- **Land and Resource Use VC (Section 7.11)** Mitigation measures that manage traffic, noise, lighting, and spill risks help maintain safe access and stable land use conditions, supporting WSÁNEĆ Nations' on-going stewardship of land and water resources and reducing stressors that can affect well-being;
- **Employment and Economy VC (Section 7.10)** Employment, training, and procurement measures create pathways for WSÁNEĆ Nations' members and businesses to participate economically in the project, supporting improved social conditions and community well-being;
- **Infrastructure and Services (Section 7.12)** Measures that manage worker demand on housing, services, and emergency response help avoid added pressure on local systems, reducing potential socioeconomic impacts on WSÁNEĆ Nations and supporting health and community stability;
- **Culture (Section 7.14)** Mitigation that limits sensory disturbance, protects cultural sites, and maintains landscape integrity helps support cultural practices and intergenerational knowledge transfer linked to WSÁNEĆ Nations' well-being;
- **Human Health (Section 7.15)** Mitigation that reduces exposure to contaminants, noise, and other stressors, while supporting access to traditional practices, helps protect WSÁNEĆ Nations members' physical, cultural, and mental health; and,
- **Groundwater (Section 7.5)** Protecting groundwater from contamination helps maintain the quality of ecosystems that support fish, plants, and wildlife relied on for WSÁNEĆ Nations' subsistence and health.

In addition to the Proponent's mitigation measures, the EAO has developed further conditions that would mitigate potential effects to social and economic conditions and Indigenous health and well-being:

- **Condition 10 (Community Feedback Process)** provides WSÁNEĆ Nations with a clear mechanism to raise concerns related to community well-being, safety, access, or environmental disturbance. Timely responses and reporting help address issues such as noise, dust, traffic, or perceived environmental effects early, reducing stress and supporting Indigenous health and well-being;
- **Conditions 12 and 13 (Construction and Operations Environmental Management Plans)** require ongoing management of noise, air quality, lighting, water quality, spills, and traffic during Operation and Construction phases. It will also require an emergency communication protocol with WSÁNEĆ Nations to be developed by the Holder in consultation with the Nation. By ensuring timely, transparent communication and coordinated response in the event of incidents, these conditions help reduce uncertainty and anxiety related to catastrophic risks, supporting a sense of safety, control, and trust that underpins mental and emotional well-being;
- **Condition 14 (Air Quality Management Plan)** requires emissions controls and monitoring to manage air contaminants during Operation. Maintaining air quality helps protect respiratory health and reduce concerns related to environmental safety, supporting WSÁNEĆ Nations' physical health and overall well-being;
- **Condition 15 (Chance Find Protocol)** requires procedures to identify and protect archaeological or cultural materials discovered during project activities. If WSÁNEĆ Nations historically used the area, this condition helps prevent disturbance to cultural materials and avoids associated cultural or emotional harm, supporting Indigenous health and well-being;
- **Condition 16 (Indigenous and Local Economic Inclusion and Monitoring Plan)** requires the development and implementation of a plan to support economic participation of First Nations and local communities. By outlining employment, contracting, and training strategies, this condition helps support socio-economic well-being; and,

- **Condition 17 (Dry Street Sweeping Report)** requires FortisBC to submit a report on the effectiveness Dry Street Sweeping to mitigate the effects of 6-PPDQ on fish within eighteen months of a Certificate being issued. By informing measures to protect downstream aquatic environments, this condition supports W̱SÁNEĆ Nations' health and well-being by helping maintain confidence in environmental quality and minimizing potential concerns related to contamination of culturally important fish and waterways.

The EAO identified the following federal Key Mitigation Measures that would mitigate potential effects to Health and Well-being:

- Accidents and Malfunctions Reporting would support mitigation of potential impacts on the Nation's interests by ensuring timely responses, incorporation of Indigenous perspectives, and continuous improvement to reduce the risk and severity of future incidents.

#### The EAO's Analysis and Conclusions

After consideration of the potential effects, mitigation measures and conditions, described above, the EAO has identified that there will not be any residual effects on W̱SÁNEĆ Nations' Indigenous health and well-being interests based on the above proposed mitigation measures and conditions, the EAO's analysis, and the lack of current use of the Project area.

#### 16.21.15 Positive Effects of Tilbury Phase 2

According to the Revised Application, Tilbury Phase 2 is expected to create job opportunities, particularly in Construction, benefit Indigenous businesses through contracting and procurement, and potentially increase revenue for the W̱SÁNEĆ Nations, while improving social and economic conditions and providing long-term skills training opportunities for Indigenous people in the area.

The positive effects of Tilbury Phase 2 depend on the level of participation and access for Indigenous people and businesses that may have to the opportunities generated, with direct positive effects on W̱SÁNEĆ Nations' interests being limited compared to existing conditions.

#### 16.21.16 Conclusions

Considering the above analyses and the EAO's engagement with W̱SÁNEĆ Nations, FortisBC's and W̱SÁNEĆ Nations' engagement, mitigation measures, cumulative effects, the EAO's recommended Table of Conditions and the identified federal Key Mitigation Measures, the EAO concludes that Tilbury Phase 2 is not anticipated to have any residual effects to W̱SÁNEĆ Nations' Indigenous interests.

Considering the above analyses, the EAO concluded that the potential for adverse effects of Tilbury Phase 2 on the Indigenous interests of W̱SÁNEĆ Nations has been adequately avoided, minimized or otherwise accommodated. Based on the engagement undertaken with W̱SÁNEĆ Nations on Tilbury Phase 2, as outlined in Section 16.22.2, the EAO has concluded that it has fulfilled the provincial Crown's duty to consult with W̱SÁNEĆ Nations.

## 17.0 APPENDIX 6 VALUED COMPONENT ASSESSMENTS

This appendix provides the detailed assessments of effects on the valued components, as required by [Section 25\(2\)](#) of the Act. The matters, or topics, to be assessed were determined by the EAO, in consultation with the TAC and the public, and with consensus with the participating Indigenous nations, through the [Application Information Requirements](#) set out by the EAO for Tilbury Phase 2.

