholds reported in Table 4.9-19 are based on physiological effects to fish - not behavioural responses. Broadly applicable thresholds for behavioural response have not been established because different fish species and life stages vary in their response (e.g., avoidance response, startle response, no response) to various sound sources, intensities and frequencies (Popper et al. 2014). Furthermore, the duration of impact pile driving at the MOF and LNG Jetty will not be continuous (i.e., will consist of multiple regular events over the medium term). With the implementation of mitigation measures, residual adverse effects for change in behaviour during all Project phases are not expected to threaten the long-term persistence of a marine fish population and are, therefore, predicted to be not significant. Zeddies, and W.N. Tavolga. 2014. Sound Exposure Guidelines for Fishes and Sea Turtles. A Technical Report prepared by ANSI-Accredited Standards Committee S3/SC1 and registered with ANSI. Published by the Acoustical Society of America.
2308.1	round 1	Gitxaala Nation	4.10.3 (from screening)	Marine Wildlife - Marine Mammals	During screening, the proponent responded to our comment (found in column f which is screening IR #133) with the answer found in column g (proponent response). We believe that there is still outstanding information and require the additional question(s) posed in column h be responded to. As stated in the Gitxaala IR excel tracking submission table: Screening comment IR#133 -It is not clear that critical habitat areas, such as upwelling areas important for feeding, have been adequately identified or that the effect of increased shipping on marine mammal use of these areas has been addressed. This will be discussed further at review stage. Proponent Response -There is currently no designated critical habitat for marine mammals in the RAA. Identified DFO Important Areas for marine mammals were considered in the assessment of potential Project residual and cumulative effects. Both designated critical habitat and DFO Important Areas are referred to under Administrative Boundaries (Section 4.10-2-5) and, where applicable, are shown in Figure 4.10-2. Working Group Determination of Status -Upwelling areas are understood to be important as feeding areas for baleen whales. The area around Triple Islands is understood to be an upwelling area and grey whales have been identified feeding in this area. Has the proponent done any baseline work to undestand the value of the area around Triple Island as an upwelling/feeding area relative to other areas in the region? Has the proponent assessed the effect to baleen whale feeding/health of increased vessel traffic leading to reduced access or avoidance of this area?	The LAA is based on a 6 km buffer around the marine terminal and a 6 km buffer extending on either side of the shipping route, which extends from the marine terminal to the Triple Island pilot boarding station. The RAA extends from the marine terminal to west of the Triple Island pilot boarding station and encompasses Prince Rupert Harbour and most of Chatham Sound. Triple Island is therefore considered within both spatial boundaries used in the assessment of marine mammals (see Figure 4.10-1). The waters around Triple Island were surveyed as part of the marine mammal survey programs for the Aurora LNG Project (see Marine Mammals Technical Data Report - Appendix N of the Application), the PNW LNG project (Stantec 2016), and the LNG Canada project (LNG Canada 2014), results of all three of which were considered in the Aurora LNG assessment. Maps showing predictions of hotspots of high marine mammal density, as referenced in Section 4.10.7.1, are presented in Stantec (2016), which is available at the link below. The assessment of change in behaviour (including potential for adverse effects to foraging patterns and foraging success) considered the potential residual and cumulative effects of LNG shipping throughout the RAA (including at Triple Island). The marine mammal assessment was also informed by potential changes in the distribution or availability of prey resources as a result of Project-related activities, as identified in the marine fish and fish habitat assessment (see Section 4.9 of the Application). LNG Canada. 2014. LNG Canada Export Terminal. Marine Resources Technical Data Report. 236 pp + Appendices. Stantec Consulting Ltd. (Stantec). 2016. Pacific NorthWest LNG Project Marine Mammal Program Final Report. Prepared for Pacific NorthWest LNG Limited Partnership. Burnaby, BC. 154 pp. Available at: http://www.pacificnorthwestlng.com/media/Marine%20Mammal%20Final.pdf.
2309.1	round 1	Gitxaala Nation	4.10.5	Marine Wildlife - Marine Mammals	During screening, the proponent responded to our comment (found in column f which is screening IR#135) with the answer found in column g (which is proponent response). We believe that there is still outstanding information and require the additional question(s) posed in column h be responded to. As per Gitxaala's IR submission excel table Screening Comment 135: In some cases, mitigation measures are not described in sufficient detail to evaluate their efficacy. This will be addresssed further at review stage. Proponent Respones - The mitigation measures identified in the Marine Mammal VC are based on an understanding of existing conditions, expected construction methods and timing, professional experience with similar projects on the Pacific North Coast of BC, and industry-accepted best management practices. As per the AIR, each mitigation measure was described in terms of how it will mitigate potential effects on marine mammals (i.e., the mechanism), why it was chosen (i.e., rationale), its expected success, potential risks and uncertainties associated with the measure (if any), the time required for it to become effective, and the Project phase during which the measure will be implemented. Aurora LNG is of the opinion that this level of information is sufficient to support the assessment of Project residual effects on marine mammals. Additional details on the mitigation measures will be provided in the Marine and Freshwater Resources Management Plan. As noted in the Application, where uncertainty remains over the exact nature of these mitigation measures, this was accounted for in the assessment's prediction confidence and in the determination of significance. Aurora LNG looks forward to further discussing Gitxaala Nation's comment, Aurora LNG's response and the related proposed mitigation measures during the Application-review phase consultation activities that will be conducted under the Aboriginal Consultation Itinerary (which will be submitted on day 30). Working Group Determination of Status - See WG determination as stated in screening comment IR #116 which states "The proponent indicates a methodology (mechanism, rationale, expected success, risks, uncertainties) in the response provided. It is Gitxaala's position that the details regarding mitigation (the "how") are insufficient to be able to evaluate the success of the measures proposed. In the absence of details regarding implementation, it is not possible for external reviewers to test the hypothesis that the mitigation will be sufficiently successful to justify a determination of "no significant effect following mitigation." Gitxaala therefore reiterates its request for a description of detailed mitigation measures that include, among other things, thresholds for adaptive management".	It is difficult for Aurora LNG to provide additional details concerning the proposed mitigation measures without greater clarity from Gitxaala Nation concerning explicitly which mitigation measures and what details are considered lacking. Mitigation measures proposed for the Project are in keeping with industry standards and BMPs for reducing potential adverse effects of marine construction projects on marine mammals in Canadian waters. The Marine and Freshwater Resources Management Plan will be developed through engagement with regulators (i.e., DFO, the BC Oil and Gas Commission) and Schedule B Aboriginal Groups. This plan will further describe measures that will be implemented during construction and operation of the LNG facility to avoid or reduce potential adverse Project effects on marine mammals. The plan will include details on the following:Prior to the start of marine construction, acoustic modelling of in-water blasting will be done to verify assumptions and predictions made in this assessment and refine mitigation measures, as necessary.Field verification will be undertaken at multiple locations to confirm predicted extents of underwater noise levels over the full range of predicted values for in-water blasting and impact pile driving.A marine mammal monitoring program will be developed and implemented to enforce an exclusion zone during in-water impact pile driving and around the in-water blasting area.Aurora LNG is willing to collaborate in regional programs planned and developed by government and in conjunction with other proponents, regarding regional management of effects of underwater noise and vessel strikes on marine mammals in the RAA.Aurora LNG's framework for adaptive management is as follows: Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended).
2310.1	round 1	Gitxaala Nation	Table 4.10-1	Marine Wildlife - Marine Mammals	This table suggests that the 160dB isopleth lies 100m away from LNG vessels travelling at 16kts (approx. 30kph). Please confirm this is correct.	Table 4.10-1 correctly outlines that the acoustic modelling showed that the 160 dB rms re 1 µPa isopleth was reached at a maximum distance of 0.1 km (100 m) from LNG vessels travelling at 16 knots during transiting.

2311.1	round 1	Gitxaala Nation	Table 4.10-2	Marine Wildlife - Marine Mammals	Please indicate whether the term "health" includes "reproductive success"? This question is raised because noise, avoidance behaviours, stress, and reliance on less preferred food sources or locations are known to reduce mating and gestational success.	It is recognized that there is potential for overlap between the issues addressed under 'change in health' and 'change in behaviour'. Similarly, increased potential for vessel strikes (assessed under 'change in mortality risk') might have been discussed under 'change in health' as sub-lethal effects from strikes are also possible. For the purposes of the Application, 'change in health' focussed on potential physical injury resulting from underwater noise or in-water blasting. Increased levels of stress, which may in turn cause physiological responses such as diminished reproductive effort, avoidance behaviour, and effects on foraging patterns and foraging success were considered in the assessment of change in behaviour in marine mammals (see Section 4.10.5.3).
2312.1	round 1	Gitxaala Nation	Table 4.10-3	Marine Wildlife - Marine Mammals	Triple Island is believed to be an upwelling zone preferred as a foraging location by grey whales. Please indicate the way in which increased vessel activity associated with boarding PPA pilots and cumulative effects of triple island as a necessary waypoint have been assessed for effects? Specifically, how have cumulative vessel presence and noise been accounted for?	The LAA is based on a 6 km buffer around the marine terminal and a 6 km buffer extending on either side of the shipping route, which extends from the marine terminal to the Triple Island pilot boarding station. The RAA extends from the marine terminal to west of the Triple Island pilot boarding station and encompasses Prince Rupert Harbour and most of Chatham Sound. Triple Island is therefore considered within both spatial boundaries used in the assessment of marine mammals (see Figure 4.10-1). Additionally, the waters around Triple Island were surveyed as part of the marine mammal survey programs for the Aurora LNG Project (see Marine Mammals Technical Data Report - Appendix N), the PNW LNG project (Stantec 2016), and the LNG Canada project (LNG Canada 2014), results of all three of which were considered in the assessment. Acoustic monitoring was conducted for 113 days near Triple Island and recordings were analyzed for current ambient noise conditions (including vessel traffic) and marine mammal vocalizations (see Prince Rupert – Aurora LNG Acoustic Monitoring Study, Appendix O). The cumulative effects assessment for marine mammals (see Section 4.10-6) considered the potential adverse effects of vessel traffic from Kitimat and Prince Rupert that overlaps with the RAA (including in the area around Triple Island) and is associated with past, present and reasonably foreseeable future projects. LNG Canada. 2014. LNG Canada Export Terminal. Marine Resources Technical Data Report. 236 pp + Appendices. Stantec Consulting Ltd. (Stantec). 2016. Pacific NorthWest LNG Project Marine Mammal Program Final Report. Prepared for Pacific NorthWest LNG Limited Partnership. Burnaby, BC. 154 pp. Available at: http://www.pacificnorthwestlng.com/media/Marine%20Mammal%20Final.pdf.
2313.1	round 1	Gitxaala Nation	Table 4.2-10	Marine Wildlife - Marine Mammals	Exclusion from preferred forage locations is a health effect that may result from a change in behaviour (noise avoidance). How was this assessed? Please indicate the locations in the Application and TDRs in which this was discussed.	The assessment of potential residual effects of change in behaviour on marine mammals considers avoidance behaviours and effects to foraging patterns and foraging success (see Section 4.10.5.3 of the Application).
2314.1	round 1	Gitxaala Nation	4.10.2.5	Marine Wildlife - Marine Mammals	The Application notes (p.4.10-9) that "it is also understood that for the assessment of underwater noise on marine mammals, some behavioural effects will extend beyond the LAA into the RAA. These effects are considered in this assessment." The area in which effects are expected is, by definition in the methodology section, the LAA. Defining an LAA for marine mammals that does not encompass all effects is therefore contrary to appropriate EA methodology. Please provide a rationale for this choice or modify the LAA appropriately, to encompass the entire area in which noise effects are expected to modify behaviour. Please also provide a figure identifying the spatial extent of potential behavioural change by marine mammal group (toothed whales; baleen whales, pinnipeds)	The extents of the LAA were originally defined prior to the completion of the underwater acoustic modelling and was determined by applying a 6 km buffer around the LNG jetty and MOF and on either side of the shipping route. During review of the AIR, DFO advised that: "The LAA should encompass the area where any project activity (construction, operations, decommissioning) will exceed 160 dB" (BC EAO 2015). Results of underwater noise modeling work confirm that the original 6 km buffer captures the area over which both the predicted Rmax and R95% sound pressure levels exceed the 160 dB re 1 µPa rms thresholds during Project-related activities. Since it is recognized that Project-related sounds will be detectable to marine mammals beyond the 160 dB behavioural disturbance threshold (and thus beyond the boundaries of the LAA), the assessment of potential residuals effects of change in behaviour for marine mammals includes underwater noise that extends into the RAA, providing a complete assessment of Project-related potential residual effects. Maps showing the extents of underwater noise in exceedance of the interim NOAA disruption thresholds (for pulse and non-pulse noise) and the species-specific behavioural thresholds are available in Appendix N: Aurora LNG Acoustic Study: Modelling of Underwater Sounds from Pile Driving, Rock Socket Drilling, and LNG Carrier Berthing and Transiting. British Columbia Environmental Assessment Office (BC EAO). 2015. Tracking Table for Working Group Comments on dAIR. BC EAO Project Information Centre (e-PIC). Accessed August 2016. Available at: http://a100.gov.bc.ca/appsdata/epic/html/deploy/epic_document_416_39606.html
2315.1	round 1	Gitxaala Nation	Table 4.10-4	Marine Wildlife - Marine Mammals	Short-term effects are defined as measurable for a few hours to a few months. Seasonality is a factor in determining overall significance of effects. For instance, noise during courting/mating season may have a greater adverse effect than during winter. How has this been accounted for in characterization efforts?	The term 'duration' in the characterization of residual effects tables refers to a length of time, but not the timing of occurrence of a residual effect. Timing, including assessment of seasonal fluctuations (where relevant), is characterized within the assessment of individual effects. See for example the section on 'Timing' under the 'Characterization of Residual Effects for Change in Health' for 'In-water Blasting' (p.4.10-45).
2316.1	round 1	Gitxaala Nation	4.10.3.1	Marine Wildlife - Marine Mammals	Acoustic monitoring in the vicinity of Triple Island occurred from July 11 to October 31 (3.5 months) and was used to identify mammals present. This does not represent a full year of acoustic data. Critically, it does not provide information in the spring, a period of high orca, and possibly grey whale, activity. What is the rationale for conducting the EA without a full year of acoustic data?	While the data collected during the acoustic monitoring program (Appendix O) was analyzed for marine mammal vocalizations, detection of marine mammals was not the primary objective of this program. The primary objective of the acoustic monitoring program was to document the baseline noise conditions near the proposed Project site so as to provide a statistical noise distribution of the pre-Project development conditions. The timing and duration of the program were therefore developed primarily in consideration of the desire to characterize the existing ambient sound levels and existing vessel traffic, both of which are adequately captured in the selected 3.5 month period that spans periods of lower and higher expected vessel traffic in the region.
2317.1	round 1	Gitxaala Nation	4.10.5.1	Marine Wildlife - Marine Mammals	Please indicate the new NOAA SPL and SEL24 (p.4.10-33) in the Application (as opposed to just the TDR).	As discussed on p.4.10-33/34 of the Application, the 2016 NOAA peak SPL and SEL24h thresholds (which are only applicable to assessment of auditory injury) were not available at the time of modelling. As such, the Application focuses on the three approaches that were considered in the acoustic modelling and assessment of injury. The methods used by Southall et al. (2007) and Wood et al. (2012) differ somewhat from the new NOAA guidance (NMFS 2016) in terms of how the peak SPL and SEL24h metrics are weighted for different marine mammal hearing groups, and are thus not directly comparable. It is therefore considered misleading to include further discussion of the 2016 NOAA guidance within the Application itself. Further details on the different thresholds, including discussion of 2016 NOAA guidance, is presented in the Aurora LNG Acoustic Study: Modelling of Underwater Sounds from Pile Driving, Rock Socket Drilling, and LNG Carrier Berthing and Transiting, Appendix P of the Application). [NMFS] National Marine Fisheries Service. 2016. Technical Guidance for Assessing the Effects of Anthropogenic Sound on Marine Mammal Hearing: Underwater Acoustic Threshold Levels for Onset Permanent and Temporary Threshold Shifts. U.S. Department of Commerce, NOAA. NOAA Technical Memorandum NMFS-OPR-55. 178 pp. http://www.nmfs.noaa.gov/pr/acoustics/Acoustic%20Guidance%20Files/opr-55_acoustic_guidance_tech_memo.pdf. Southall, B.L., A.E. Bowles, W.T. Ellison, J.J. Finneran, R.L. Gentry, C.R. Greene, Jr., D. Kastak, D.R. Ketten, J.H. Miller, et al. 2007. Marine mammal noise exposure criteria: Initial scientific recommendations. Aquatic Mammals 33(4): 411-521. Wood, J., B.L. Southall, and D.J. Tollit. 2012. PG&E offshore 3 D Seismic Survey Project EIR-Marine Mammal Technical Draft Report. SMRU Ltd.