The EAO uses a values-based method that relies on “valued components” as the framework for assessing project effects. Valued components are those elements of the natural and human environments considered by the proponent, public, Indigenous peoples, scientists and other technical specialists, and government agencies involved in the environmental assessment process to have scientific, conservation, ecological, economic, social, cultural, archaeological, or other importance. This Appendix assesses the effects of Tilbury Phase 2 on these valued components, identifies mitigation measures, discusses the key issues raised, and reaches conclusions on the significance of residual effects on each valued component and other required assessment matters.

### What is a Valued Component?

Components of the biophysical and human environment that are considered to have scientific, ecological, economic, social, health, cultural, archaeological, historical, or other importance to an environmental assessment.

## 17.1 Air Quality

### 17.1.1 Summary

Air quality influences human health, ecosystem integrity, and the use and enjoyment of culturally significant areas. The air quality Valued Component (VC) includes the subcomponents of existing air contaminant levels, modeled project emissions, and potential for cumulative effects. Key indicators for assessment include changes in concentrations of criteria air contaminants (CAC), particularly nitrogen dioxide (NO<sub>2</sub>), sulfur dioxide (SO<sub>2</sub>), and particulate matter (PM<sub>2.5</sub> and PM<sub>10</sub>).

Tilbury Phase 2 Liquefied Natural Gas (LNG) Expansion Project (Tilbury Phase 2 or the Project) is in a highly developed urban-industrial area within the Metro Vancouver Regional District. Current data indicates that Base Case (Background concentrations without the Project) concentrations of NO<sub>2</sub> exceed both the Metro Vancouver Ambient Air Quality Objective (MV AAQO 2025) and the Canadian Ambient Air Quality Standards (CAAQS 2025) when assessed using the worst case (98th percentile) metric, which represents < 2% of all days in a year (< 7 days). In contrast, ambient concentrations of SO<sub>2</sub>, carbon monoxide (CO), PM<sub>2.5</sub>, and PM<sub>10</sub> near the Tilbury Phase 2 site remain below Provincial and Federal objectives and standards. Additionally, recent measurements show no exceedances of MVAAQO or CAAQS 2025 for Ozone (O<sub>3</sub>). MVAAQO and CAAQS 2025 are set to protect human health and the environment.

Air dispersion modeling identified increases in nitrogen oxides (NO<sub>x</sub>), SO<sub>2</sub>, and PM<sub>2.5</sub> during both Construction and Operation phases. Operation NO<sub>2</sub> concentrations could result in temporary exceedances of MVAAQO and CAAQS 2025 at sensitive receptors, including care facilities. SO<sub>2</sub> Annual concentrations from Tilbury Phase 2 may increase from existing background concentrations but are expected to remain below MVAAQO and CAAQS 2025. PM<sub>2.5</sub> levels could rise by up to 9%, but are also projected to remain below MVAAQO and CAAQS 2025.

Nonroutine flaring associated with Tilbury Phase 2 would occur infrequently during events such as commissioning, start-up, shutdown, upset conditions, and power outages. Conservative modelling indicates that flaring can result in short-term 1-hour NO<sub>2</sub> and SO<sub>2</sub> exceedances of applicable air quality objectives, with concentrations reaching up to several times the short-term thresholds under worst-case scenarios, though these exceedances are high in magnitude, extend several kilometers (depending on weather), but limited in duration, and frequency (less than 1% of the year), and are not expected to result in significant adverse residual or cumulative effects on air quality.

Key issues raised by reviewers include potential to exceed air quality standards, monitoring data quality, cumulative impacts, and mitigation effectiveness. In response, FortisBC (Proponent) undertook additional air quality modelling that included mitigation measures and addressed concerns about emissions, cumulative effects, and health risks. The revised assessment showed that emissions would not extensively affect regional air quality.

Potential residual effects include increased ambient concentrations of NO<sub>2</sub>, SO<sub>2</sub>, and other CACs during Tilbury Phase 2 operation, as well as during site preparation and construction. In response, the British Columbia (B.C.) Environmental Assessment Office (EAO) has proposed Condition 14 (Air Quality Management Plan) requiring an Air Quality Management Plan, ambient air quality monitoring and specific reporting requirements and Condition 18 (Regional Cumulative Effects Initiatives) which may require FortisBC to join any future provincial or Metro Vancouver airshed initiatives, FortisBC has also proposed mitigation measures to help manage adverse impacts to air quality. Furthermore, if an Environmental Assessment Certificate (Certificate) is granted, Tilbury Phase 2 will also require permit amendments from Metro Vancouver and BC Energy Regulator (BCER).

Based on the below assessment, the EAO is satisfied that Tilbury Phase 2 would not have significant adverse residual or cumulative effects on the air quality VC.

### 17.1.2 Assessment Boundaries

The spatial boundaries for the air quality assessment included:

- Project footprint: the area directly disturbed by project activities;
- Local Assessment Area: 20 kilometers (km) by 20 km area centred on the Tilbury Phase 2 site; and
- Regional Assessment Area: 30 km by 30 km area centred on the Tilbury Phase 2 site.

The temporal boundaries for air quality include the Construction (3-6 years), Operation (40 plus years), and Decommissioning (2 years) phases of Tilbury Phase 2.

Tilbury Phase 2 components and anticipated duration of activities are described in detail in [Section 2.2](#) (Project Description and Schedule) of this Environmental Assessment Report (the Report).

### 17.1.3 Existing Conditions by Proponent

Current air quality conditions are assessed in [Section 7.2.3](#) of the Revised Application. While Metro Vancouver's monitoring network captures regional ambient or "background" conditions, it does not reflect the short-range effects of the existing Tilbury Phase 1A production and storage expansion (Phase 1A). To address this, emissions from Phase 1A were included in the "base case" conditions.

The Proponent noted that Tilbury Phase 2 is in a heavily developed, urban and industrial area. The region is influenced by industrial, commercial, and residential zones, with significant traffic from vehicles and vessels. However, air pollutant levels in the Metro Vancouver area have generally been improving over the last decade, despite population growth, according to Metro Vancouver data. Ambient air quality was characterized based on data from Metro Vancouver air quality monitoring stations in the Regional Assessment Area (City of Richmond South (Richmond), North Delta (Delta), Burnaby South (Burnaby) and Richmond Airport). The air contaminants of concern are: NO<sub>x</sub>, sulphur oxides (SO<sub>x</sub>), CO, PM<sub>10</sub>, PM<sub>2.5</sub>, Ozone and Volatile Organic Compounds (VOC). Concentrations are compared to the Canadian Ambient Air Quality Standards (CAAQS 2025) and Metro Vancouver Air Quality Objectives (MV AAQO 2025). CAAQS and MV AAQO 2025 are set to protect human health and the environment.

#### What's the difference between 1-hour and annual standards?

Air quality standards use different averaging periods to protect health:

1-hour standard applies to the average concentration of a pollutant over any single hour. In air quality modelling, concentrations are predicted on an hourly basis and compared to this standard to assess short-term exposure. The use of a 1-hour standard reflects that certain pollutants, such as NO<sub>2</sub> and SO<sub>2</sub>, can cause health effects following brief periods of elevated exposure. This approach helps identify whether short-duration concentration peaks may occur and how often they are expected, rather than masking those peaks through longer-term averaging.

Annual standard: Reflects long-term exposure over a year. It averages concentrations to assess chronic health risks and overall air quality trends.

Background Concentrations are a conservative representation of existing concentrations of pollutants within the study area. In air dispersion studies, background concentrations are added to the modelled concentrations resulting from Tilbury Phase 2 combustion emissions sources. Background concentrations are calculated using historical observations from ambient monitoring stations. Measured background concentrations have a wide temporal variability (seasonal and diurnal). As a conservative measure, when calculating background concentrations, the higher end of observed values is used as a fixed value throughout the model period and domain. In other words, the temporal variability in ambient background concentrations is replaced by a single conservative value representing the higher end (98th percentile of hourly values for NO<sub>2</sub>) of all historically observed values.

For NO<sub>2</sub> only, due to higher background concentrations, and more stringent objectives, Metro Vancouver has directed that air dispersion studies assess background concentrations using three different background percentiles to provide a better understanding of expected resulting concentrations from a proposed source activity.

**Metro Vancouver's prescribed background percentiles** (98th, 90th, 75th) for NO<sub>2</sub> are based on hourly monitored air quality data and describe how often certain ambient concentrations occur in the region. They help indicate whether a background level represents a rare, occasional, or fairly common condition.

This means:

- 98th percentile background = the concentration that 98% of hourly measurements are below (only ~2% of hours are higher);
- 90th percentile background = the concentration that 90% of hourly measurements are below (~10% of hours are higher); and
- 75th percentile background = the concentration that 75% of hourly measurements are below (~25% of hours are higher).

Base Case concentrations evaluate ambient concentrations without Tilbury Phase 2, by adding background concentrations and the modelled concentrations from existing Phase 1A sources.

**Nitrogen oxides (NO<sub>2</sub> and NO<sub>x</sub>)** are mainly produced by high-temperature combustion. Most emissions start as nitric oxide (NO) and quickly convert to NO<sub>2</sub>, which is linked to respiratory illness and environmental impacts such as acid rain and ground-level ozone formation.

Transportation accounts for about 77% of NO<sub>x</sub> emissions in the Lower Fraser Valley, with additional contributions from vessel traffic, two cement plants, and Phase 1A.

The following modelled Base Case (background with the existing Phase 1A facility) concentrations were predicted. Note that per Metro Vancouver's guidance, background concentrations were evaluated using three different percentiles.

- At the 98<sup>th</sup> percentile background, 1-hour: 87.3 micrograms per cubic meter (µg/m<sup>3</sup>) (threshold; 79 µg/m<sup>3</sup>, MV AAQO & CAAQS 2025);
- At the 90<sup>th</sup> percentile background, 1-hour: 73.2 µg/m<sup>3</sup> (threshold; 79 µg/m<sup>3</sup>, MV AAQO & CAAQS 2025); and
- At the 75<sup>th</sup> percentile background, 1-hour: 61.0 µg/m<sup>3</sup> (threshold; 79 µg/m<sup>3</sup>, MV AAQO & CAAQS 2025).

This modelling indicates that exceedances are expected to occur only when the 98th percentile metric for background is used, which applies to the Base Case background concentration only and does not include modelled upset or abnormal operating conditions, and is indicative of infrequent (approximately 2% of time) background conditions. Any upset conditions were assessed separately and would fall within the upper 2% of concentrations if a more typical ("normal") operating distribution were considered. The predicted concentrations also represent maximum emissions from Tilbury Phase 2 sources along with less favorable dispersion conditions rather than typical operating scenarios.

This combination of factors is considered the worst-case scenario and a conservative approach, which means that this combination of factors (weather, emissions etc.) is relatively unlikely to happen in real world environment.

Annual background concentrations of NO<sub>2</sub> (17.23 µg/m<sup>3</sup> and the Base Case scenario (18.9 µg/m<sup>3</sup>) are below the air quality thresholds 22.6 µg/m<sup>3</sup>.

**Sulfur Dioxide (SO<sub>2</sub>)** concentrations in Metro Vancouver are generally low compared to other cities of similar size because of limits on sulphur in fuels for on road and offroad uses and most heating relies on natural gas and electricity rather than coal or oil. The marine sector is the largest contributor, followed by nonroad engines, industry, heating, and transportation.

Long-term trends show a steady decline in SO<sub>2</sub> concentrations, driven by stricter marine fuel sulphur limits and the transition to LNG-powered vessels and electric tugboats. Recent monitoring (2022–2024) confirms that background SO<sub>2</sub> levels near the Tilbury Phase 2 site are very low.