2318.1	round 1	Gitxaala Nation	4.10.5.1 (p.4.10-34)	Marine Wildlife - Marine Mammals	Reference is made to zones of audibility identifying the "maximum zone over which project noise might be detectable) for killer and humpback whales, harbour seals, and harbour porpoises. Please provide a figure identifying these zones by species.	Maps of thresholds and zones of audibility are available in Appendix P (Aurora LNG Acoustic Study: Modelling of Underwater Sounds from Pile Driving, Rock Socket Drilling, and LNG Carrier Berthing and Transiting) of the application.
2319.1	round 1	Gitxaala Nation	Table 4.10-8	Marine Wildlife - Marine Mammals	The text of the application indicates that blasting will be restricted to least-risk-windows. Please ensure that this mitigation is added to this table.	As noted in the IR, DFO's north coast least risk timing window for marine fish will be applied during blasting activities. As discussed in the first paragraph following Table 4.10-8 in the Application, timing windows were specifically designed by DFO to reduce potential harm to marine fish and are not optimized to benefit marine mammals. While there may be some collateral benefits for certain marine mammal species (see discussion under 'Characterization of Residual Effects for Change in Health for In-water Blasting' on page 4.10-45), it was considered misleading to include mention of this marine fish mitigation measure under the table of mitigation measures designed specifically to reduce adverse effects to marine mammals.
2320.1	round 1	Gitxaala Nation	4.10.5.2, p. 4.10-46	Marine Wildlife - Marine Mammals	The application notes that "Timing windows for marine fish will not be applied to pile installation". The Application further notes that it is "assumed that marine mammals will be present". How is the differential (greater) effect of ensonification during critical life-cycle stages (notably courting/mating) assessed and mitigated for?	As discussed in the Application, while timing of peak marine mammal occurrence in the RAA is likely to coincide with other peak periods of biological activity in the region (e.g., northern resident killer whales following the migration of the Skeena and Nass rivers Chinook salmon [Ford 2006; Ford and Ellis 2006]), this assessment is based on the assumption that marine mammals may be present in the LAA and RAA at any time of the year, and thus may interact with Project activities regardless of the construction schedule or timing of such activities.As a result, all marine mammal life-cycle stages are considered in the assessment of potential residual effects. Timing, including assessment of seasonal fluctuations (where relevant), is characterized within the assessment of individual effects. See for example the section on 'Timing' under the 'Characterization of Residual Effects for Change in Health' for 'In-water Blasting' (p.4.10-45). Ford, J.K.B. 2006. An Assessment of Critical Habitats of Resident Killer Whales in Waters off the Pacific Coast of Canada. Canadian Science Advisory Secretariat, Research Document. Nanaimo, BC. 1-34 pp. Ford, J.K.B. and G.M. Ellis. 2006. Selective foraging by fish-eating killer whales Orcinus orca in British Columbia. Marine Ecology Progress Series 316:185-199.
2321.1	round 1	Gitxaala Nation	4.10.5.2, p. 4.10-48	Marine Wildlife - Marine Mammals	Please provide figures that identify 160 dB isopleths for both SPL and SEL24 at both the MOF and the berthing jetty in order to facilitate a discussion regarding an appropriate exclusion zone during pile driving. There is some concern that this isopleth extends across the channel between Digby and Kaien Islands, effectively creating a sonic barrier to movement that will have behavioural and health effects (trapping marine mammals within, or excluding mammals from, the inner harbour during pile driving).	Maps showing the extents of underwater noise to the selected injury and behavioural thresholds for model scenarios are available in Appendix P: Aurora LNG Acoustic Study: Modelling of Underwater Sounds from Pile Driving, Rock Socket Drilling, and LNG Carrier Berthing and Transiting. The extent of underwater noise above 160 dB SPL (rms) from pile driving activities at the MOF and the LNG jetty do extend between Digby and Kaien Islands. The Marine and Freshwater Resources Management Plan will be developed in consultation with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended). This plan will describe BMPs and mitigation measures that will be implemented during construction and operation of the LNG facility to avoid or reduce potential adverse effects of Project activities on marine mammals. The plan will include details on the following: Prior to the start of marine construction, acoustic modelling of in-water blasting will be done to verify assumptions and predictions made in this assessment and refine mitigation measures, as necessary.Field verification will be undertaken at multiple locations to confirm predicted extents of underwater noise levels over the full range of predicted values for in-water blasting and impact pile driving.A marine mammal monitoring program will be developed and implemented to enforce an exclusion zone during in-water impact pile driving and around the in-water blasting area.Aurora LNG is willing to collaborate in regional programs planned and developed by government and in conjunction with other proponents, regarding regional management of effects of underwater noise and vessel strikes on marine mammals in the RAA
2322.1	round 1	Gitxaala Nation	4.10.5.2, p. 4.10-51	Marine Wildlife - Marine Mammals	Please provide acoustic information regarding disposal at sea and provide a figure that shows the 120 and 160dB isopleths associated with dredge disposal at Brown Passage. This is critical in order to understand the potential sonic limitations to marine mammal movement through Brown Pass to and from the open ocean.	As discussed on page 4.10-51 of the Application, and based on literature reported values (e.g., Todd et al. 2015), it is considered unlikely that the NOAA (n.d.) interim thresholds for behavioural disturbance (i.e., 120 and 160 dB re 1 µPa rms) will be exceeded during dredging and disposal at sea activities. As such, acoustic modelling of dredging and disposal at sea were not undertaken. This approach is in keeping with that taken on other recently-approved projects in northern BC. Aurora LNG maintains that the Application adequately characterizes potential residual effects of dredging and disposal at sea on marine mammals, and that additional quantitative modelling is unlikely to change the conclusions presented in the Application.
2323.1	round 1	Gitxaala Nation	Table 4.10-9	Marine Wildlife - Marine Mammals	The principles guiding the determination of exclusion zones (in consultation with DFO) must include the creation of a corridor in which sound levels are below 160dB. This may require significant reductions in vessel speed within narrow channels.	Acoustic modelling of Project-related vessels in transit predicted that sound levels would drop below 160 dB re 1 µPa rms within 0.1 km of the vessel propellers based on conservative assumptions. Modelling assumed that LNG carriers were accompanied by two tugs (which will not occur beyond the boundaries of the PRPA) and that vessels were travelling at the maximum speed of 16 knots (30 km/hr) (while the average speeds throughout the PRPA will be 12 knots [22 km/hr]). Further details on vessel scenarios and acoustic modelling results are provided in Appendix P.
2324.1	round 1	Gitxaala Nation	4.10.5.4	Marine Wildlife - Marine Mammals	The Application notes that the proposed upper-end LNG carrier transit speed within the RAA is 16kts. Literature from the US suggests that baleen whales have difficulty maintaining speeds over 10kt and may therefore have difficulty outrunning vessels travelling at top speed if startled or otherwise engaged in an activity (mating/foraging) that prevents early vessel detection. Speeds from triple island to the jetty should be maintained at no more than 10kts. This is expected to reduce behavioural changes associated with noise, as well, because noise from LNG carriers generally increases more than proportionally with increases in speed.	The relationship between vessel speed and strike risk was considered in the assessment (see Section 4.10.5.4) and the relationship between sound levels and vessel speeds is recognized. The Technical Review Process of Marine Terminal Systems and Transshipment Sites (TERMPOL) process, conducted by Transport Canada, will address vessel speeds and routing, in consideration of mariner safety, environmental effects, and feedback through engagement with PRPA, DFO, Aboriginal Groups, and others. Project-related vessels will proceed at a safe speed and respect any regionally-defined or PRPA-specific speed profiles that are applicable at the time of operations, subject to navigational safety. Aurora LNG is willing to collaborate in regional programs planned and developed by government and in conjunction with other proponents, regarding regional management of effects of vessel strikes on marine mammals in the RAA.
2325.1	round 1	Gitxaala Nation	Appendix Q	Marine Wildlife - Marine Birds	Please explain the reasoning for the following methods: Why were there no shoreline stationary counts conducted on Tuck Island or the Kinahan Islands? Why were shoreline surveys only conducted for fall migration and summer, and only in one year? Why were vessel-based surveys conducted at different months for summer surveys (July 2014 vs. June 2015)? Why were vessel-based surveys only conducted once per season, with the exception of summer? Why were vessel-based surveys conducted to survey marine birds 300m on either side of the centreline? Standard is 300m total width, at 150m on either side of the centreline. Marbled murrelets are increasingly difficult to detect beyond 100m. Why were surveys conducted between 8am and 6pm? Marine birds are typically best to sample in the morning or dawn/dusk. Why were vessel-based surveys so concentrated in Chatham Sound, outside the RAA? More effort should have been taken to survey within the RAA. This was not explained. Why were results not shown by habitat type? Please show more information about the results of the survey and describe the importance/significance of the results. Why were vessel-based surveys conducted in a different pattern (continuous straight lines) during the February 2015 survey? Why were some habitat types not sampled during the July 2014, June 2015 and November 2014 vessel-based surveys?	Methods for shoreline stationary counts and vessel-based surveys are described in Section 4.1.2 and 4.2.2 of Appendix Q. Field studies for marine birds were completed to provide a record of occurrence and patterns in habitat use within the LAA and RAA. The scope and timing of field studies were consistent with recommendations within applicable sampling protocols referenced in Appendix Q. Shoreline stationary counts and vessel-based surveys were completed across different months, times of day, and at variable tide heights to account for seasonal, diurnal, or tidal patterns of use during overwintering, migration, and breeding periods. Although surveys were generally completed once per season, survey effort was replicated across and within habitat types in LAA and RAA. Surveys were completed in July 2014 and June 2015 to provide additional information about patterns in marine bird use of the LAA and RAA across the summer breeding period. To provide greater regional context, results of field studies were evaluated in consideration of regional datasets and information sources (see Appendix Q). Shoreline stationary counts were located to maximize survey coverage in habitats within the LAA. Specific placement of individual points was intended to survey across various nearshore environments within the LAA, targeting unique marine features. A shoreline stationary count was located on Spire Island (MBDI20) and included Tuck Island in its radius of detection (see Figure 2 of Appendix Q). Although no shoreline stationary counts were located on Kinahan Islands, vessel-based surveys included survey effort in adjacent marine habitats. Vessel transects were stratified across four primary habitat guilds to account for potential differences in marine bird habitat use. Transects were distributed throughout the RAA but also Chatham Sound more broadly, to account for regional patterns in seasonal richness, abundance, and distribution. Transects placement was random within each guild to provide an indiscriminate sample of species presence, richness, abundance, and distribution. As noted in Appendix Q, the number and placement of transects completed in each season (including distribution across habitat guilds) varied based on constraints in weather and sea conditions. A complete summary of marine bird detections by habitat guild is provided in Appendix 3 and discussed in Section 4.2.3 of Appendix Q. Vessel-based survey methods (e.g., RIC 1997; Gjerdrum et al. 2012) recommend that observers scan out to 300 m ahead and to one side of the vessel. This can result in an underestimate of difficult to detect species (e.g., alcids) if surveying under challenging weather conditions, however a 300 m transect width better accounts for species that avoid transiting vessels that would also be underestimated using a narrower transect width (e.g., loons, diving ducks; RIC 1997, Gjerdrum et al. 2012). Detection of smaller species beyond 150 m is optimized by surveying during conditions were visibility is not compromised and through the use of skilled observers (see Appendix Q for details). References: Gjerdrum, C., D.A. Fifield, and S.I. Wilhelm. 2012. Eastern Canada Seabirds at Sea (ECSAS) Standardized Protocol for Pelagic Seabird Surveys from Moving and Stationary Platforms. Canadian Wildlife Service Technical Report Series No. 515. Atlantic Region. Resource Inventory Committee (RIC). 1997. Inventory Methods for Seabirds: cormorants, gulls, murres, storm-petrels, Ancient Murrelet, auks, puffins, and Pigeon Guillemot. Victoria, BC.

2326.1	round 1	Gitxaala Nation	Appendix Q	Marine Wildlife - Marine Birds	Survey methodology was not well described. Nor were there justifications for locations chosen for surveys. Please elaborate on the methodology and provide justifications.	Methods for shore and vessel-based surveys are described in Section 4.1.2 and 4.2.2 of Appendix Q and are consistent with the level of information required based on the survey protocol standards referenced within each section. Shore-based points were located to maximize survey coverage in habitats within the LAA while preventing overlap of the observation radius of individual points to avoid duplication in survey effort. Specific placement of individual points were intended to survey across various nearshore environments within the LAA, targeting unique marine features (e.g., Delusion Bay, Casey Cove, surrounding islands and islets). Vessel transects were stratified across four primary habitat guilds to account for potential differences ir marine bird habitat use. Transects placement was random within each guild to provide an indiscriminate sample of species presence, richness, and abundance.
2327.1	round 1	Gitxaala Nation	Appendix Q	Marine Wildlife - Marine Birds	Were shoreline surveys conducted within 2hrs of high tide at each survey location? Methodology only states that surveys were conducted between 8am and 4pm.	Consistent with sampling protocols referenced in Appendix Q, shore and vessel-based surveys were completed across different months, times of day, and at variable tide heights to account for seasonal, diurnal, or tidal patterns of use. Stationary shoreline points situated around mudflats (e.g., Delusion Bay, Casey Cove) were surveyed at mid- or high-tide, to optimize detection of shorebirds and dabbling ducks, as well as to facilitate access to survey locations.
2328.1	round 1	Gitxaala Nation	Appendix Q	Marine Wildlife - Marine Birds	Were shoreline surveys conducted with spotting scopes and binoculars? 300m is a long distance to see with just binoculars and many species including marbled murrelet may be missed. Please provide more information, including the number of observers.	Shoreline surveys were completed using a combination of a spotting scope and binoculars to support species identification (including for species that are more difficult to detect at greater distances, such as marbled murrelet).
2329.1	round 1	Gitxaala Nation	4.11.2.5	Marine Wildlife - Marine Birds	Please explain why Dodge Cove was not included in the LAA? This area looks to be within 1km of the MOF, thus should be included.	The LAA for marine birds includes a 1 km buffer around the proposed marine terminal, including the MOF. Dodge Cove is located just outside of this 1 km buffer (see Figure 4.11-1 in Section 4.11); however, Project studies included three shoreline stationary counts in Dodge Cove to understand marine bird presence, abundance, and distribution in this area. Given its proximity to the LAA, potential effects to marine birds using habitats in Dodge Cove are expected to be similar to those characterized for other areas within the LAA. A discussion of potential effects to nesting herons in Dodge Cove is also considered in Section 4.7 of the Application.
2330.1	round 1	Gitxaala Nation	1.2	Proposed Project Overview	Please show the infrastructure for the natural gas delivery on the site maps. This context is important for determining the constructed layout and allows for a broader picture of the end product.	As noted in section 1.2.7.1 of the Application, natural gas will be delivered to the Project via a third party-owned pipeline, which is yet to be determined, and not in the scope of this Project. The feed gas pipeline will enter the PDA via a dedicated pipeline delivery station. It is expected that the marine-based feed gas pipeline would approach Digby Island from the south to avoid further disturbance to areas on Digby Island outside of the PDA. However, the exact location for landfall is subject to change since the pipeline supplier has not been selected.
2331.1	round 1	Gitxaala Nation	4.11.3.1 and Table 4.11-7	Marine Wildlife - Marine Birds	Despite scoping in section 4.11.2 that lists Bird Conservation Region 5 and First Nations interests (section 4.11.3.2) as part of the scope, these species of interest have not been carried forward in the assessment. Please explain why priority species for BCR5 and harvestable marine birds of value to FNs have not been included in the assessment.	Sections 4.11.2.2 and 4.11.2.3 of the Application describe the Aboriginal Groups from which traditional knowledge and traditional use information was gathered, and how information was incorporated into the assessment. Section 4.11.3.2 provides a summary of findings of traditional ecological knowledge for marine birds and is described in more detail in Appendix Q of the Application. Traditional ecological knowledge provided on traditionally harvested species, seasons, and locations are used in combination with Project and regional studies, and scientific literature to determine the appropriate extent of spatial boundaries, characterize residual Project and cumulative effects, and to assign significance determinations. Species of cultural importance are discussed throughout Section 4.11.5 and 4.11.6 where there was an identified mechanism for interaction with Project activities and infrastructure. Additional details on the timing and location of marine bird harvesting practices are provided in Appendix S.2. Information on harvesting practices was used to support Section 4.11, Section 11, and Part C of the Application. The assessment also integrated information from the Bird Conservation Region 5 (BCR 5) Strategy (Environment Canada 2013), recognizing that the BCR 5 extends from the western Gulf of Alaska to northern California. The Application draws information on conservation objectives outlined in the Strategy that is relevant to marine bird species present, and habitats available, within the LAA and RAA. Priority species identified in the Strategy align with those presented in Section 4.11.3.2 and Appendix Q of the Application. Supporting field studies were developed in consideration of habitat requirements for priority species / species of management concern. The key threats identified for priority species in the Strategy are considered in the Application, where the Project has potential to contribute to residual effects (e.g., habitat change and alteration, mortality, and disturbance). Section 4.11.5.6 of the Application describes residual Project effects that have potential to interact cumulatively with other projects and activities within the RAA, including those identified in the Strategy (e.g., commercial fishing and by-catch, marine transportation). Environment Canada (2013) further outlines that BCR strategies are not intended to be highly prescriptive. Proponents are recommended to integrate local information, recommendations, and management practices. Accordingly, Aurora LNG incorporated information from regional data and information sources (e.g., land use plans, traditional ecological studies) into Section 4.11 of the Application. Mitigation measures are developed in consideration of other relevant provincial and federal regulations and best management practices. Reference: Environment Canada. 2013. Bird Conservation Strategy for Bird Conservation Region 5: Northern Pacific Rainforest. Canadian Wildlife Service, Environment Canada. Delta, British Columbia. 128 pp. + appendices.
2332.1	round 1	Gitxaala Nation	4.11.4	Marine Wildlife - Marine Birds	Why is marine construction not considered a mortality risk? Effect of blasting on diving birds includes concussive force and pressure. This effect should be included in the assessment. Why is discharge to the marine environment under commissioning and start-up not considered as a change in habitat? Hydro-testing will include fresh water plus impurities in the pipe, which gets discharged to the marine environment. This poses a risk to change in environment for marine birds. Why is LNG shipping not considered a mortality risk? There is a risk that marine birds disoriented by lights or avoiding ships are not able to make it to a rest area or suitable landing site. Why has LNG production not been considered a risk to change in behaviour of marine birds? Flaring and lighting may cause marine birds to avoid the area, or be disoriented by the lights, changing their behaviour.	Effects of underwater noise to marine birds is primarily expected to result in sensory disturbance that could influence change in habitat use or change in behaviour, and is discussed in Sections 4.11.5.2 and 4.11.5.4 of the Application, respectively. As per mitigation 4.11.2, a Noise Management Plan and a Marine Activities Plan will be implemented to decrease the extent of in-air and underwater acoustic emissions during Project construction, and considers timing windows to reduce effects to key species (see Section 14.5 and 14.11 for details). Additional procedures related to blasting, pile driving, and dredging will be outlined in the Marine and Freshwater Resources Management Plan. The Plan will include measures to reduce disturbance to marine fish, which will, by extension, benefit marine birds (see Section 14.9). Recognizing that the detailed technical information and effects thresholds necessary to assess effects of noise levels encountered by marine birds is currently limited, the Application incorporates best-available information in scientific literature to characterize potential effects of underwater noise on marine birds (see Section 4.11 for applicable citations). Marine birds are likely to avoid areas of elevated underwater noise during all Project phases through behavioural adaptation, which in turn is expected to reduce the risk of noise-induced injury or mortality. As per mitigation 4.7.14, facility staff will document and report bird injuries or fatalities, including birds that would be potentially affected by underwater noise. Methods for waste discharge into the marine environment, and potential effects to the physical or chemical composition of marine waters is assessed in Section 4.5.15.3 of the Application. Changes in physical or chemical conditions, and resulting effects to marine bird prey, are considered as part of the assessment of change in habitat under Section 4.11.5.2 of the Application. Section 4.11.5.3 indicates that for marine birds, change in mortality risk for the Project is primarily associated with increased nighttime lighting at the LNG facility, marine terminal, and from berthed or transiting vessels (inclusive of LNG carriers). The assessment of change in mortality risk specifically addresses effects of disorientation that could result in stranding, injury, or mortality from all Project-related anthropogenic light sources. Section 4.11.5.4 further acknowledges that marine birds are also expected to adjust behaviour patterns, either through attraction to, or disorientation caused by, nighttime lighting at the marine terminal and at berthed or transiting vessels. However, because behaviour-related changes as a function of Project-related lighting can ultimately result in injury or mortality of marine birds, this mechanism for effect was assessed in Section 4.11.5.3.
2333.1	round 1	Gitxaala Nation	4.11.4	Marine Wildlife - Marine Birds	How will wastes be treated during waste management? Will there be any disposal or discharge to the marine environment?	Methods for waste storage, treatment, disposal, and discharge into the marine environment, and potential effects to the physical or chemical composition of marine waters are assessed in Section 4.5.15.3 of the Application. Changes in physical or chemical conditions, and resulting effects to marine bird prey, are considered under Section 4.11.5.2 of the Application. Details regarding Project waste sources, anticipated waste streams, and disposal options will be described in the Waste Disposal Management Plan (see Section 14.14 of the Application).
2334.1	round 1	Gitxaala Nation	4.11.5.2	Marine Wildlife - Marine Birds	A general assumption has been made that "most marine birds present in the LAA and RAA have secure populations and have access to other suitable marine habitats, marine birds are expected to demonstrate a moderate degree of resilience to change in habitat availability". However, 22 species of marine birds of management concern have been identified as potentially occurring in the LAA or RAA. These species do not have secure populations, or are at risk of having unsecure populations. In addition, species traditionally harvested by First Nations have not been included in the assessment (unless already of management concern). The inability to harvest traditionally harvested marine birds, either due to a decrease in availability, change in behaviour of the species, or because the added pressure of harvesting would be detrimental to the species, is in conflict with the rights of FNs to practice Aboriginal rights. Marine birds on the priority list for BCR5 (including species where an increase in population is desired) have also not been included. Please explain rationale for concluding that marine birds are expected to demonstrate a moderate degree of resilience.	Species of management concern and traditionally harvested species have been included in the assessment (see subsections within Section 4.11.3.2) and although there is some overlap, they are not necessarily representative of the same marine bird species or species groups. Traditional ecological knowledge provided on traditionally harvested species, seasons, and locations are used in combination with Project and regional studies and scientific literature to characterize residual Project and cumulative effects, and to assign significance determinations. The assessment also integrated information from the Bird Conservation Region 5 (BCR 5) Strategy (Environment Canada 2013), drawing information on conservation objectives outlined in the Strategy that is relevant to marine bird species present, and habitats available, within the LAA and RAA (see response to comment 1988 for more information). As per Table 4.11-15, resilience was determined for marine bird species and species groups (including species of management concern and traditionally harvested species) based on the existing conditions, the potential for interaction with Project activities and infrastructure, the nature of that interaction, and the sensitivity of marine birds to respond. Given these criteria, marine birds were assessed to have moderate tolerance to change from existing conditions; the viability of local or regional populations was not expected to be affected by residual project effects. The prediction confidence is moderate or high (see Section 4.11.8) given some uncertainty over the degree to which some marine bird species may be affected by the Project. Information presented in Section 4.11 was carried forward to Section 11 (see Section 11.3.8.3 starting on page 11-123) and Part C (see Section 12.5.5.6) of the Application and considers the resilience of harvested species to residual Project and cumulative effects in combination with traditional harvesting practices. Reference: Environment Canada. 2013. Bird Conservation Strategy for Bird Conservation Region 5: Northern Pacific Rainforest. Canadian Wildlife Service, Environment Canada. Delta, British Columbia. 128 pp. + appendices.
2335.1	round 1	Gitxaala Nation	4.11.5.2	Marine Wildlife - Marine Birds	Please provide the lowest noise levels that cause disturbance to marine birds. This information is important in determining potential effects on birds. Please show isopleth lines on a map of the project area, along with marine bird concentrations. Please show attenuation distance of underwater noise and model used to determine this.	Scientific understanding and recognition of the potential effects of underwater noise (i.e., behavioural and injury thresholds) on marine mammals have increased dramatically in recent decades. However, for other marine taxa (e.g., marine birds) there remain substantial limitations in current scientific understanding of this potential stressor. Recognizing that the detailed technical information and effects thresholds necessary to assess effects of noise levels encountered by marine birds, an acoustic model for marine birds was deemed inappropriate. The nature and extent of underwater noise effects are limited to species who spend a portion of their life cycle below the water surface (i.e., diving and pursuit foragers) that are likely to use marine habitats experiencing elevated noise levels. Recognizing that the detailed technical information and effects thresholds necessary to assess effects of noise levels encountered by marine birds is currently limited, the Application incorporates best-available information in scientific literature to characterize potential effects of underwater noise on marine birds (see Section 4.11 for applicable citations).
2336.1	round 1	Gitxaala Nation	4.11.5.2	Marine Wildlife - Marine Birds	What is the rationale for determining that adverse effects are not expected on marine birds given that noise produced by the Project vessels is expected to be 206dB re 1uPa for transiting tugs and pile driving is expected to reach 230dB re1uPa, yet an expose level of 202dB can caused injury to marbled murrelet? This is a clear exceedance, yet the assessment claims that the noise produced by ships in the shipping lane "are well below the threshold expected to cause injury in diving bird species". What threshold is this if not the 202dB for marbled murrelet? At what dB level does noise cause disturbance or change in behaviour for marbled murrelet?	Effects of underwater noise to marine birds was expected to result in sensory disturbance that could influence change in habitat use or change in behaviour, and was discussed in Sections 4.11.5.2 and 4.11.5.4 of the Application, respectively. The assessment did indicate that underwater noise would result in an adverse residual effect of displacement or disturbance within each section. Given available scientific evidence, the SAIC (2011) concluded that terrestrial and marine mammals represent reasonable surrogates for characterizing auditory injuries to marbled murrelets, while thresholds for fish are useful for estimating non-auditory injuries. Based on that species extrapolation, the SAIC (2011) estimated that a continuous 24-hour sound exposure level (SEL) greater than 202 dB dB re 1uPa could cause disturbance or injury to marbled murrelet. However, the SAIC (2011) recommends this as a guideline given that the SEL threshold represents a 24-hour cumulative exposure period (i.e., an individual remains submerged and its distance to the noise source remains constant for a continuous 24-hour exposure period) and has limitations in its application for species that are a) mobile, and b) spend only a proportion of its daily cycle below the surface of the water. Detailed technical information on the nature and extent of underwater noise effects continue to be limited for marine birds. Although Project-related activities may result in underwater noise production above 202 dB re 1uPa, marbled murrelets or other marine bird species are not expected to be exposed for a sufficient period to sustain injury. Marine birds are likely to avoid areas of elevated underwater noise during all Project phases through behavioural adaptation, which in turn is expected to reduce the risk of noise-induced injury or mortality. As per mitigation 4.11.2, a Noise Management Plan and a Marine Activities Plan will be implemented to decrease the extent of in-air and underwater acoustic emissions during Project construction; these plans will consider timing windows to reduce effects to key species (see Section 14.5 and 14.11 for details). Additional procedures related to noise reduction for blasting, pile driving, and dredging will be outlined in the Marine and Freshwater Resources Management Plan. The Plan will include measures to reduce disturbance to marine fish, which will, by extension, benefit marine birds (see Section 14.9). Reference: Science Applications International Corporation (SAIC). 2011. Environmental science panel for marbled murrelet underwater noise injury threshold. Prepared for: US Navy, Bothell, WA. 34 pp.
2337.1	round 1	Gitxaala Nation	4.11.5.3	Marine Wildlife - Marine Birds	Table 4.11-10: Mitigation for marine construction/operations is incomplete. Suggested mitigation measures include: -bubble curtain to limit risk of marine birds (and fish) from getting too close to pile driving operations; surveys/monitoring for birds during construction and operations; timing of works to avoid sensitive periods, such as when young are present (likely more susceptible to noise effects); shielding of the flare to prevent accidental mortality	As per mitigation 4.11.2, a Noise Management Plan and a Marine Activities Plan will be implemented to decrease the extent of in-air and underwater acoustic emissions during Project construction, and considers timing windows to reduce effects to key species (see Section 14.5 and 14.11 for details). Additional procedures related to blasting, pile driving, and dredging will be outlined in the Marine and Freshwater Resources Management Plan. The Plan will include measures to reduce disturbance to marine fish, which will, by extension, benefit marine birds (see Section 14.9). Section 1.2.5.1 describes the proposed flare system design and does not include a shielding mechanism, due to infrastructure constraints. However, maintenance flaring events will be scheduled during daylight hours to the extent practicable to reduce the potential of accidental mortality of marine birds (mitigation 4.7.20). Aurora LNG has further committed to limit exterior lighting, and use of directional or shielded lighting to reduce the risk of injury or mortality of marine birds during all Project phases (mitigation 4.7.9).
2338.1	round 1	Gitxaala Nation	4.11.5.2 & 4.11.5.3	Marine Wildlife - Marine Birds	Please describe in-air noise effects on marine birds. Include information on pressure and vibration changes associated with flaring and how these will affect birds (vibration cavity of birds differs from humans, and as such, human-centric thresholds are not applicable).	Effects of in-air noise on marine birds are described in Sections 4.11.5.2 and 4.11.5.4. While flaring will contribute to noise production during Project operations, it is not expected to generate substantial noise for marine bird receptors unless they are in the immediate vicinity of an active flare, in which case individuals are likely sufficiently close to the pilot flare to be at risk of injury or mortality from collision with the flare stack or flame (see Figure 11 of Appendix C). Changes in mortality risk from injury or collision with the flare system are discussed in Section 4.11.5.3. While effects from sudden pressure changes (e.g., barotrauma) are well documented among bats, the unique respiratory anatomy of birds is thought to make them less susceptible to changes in pressure and is not expected to be a potential effect for marine birds (Baerwald et al. 2008). Aurora LNG has committed to mortality monitoring and reporting (mitigation 4.7.14). The Wildlife Management Plan will provide details on procedures for identifying, recording, and reporting on injuries or mortalities related to Project activities; where possible, Project personnel will be required to describe the cause of mortality. Reference: Baerwald, E.F., D;Amours, G.H., Klug, B.J., and Barclay, R.M.R. 2008. Barotrauma is a significant cause of bat fatalities at wind turbines. Current Biology, 18(16): 695-696.

2339.1	round 1	Gitxaala Nation	4.11.5.3	Marine Wildlife - Marine Birds	Please describe how sudden pressure changes, sudden noise, burns and collisions related to flaring will affect marine birds.	Effects of flaring on marine birds are described in Section 4.11.5.3. While flaring will contribute to noise production during Project operations, it is not expected to generate substantial noise for marine bird receptors unless they are in the immediate vicinity of an active flare (see Figure 11 of Appendix C to see predicted noise levels of Project infrastructure within the PDA). If individuals are sufficiently close to the pilot flare to experience elevated noise levels, they're also likely sufficiently close to the pilot flare to be at risk of injury or mortality from collision with the flare stack or flame. While effects from sudden pressure changes (e.g., barotrauma) are well documented among bats, the unique respiratory anatomy of birds is thought to make them less susceptible to changes in pressure and is not expected to be a potential effect for marine birds (Baerwald et al. 2008). Aurora LNG has committed to mortality monitoring and reporting (mitigation 4.7.14). The Wildlife Management Plan will provide details on procedures for identifying, recording, and reporting on injuries or mortalities related to Project activities; where possible, Project personnel will be required to describe the cause of mortality. Reference: Baerwald, E.F., D;Amours, G.H., Klug, B.J., and Barclay, R.M.R. 2008. Barotrauma is a significant cause of bat fatalities at wind turbines. Current Biology, 18(16): 695-696.