SO<sub>2</sub> in Regional Assessment Area is less than 2% and 6% of their 1-hour (both MV AAQO and CAAQS 2025) and annual MV AAQO, respectively. The following Base Case concentrations are as follows

- 1-hour: 90.6 µg/m<sup>3</sup> (using Metro Vancouver metric of 100<sup>th</sup> percentile of the 1-hour predictions)
  - Threshold: 183 µg/m<sup>3</sup> (MV AAQO 2025);
- 1-hour: 60.0 µg/m<sup>3</sup> (using CAAQS metric of 99<sup>th</sup> percentile of the D1HM predictions)
  - Threshold: 170 µg/m<sup>3</sup> (CAAQS2025); and
- Annual: 2.0 µg/m<sup>3</sup>
  - Threshold: 10.5 µg/m<sup>3</sup> (MV AAQO & CAAQS 2025).

## CO, PM and VOC

According to the Revised Application CO levels in Metro Vancouver have declined extensively since the late 1990s due to improved vehicle emission standards and programs like the earlier AirCare initiative, and the subsequent Clean Air Plan, with motor vehicles and non-road engines still accounting for the vast majority of emissions.

PM<sub>10</sub> and PM<sub>2.5</sub> remains a concern for health and visibility; PM<sub>10</sub> is primarily from road dust, while PM<sub>2.5</sub> comes from heating, transportation, industry, and wildfire smoke. Long-term trends show gradual declines for PM<sub>10</sub> and stable levels for PM<sub>2.5</sub>, though short-term spikes occur during events such as wildfires or dust storms.

The following Base Case concentrations are as follows:

### CO

- 1-hour: 602.0 µg/m<sup>3</sup> (Threshold: 14,900 µg/m<sup>3</sup>, MV AAQO);
- 8-hour: 535.7 µg/m<sup>3</sup> (Threshold: 5,700 µg/m<sup>3</sup>, MV AAQO);

### PM<sub>2.5</sub>

- 24-hour: 13.8 µg/m<sup>3</sup> (Threshold: 25 µg/m<sup>3</sup>, MV AAQO);
- Annual: 5.2 µg/m<sup>3</sup> (Threshold: 8 µg/m<sup>3</sup>, MV AAQO; planning goal: 6 µg/m<sup>3</sup>);

### PM<sub>10</sub>

- 24-hour: 20.2 µg/m<sup>3</sup> (Threshold: 50 µg/m<sup>3</sup>, MV AAQO);
- Annual: 9.5 µg/m<sup>3</sup> (Threshold: 20 µg/m<sup>3</sup>, MV AAQO);

### VOCs

- 1-hour: 158.1 µg/m<sup>3</sup> (No standard);
- 24-hour: 91.6 µg/m<sup>3</sup> (No standard); and
- Annual: 33.0 µg/m<sup>3</sup> (No standard).

The EAO notes that a number of First Nations have identified concerns regarding air quality on the Fraser River including areas offshore from Tilbury Island, that are used for fishing. The Proponent acknowledged the Historic Indigenous Village Site<sup>56</sup>, located directly across the river from the Tilbury Phase 2 Site, has high cultural significance to x̣ṃəθḳʷəỵəm, Quw'utsun Nation, Ts'uubaa-asatx, Tsawwassen First Nation (Tsawwassen), Tsleil-Waututh Nation (Tsleil-Waututh), Kwantlen First Nation (Kwantlen), Semiahmoo First Nation (Semiahmoo), and Stó:lō communities and was therefore included as a sensitive receptor in the air quality modelling assessment.<sup>57</sup>

#### 17.1.4 Potential Project Effects by Proponent

To assess how Tilbury Phase 2 may affect air quality, the Proponent used several methods including:

- Analysing potential emissions during construction, start-up, normal operations, and unusual situations. This included estimating emissions from construction vehicles, handling materials, and excavation. Emissions during normal operations were based on the conceptual design of Tilbury Phase 2;
- Using air-dispersion models to estimate how Tilbury Phase 2-related emissions disperse in the atmosphere and comparing the resulting predicted concentrations to the 2025 CAAQ and 2025 MVAQO standards; and
- Modelling the deposition of nitrogen and acid compounds from Tilbury Phase 2 to assess potential effects on soils, vegetation, and surface water.

Effects to changes in human health due to air quality are as part of [Appendix 6, Section 17.14](#) (Human Health) of this the Report. Maps showing all receptor locations and sensitive sites used in the air quality modeling are included in the Proponent's Revised Application [Section 7.02](#) (Air Quality) Figure 7-2.2 and 7-2.3.

##### 17.1.4.1 Construction and Decommissioning

During the Construction Phase of Tilbury Phase 2 there is the potential for short-term effects on local air quality. The Construction Phase is expected to span three to six years. Total emissions generated over the construction period are estimated to be 50.53 tonnes of NO<sub>x</sub>, 0.09 tonnes of SO<sub>2</sub>, 15.89 tonnes of CO, 11.28 tonnes of PM<sub>2.5</sub>, and 25.95 tonnes of PM<sub>10</sub>.

These effects are mainly due to increased pollutant concentrations from activities such as site preparation, excavation, grading, and material handling. These activities require vehicles and equipment, with materials delivery alone involving an estimated 27,000 trucks and 1,080,000 km traveled based on round-trip distance. Construction emissions of PM<sub>2.5</sub> and PM<sub>10</sub> from diesel engines represented approximately 37% to 84% of the corresponding annual emissions projected during the unmitigated operation phase. The unmitigated case is used as a reference point because Tilbury Phase 2 operational emissions contribution alone, even without mitigation, remain below the CAAQS and MVAQO 2025 limits. Overall, Construction activities generate fugitive particulate emissions (PM<sub>10</sub> and PM<sub>2.5</sub>) and combustion-related pollutants from construction equipment and vehicles, including NO<sub>x</sub>, SO<sub>2</sub>, CO, diesel particulate matter (DPM), and trace amounts of VOCs.

Emissions from Construction activities are expected to be temporary and localized, primarily affecting areas near the facility and along transport routes within the 20 km by 20 km Local Assessment Area.