2340.1	round 1	Gitxaala Nation	4.11.5.3	Marine Wildlife - Marine Birds	Discussion of residual effects for change in mortality fails to mention discussion of underwater noise, as in the previous section. As shown in above comment, underwater noise is expected to exceed thresholds for marbled murrelet (and likely other species). Please include underwater noise in this discussion.	Effects of underwater noise to marine birds is primarily expected to result in sensory disturbance that could influence change in habitat use or change in behaviour, and is discussed in Sections 4.11.5.2 and 4.11.5.4 of the Application, respectively. As per mitigation 4.11.2, a Noise Management Plan and a Marine Activities Plan will be implemented to decrease the extent of in-air and underwater acoustic emissions during Project construction, and considers timing windows to reduce effects to key species (see Section 14.5 and 14.11 for details). Additional procedures related to blasting, pile driving, and dredging will be outlined in the Marine and Freshwater Resources Management Plan. The Plan will include measures to reduce disturbance to marine fish, which will, by extension, benefit marine birds (see Section 14.9). Scientific understanding and recognition of the potential effects of underwater noise (i.e., behavioural and injury thresholds) on marine mammals have increased dramatically in recent decades. However, for other marine taxa (e.g., marine birds) there remain substantial limitations in current scientific understanding of this potential stressor. The nature and extent of underwater noise effects are limited to species who spend a portion of their life cycle below the water surface (i.e., diving and pursuit foragers) that are likely to use marine habitats experiencing elevated noise levels. Recognizing that the detailed technical information and effects thresholds necessary to assess effects of noise levels encountered by marine birds is currently limited, the Application incorporates best-available information in scientific literature to characterize potential effects of underwater noise on marine birds (see Section 4.11 for applicable citations). Marine birds are likely to avoid areas of elevated underwater noise during all Project phases through behavioural adaptation, which in turn is expected to reduce the risk of noise-induced injury or mortality. As per mitigation 4.7.14, facility staff will document and report bird injuries or fatalities, including birds that would be potentially affected by underwater noise.
2341.1	round 1	Gitxaala Nation	4.11.5.3	Marine Wildlife - Marine Birds	Table 4.11-11: Mitigation describes LNG carriers as having to maintain a distance of greater than 500m from known marine bird colonies, and 1km from Lucy Island. However, the existing shipping lane is 6km from Lucy Island. Limiting ships to >5km from Lucy Islands Conservancy would be more prudent.	Aurora LNG is committed to complying with available guidance provided by federal agencies, such as Environment and Climate Change Canada (ECCC). ECCC provides guidance to avoid disturbance to seabird and waterbird colonies in Canada and recommend that large vessels maintain a minimum distance of 500 m from marine bird colonies (ECCC 2016). Given the distance between the existing shipping lane and Lucy Island (approximately 6 km), LNG carriers for the Project are expected to exceed ECCC's recommendations and vessel-based disturbance to colonial breeding marine birds are expected to be low as a result of Project activities. Details of this mitigation measure will be provided in the Wildlife Management Plan (see Section 14.8 in Section 14). Reference: Environment and Climate Change Canada (ECCC). 2016. Guidelines to Avoid Disturbance to Seabird and Waterbird Colonies in Canada. Available at: https://www.ec.gc.ca/paomitmb/default.asp?lang=En&n=E3167D46-1. Accessed: March 2017.
2342.1	round 1	Gitxaala Nation	4.11.5.3	Marine Wildlife - Marine Birds	Please describe wake effect of LNG carriers on marine habitats, including nesting areas. How will wake be attenuated (show on map)? How will this affect marine bird colonies 500m from the shipping lane?	Section 6.5.4.2 of the Application provides details on wake from operational shipping traffic. Waves generated by LNG carriers and escort tugs travelling at 12 knots will be less than 0.4 m high at the source vessel and is within the size range of naturally occurring waves in the region. Historical data collected at weather buoys operated by Environment and Climate Change Canada indicate the average wave heights in Hecate Strait were 1.8 m. The Project's shipping route passes through unconfined waters in Chatham Sound towards Hecate Strait, which lends itself to larger distances between transiting carriers and shoreline habitats. This will allow wake waves to grow smaller (attenuate) as they travel over distance. As outlined in Section 4.11.5, Environment and Climate Change Canada recommends that large vessels maintain distances greater than 500 m from breeding colonies to reduce disturbance effects while transiting. Because the Project's shipping route is located more than 1 km from the nearest marine bird colony, the disturbance caused by LNG carriers for the Project are expected to attenuate to levels representative of average ambient wave conditions within the LAA and RAA. Maintaining distance from active marine bird colonies will reduce the potential for disturbance, including flushing of breeding adults from active nests.
2343.1	round 1	Gitxaala Nation	4.11.5.3	Marine Wildlife - Marine Birds	Please describe monitoring programs to determine whether construction, operations or decommissioning are having an impact on marine birds.	Aurora LNG has committed to implementing standard mitigation measures, guidelines, and practices to avoid or reduce potential adverse effects of Project activities on marine birds during construction, operations, and decommissioning. These mitigation measures are described in Tables 4.11-9 (to avoid or reduce change in habitat), 4.11-10 (to avoid or reduce change in mortality risk), and 4.11-11 (to avoid or reduce change in behaviour for marine birds). To monitor potential effects of lighting on bird and bat mortality, facility personnel will be required to document and report injuries or fatalities related to Project activities (mitigation 4.7.14). As per mitigation 4.7.16, light-induced stranding's of migratory birds (including marine bird species) at the LNG facility, marine terminal, supporting infrastructure and facilities, and on berthed vessels will also be documented and reported. Reporting the extent to which birds are susceptible to light-induced mortality allows for monitoring and adaptive management of lighting mitigation measures, as necessary, throughout Project operations. Aurora LNG's framework for adaptive management is as follows: Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended). Full details will be described in the Wildlife Management Plan (see Section 14.8 of the Application).
2344.1	round 1	Gitxaala Nation	4.11.6.3	Marine Wildlife - Marine Birds	Please describe resiliency of SAR to cumulative changes in habitat.	As per Table 4.11-5, resilience was determined for marine bird species and species groups (including species of management concern) based on the existing conditions, the potential for interaction with Project activities and infrastructure, the nature of that interaction, and the sensitivity of marine birds to respond to changes. Cumulative changes in habitat for marine bird species of management concern were assessed in Section 4.11.6.3. Given the criteria for resilience in Table 4.11-5, marine birds were assessed to have moderate tolerance to change from existing conditions; the viability of local or regional populations was not expected to be affected by residual Project and cumulative effects from change in habitat. The prediction confidence is high for residual Project and cumulative effects on change in marine bird habitat (see Section 4.11.8 of the Application), based on the availability of data used to characterize existing conditions in the LAA and RAA, the quality of available literature to understand the Project and cumulative effect mechanisms, the effectiveness of proposed mitigation measures, and professional judgement. The Project's residual effects, and its contribution to cumulative effects will be offset by implementation of the Fish Habitat Offsetting Plan. The Fish Habitat Offsetting Plan is expected to reduce regional changes to marine bird habitats, particularly in nearshore areas in the Prince Rupert region. Proposed mitigation measures for change in habitat have incorporated federal and provincial regulations and guidelines as well as measures that have been recommended or proven effective on similar projects in the RAA which will further reduce cumulative effects to marine bird habitats throughout the RAA.
2345.1	round 1	Gitxaala Nation	4.11.7.1	Marine Wildlife - Marine Birds	Please describe population thresholds for SAR populations. At what point will populations be unable to rebound from loss of habitat or incidental mortalities? What percentage of SAR populations are affected by the Project? What about cumulative effects from other projects?	Significance thresholds for marine birds present the limits of an acceptable change in a measurable parameter or state of regional marine bird populations and are based on applicable legislation, regulatory guidance documents, or other management standards (including cultural use). Where thresholds are not set by legislation, policy, and regulatory guidance documents, a threshold has been developed based on existing data and information, scientific literature and professional judgement, and with the incorporation of available traditional ecological knowledge. Significance thresholds vary between species or species groups and potential effects. As described in Section 4.11.2.8 of the Application, a residual effect is considered significant if it affects the viability of local or regional marine bird populations. The viability of species can be affected by several factors, including reproduction, mortality, immigration, emigration, and habitat availability, where viability was defined in the Application as the long-term maintenance in abundance, diversity, or distribution of marine birds through natural recruitment. Species of management concern with potential to occur in the LAA and RAA are described in Section 4.11.3 (see Table 4.11-7). A total of 22 species of management concern were identified as having potential to interact with Project activities and infrastructure, the effects of which may act cumulatively with other projects and activities within the RAA. Potential residual Project and cumulative effects are described in Section 4.11.5 and 4.11.6, respectively. Species listed on Schedule 1 of the Species at Risk Act that are expected to interact with the Project, including mitigation measures for each, are listed in Table 4.11-13 of the Application. The number of affected species cannot be reported as a percentage, because regional populations for each of these species has potential to experience effects, however the degree will vary based on species presence, abundance, and distribution within the RAA and mechanisms for interaction with the Project.
2346.1	round 1	Gitxaala Nation	4.11.7 & 4.11.8	Marine Wildlife - Marine Birds	Given the lack of discussion on in-air noise and dismissal of effects of underwater noise on marine birds, lack of discussion of marine birds of interest to FNs, lack of inclusion of priority birds for BCR5, and lack of fully comprehensive mitigation plans, we disagree in the significance and confidence predictions.	Effects of in-air and underwater noise on marine birds are described in Sections 4.11.5.2 and 4.11.5.4 of the Application. The assessment for marine birds considered results of acoustic models developed for the Project in combination with best-available information in scientific literature to characterize residual Project effects. As per mitigation 4.11.2, a Noise Management Plan and a Marine Activities Plan will be implemented to decrease the extent of in-air and underwater acoustic emissions during Project construction (see Section 14.5 and 14.11 for details). Additional procedures related to blasting, pile driving, and dredging will be outlined in the Marine and Freshwater Resources Management Plan. The Plan will include measures to reduce disturbance to marine fish, which will, by extension, benefit marine birds (see Section 14.9). Sections 4.11.2.2 and 4.11.2.3 describe the Aboriginal Groups from which traditional knowledge and traditional use information was gathered, and how information was incorporated into the assessment. Section 4.11.3.2 provides a summary of findings of traditional ecological knowledge for marine birds and is described in more detail in Appendix Q. Traditional ecological knowledge provided on traditionally harvested species, seasons, and locations are used in combination with Project and regional studies and scientific literature to inform the assessment. Species of cultural importance are discussed throughout Section 4.11.5 and 4.11.6 where there was an identified mechanism for interaction with Project activities and infrastructure. The assessment also integrated information from the Bird Conservation Region 5 (BCR 5) Strategy (Environment Canada 2013), recognizing that the BCR 5 extends from the western Gulf of Alaska to northern California. The Application draws information on conservation objectives outlined in the Strategy that is relevant to marine bird species present, and habitats available, within the LAA and RAA. Priority species identified in the Strategy align with those presented in Section 4.11.3.2 and Appendix Q of the Application and occur within the LAA and RAA. Supporting field studies were developed in consideration of habitat requirements for priority species / species of management concern. The key threats identified for priority species in the Strategy are considered in the Application, where the Project has potential to contribute to residual effects (e.g., habitat change and alteration, mortality, and disturbance). Section 4.11.5.6 of the Application describes residual Project effects that have potential to interact cumulatively with other projects and activities within the RAA, including those identified in the Strategy (e.g., commercial fishing and by-catch, marine transportation). As noted in Section 4.11.7, the Project is not expected to adversely affect the long-term viability of local or regional marine bird populations and Project effects are considered to be not significant. The prediction confidence was considered moderate or high given some uncertainty over the degree to which some marine bird species may be affected by Project activities or infrastructure. Reference: Environment Canada. 2013. Bird Conservation Strategy for Bird Conservation Region 5: Northern Pacific Rainforest. Canadian Wildlife Service, Environment Canada. Delta, British Columbia. 128 pp. + appendices.
2347.1	round 1	Gitxaala Nation	4.11.9	Marine Wildlife - Marine Birds	Follow-up monitoring is an important part of large industry projects. Follow-up monitoring is recommended to confirm that Project related impacts are not causing significant impacts on marine birds, ensuring that mitigation measures are being followed, and allows for issues to be addressed in a timely matter. As such, a monitoring program and an adaptive management plan should be developed.	The criteria for proposed inclusion of a follow-up program are consistent with the Considerations for Developing a Follow-up Program as outlined in the Operational Policy Statement Follow-up Programs under the Canadian Environmental Assessment Act (Government of Canada, 2011). The criteria included a conclusion of potential residual adverse effect and either a low prediction confidence in that conclusion or uncertainty in a specific component of the VC assessment. In cases where the criteria are met, the proposed follow-up program will be used to verify the accuracy of assessment predictions. For VC assessments that concluded moderate to high prediction confidence, these will be managed through the development of Environmental and Operational Management Plans (Section 14) designed to verify compliance of the Project with commitments in the Application and conditions in an Environmental Assessment Certificate.
2348.1	round 1	Gitxaala Nation	6.5.2.5	Marine Use and Navigable Waters	A figure identifying alternate routes has not been provided. It is inappropriate to exclude alternate routes from assessment without identifying their locations and quantifying what "infrequent" use means as part of an overall rationale for exclusion. This is particularly important if alternate routes used in inclement conditions will bring vessels into areas with high harvesting intensity or closer to conservancies where accidents or malfunctions may have greater adverse consequences.	The assessment of Marine Use and Navigable Waters was done using the primary shipping route. This choice was conservative because it represents the route that most large shipping traffic will use and therefore has the greatest potential for adverse effects to marine navigation and fisheries. As described in Section 6.5.2 of the Application, while alternative shipping routes exist, LNG carriers would only ever deviate from the prescribed route under extraneous circumstances (e.g., such as under the direction of the LNG carrier captain or marine pilot to avoid a collision or other emergency). As a result, the assessment focused on the primary shipping route.
2349.1	round 1	Gitxaala Nation	6.5.2.8	Marine Use and Navigable Waters	please define "widely" in the threshold definition ("where the proposed project will create a change or disruption that *widely* restricts or degrades present marine use…[emphasis added to identify word requiring greater definition])	A determination of significant residual effects for Marine Use and Navigable Waters is one where the proposed Project activities are not compatible with established marine use plans or policies, or where the Project will create a change or disruption that widely restricts or degrades present marine uses to a point where the activities cannot continue at current levels and for which this change cannot be mitigated (see Section 6.5.2.8 of the Application). Key elements of this threshold are explained further:"Not compatible" indicates that the Project completely eliminates the option to practice a present marine activity."change or disruption that widely restricts or degrades present marine use" indicates that the potential Project effect has a large geographical extent or severely reduces the ability to practice a marine activity relative to the existing conditions."Cannot continue at current levels and for which this cannot be mitigated" indicates that the current marine practices cannot continue even with mitigation.

2350.1	round 1	Gitxaala Nation	6.5.3	Marine Use and Navigable Waters	It is inappropriate to suggest that "most invertebrate harvesting locations do not appear to overlap with the shipping route (mainly because they are harvested during low tide in the intertidal zone." In fact, harvesters working on foot in the intertidal zone have repeatedly expressed concern that vessel wake in specific local areas may cause a danger to harvesters. Since wave patterns are extremely difficult to predict, a robust monitoring and adaptive management program is required to identify any locations where wake appears to be a problem during operations and to develop additional mitigations.	If it is conservatively assumed that intertidal harvesters on foot are using both low tide periods in a day (this is unlikely, because the two low tides in a day are not often the same tidal height and, therefore, one is more suitable for harvesting than the other), and harvesting can be undertaken for two hours during each low tide (i.e., one hour on each side of each low), then approximately 17% (4/24 hours) of each day is available for intertidal harvesting. The potential for intertidal harvesters to interact with Project-related shipping is temporally restricted on a daily basis; for approximately 83% of each day, wake from Project-related shipping cannot interact with intertidal harvesters Section 6.5.4.2 states that the mean monthly average natural wave height in the Project area is assumed to be between 0.14 m and 1.8 m. The potential maximum wave height (immediately adjacent to the source vessel) of 0.4 m produced by LNG carriers and escort vessels at 12 knots is within the range of anticipated mean monthly average wave height in the Project area. The modeled wake height of LNG carriers (and other vessel types) indicates that wake-related waves attenuate as they travel further from the source vessel (Oceanic Consulting Corporation 2014). This means that the actual wave height at the shoreline is expected to be lower than the wake height at the source vessel, and within the natural wave height range currently experienced by intertidal harvesters. Project-related traffic will travel along the existing and established shipping route currently used by marine traffic (e.g., container ships, cargo ships, breakbulk ships, ferries) to enter and exit Prince Rupert harbour. The predicted wake-related wave height 300 m from the centreline of travel of a large loaded LNG carrier traveling 12 knots (and that modeled for 14 knots) is similar to those predicted for ore carriers, cruise ships, and BC Ferries vessels (Oceanic Consulting Corporation 2014), all of which call at the Port of Prince Rupert. Project-related wake effects are not expected to differ from the variable wave heights and conditions already experienced by intertidal harvesters, relating to natural weather patterns and existing shipping. Reference Oceanic Consulting Corporation. 2014. Kitimat Ship Wake Study. Prepared for: LNG Canada Development Inc.
2351.1	round 1	Gitxaala Nation	6.5.3	Marine Use and Navigable Waters	See comment above.	It is not clear what this comment refers to.
2352.1	round 1	Gitxaala Nation	Figure 6.5-15	Marine Use and Navigable Waters	There appears to be an error in the legend: IUCN Category IV is identified twice. Please correct or clarify.	An errata document is being created that will capture the correction and it will be filed with the BC EAO.
2353.1	round 1	Gitxaala Nation	Table 6.5-12	Marine Use and Navigable Waters	First Nations have consistently indicated concern about the effects of dredge disposal traffic on marine fisheries and other uses. Please provide a rationale for its exclusion from consideration and assessment.	Dredging and disposal at sea activities will be limited to the DFO least risk timing window (November 30 to February 15) and is planned to take place over two years. See Appendix G (Technical Memorandum - Aurora LNG: MOF and Terminal Dredge Modelling) and Appendix H (Technical Memorandum - Aurora LNG: Disposal at Sea Modelling) for additional dredge timing information. Table 6.5-12 indicates that dredging was identified as a construction-related physical activity that could affect marine use and navigable waters. In the context of the operational life of the Project, dredging will occur over a relatively short period during the construction phase, barges will be located outside of major navigation routes during loading, and barges will travel at relatively slow speeds while under way. For these reasons, the effects of dredge-related traffic was not assessed further (see rationale provided in Section 6.5.4.1). However, see the "Effects of Additional Project-related Traffic" technical memo for additional information on dredge-related marine traffic. The technical memo will be filed with the BC EAO.
2354.1	round 1	Gitxaala Nation	6.5.4.1	Marine Use and Navigable Waters	The Application states that smaller vessels associated with construction "were not carried forward in the assessment of marine use and navigable waters because this vessel traffic does not represent the worst case scenario for potential adverse effects." Failure to include these vessels significantly underrepresents effects to efficiency of movement, access to berthing, and potential for vessel accidents due to vessel congestion between Digby and Kaien Island. To adequately assess effects; both vessel types need to be included in the assessment; numbers, however, should be disaggregated to identify increases in number of small vessels. This is of particular interest and relevance to harvesters in smaller vessels.	See the "Small Craft Assessment" technical memo which will be filed with the BC EAO.
2355.1	round 1	Gitxaala Nation	6.5.4.1	Marine Use and Navigable Waters	Please provide duration (weeks or months) for disposal, season, and number of seasons, and use this information to provide a robust rationale for the decision not to assess the potential adverse effects of dredging traffic on marine use.	See the "Effects of Additional Project-Related Traffic" technical memo which will be filed with the BC EAO.
2356.1	round 1	Gitxaala Nation	6.5.4.2	Marine Use and Navigable Waters	please see comment associated with section 6.5.3, above. Rather than stating that "no further assessment of vessel wake is warranted", it is appropriate to state that the complexities of modelling suggest uncertainty regarding effects; an adaptive management program is therefore required.	Aurora LNG disagrees with the statement that "complexities of modelling suggest uncertainty regarding (wake) effects; an adaptive management program is therefore required." Wake modelling has demonstrated that wake waves from LNG carriers are within the range of naturally occurring waves in the assessment area. Section 6.5.4.2 of the Application states that the mean monthly average natural wave height in the Project area is assumed to be between 0.14 m and 1.8 m. The potential maximum wave height (immediately adjacent to the source vessel) of 0.4 m produced by LNG carriers and escort vessels at 12 knots is within the range of anticipated mean monthly average wave height in the Project area. The modeled wake height of LNG carriers (and other vessel types) indicates that wake-related waves attenuate as they travel further from the source vessel (Oceanic Consulting Corporation 2014). This means that the actual wave height when it reaches the shoreline or a fishing vessel is expected to be lower than the original wake height at the source vessel, and within the natural wave height range currently experienced by shoreline harvesters and fishing vessels. Project-related traffic will travel along the existing and established shipping route currently used by other marine traffic (e.g., container ships, cargo ships, breakbulk ships, ferries) to access the Port of Prince Rupert. The predicted wake-related wave height 300 m from the centreline of travel of a large loaded LNG carrier traveling at 12 knots (and that modeled for 14 knots) is similar to those predicted for ore carriers, cruise ships, and BC Ferries vessels (Oceanic Consulting Corporation 2014), all of which call at the Port of Prince Rupert. Project-related wake effects are not expected to differ from the variable wave heights and conditions already experienced by fishing vessels and shoreline harvesters, relating to natural weather patterns and existing shipping. Consequently, no significant effects from Project generated wake are predicted. Reference Oceanic Consulting Corporation. 2014. Kitimat Ship Wake Study. Prepared for: LNG Canada Development Inc.
2357.1	round 1	Gitxaala Nation	6.5.4.3	Marine Use and Navigable Waters	See comment associated with section 6.5.2.5	It is not clear what this comment specifically refers to.
2358.1	round 1	Gitxaala Nation	6.5.5.1	Marine Use and Navigable Waters	Please define the term "frequent enough" with respect to different fisheries (where the Application states that 'shipping traffic could reduce access if traffic is frequent enough such that a site can no longer be used.)	No quantitative definition is given to the term in question. Instead, the sentence is meant to highlight the mechanism by which a potential adverse effect might manifest. Further explanation of the qualitative language used to describe the residual effects in Section 6.5 of the Application is provided below: Residual effects are described using multiple characterizations (e.g., magnitude, geographical extent, frequency, etc.) with either quantitative (e.g., an area, distance, or count) or qualitative (e.g., low, medium, high) measures for each characterization. Wherever possible and reasonable, quantitative measures are preferred to promote understanding of the potential environmental effects. However, where quantitative federal or provincial standards, or industry guidelines are lacking, qualitative descriptions must be used to describe potential effects. The characterizations, descriptions, and definitions used for Marine Use and Navigable Waters are provided in Table 6.5-5. The intent of Table 6.5-5 is to provide a simplified understanding of each characterization and how each one was defined in the effects assessment.
2359.1	round 1	Gitxaala Nation	6.5.5.1	Marine Use and Navigable Waters	See comment associated with section 6.5.4.1. Effects of carriers and small vessels must each be assessed; data on each should be disaggregated to understand individual effects by vessel size class ("large size" versus "other")	Please see the "Small Craft Assessment" technical memo which will be filed with the BC EAO.
2360.1	round 1	Gitxaala Nation	Table 6.5-13	Marine Use and Navigable Waters	All of these mitigations assume smaller vessels must give way to larger (LNG) vessels. While this is appropriate mariner behaviour, it does not address the fact that changing behaviour to accommodate LNG vessels requires may require a deviation from preferred routing or activities. This represents an adverse effect on the exercise of traditional rights and must be addressed in Part C of the application.	Aurora LNG acknowledges that in some cases the collision regulations would stipulate that other vessels give way to LNG carriers. Notwithstanding, with implementation of the proposed mitigation measures, Aurora LNG is confident that the potential effects on Marine Use and Navigable Water will not be significant. Issues related specifically to traditional harvest are covered in Section 12.5.6 of the Application, and determined that the ability to exercise this right will be maintained.
2361.1	round 1	Gitxaala Nation	6.5.5.2	Marine Use and Navigable Waters	The Application notes that 17% of the small vessel corridor will be alienated. The Application does not, however, indicate how many more small vessels will be using this corridor during the 5-year construction period. It is not possible, therefore, to fully assess the effects of the project on marine use. Vessel congestion in the reduced small vessel corridor may be considerable and needs to be quantified before it can be dismissed from consideration.	See the "Small Craft Assessment" technical memo which will be filed with the BC EAO.
2362.1	round 1	Gitxaala Nation	6.5.5.3	Marine Use and Navigable Waters	The Application notes that "a fisher may lose a total of one hour of fishing per day). This is a misleading statement because it implies fishing occurs year round. Harvesting windows for many species are considerably smaller and weather conditions further limit fishing opportunity, thus a one-hour limitation may be more significant than implied. To be adequately calculated, the hours lost should be represented as a percentage of the total number of hours available for the fishery and the average number of days during that window in which winds are too strong to harvest.	See the "Effects of Lost Fishing Time" technical memo which will be filed with the BC EAO.
2363.1	round 1	Gitxaala Nation	Table 6.5-15	Marine Use and Navigable Waters	Given the exclusion of small construction vessels from assessment, the determination of magnitude of residual effects of construction is suspect.	See the "Effects of Additional Project-Related Traffic" technical memo which will be filed with the BC EAO.
2364.1	round 1	Gitxaala Nation	6.5.6.3	Marine Use and Navigable Waters	See comment above.	See the "Effects of Additional Project-Related Traffic" technical memo which will be filed with the BC EAO.
2365.1	round 1	Gitxaala Nation	6.5.6.5	Marine Use and Navigable Waters	See comments above.	See the "Effects of Additional Project-Related Traffic" technical memo which will be filed with the BC EAO.
2366.1	round 1	Gitxaala Nation	Application, 8.2.3.2.3	Human Health	Consumptions rates of Dungeness crabs and horse clams were taken from a First Nations Food Nutrition & Environment Study (Chan et al., 2011). The study solicited information from First Nation communities across the province, including some along the BC coast. Please confirm/verify that the consumption rates taken from this study are relevant and applicable to the Gitxaala FN.	Refer to the document titled, "Supplemental Information for Traditional Marine Foods", which will be filed with the BC EAO. The "Supplemental Information for Traditional Marine Foods" technical memo was presented to the Working Group in draft for a pre-read on April 18, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2367.1	round 1	Gitxaala Nation	Application, 8.2.3.2.3	Human Health	The recommended maximum weekly intake value was estimated for each food type for a toddler and adult. Consumption of a food type up to this value consistently throughout the year is assumed to be safe (i.e. without a health concern). Please provide a sample calculation with the values for each input parameter, with justification for each value. Is it considered safe for an individual to consume up to the RMWI for multiple food types?	The "Supplemental Information for Traditional Marine Foods" technical memo has been created that includes responses to this comment and it will be filed with the BC EAO. The "Supplemental Information for Traditional Marine Foods" technical memo was presented to the Working Group in draft for a pre-read on April 18, 2017. The memo was updated as a result of the discussion during the Working Group meeting.

2368.1	round 1	Gitxaala Nation	Application, 8.2.5.1.2	Human Health	The Application notes that a key assumption related to air emissions is that the operations phase at full build-out has the greatest emission rates and emission volumes of airborne COPCs among all Project Phases. During construction and decommissioning, the site activities are quite different than during operations (movement of fill, paving, construction of facilities, installation of utilities, etc.); subsequently, the emission sources and airborne COPCs could be significantly different than during operations. Verify this assumption is correct given the different types of equipment, site activities, and potential for different airborne COPCs as a result of construction/decommissioning specific activities. Additionally, during construction, there would be days where emissions would be higher than others. An evaluation of the emissions should include average and peak emission days.	The potential health risk associated with the construction phase was not assessed in the Application because the amount of PM10 and PM2.5 produced was similar between the construction and project-alone phase. For example, the Air Quality TDR (Appendix A of the Application), Table 13 (page 21) shows the relative emissions of sulphur dioxide, nitrous oxides, PM10 and PM2.5 for the construction and operations phases. Emissions of sulphur dioxide and nitrous oxides are substantially greater in the operations phase. The average annual emissions of PM10 and PM2.5 during the construction phase and project-alone phase. - Construction PM10 emissions = 21.5 tonnes/year. - Construction PM2.5 emissions = 20.9 tonnes/year. - Project operations PM10 emissions = 19.2 tonnes/year. - Project operations PM2.5 emissions = 18.4 tonnes/year. Based on the results of the Human Health assessment (Chapter 8 of the Application), Table 8.2-9 (page 8-34), the potential change in health risk from particulate matter in the operations phase is negligible. In locations such as Dodge Cove (i.e., Receptor ID: D-337D, D-372F and D-385) and the worker camp within the Project fenceline (i.e., Receptor ID: IF-1764, IF-1825, and IF-385), the concentration ratio increases marginally from 0.00 to 0.04 above the Base Case. There are negligible changes in the health risk to people from particulate matter in the communities that are closest to the proposed Project. People in communities more distal from the proposed Project (e.g., Prince Rupert, Port Edward, Metlakatla Village) would experience even lower exposures. Given this information, it is logical to conclude that the assessment of particulate matter in the operations phase (i.e. Application Case) would provide sufficient information to conclude a similar degree of health risk in the construction phase. For other types of substances belonging to the class of chemicals known as volatile organic compounds (VOC), which includes acrolein, benzene, 1,3-butadiene...etc..., refer to the technical memorandum, "Volatile Organic Compounds and Human Health Assessment" which will be filed with the BC EAO. The "Volatile Organic Compounds and Human Health Assessment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2369.1	round 1	Gitxaala Nation	Application, 8.2.5.2.1	Human Health	The Application indicates construction activities include the use of heavy equipment and vehicles during site clearing and grading, construction of new roads, and mobilization of materials to Digby Island. US EPA mobile source air toxics considers the following national and regional scale cancer risk drivers: acrolein, benzene, 1,3-butadiene, diesel particulate matter plus diesel exhaust organic gases (diesel PM), formaldehyde, naphthalene, and polycyclic organic matter. These substances should be included in the HHRA or a rationale provided as to why it is suitable to exclude these as airborne COPCs?	The potential health risk associated with the construction phase was not assessed in the Application because the amount of PM10 and PM2.5 produced was similar between the construction and project-alone phase. For example, the Air Quality TDR (Appendix A of the Application), Table 13 (page 21) provides the average annual emissions of PM10 and PM2.5 during the construction phase and project-alone phase. - Construction PM10 emissions = 21.5 tonnes/year. - Construction PM2.5 emissions = 20.9 tonnes/year. - Project operations PM10 emissions = 19.2 tonnes/year. - Project operations PM2.5 emissions = 18.4 tonnes/year. Based on the results of the Human Health assessment (Chapter 8 of the Application), Table 8.2-9 (page 8-34), the potential change in health risk from particulate matter in the operations phase is negligible. In locations such as Dodge Cove (i.e., Receptor ID: D-337D, D-372F and D-385) and the worker camp within the Project fenceline (i.e., Receptor ID: IF-1764, IF-1825, and IF-385), the concentration ratio increases marginally from 0.00 to 0.04 above the Base Case. There are negligible changes in the health risk to people from particulate matter in the communities that are closest to the proposed Project. People in communities more distal from the proposed Project (e.g., Prince Rupert, Port Edward, Metlakatla Village) would experience even lower exposures. Given this information, it is logical to conclude that the assessment of particulate matter in the operations phase (i.e. Application Case) would provide sufficient information to conclude a similar degree of health risk in the construction phase. For other types of substances belonging to the class of chemicals known as volatile organic compounds (VOC), which includes acrolein, benzene, 1,3-butadiene...etc..., refer to the technical memorandum, "Volatile Organic Compounds and Human Health Assessment" which will be filed with the BC EAO. The "Volatile Organic Compounds and Human Health Assessment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2370.1	round 1	Gitxaala Nation	Application, 8.2.3.2.1	Human Health	The Application indicates 29 gridpoints were selected to represent human receptor locations. Do any of these correspond to the maximum points of impingement (highest air concentration predicted to occur over land and over water)? The MPOI may be important considerations for short-term exposures to airborne contaminants.	Among the 1,905 land-based gridpoints identified in the human health chapter, the sub-set of 29 gridpoints representing human receptor locations (i.e., populated areas) do not correspond to the maximum point of impingement (MPOI). The location of the MPOI for a criteria air contaminant is a function of its proximity toan emission source. Therefore, the MPOI for any given criteria air contaminant will likely be located immediately adjacent to the Aurora LNG fenceline, or another project within the Prince Rupert and Port Edward area. The location of the MPOI is not a human receptor location for one or both of the following reasons: 1. The location is over water. 2. The location is not populated, or may be zoned for non-residential land use (e.g., industrial land use). As part of the April 19, 2017 working group meeting, Aurora LNG has agreed to provide the map locations of the MPOI for 1-hour NO2. Refer to the document titled, "Maximum Points of Impingement for 1-hour Nitrogen Dioxide Concentrations", which will be filed with the BC EAO.