The proposed Decommissioning Phase is anticipated to last two years. Air quality effects during Decommissioning were assessed in a limited qualitative manner because it is anticipated to be lower in magnitude than Construction. This reflects several factors; Decommissioning is expected to rely on less heavy equipment, generate fewer emissions overall, and benefit from continued improvements in engine and emissions-control technologies. For

---

<sup>56</sup> See Section 3.1 for naming and jurisdictional context regarding the Historic Indigenous Village Site.

these reasons, the Construction Phase air emissions assessment provides a conservative basis for understanding the potential air quality implications during Decommissioning.

#### 17.1.4.2 Operation

The following summarizes key air quality outcomes from the assessment during regular Operation phase; further details are available in Section 7.2.4 (Potential Effects) of the Revised Application. In the Revised Application, [Section 7.02](#) (Air Quality), Operation emissions were modelled within the Regional Assessment Area under the following scenarios:

- **Base Case** – The predicted air concentrations resulting from the existing Phase 1A and background conditions as discussed in the Existing Conditions by Proponent above;
- **Application Case (Base Case + Project)** – The predicted air concentrations resulting from Tilbury Phase 2 during Operation with the Base Case; and
- **Cumulative Case** – The predicted air concentrations resulting from all reasonably foreseeable projects and activities, such as Tilbury Marine Jetty (TMJ), Tilbury Phase 1B (T1B), that may influence future air quality within the Regional Assessment Area, along with Tilbury Phase 2 and Base Case concentrations and are assessed in the cumulative effects section below.

Section 7.2.4.3 of the Revised Application provides a general comparison of unmitigated and mitigated emissions for NO<sub>2</sub> and SO<sub>2</sub>, showing overall reductions following the application of mitigation measures. Additional detail on unmitigated and mitigated emissions scenarios are available in Appendix B (Air Quality Technical Data Report).

For CO, PM, and VOCs, unmitigated concentrations remained below the MV AAQO and CAAQS 2025 under conservative assumptions. Because these parameters did not exceed relevant air-quality objectives in the unmitigated case, no mitigated modelling was required.

Consistent with EAO's approach, the subsequent sections of this report focus on the mitigated scenario where they are available (NO<sub>2</sub> and SO<sub>2</sub>), and relies on the unmitigated scenario for CO, PM, and VOCs where mitigation modelling was not warranted.

#### 17.1.4.3 NO<sub>x</sub> During Operation

FortisBC completed revised air dispersion modelling that incorporated conceptual mitigation measures, including low-NO<sub>x</sub> burner technologies. These measures are expected to extensively reduce emissions, lowering Tilbury Phase 2 alone contribution to maximum 1-hour NO<sub>2</sub> concentrations by approximately 83% and annual NO<sub>2</sub> concentrations by 88% compared to the unmitigated case.

The hourly concentration value is based on the 98th percentile of daily 1-hour maximum predicted concentrations. This means the model looks at the highest hourly modelled value for each day of the year and discards the top 2%. In practical terms, this is the concentration level that is not predicted to exceed on 98% of days—only about 7 days in a year are higher. This approach reflects worst-case short-term air quality without being distorted by a few anomalies in the meteorological model. The annual concentration value is the average of all predicted hourly concentrations across the entire year. It represents the long-term, overall air-quality level by smoothing out both high and low days.

Under the mitigated scenario, Tilbury Phase 2 is predicted to make a small contribution to overall air-quality levels in the Application Case compared with the Base Case. It adds about 1% (0.86 µg/m<sup>3</sup>) to the hourly concentration and about 6% (1.36 µg/m<sup>3</sup>) to the annual average concentration.

Under the Application Case, Metro Vancouver's guidance for assessing hourly NO<sub>2</sub> is applied by evaluating background concentrations using three different percentiles. The model-predicted results for these percentiles are as follows:

- **At the 98th percentile background:** The total 1-hour NO<sub>2</sub> concentration is predicted to reach 88.1 µg/m<sup>3</sup>, which is above the CAAQS and MVAAQO 2025 threshold of 79 µg/m<sup>3</sup>. This exceedance is limited to an area within roughly 50 m of the property line;
- **At the 90th percentile background:** The maximum predicted 1-hour NO<sub>2</sub> concentration decreases to 74.1 µg/m<sup>3</sup>, which is below the CAAQS and MVAAQO 2025 threshold;
- **At the 75th percentile background:** The maximum predicted 1-hour NO<sub>2</sub> concentration is 62.7 µg/m<sup>3</sup>, also below the standard; and
- **Annual:** The annual average concentration of NO<sub>2</sub> for the Application case is 20.3 µg/m<sup>3</sup>, below the CAAQS and MVAAQO 2025 standard of 22.6 µg/m<sup>3</sup>, with Tilbury Phase 2 contributing only 1.36 µg/m<sup>3</sup> when compared to the Base Case.

#### 17.1.4.4 SO<sub>2</sub> During Operation

FortisBC completed revised air dispersion modelling that incorporated conceptual mitigation measures, including addition of a flue gas desulphurization unit. These measures are expected to extensively reduce emissions, lowering Tilbury Phase 2's contribution to SO<sub>2</sub> concentrations by approximately 73–80% compared to the unmitigated case.

Under the mitigated Application Case (Base Case + Mitigated Project):

- **1hour SO<sub>2</sub> – MV AAQO metric (100th percentile):**  
Tilbury Phase 2 adds 4.46 µg/m<sup>3</sup>, resulting in a combined value of 95 µg/m<sup>3</sup> (well below the 183 µg/m<sup>3</sup> Metro Vancouver AAQO);
- **1hour SO<sub>2</sub> – CAAQS metric (99th percentile):**  
Tilbury Phase 2 adds 5.5 µg/m<sup>3</sup>, resulting in a combined value of about 81 µg/m<sup>3</sup>, compared to the 170 µg/m<sup>3</sup> 2025 CAAQS; and
- **Annual SO<sub>2</sub> concentrations:**  
The overall annual concentration under the Application Case is 5.7 µg/m<sup>3</sup>, staying below the 10.5 µg/m<sup>3</sup> standard. Tilbury Phase 2's contribution relative to the Base Case is an increase of 3.73 µg/m<sup>3</sup>.