2371.1	round 1	Gitxaala Nation	Application, 8.2.5.2.3	Human Health	The Application indicates the potential effects to human health from changes to air quality during construction and decommissioning phases of the Project would be substantially lower than the operations phase. Please verify this is correct since the emission sources during construction/decommissioning may be significantly different than during operations.	The information in the Application regarding changes to air quality between the three Project phases is correct. The emissions during the construction phase are primarily associated with diesel-powered equipment, but the emission volumes are deemed to be highly unlikely to change the ambient air quality of the airshed, and therefore, are not identified in the Application Information Requirements for the Human Health VC. The potential health risk associated with the construction phase was not assessed in the Application because the amount of PM10 and PM2.5 produced was similar between the construction and project-alone phase. For example, the Air Quality TDR (Appendix A of the Application), Table 13 (page 21) provides the average annual emissions of PM10 and PM2.5 during the construction phase and project-alone phase. - Construction PM10 emissions = 21.5 tonnes/year. - Construction PM2.5 emissions = 20.9 tonnes/year. - Project operations PM10 emissions = 19.2 tonnes/year. - Project operations PM2.5 emissions = 18.4 tonnes/year. Based on the results of the Human Health assessment (Chapter 8 of the Application), Table 8.2-9 (page 8-34), the potential change in health risk from particulate matter in the operations phase is negligible. In locations such as Dodge Cove (i.e., Receptor ID: D-337D, D-372F and D-385) and the worker camp within the Project fenceline (i.e., Receptor ID: IF-1764, IF-1825, and IF-385), the concentration ratio increases marginally from 0.00 to 0.04 above the Base Case. There are negligible changes in the health risk to people from particulate matter in the communities that are closest to the proposed Project. People in communities more distal from the proposed Project (e.g., Prince Rupert, Port Edward, Metlakatla Village) would experience even lower exposures. Given this information, it is logical to conclude that the assessment of particulate matter in the operations phase (i.e. Application Case) would provide sufficient information to conclude a similar degree of health risk in the construction phase. For other types of substances belonging to the class of chemicals known as volatile organic compounds (VOC), which includes acrolein, benzene, 1,3-butadiene...etc..., refer to the technical memorandum, "Volatile Organic Compounds and Human Health Assessment" which will be filed with the BC EAO. The "Volatile Organic Compounds and Human Health Assessment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2372.1	round 1	Gitxaala Nation	8.2.2.5.1 & Table 8.2-3	Human Health	The spatial boundaries established for air quality and harvested food quality are based on models used to assess air quality and sediment plume dispersion. For the assessment of human health from harvested food quality, were these boundaries used for the cumulative effects assessment? If yes, is this appropriate since marine food harvesting could occur throughout the region, thus exposure would occur from a number of locations.	The assessment of human health from marine harvested food quality applies the same spatial boundary established for air quality and harvested food quality based on models used to assess air quality and sediment plume dispersion including for the cumulative effects assessment. If an individual also harvests from multiple locations outside of the RAA (area within which the potential for cumulative effects are considered), exposure to chemical substances in those foods are considered to be independent and not affected by the Project on a cumulative basis.
2373.1	round 1	Gitxaala Nation	Application, Table 8.2-11	Human Health	The Application indicates interactions between Project residual effects and residual effects of other projects are not expected. Please explain how the potential for an individual to harvest food from a number of sites, including at/near this Project then at other Project sites, was assessed taking into consideration the areal extent of traditional food harvesting areas.	A cumulative effects assessment evaluates project interactions that overlap (spatially and or temporally) with those of other known or proposed projects. In the case of marine harvested foods, no other past, present or reasonably foreseeable future projects were identified in the vicinity of the proposed Project dredge footprint and surrounding sediment plume area that would overlap spatially or temporally (i.e., no other dredging or similar activities were identified in the area of the predicted plume or within the same time period). If there are no spatial or temporal overlaps of activities from other projects that could affect marine food quality, the effects would be assessed independently for each project because the effects are not cumulative.
2374.1	round 1	Gitxaala Nation	HH TDR, 4.1.2	Human Health	The TDR states that CCME ISQGs were used for screening purposes to select COPCs in lieu of environmental quality guidelines applicable to seafood quality for the protection of human health. Is this appropriate and protective of human health? There are instances where something is not toxic to sediment/aquatic life but would be toxic to human health (e.g. red tides).	As noted, there are no sediment quality guidelines for the protection of human health from any provincial, federal or international regulatory agency. Screening for chemicals is not intended to be protective of human health, since the purpose of screening is only to identify chemicals of potential concern. The risk assessment evaluates the level of exposure to chemicals of potential concern to determine the health risk. There are many substances that exhibit varying degrees of toxicity (or no toxicity) to animals and plants, which is why there are environmental guidelines specific to the protection of various forms of life (e.g., marine aquatic life, freshwater aquatic life, humans).
2375.1	round 1	Gitxaala Nation	HH TDR, 5.1 and Table 2	Human Health	The TDR states health-based BC MOE AAQOs were used in this risk assessment. Air quality objectives are used to guide air-management decisions and may not be suitable to use in a human health risk assessment. TRVs used in most human health risk assessments typically consider "toxicity-based" and "persistence and bioaccumulation-based" criteria. Please provide a rationale for the use of each screening criteria in this risk assessment.	The BC Ministry of Environment indicates that "Air quality objectives are limits on the acceptable presence of contaminants in the atmosphere, established by government agencies to protect human health and the environment." http://www.bcairquality.ca/regulatory/air-objectives-standards.html Further guidance on the application of provincial air quality objectives for sulphur dioxide indicate that, "A provincial interim ambient air quality objective of 75 ppb (1-hour) was adopted in 2014 to provide a health-based tool". http://www.bcairquality.ca/pdf/so2_aqo-implementation_guide.pdf The use of the BC MOE AAQOs as guides for air management decisions does not exclude its application in health-based assessments.
2376.1	round 1	Gitxaala Nation	HH TDR, 6.2.4, 6.3.2.1 and 6.3.2.2	Human Health	Please provide a sample calculation for the estimated daily intakes, non-carcinogenic and carcinogenic risk estimates, showing site-specific and assumed input values.	The "Supplemental Information for Traditional Marine Foods" technical memo has been created that includes responses to this comment and it will be filed with the BC EAO. The "Supplemental Information for Traditional Marine Foods" technical memo was presented to the Working Group in draft for a pre-read on April 18, 2017. The memo was updated as a result of the discussion during the Working Group meeting.
2377.1	round 1	Gitxaala Nation	9.0	Accidents or Malfunctions	Gitxaala is concerned that the addition of significant infrastructure at the entrance to Prince Rupert will increase the severity of tsunami, surge, or seiche events. Gitxaala requests that a full tsunami risk assessment be completed for the Prince Rupert Harbout, in light of the infrastructure being proposed. To be covered will be the effect of debris from Nexen infrastructure and vessels on the harbour.	The Project infrastructure installed on Digby Island are not expected to increase the severity of tsunami, surge or seiche events in the Prince Rupert Harbour. The Project will be designed to withstand extreme environmental events as outlined in Section 10 of the Application. The LNG plant and marine terminal will be designed to accommodate tsunamis according to the design standards of Canadian Standards Association EXP276.1-2015 express document (CSA 2015b). Additional assessment details are provided in the Tsunami Hazard Assessment report (ITR 2015).
2378.1	round 1	Gitxaala Nation	9.0	Accidents or Malfunctions	Gitxaala is concerned that the addition of significant infrastructure at the entrance to Prince Rupert will increase the severity of tsunami, surge, or seiche events. In the event that a maximum credible surge occurs, will ships at anchor be affected (dragged on anchor)?	Section 10.2.6 of the Application considers the effects of potential tsunami and seiche events on the proposed Project. The potential for tsunamis, surge, or seiche events to affect vessels at anchor would depend on various factors specific to such events (e.g., the magnitude of the physical event, the location of the event relative to the anchored vessel, the location of the vessel at anchor, the tide conditions at the time of the event, the water depth of the vessel, the level of coastal sheltering, and the warning time following event detection).
2379.1	round 1	Gitxaala Nation	9.2	Accidents or Malfunctions	The application notes that "Hypothetical events or interactions were identified for each scenario and were selected if they were recognized as a likely accident***and*** had a potential consequence of concern [emphasis added]". This is incorrect methodology for accidents which, by definition, are unplanned. This statement must be revised to read "...were selected if they were recognized as a likely accident ***or*** had a potential consequence of concern." and re-assessed accordingly.	Aurora LNG agrees that there is a wording error. An erratum to correct the wording in the sentence quoted in the comment, by replacing 'and' with 'or', will be submitted. This is a wording error only and its correction will not affect the methodology, scenarios or the characterization of effects in the assessment. An errata document is being created that will capture these corrections and it will be filed with the BC EAO.
2380.1	round 1	Gitxaala Nation	Table 9.3-1	Accidents or Malfunctions	Please add an interaction between Vessel grounding/collision and Archaeological/Heritage resources: a marine accident resulting in a release of LNG or fuel (diesel or bunker) may affect the perceived quality of the environment and therefore affect traditional use assessed in Part C.	A screening of potential interactions with each VC against the VCs specific characterization of residual effects criteria was done in section 9.3.1. Based on the criteria for Archaeological and Heritage Resources, there isn't expected to be a potential effect of concern resulting from vessel grounding or collision. Accidents and malfunctions as they relate to Aboriginal Interests are addressed in Section 12.6.
2381.1	round 1	Gitxaala Nation	9.4.1	Accidents or Malfunctions	It is an overstatement to say that there are no interactions associated with VCs from motor vehicle collisions. Revise to indicate that interactions may occur but the residual effect is not expected to be significant.	The potential interactions between a motor vehicle collision and VCs could arise if the collision resulted in an on-shore fire/explosion or an on-shore spill. Potential interactions between an on-shore fire/explosion and on-shore spill on VCs are described in Section 9.6 and Section 9.8, respectively.Please reference these sections for VC interactions and the overall significance determination.

2382.1	round 1	Gitxaala Nation	9.5.2	Accidents or Malfunctions	Please indicate the way in which First Nations communities will be integrated into response planning.	As stated in Section 12.6 of the Application, 'Aurora LNG looks forward to continuing to consult with Aboriginal Groups about safety and emergency response strategies'. Aurora LNG is hopeful that such discussions will help identify meaningful ways in which Aboriginal Groups such as the Gitxaala Nation may be integrated into Project-related response planning and preparedness.
2383.1	round 1	Gitxaala Nation	9.7.3	Accidents or Malfunctions	Given the presence of SARA listed species and the potential for interactions with flare events, population effects may occur. A flare screen or other exclusion device should be added to project mitigation.	The assessment of an LNG Plant Malfunction on wildlife determined that potential residual effects on terrestrial wildlife (including SARA species) are not expected to have a population level effect and are predicted to be not significant. The mitigation measures that Aurora LNG have planned are intended to protect all terrestrial wildlife species, including those that are SARA listed. As such, Aurora LNG believes that no additional mitigation is warranted to protect SARA listed species from emergency flaring. Aurora LNG will continue to consult with Metlakatla First Nation on various aspects of the Project including the development of environmental management plans.
2384.1	round 1	Gitxaala Nation	10.2.1.2	Effects of the Environment on the Project	The application notes that vessel icing is an issue but preventative and response measure to manage this potential effect are not provided. Please indicate how vessel and berth icing and effects on weight, stability, seaworthiness, and berthing will be managed.	Potential structural icing on an LNG processing facility, marine terminal, or on LNG carriers or associated support vessels is addressed through facility design and by implementing a de-icing program where required during operations. The program would be developed during detailed design.
2385.1	round 1	Gitxaala Nation	10.2.2.1	Effects of the Environment on the Project	The curve used to predict a 1:100-year flood is an historical record from the PRPA. It is generally recognized, in light of climate change, that the past is not a reliable predictor of the future and, in the case of rainfall events, a plus/minus 20% change is considered plausible. Please ensure that the facility design will accommodate a rainfall event equivalent to 1:100 value plus 20%. (165.6mm + 33.12 = 198.72mm) or provide a rationale for why this is not appropriate/necessary.	Climate change effects on precipitation during the life of the Project will be considered during final Project design. As stated in Section 10.2.2.1 of the Application, the intensity-duration-frequency curve does not consider potential changes to rainfall patterns associated with climate change. Section 10.2.2.2 of the Application also states that a Stormwater Management Plan will be developed that will be designed to account for extreme weather events and will incorporate climate change factors over the life of the project.
2386.1	round 1	Gitxaala Nation	10.2.3.2	Effects of the Environment on the Project	Please indicate how the deck heights for the MOF and marine terminal platforms (9m and 12m respectively) were derived. If an extreme event at low tide plus storm surge generated an extreme water level of 8.06m (application p.10-8), how is a MOF deck height of 9 m sufficient to accommodate a similar storm at high tide accompanied by increased sea levels associated with climate change.	Aurora LNG notes that the wording in Section 10.2.3.1, p. 10-8 would benefit from additional clarification. The surge peaked at low tide; however, the peak total water level was attained six hours later (around high tide). As an erratum, Aurora LNG will revise the third from last sentence in the first paragraph on p. 10-8 to 'Abeysirigunawardena and Walker (2008) showed that an intense storm during the winter of 2003 generated a maximum surge of 73 cm at low tide, which produced an extreme water level of 8.06 m above Chart Datum six hours after low tide.' An errata document is being created that will capture this correction and it will be filed with the BC EAO.
2387.1	round 1	Gitxaala Nation	10.2.6	Effects of the Environment on the Project	The Application has not considered tsunamis to pose a risk to the Project. Community members are nevertheless concerned by the damaging effect of or on project infrastructure by material put in motion by a tsunami.	Aurora LNG acknowledges Gitxaala Nation's concerns regarding risks associated with tsunamis. The Application provides an assessment of the effect of tsunami on the proposed Project in Section 10.2.6. As stated in Section 10.2.6.4 'By adhering to the relevant codes and recommendations from the tsunami hazard assessment, the potential effects of tsunamis will be prevented, avoided, or reduced through design, construction and operational standards.'
2388.1	round 1	Gitxaala Nation	14	Environmental and Operational Management Plans	The EMPs are deficient in detail per requirements in the AIR, which states that "The Application will provide a list and **comprehensive description** of the Environmental Management and Operational Plans for construction and operations of the proposed Project which will be refined during the Assessment of each VC." (bold underline added for emphasis). The Application, however, does not provide "comprehensive descriptions" of the EMPs. The brief descriptions largely identify information that is required for a "comprehensive description" without actually providing the description that the AIR demands. Further, as the Application states, "The EMPs describe the protection measures implemented onsite to avoid or reduce potential adverse effects." Since the EMPs are not provided - even in a preliminary form - we are therefore being asked to conclude on the significance of residual effects without the protection measures described in the EMPs. The brief descriptions and references to the list of relevant mitigation measures is not sufficient to determine adequacy for the purpose of this assessment. A key importance of an EMP is for reviewers to understand how the mitigation measures will be implemented and how they may collectively prevent significant harm to the sustainability of the VC. The EMP should also be very clear as how specific potential effects will be mitigated, including additional mitigation options and risk management procedures. The current descriptions don't explain how the EMPs relate to the results of the effects assessments (apart from simply listing related effects in a table). In the absence of comprehensive EMPs to review, the Working Group and decision makers are not able to determine whether the impacts are going to be reasonably addressed with what has been provided.	Section 14 of the Application provides a comprehensive list of proposed management plans to be developed as Project design details become available and the conditions of an approval are presented to the proponent. The proposed contents of these plans are substantively presented in the form of the many mitigation measures that have been developed for each VC and are summarized in Section 16. These mitigation measures, as well as design mitigation presented in the Project Overview, form the basis of the assessment of residual effects that is, in general, highly confident. Aurora LNG will engage with the appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the EMPs.
2389.1	round 1	Gitxaala Nation	14	Environmental and Operational Management Plans	Please provide clarity as to when an appropriate level of detail will be provided and that sufficient time be provided for the Working Group to review and comment by the end of the assessment.	Details of the Environmental Management Plans will be developed prior to commencement of the Project phase to which they apply, consistent with any requirements outlined in Environmental Assessment Certificate Conditions.
2390.1	round 1	Gitxaala Nation	15.2.1	Follow-up Programs and Compliance Reporting	A complete follow up program is not provided, as required by the AIR: "*The Application will provide a description of the proposed monitoring and follow-up programs, including the activities, objectives, and reporting,* ***in sufficient detail to reliably verify predicted effects (or absence of them) and to confirm both the assumptions and the effectiveness of mitigation***." (bold underline added for emphasis). The brief general description of the contents of the follow up program to be provided in the future is not sufficient for this assessment (per the AIR). Please provide a complete proposed follow up program for the heron rookery.	Aurora LNG is committing to maintaining setbacks to decrease the extent of sensory disturbance in the vicinity of active nesting sites for great blue heron and to reduce the potential for flushing during the nesting and rearing period. Aurora LNG acknowledges that Develop with Care recommends as a best management practice that excessive noises should not occur within 1,000 m of a great blue heron colony during the nesting window (BC MOE 2014). As per mitigation 4.7.4, high-disturbance Project-related activities (e.g., blasting, pile driving) will be avoided where practicable during the breeding window (i.e., January 15 through September 15) within 500 m of the great blue heron rookery at Dodge Cove. To address the uncertainty over the degree to which high disturbance activities occurring within 1,000 m of the heron rookery may result in disturbance displays by nesting herons (as per provincial guidelines), Aurora LNG is committing to monitoring for changes in breeding activity at the rookery if high disturbance activities for Project construction occur within 1,000 m of the rookery during the breeding window (January 15 to September 15 for great blue heron). Given the geography of the area and the fact that there is a ridge of land that visually separates the rookery from proposed road corridor it is unlikely that road construction activities will cause a change in breeding activity. Monitoring protocols will follow the Survey Protocol for Measurement of Nesting Productivity at Pacific Great Blue Heron Nesting Colonies (Vennesland and Norman 2006). Monitoring and adaptive approaches will be described in detail in the Wildlife Management Plan. Aurora LNG will engage with the appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding development of the Wildlife Management Plan. Reference: British Columbia Ministry of Environment (BC MOE). 2014. Develop with Care 2014: Environmental Guidelines for Urban and Rural Land Development in British Columbia. Available at: http://www.env.gov.bc.ca/wld/documents/bmp/devwithcare/index.html#Main. Accessed: April 2016. Vennesland, R. G. and D. M. Norman, 2006. Survey Protocol for Measurement of Nesting Productivity at Pacific Great Blue Heron Nesting Colonies. The Heron Working Group.
2391.1	round 1	Gitxaala Nation	15.2.2	Follow-up Programs and Compliance Reporting	A complete follow up program is not provided, as required by the AIR: "*The Application will provide a description of the proposed monitoring and follow-up programs, including the activities, objectives, and reporting,* ***in sufficient detail to reliably verify predicted effects (or absence of them) and to confirm both the assumptions and the effectiveness of mitigation***." (bold underline added for emphasis). The brief general description of the contents of the follow up program to be provided in the future is not sufficient for this assessment (per the AIR). Please provide a complete proposed follow up program for Acidification and Eutrophication.	The acidification and eutrophication follow-up and monitoring programs are expected to be developed on a regional level and the plan is to consult with Aboriginal Groups, MOE and other local industry to finalize those programs. It is expected that Aboriginal Groups will be involved in the implementation of those programs. Please see the "Additional Information about Eutrophication and Acidification in Freshwater" technical memo for additional details on future monitoring programs. The "Additional Information about Eutrophication and Acidification in Freshwater" technical memo was presented to the Working Group in draft for pre-read on April 17, 2017 under the title of "Nutrient Nitrogen in Lakes." The memo was updated as a result of the discussion during the Working Group meeting.
2392.1	round 1	Gitxaala Nation	15.2.3	Follow-up Programs and Compliance Reporting	A complete follow up program is not provided, as required by the AIR: "*The Application will provide a description of the proposed monitoring and follow-up programs, including the activities, objectives, and reporting,* ***in sufficient detail to reliably verify predicted effects (or absence of them) and to confirm both the assumptions and the effectiveness of mitigation***." (bold underline added for emphasis). The brief general description of the contents of the follow up program to be provided in the future is not sufficient for this assessment (per the AIR). Please provide a complete proposed follow up program for the Marine Sediment Deposition.	Aurora LNG is committed to developing and implementing a Marine Water Quality Monitoring Program to monitor turbidity and total suspended solids associated with dredging activities, to characterize water quality parameters in effluent discharges as per permitting requirements, and to monitor the implementation and effectiveness of mitigation measures. The plan will include water quality thresholds, monitoring frequency, and specific monitoring locations. This plan, as well as details specific to monitoring potential sediment deposition, will be developed in accordance with industry best management practices and standards, applicable regulations, and conditions of the Environmental Assessment Certificate and relevant permits. The plan will be developed through engagement with applicable regulators, Schedule B Aboriginal Groups, and specific stakeholders.It is standard practice for these management plans to include (at least) the following information: background on the need for the program or planregulatory context consultation and engagementobjectivesmonitoring and field methodsreporting requirements adaptive management framework. Aurora LNG's framework for adaptive management is as follows: Environmental management plans, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended).
2393.1	round 1	Gitxaala Nation	15.3	Follow-up Programs and Compliance Reporting	Complete monitoring programs are not provided, as required by the AIR: "*The Application will provide a description of the proposed monitoring and follow-up programs, including the activities, objectives, and reporting,* ***in sufficient detail to reliably verify predicted effects (or absence of them) and to confirm both the assumptions and the effectiveness of mitigation***." (bold underline added for emphasis). The brief general description of the contents of the monitoring programs to be provided in the future is not sufficient for this assessment. This is a deficiency per the AIR. Please provide complete proposed monitoring programs at a sufficient level of detail.	As outlined in Section 14.2 of the Application, each Environmental Management Plan (EMP) will include requirements for monitoring (e.g., compliance and/or effectiveness) and reporting. Aurora LNG will engage with the appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the EMPs. The implementation of EMPs will be overseen by environmental professionals to confirm compliance with monitoring and reporting requirements. EMPs, where appropriate, will be updated as the Project progresses and monitoring results are analyzed. Annual reviews of the plans will be undertaken, subject to the requirements of the program and the effects being monitored. Should any issues be identified during the scheduled reviews, modification to the management plans will be discussed with appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended).
2394.1	round 1	Gitxaala Nation	15.3	Follow-up Programs and Compliance Reporting	The six topics for monitoring programs (still to be provided) do not cover some components that should be expected to include compliance monitoring and reporting, such as noise, wildlife (marbled murrelet and bats), marine mammals, freshwater & marine fish habitat (not just monitoring of the offsetting plan), social values, and archaeology. All these components warranted EMPs to mitigate impacts, so some form of compliance monitoring and reporting should be expected. When complete monitoring programs are provided, they should include proposed monitoring related to all EMPs.	As outlined in Section 14.2 of the Application., each EMP will include requirements for monitoring (e.g., compliance and/or effectiveness) and reporting.Aurora LNG will engage with the appropriate regulatory agencies and the Aboriginal Groups identified in Schedule B of the Section 11 Order (as amended) regarding the development of the EMPs. The implementation of EMPs will be overseen by environmental professionals to confirm compliance with monitoring and reporting requirements.
2395.1	round 1	Gitxaala Nation	Appendix N	Marine Wildlife - Marine Mammals	Please indicate exactly what changes were made to Figure 1 when the appendice was updated in early February.	A draft version of this Appendix was incorrectly posted on e-PIC at the start of Application Review. This error was corrected when the final version of the Appendix was uploaded on February 3, 2017. Figure 1 of the Marine Mammals TDR (Appendix N of the Application) was erroneously omitted from the original final Application submission. This missing figure was included in the update to the Marine Mammals TDR. There were no specific changes made to any figures.
2396.1	round 1	Gitxaala Nation	Appendix N	Marine Wildlife - Marine Mammals	Please indicate exactly what changes were made to Figure 2 when the appendice was updated in early February.	Adraft version of this Appendix was incorrectly posted on e-PIC at the start of Application Review. This error was corrected when the final version of the Appendix was uploaded on February 3, 2017. Figure 2 of the Marine Mammals TDR (Appendix N) was included in the update to the Marine Mammals TDR, as it was erroneously omitted from the original submission. No specific changes were made to any figures.
2397.1	round 1	Gitxaala Nation	Appendix N	Marine Wildlife - Marine Mammals	Please indicate exactly what changes were made to Figure 3 when the appendice was updated in early February.	A draft version of this Appendix was incorrectly posted on e-PIC at the start of Application Review. This error was corrected when the final version of the Appendix was uploaded on February 3, 2017. Figure 3 of the Marine Mammals TDR (Appendix N) was included in the update to the Marine Mammals TDR, as it was erroneously omitted from the original submission. No specific changes were made to any figures.
2398.1	round 1	Gitxaala Nation	Appendix N	Marine Wildlife - Marine Mammals	Please indicate exactly what changes were made to Figure 4 when the appendice was updated in early February.	A draft version of this Appendix was incorrectly posted on e-PIC at the start of Application Review. This error was corrected when the final version of the Appendix was uploaded on February 3, 2017. Figure 4 of the Marine Mammals TDR (Appendix N) was included in the update to the Marine Mammals TDR, as it was erroneously omitted from the original submission. No specific changes were made to any figures.
2399.1	round 1	Gitxaala Nation	Appendix N	Marine Wildlife - Marine Mammals	Please indicate exactly what changes were made to Figure 5 when the appendice was updated in early February.	A draft version of this Appendix was incorrectly posted on e-PIC at the start of Application Review. This error was corrected when the final version of the Appendix was uploaded on February 3, 2017. Figure 5 of the Marine Mammals TDR (Appendix N) was included in the update to the Marine Mammals TDR, as it was erroneously omitted from the original submission. No specific changes were made to any figures.
2400.1	round 1	Gitxaala Nation	Appendix N	Marine Wildlife - Marine Mammals	Please indicate exactly what changes were made to Figure 6 when the appendice was updated in early February.	A draft version of this Appendix was incorrectly posted on e-PIC at the start of Application Review. This error was corrected when the final version of the Appendix was uploaded on February 3, 2017. Figure 6 of the Marine Mammals TDR (Appendix N) was included in the update to the Marine Mammals TDR, as it was erroneously omitted from the original submission. No specific changes were made to any figures.

2401.1	round 1	Gitxaala Nation	Appendix N	Marine Wildlife - Marine Mammals	Please indicate exactly what changes were made to Figure 7 when the appendice was updated in early February.	A draft version of this Appendix was incorrectly posted on e-PIC at the start of Application Review. This error was corrected when the final version of the Appendix was uploaded on February 3, 2017. Figure 7 of the Marine Mammals TDR (Appendix N) was included in the update to the Marine Mammals TDR, as it was erroneously omitted from the original submission. No specific changes were made to any figures.
2402.1	round 1	Gitxaala Nation	Appendix N	Marine Wildlife - Marine Mammals	Please indicate exactly what changes were made to Figure 8 when the appendice was updated in early February.	A draft version of this Appendix was incorrectly posted on e-PIC at the start of Application Review. This error was corrected when the final version of the Appendix was uploaded on February 3, 2017. Figure 8 of the Marine Mammals TDR (Appendix N) was included in the update to the Marine Mammals TDR, as it was erroneously omitted from the original submission. No specific changes were made to any figures.
2403.1	round 1	Gitxaala Nation	Appendix N	Marine Wildlife - Marine Mammals	Please indicate exactly what changes were made to Figure 9 when the appendice was updated in early February.	A draft version of this Appendix was incorrectly posted on e-PIC at the start of Application Review. This error was corrected when the final version of the Appendix was uploaded on February 3, 2017. Figure 9 of the Marine Mammals TDR (Appendix N) was included in the update to the Marine Mammals TDR, as it was erroneously omitted from the original submission. No specific changes were made to any figures.
2404.1	round 1	Gitxaala Nation	Appendix N	Marine Wildlife - Marine Mammals	Please indicate exactly what changes were made to Figure 10 when the appendice was updated in early February.	A draft version of this Appendix was incorrectly posted on e-PIC at the start of Application Review. This error was corrected when the final version of the Appendix was uploaded on February 3, 2017. Figure 10 of the Marine Mammals TDR (Appendix N) was included in the update to the Marine Mammals TDR, as it was erroneously omitted from the original submission. No specific changes were made to any figures.
2405.1	round 1	Gitxaala Nation	Appendix N	Marine Wildlife - Marine Mammals	Please indicate exactly what changes were made to Figure 11 when the appendice was updated in early February.	A draft version of this Appendix was incorrectly posted on e-PIC at the start of Application Review. This error was corrected when the final version of the Appendix was uploaded on February 3, 2017. Figure 11 of the Marine Mammals TDR (Appendix N) was included in the update to the Marine Mammals TDR, as it was erroneously omitted from the original submission. No specific changes were made to any figures.
2406.1	round 1	Gitxaala Nation	Appendix N	Marine Wildlife - Marine Mammals	Please indicate exactly what changes were made to Figure 12 when the appendice was updated in early February.	A draft version of this Appendix was incorrectly posted on e-PIC at the start of Application Review. This error was corrected when the final version of the Appendix was uploaded on February 3, 2017. Figure 12 of the Marine Mammals TDR (Appendix N) was included in the update to the Marine Mammals TDR, as it was erroneously omitted from the original submission. No specific changes were made to any figures.
2407.1	round 1	FLNRO, RMD	4.7.2.6	Wildlife Resources (Terrestrial)	Comment. No response required. For EAO's information. Table 4.7-5. The application presents a very simplistic description of Context. A binary description (resilient, not resilient) misses a great deal of the contextual nuance usually captured in this part of the residual impact description.	Comment noted. The characterization of residual effects criteria used to describe the "Context" for Wildlife Resources (Terrestrial) is consistent with the description provided in Section 3.6.4 of the Application Information Requirements and the Guideline for the Section of Valued Components and Assessment of Potential Effects guidance document provided by the Environmental Assessment Office.
2408.1	round 1	FLNRO, RMD	4.7.5.2	Wildlife Resources (Terrestrial)	Comment. Table 4.7-10. The 30m marine buffer is a key component to mitigate impacts (e.g.: wildlife, marine, visual quality, etc.). Risk and uncertainty are characterized as low. The success of this mitigation depends on its persistence in the face of strong coastal storm winds. There has been no attempt to assess this buffer for wind firmness, which is a key consideration that could lead to the complete failure. In addition, the Project Development Area (PDA) delineates an excessively large clearing area. Along the eastern edge of the project, clearing is shown to extend 150-500m away from the project infrastructure. This appears to be excessive and not justified in the Application. Recommendation for EA certificate condition: Prior to issuance of a permit to construct, the proponent should submit a management plan that would include a fulsome assessment of the structure and function of the marine buffer, and outline strategies and measures to achieve and maximize its intended mitigation functions. As assessment of wind firmness and an examination of options to maximize buffer width would be part of this management plan.	A description of the coastal forest communities that comprise the marine riparian buffer is found in Appendix I of the Application. Shoreline forest units border Digby Island and are generally characterized by mature and old-growth western redcedar, western hemlock, and sitka spruce. Trees within shoreline forests on Digby Island have developed under a coastal environmental regime; their stunted growth pattern is partially a result of their ability to withstand strong coastal weather conditions (Zielke et al. 2010). Characteristic of many coastal islands within the RAA, shoreline forests on Digby Island naturally transition to open wetlands or shrub-dominated bogs. The currently proposed boundaries of the PDA, as presented in the Application, are the maximum extent of areas expected to be cleared and disturbed by Project construction and operations. These PDA areas include some variable amount of setback from vegetation for safety (e.g., fire) or other management reasons. During facility design and into site construction, opportunities may be identified to avoid certain areas and or reduce the extent of clearing or disturbance in select areas. The PDA boundaries will follow, to some extent, the contours of these transitional areas. Accordingly, the marine riparian buffer is expected to be sustained for the duration of Project operations and is not expected to require a stand-alone management plan. However, please also note the forested marine riparian buffer will be subject to Mitigation 4.6.8 which states that "Windthrow management (e.g., edge stabilization techniques) in forested areas will be implemented following BC windthrow management guidelines". Aurora LNG will consider whether development of a management plan for the riparian areas might help to consolidate these various measures.
2409.1	round 1	FLNRO, RMD	4.7.5.2	Wildlife Resources (Terrestrial)	Comment. Tables 4.7-10, 14, 15. There are numerous references here to mitigation actions that will be undertaken "where practicable", "to the extent practicable", "to increase awareness", and management plans that will provide "guidelines" for avoiding impacts. The lack of commitment in these statement erodes the certainty of the effectiveness of the associated mitigation measures.	Aurora LNG is committed to following a mitigation hierarchy to avoid, limit, and mitigate for potential effects to wildlife resources and will implement options that result in avoiding or reducing effects to wildlife resources. Some Project activities (e.g., vegetation clearing within the PDA) will result in direct and indirect loss of habitat, however, these activities will be scheduled to occur outside of restricted activity periods to avoid effects on wildlife (as per mitigation 4.7.17). In cases where Project activities or infrastructure cannot avoid effects to wildlife resources, Aurora LNG has proposed alternative mitigation measures to reduce and mitigate those effects. For example, if vegetation clearing is required during breeding bird and amphibian periods, pre-clearing surveys will be completed (as per mitigation measures 4.7.18 and 4.7.19). Applicable management plans will provide detail on timelines for implementing Project mitigation measures, and will describe monitoring and reporting requirements, as appropriate, to support compliance monitoring.