#### 17.1.4.5 Nitrogen and Acid deposition

Airborne emissions of NO<sub>x</sub> and SO<sub>2</sub> during Tilbury Phase 2 operation may convert into nitrates and sulphates and settle on nearby soil and waterways. These substances can contribute to acidification and nutrient loading, which may affect water quality, soil chemistry, and aquatic ecosystems.

Potential acid and nitrogen deposition into the Fraser River resulting from the Tilbury Phase 2 was explicitly modelled using the unmitigated scenario and is presented in Appendix H of the Revised Application.

Section 7.4 of the Revised Application (Surface Water) determines that no residual effects are anticipated specifically due to acid and nitrogen deposition from the Tilbury Phase 2 on the Surface Water VC. Potential deposition effects are addressed in the following sections of the EAO's Environmental Assessment Report (Assessment Report): Surface Water, Soil, and Fish and Fish Habitat.

#### 17.1.4.6 Other CACs (CO, PM<sub>2.5</sub>, PM<sub>10</sub>, VOCs) During Operation

FortisBC completed revised air dispersion modelling for other CACs, including CO, PM<sub>2.5</sub> and PM<sub>10</sub>, and VOCs. These pollutants were assessed under the unmitigated scenario.

Under the unmitigated scenario:

- **CO** Predicted concentrations remain well below MVAAQO air quality objectives for both 1-hour and 8-hour averaging periods, with no increases from Tilbury Phase 2 compared to the Base Case;

- **PM<sub>2.5</sub>** 24-hour (15 µg/m<sup>3</sup>) and annual (5.4 µg/m<sup>3</sup>) concentrations are below the MVA AQO (25 µg/m<sup>3</sup> and 8 µg/m<sup>3</sup>) in the Application Case, with Tilbury Phase 2 contributing negligibly (1.2 µg/m<sup>3</sup> and 0.2 µg/m<sup>3</sup>);
- **PM<sub>10</sub>** 24-hour (21.4 µg/m<sup>3</sup>) and annual (9.7 µg/m<sup>3</sup>) concentrations stay below MVA AQO (50 µg/m<sup>3</sup> and 20 µg/m<sup>3</sup>) in the Application Case with Tilbury Phase 2 contributing negligibly (1.2 µg/m<sup>3</sup> and 0.2 µg/m<sup>3</sup>); and
- **VOCs** There are no regulatory standards for total VOCs; predicted concentrations show that 1-hour concentrations will not increase due to Tilbury Phase 2, 24-hour concentrations from the Application Case total 92.9 µg/m<sup>3</sup> with Tilbury Phase 2 contributing 1.3 µg/m<sup>3</sup>. Annual concentrations in the Application Case are 33.3 µg/m<sup>3</sup> with Tilbury Phase 2 contributing 0.3 µg/m<sup>3</sup>.

#### 17.1.4.7 Flaring and Abnormal Conditions

The assessment of abnormal operating scenarios, including commissioning, startup and shutdown, upset conditions, and grid power outages, was conducted in the Revised Application AQ- Appendix E using conservative assumptions under the unmitigated case. For the abnormal condition involving flaring, the flare was modeled as a continuous point source rather than an intermittent one. This approach ensures that the modelling captures a flaring event under the worst dispersion condition.

##### Commissioning:

- Commissioning includes three activities: LNG tank commissioning (venting of methane and inert nitrogen), liquefaction train warm commissioning (includes flaring), and liquefaction train cold commissioning (includes flaring), with duration of air emissions approximately 2 weeks, 72 hours, and 144 hours, respectively;
- Predicted maximum NO<sub>2</sub> concentrations are associated with flaring during liquefaction train warm and cold commissioning. Tilbury Phase 2-related NO<sub>2</sub> concentrations are expected to reach 392 µg/m<sup>3</sup>; when combined with background concentrations, total NO<sub>2</sub> levels are predicted to reach 450 µg/m<sup>3</sup>, exceeding the CAAQS and MVA AQO 2025 of 79 µg/m<sup>3</sup>. Exceedances are expected to extend into the Local Assessment Area, see Figure E.1 in the [Air Quality Appendix B, Appendix E Abnormal Conditions](#) of the Revised Application;
- The LNG tank commissioning scenario assessed in the Revised Application consists of venting methane and inert nitrogen and is not expected to generate material NO<sub>2</sub> emissions because no combustion occurs during this activity;
- Model predictions represent most adverse weather conditions coinciding with the flaring activities; and
- SO<sub>2</sub> concentrations from Tilbury Phase 2 are expected to remain below the applicable CAAQS and MVA AQO 2025.

##### Start up and Shutdown;

- Startup and shutdown events are expected to last less than 5 hours and to occur up to five times per year; and
- Tilbury Phase 2-related SO<sub>2</sub> and NO<sub>2</sub> concentrations and extent during these events are expected to be the same as those predicted for commissioning.

##### Upset Conditions

- Upset events are expected to be infrequent (approximately once per year) and to last less than 5 hours;
- Tilbury Phase 2-related NO<sub>2</sub> concentrations are expected to reach 278 µg/m<sup>3</sup>; including background, total NO<sub>2</sub> levels are predicted to reach 336 µg/m<sup>3</sup>, exceeding the CAAQS and MVA AQO 2025 of 79 µg/m<sup>3</sup>;
- Exceedances are expected to extend into the Local Assessment Area;

- Tilbury Phase 2-related SO<sub>2</sub> concentrations are expected to increase to 429 µg/m<sup>3</sup>, exceeding the CAAQS and MVAAQO 2025 of 183 µg/m<sup>3</sup>; and
- Exceedances are expected to extend into the Local Assessment Area. See Figure E.4 in the [Air Quality Appendix B, Appendix E Abnormal Conditions](#) of the Revised Application.