2410.1	round 1	FLNRO, RMD	4.7.3.2	Wildlife Resources (Terrestrial)	Seeking clarification of information in application. Figure 4.7-7 shows the location of the great blue heron rookery. The Breeding season buffer should be 500m (as noted in table 4.7-14) but appears to be less than that on this map according to the scale. In addition, clearing will occur within the 500m buffer in order to allow for a 150m clearing on the east side of the road. There is no rational presented for this large of a road side clearing. I would suggest that much less road side clearing could occur, resulting in no clearing within 500m of the rookery, with no material impact on the project.	The breeding season buffer for the heron rookery is intended to illustrate a 500 m buffer, and is not shown to scale on Figure 4.7-7. The 500 m buffer is intended to limit effects caused by high-disturbance activities, as described in Section 4.7 of the Application (e.g., blasting, helicopter flights, etc.). Aurora LNG anticipates that the road right-of-way will be approximately 75 m wide and occur within the PDA boundaries, as shown in Figure 4.7-7. The revised road alignment is located further west within the right-of-way and will occur outside of the 500 m setback around the heron rookery.Clearing for construction of the road will be minimized within the setback area. As per Mitigation 4.7.17, Aurora LNG will avoid clearing within restricted activity periods, including portions of the road that intersect the breeding season buffer, to limit sensory disturbance effects at the rookery. Aurora LNG is further committed to monitoring the rookery for changes in breeding activity if vegetation clearing for Project construction overlaps with the breeding window for great blue heron. An errata document is being compiled that captures these corrections, including a revised figure, and it will be filed with the BC EAO.
2411.1	round 1	FLNRO, RMD	4.7.5.3	Wildlife Resources (Terrestrial)	Seeking clarification of information in application. Table 4.7-14 (mitigation 4.7.22) is the first mention of fencing around the project (it is not mentioned in section 4.7.5.4 Assessment of change in movement), and should be described in more detail. Is it going to be an electric bear/wolf exclusion fence? Will it be located adjacent to project infrastructure or closer to the clearing boundary which is often several hundred meters away? Will it include the access road corridor? It is a significant feature, and may interrupt natural movement patterns and should therefor be presented in more detail.	Aurora LNG is proposing to install fencing around the LNG facility to support security requirements and to reduce the potential for negative interaction between Project personnel and wildlife (e.g., bears, wolves). The entire PDA will not be fenced; first priority will be to fence the camp during construction phase. The core LNG facility (administration buildings, utilities and trains) would be fenced later in construction phase or during operations. There will be, at minimum, two discrete fenced areas allowing wildlife passage to be maintained between these areas. Expected fence style will be metal chainlink although final design will be determined during FEED. Currently there is no plan to electrify the fence.
2412.1	round 1	FLNRO, RMD	4.7.5.5	Wildlife Resources (Terrestrial)	Comment. No response required. For EAO's information. Note that several of the residual effects that are characterised as reversible in table 4.7-16 depend on forest regeneration after site reclamation. This will be on the scale of tens to hundreds of years for full "reversibility".	Comment noted. Aurora LNG recognizes that the timelines for reversibility of effects to Wildlife Resources depends, in part, on the the rate of vegetation regeneration for some habitat communities following site reclamation.
2413.1	round 1	FLNRO, RMD	4.7.5.5	Wildlife Resources (Terrestrial)	Request for additional information: Table 4.7-17 notes no impact on change in movement to western toad. Given the project's proximity to toad habitat and the roads, laydown areas, soil stockpiles, and large structures, I would have thought an effect on toad movement to be likely. Please explain the rational for no effects here; I did not find one in section 4.7.5.4.	Table 4.7-17 should identify that western toads may experience effects on movement as a result of Project activities and infrastructure. An errata document is being compiled that captures these corrections and it will be filed with the BC EAO. Section 4.7.5.4 provides a discussion of potential effects to toad movements in consideration of seasonal dispersal patterns and Project infrastructure. The mitigation measures listed in Table 4.7-17 are intended to reduce the potential for effects to western toad movement. Inclusion of change in movement for western toad in Table 4.7-17 does not change the overall conclusions on residual Project effects for this species.
2414.1	round 1	FLNRO, RMD	Appendix J 5.4.3.2	Wildlife Resources (Terrestrial)	Comment. RISC standards for northern goshawk call playback surveys recommend a spacing of 400m between call playback locations, or less in dense coastal forests. This implies a maximum effective range of 200m for a call playback location. Northern goshawk habitat was not modeled, but generally has a high overlap with marbled murrelet habitat. The 8 diurnal raptor call playback locations cover some of these areas, but the coverage is far from complete. It would appear that surveys for northern goshawk were incomplete, and the findings therefor inconclusive. Northern goshawk (laingi subspecies) is red listed in BC and is known to occur around Digby Island. As such, we would expect a fulsome effort at examining project effects on this species.	Diurnal raptor call-playback stations were located in habitats expected to support target species and included survey effort in contiguous stands of mature or old-growth forest. Site selection was expected to target habitats within the PDA and LAA most likely to support breeding by northern goshawk. Although there was no detection of northern goshawk during field studies, the assessment of wildlife resources also considers how change in habitat will potentially affect the species through the wildlife habitat community model (see Section 4.1.3 of Appendix J and Section 4.7.5.2 of the Application). Table 4.7-17 outlines mitigation measures that Aurora LNG has developed, in part, to avoid, reduce, or mitigate potential effects from Project activities or infrastructure on northern goshawk. To improve prediction confidence of potential Project effects to northern goshawk, additional information on species presence has been prepared as a technical memo entitled "Wildlife Passive Acoustic Monitoring Program" and it will be filed with the BC EAO.
2415.1	round 1	FLNRO, RMD	Appendix J 5.8.3.1	Wildlife Resources (Terrestrial)	Request for additional information: Are there any indications that a bat hibernaculum may be present in the PDA or LAA? Karst geology, rocky outcrops, etc.? Have these features been surveyed?	Opportunities for winter hibernaculum in rocky outcrops or underground caverns or caves within the PDA or LAA were not identified during field studies. Wildlife habitat community models, supported by ground-truthed vegetation and wildlife habitat assessments, did not classify any portions of the PDA or LAA as a primarily rock-based community type (see Section 4.1 of Appendix J). Additional field studies for wildlife resources did not identify winter hibernacula features. It is expected that habitats within the PDA and LAA primarily support summer roosting and foraging habitat for bats. Additional information on seasonal activity patterns for bats has been prepared as a technical memo, entitled "Aurora LNG Project Bat Monitoring Program" and it will be filed with the BC EAO.
2416.1	round 1	FLNRO, RMD	4.8.3.3	Freshwater Fish and Fish Habitat	Comment. The riparian management zone and riparian management areas around J1-5 and J1.1 are subject to windthrow and should be assessed for wind firmness prior to reliance on these mitigations as effective options.	Comment noted. As part of the delineation of the riparian zones around creeks J1-5 and J1.1 during pre-construction works, vegetation stability and windthrow assessments will be completed.
2417.1	round 1	FLNRO, RMD	4.8.9	Freshwater Fish and Fish Habitat	Comment. Resource Management Division of FLNRO manages fish populations for coastal cutthroat trout and Dolly Varden. We should also be consulted on the Fish Habitat Offsetting Plan.	Aurora LNG acknowledges the comment and will consult with appropriate regulatory agencies including FLNRO in development of the Fish Habitat Offsetting Plan.
2418.1	round 1	FLNRO, RMD	Appendix U	Vegetation and Wetland Resources	Comment. No response required. For EAO's information. The Conceptual Wetland Compensation Plan serves largely to outline the loss of wetland structure and function caused by the project. There is very little reviewable content with respect to an actual compensation plan. Candidate site(s) have not been identified, and very few strategies have been proposed. This is one of the least developed conceptual compensation plans I have seen as part of an EAO Application.	Comment noted.
2419.1	round 1	Gitxaala Nation	Appendix N	Marine Wildlife - Marine Mammals	Please indicate exactly what changes were made to Figure 13 when the appendice was updated in early February.	A draft version of this Appendix was incorrectly posted on e-PIC at the start of Application Review. This error was corrected when the final version of the Appendix was uploaded on February 3, 2017. Figure 13 of the Marine Mammals TDR (Appendix N) was included in the update to the Marine Mammals TDR, as it was erroneously omitted from the original submission. No specific changes were made to any figures.
2420.1	round 1	Gitxaala Nation	Appendix N	Marine Wildlife - Marine Mammals	Please indicate exactly what changes were made to Figure 14 when the appendice was updated in early February.	A draft version of this Appendix was incorrectly posted on e-PIC at the start of Application Review. This error was corrected when the final version of the Appendix was uploaded on February 3, 2017. Figure 14 of the Marine Mammals TDR (Appendix N) was included in the update to the Marine Mammals TDR, as it was erroneously omitted from the original submission. No specific changes were made to any figures.
2421.1	round 1	Gitxaala Nation	Appendix N	Marine Wildlife - Marine Mammals	Please indicate exactly what changes were made to Figure 15 when the appendice was updated in early February.	A draft version of this Appendix was incorrectly posted on e-PIC at the start of Application Review. This error was corrected when the final version of the Appendix was uploaded on February 3, 2017. Figure 15 of the Marine Mammals TDR (Appendix N) was included in the update to the Marine Mammals TDR, as it was erroneously omitted from the original submission. No specific changes were made to any figures.
2422.1	round 1	Gitxaala Nation	Appendix N	Marine Wildlife - Marine Mammals	Please indicate exactly what changes were made to Figure 16 when the appendice was updated in early February.	A draft version of this Appendix was incorrectly posted on e-PIC at the start of Application Review. This error was corrected when the final version of the Appendix was uploaded on February 3, 2017. Figure 16 of the Marine Mammals TDR (Appendix N) was included in the update to the Marine Mammals TDR, as it was erroneously omitted from the original submission. No specific changes were made to any figures.
2423.1	round 1	Gitxaala Nation	Appendix N	Marine Wildlife - Marine Mammals	Please indicate exactly what changes were made to Figure 17 when the appendice was updated in early February.	A draft version of this Appendix was incorrectly posted on e-PIC at the start of Application Review. This error was corrected when the final version of the Appendix was uploaded on February 3, 2017. Figure 17 of the Marine Mammals TDR (Appendix N) was included in the update to the Marine Mammals TDR, as it was erroneously omitted from the original submission. No specific changes were made to any figures.
2424.1	round 1	Gitxaala Nation	Appendix N	Marine Wildlife - Marine Mammals	Please indicate exactly what changes were made to Figure 18 when the appendice was updated in early February.	A draft version of this Appendix was incorrectly posted on e-PIC at the start of Application Review. This error was corrected when the final version of the Appendix was uploaded on February 3, 2017. Figure 18 of the Marine Mammals TDR (Appendix N) was included in the update to the Marine Mammals TDR, as it was erroneously omitted from the original submission. No specific changes were made to any figures.

2425.1	round 1	Gitxaala Nation	Appendix T	Marine Fish and Fish Habitat	Please indicate exactly what changes were made to Figure 1 when the appendice was updated in early February.	A draft version of this Appendix was incorrectly posted on e-PIC at the start of Application Review. This error was corrected when the final version of the Appendix was uploaded on February 3, 2017. Figure 1 of the Hydrology TDR (Appendix T of the Application) was erroneously omitted from the original final Application submission. This missing figure was included in the update to the Hydrology TDR. There were no specific changes made to any figures.
2426.1	round 1	Gitxaala Nation	Appendix I	Vegetation and Wetland Resources	Please indicate exactly what changes were made to the appenice when it was revised in early February.	The following species were added to Table 13 in Appendix I of the Application in February 2016 after receiving additional traditional use studies:green alder (Alnus viridis) lady fern (Athyrium filix-femina) false Solomon's-seal (Maianthemum racemosum) clasping twistedstalk (Streptopus amplexifolius)
2427.1	round 1	Gitxaala Nation	Air Quality Technical Data Report	Air Quality	"Emissions of VOC's are not modelled as Canada and BC have not established objectives for total VOC's...are not considered further in this assessment." This statement is partially correct in that there are currently no ambient air quality objectives for specific VOCs like benzene in BC or nationally; however, it is quite common to model VOC's and in both national and provincial Environmental Assessments (EA's) to adopt suitable values from other representative jurisdictions. For example, the TransMountain Expansion Project which recently was approved by the NEB, and the Canadian and BC governments (EAC Certificate was issued) and TransMountain agreed to adopt ambient air quality objectives from regulators outside of BC. In addition, TransMountain agreed to comply with ambient objectives from Alberta for benzene, toluene, ethyl benzene and xylenes (BTEX), and H2S and mercaptans objectives and guidelines from Ontario. TransMountain incorporated these objectives into their engineering design process and dispersion modelling was conducted routinely to inform engineering design and site ambient air quality monitoring locations. In addition to adopting suitable ambient objectives and guidelines into the EA process, potential health effects from the Project and Cumulative Cases can be more rigourously examined in the Human Health Risk Assessment (HHRA). The natural gas or fuel gas being combusted by the compressor gas turbines (16), power generators (6), heaters (4), thermal oxidizers (4), flares (3) and camp site power generators (2) contains air toxics like BTEX and other contaminants and the combustion process will create other toxics like benzo (a) pyrene and formaldehyde. The Aurora project will comsume a huge daily volume of feed gas estimated to be 104 million cubic meters per day. Section 1.2.7.2 (Natural Gas Pre-treatment and Liquids Extraction, page 1-37) of the EAC Application indicates that C5+ and BTEX compounds will be removed from the feed gas before the liquefaction process but will not remove any contaminants from the feed gas for use in the on-site stationary combustion equipment listed above. Section 3.2 of the AQ TDR identifies the major fugitive and incomplete combustion sources and primary VOC emitters for the Project. There are several speciated VOC calculation tools and emission factors available from respected regulators such as CARB, US EPA, USAF, TCEQ and others which Stantec have previously referenced in similar air quality assessments for other oil sands and upgrader projects. Question: Will Aurora amend the air quality assessment to include: (1) predicted concentrations for all fugitive, combusted and non-combusted VOC, PAH and heavy metals in their assessment of Project effects and (2), include the same calculated emissions in combination with emission estimates from other proposed LNG projects in the RSA in the CALPUFF dispersion model for a Cumulative Case (as listed in Table 15 of the AQ TDR) to provide a more representative analysis of potential air quality/human health effects for the Application and CEA Cases?	Refer to the technical memorandum, "Volatile Organic Compounds and Human Health Assessment" which will be filed with the BC EAO. The "Volatile Organic Compounds and Human Health Assessment" technical memo was presented to the Working Group in draft for a pre-read on April 17, 2017. The memo was updated as a result of the discussion during the Working Group meeting. Other substances (e.g., PAHs, heavy metals) were not identified by regulators and stakeholders during the development of the Application Information Requirements as health concerns associated with air quality. While the TransMountain project may have included PAHs (as benzo-a-pyrene) and heavy metals in the Screening Level Human Health Risk Assessment, the risk quotients and incremental lifetime cancer risk associated with inhalation of heavy metals and benzo-a-pyrene were 3 to 8 orders of magnitude (i.e, 1,000 to 100,000,000 times) below the levels that would constitute a significant health risk in a highly populated and industrialized region (i.e., Burrard Inlet and Metro Vancouver) for which the air quality is already affected by industry. These values do not support the need to evaluate heavy metals in the air.
2428.1	round 1	Gitxaala Nation	Air Quality Technical Data Report	Air Quality	Multiple references to "with consideration given" to other monitoring data. It is not clear exactly how measured CAC data from multiple stations is used to calculate Baseline values. This should be clarified.	With respect to the baseline air quality, the phrase 'with consideration given' means that the stations referred to were studied to determine if their data differed meaningfully from the data used to determine baseline. The baseline is determined entirely on the primary station cited, with the other stations merely being reviewed for consistency.
2429.1	round 1	Gitxaala Nation	Air Quality Technical Data Report	Air Quality	Baseline values given in this table do not all agree with those given in Detailed Model Plan (Appendix 1) submitted to MOE. For example, PM2.5 24-hour and Annual values are less than specified in Detailed Model Plan Table 2.	In the intervening time period between the approval of the Detailed Model Plan by the Ministry of Environment and completion of the assessment, better information on local air quality became available. Discussions with the Ministry of Environment resulted in three parameters having increased baseline values, and two parameters having reduced baseline values. These changes are small and did not result in any material changes to the results and the assessment or its conclusions.