#### Grid Power Outage

- The frequency of grid power outages is uncertain and was conservatively modeled as 10 hours per year;
- Tilbury Phase 2-related NO<sub>2</sub> concentrations are expected to reach 171 µg/m<sup>3</sup>; including background, total NO<sub>2</sub> levels are predicted to reach 229 µg/m<sup>3</sup>, exceeding CAAQS and MVAAQO 2025 of 79 µg/m<sup>3</sup>;
- Exceedances are expected to extend into the Local Assessment Area, see Figure E.7 in the [Air Quality Appendix B, Appendix E Abnormal Conditions](#) of the Revised Application; and
- SO<sub>2</sub> concentrations are not expected to increase during grid power outage conditions.

No updated modelling was completed for upset conditions under the mitigated scenario as flaring events are independent of the emissions control technologies applied to normal operations and, by design, do not incorporate additional control systems. The abnormal condition assessment therefore conservatively assumes uncontrolled flaring emissions coincident with worst-case dispersion conditions.

#### 17.1.5 Proposed Mitigation Measures by Proponent

The Tilbury Phase 2 must comply with Metro Vancouver's air quality permitting requirements, including obtaining an air quality permit post-certificate approval. This permitting process will set specific operational conditions, such as stack testing frequency and emission limits, developed collaboratively with Metro Vancouver, First Nations and involving Fraser Health Authority to address health considerations.

FortisBC noted they would implement Best Available Technologies (BAT) during final design to meet these requirements, recognizing that technology choices will evolve through detailed engineering and regulatory input.

FortisBC will also conduct updated air dispersion modelling as part of permitting and adhere to ongoing monitoring and follow-up measures mandated by regulatory authorities to ensure compliance with all applicable standards.

Mitigations measures proposed by the Proponent are:

##### During Construction:

- Vehicle idle reduction policies;
- Dust-control measures in the Construction Environmental Management Plan (CEMP);
- Regular inspection and maintenance of equipment;
- Noise attenuation for compressors;
- Complaint management for odour issues; and
- Avoidance of waterborne deliveries (no marine offloading facility required).

##### During Operation:

- Incorporate emissions reduction and control technologies in Tilbury Phase 2 design to ensure compliance with regulatory air quality requirements and industry best practices;
- Electrify Tilbury Phase 2 refrigeration and feed gas compression processes to reduce project CACs and GHG emissions; and

- Establish a refuelling and spill response plan. The measures will be incorporated into the CEMP.

As part of the substituted process, the EAO has identified Key Mitigation Measures (KMM) for effects within federal jurisdiction to inform Impact Assessment Agency of Canada's draft potential federal conditions. The KMM related to the health, social, and economic conditions of Indigenous peoples (which considers Tilbury Phase 2's potential effects to air quality) are outlined in [Appendix 2](#).

### 17.1.6 Key Issues Raised

#### 17.1.6.1 Exceedances of Air Quality Standards and Guidelines

Tsawwassen, Quw'utsun Nation, x̣ẉməθḳẉəỵəm, Tsleil-Waututh, Ts'uubaa-asatax, the S'ólh Téméxw Stewardship Alliance (STSA), Metro Vancouver, Vancouver Coastal Health Authority and Richmond raised concerns about potential exceedances of air quality standards and objectives (CAAQS 2025 and MVAAGO 2025) due to the existing high background combined with Tilbury Phase 2's emissions. Metro Vancouver and other organizations above, noted that a significant portion of the year could have exceedances of air quality objectives for NO<sub>2</sub>, if Fortis' proposed mitigations and further conditions were not in place. Quw'utsun Nation, Tsleil-Waututh and x̣ẉməθḳẉəỵəm questioned the reliability of air quality monitoring data used to establish ambient background conditions, given that the data is at least three years old and does not account for ongoing regional development. Several comments were also raised during public comment period about flaring events, particularly during facility start-up, and questioned whether these episodic emissions were adequately assessed or mitigated in the air quality modelling and management plans.

FortisBC initially completed air dispersion modelling under a conservative, unmitigated scenario to establish a precautionary baseline for potential impacts. In response to Technical Advisory Committee (TAC) concerns, additional modelling was conducted for NO<sub>2</sub> and SO<sub>2</sub> under a mitigated scenario reflecting planned emission controls, and a separate assessment addressed flaring during abnormal operating conditions.

The flaring analysis assessed commissioning, startup and shutdown, upset conditions, and grid power outage scenarios using conservative, unmitigated assumptions and 98th-percentile modeled concentrations to represent worst-case conditions. Modeled exceedances of applicable air quality objectives were limited to short-duration events, with commissioning activities occurring over defined periods (up to approximately two weeks for LNG tank commissioning and up to 72 and 144 hours for liquefaction train commissioning), startup and shutdown events lasting less than 5 hours and occurring up to five times per year, upset events occurring approximately once per year for less than 5 hours, and grid power outages conservatively modeled as up to 10 hours per year.

The mitigated scenario analysis showed that emission controls would further reduce risks from CACs from Tilbury Phase 2. Further modelling for other CACs, such as PM, VOC's, was not completed because they were not expected to exceed health-based thresholds under the more conservative unmitigated scenario.

Metro Vancouver confirmed that its air quality permitting process will consider requirements for monitoring, performance testing, and evaluating mitigation effectiveness, and will include consultation with health authorities and First Nations.

EAO notes Tilbury Phase 2 must comply with Metro Vancouver's air quality objectives and emissions permitting requirements, in addition to provincial and federal regulations (see Section 17.1.15 on proposed mitigation measures above).

In addition, the EAO is proposing condition 14 (Air Quality Management Plan) requiring the development and implementation a plan to manage the effects of Tilbury Phase 2 on air quality and condition 18 (Regional Cumulative Effects Initiatives) that may require FortisBC to participate in and contribute to the appropriate airshed group if such a group or program(s) is created by the provincial government or Metro Vancouver. These conditions are intended to ensure alignment with regulatory objectives and support broader regional air quality goals.

### 17.1.6.2 Cumulative Impacts

Tsawwassen, Quw'utsun Nation, xʷməθkʷəy̓əm, Tsleil-Waututh, Ts'uubaa-asatx, the STSA, Metro Vancouver, expressed concerns about cumulative air quality impacts from Tilbury Phase 2 in combination with other regional developments. xʷməθkʷəy̓əm noted that the decommissioning phase was not considered in the assessment of residual and cumulative effects on air quality. xʷməθkʷəy̓əm and Tsleil-Waututh also emphasized that culturally significant sites, such as fishing areas in the Fraser River, were not included as sensitive receptors in the air quality assessment.

In response, Fortis acknowledged existing cumulative effects in the area, particularly along the Fraser River, these were identified in "Historical Context" section of the specific First Nation sections. EAO noted that effects to surface water, which included effects from changes to Air Quality, were assessed in the Surface Water section of the Revised Application and agreed with Fortis' assessment that there would be no noticeable or measurable impacts to the Fraser River.

The EAO determined there would be no residual effects to Surface Water and excluded from cumulative effects. This is mainly due to high river flow in the Fraser River, making changes due to air quality impacts undetectable, after mitigation measures are applied. EAO also recognizes that some First Nations hold different views on the Cumulative Effects Assessment (CEA) methodology and Tilbury Phase 2's contribution, which are reflected in section 11 of the Revised Application and in First Nations-authored sections of this Report.

Fortis also completed additional air modelling incorporating mitigation measures (see Section 17.1.6.1 *Exceedances of Air Quality Standards and Guidelines* above).

### 17.1.6.3 Effectiveness of Mitigation Measures Uncertainty

Fraser Valley Health, Metro Vancouver, Tsawwassen, Quw'utsun Nation, xʷməθkʷəy̓əm, and, and Tsleil-Waututh expressed concern and requested additional details on mitigation measures, monitoring and their effectiveness in reducing air contaminant levels. Fraser Health Authority requested a quantitative assessment of the effectiveness of mitigation controls on emissions reductions, including dispersion modeling scenarios incorporating these controls.

In response, FortisBC conducted additional air dispersion modelling using a conceptual mitigated design that incorporates proposed emission control technologies as a proof-of-concept. The modelling predicts that implementing these controls would substantially reduce Tilbury Phase 2's air quality impacts during normal Operation, lowering residual effects to negligible or low magnitude.

Under this mitigated scenario, predicted offsite concentrations for NO<sub>2</sub> and SO<sub>2</sub> remain below applicable CAAQS 2025 and MVAQO 2025 at all sensitive receptor locations.

While brief exceedances of short-term NO<sub>2</sub> objectives may persist immediately adjacent to the facility property line and to the centre of the Fraser River, these are confined to non-sensitive business areas and do not affect residential or other sensitive receptors.

The results informed updates to the Human Health Risk Assessment (HHRA), discussed in more detail in [Section 7.15 \(Human Health\)](#) of the Revised Application, and supported the assessment of potential air quality impacts.

### 17.1.7 The EAO's Characterization of Residual Effects

After considering the proposed mitigation measures and conditions proposed, the information contained in the [Joint Permitting/Regulatory Coordination Plan](#) and the [Regulatory Coordination Issues Tracking Table](#), the EAO concludes that Tilbury Phase 2 would result in the following residual adverse effects on air quality:

- Increase in ambient CAC concentrations during site preparation and Project construction
  - CAC emissions during site preparation and construction may be transported and dispersed by weather outside of the facility property line;

- Increase in ambient NO<sub>2</sub>, SO<sub>2</sub>, and other CAC concentrations during Project operation
  - CAC emissions from the combustion sources associated with the unmitigated conceptual design during Tilbury Phase 2 operation will be transported and dispersed by weather outside of the facility property line; and
- Increase in short-term CAC concentrations during abnormal operating conditions (flaring).

Impacts to air quality can affect human health; however, potential health effects are addressed separately in [Appendix 6, Section 17.14](#) (Human Health).

The EAO's characterization of the expected residual effects of Tilbury Phase 2 on air quality is summarized in Table 55 below, as well as the EAO's level of confidence in the effects determination (including their likelihood and significance).

Table 51: Summary of Residual Effects for Air Quality<sup>58</sup>

| Residual Effect                                                                | Assessment Rating*                                                                                                                                                                                                                                                                                                        | Rationale                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Increase in ambient NO <sub>2</sub> , concentrations during project Operation. | Context (resilience): Low<br>Magnitude: Negligible to Low<br>Extent: Local<br>Duration: Medium-term<br>Reversibility: Partially Reversible<br>Frequency: Continuous<br>Affected Populations: Evenly/Disproportionate<br>Risk (likelihood and consequences): Moderate<br>Uncertainty: Moderate to High<br>Importance: High | <p><b>Not Significant</b></p> <p>NO<sub>2</sub> can affect health even at low concentrations, and current monitoring shows that background levels combined with emissions from the existing Phase 1A facility already exceed 1-hour CAAQS 2025 and MVAAQO 2025 at non-sensitive receptors across the Local Assessment Area.</p> <p>Tilbury Phase 2's contribution to 1-hour NO<sub>2</sub> concentrations after mitigation is predicted to be negligible, adding less than 1% of the applicable regulatory threshold. EAO acknowledges that current 1-hour NO<sub>2</sub> levels, without Tilbury Phase 2, are already high and exceed health-based air quality standards at the 98th percentile which represents less than 2% of all hours in a year (approximately 175 hours). Annual NO<sub>2</sub> concentrations are rated low magnitude, reflecting about a 6% increase over the Base Case with no health-based thresholds exceeded.</p> <p>EAO also recognizes input from multiple First Nations emphasizing that air quality impacts should be considered holistically rather than in isolation; these perspectives are addressed in the Context assessment rating and Current Conditions by Proponent section above, and the Cumulative Effects sections below.</p> <p>Operational emissions will extend beyond the facility property line into the Local Assessment Area and persist throughout the operational phase.</p> <p>Based on mitigated predictions, NO<sub>2</sub> 1-hour concentrations exceedance of MVAAQO or CAAQS 2025 extend within 50 m of the property line and expected to occur infrequently under the 98<sup>th</sup> percentile.</p> <p>Predicted concentrations at sensitive receptors, including childcare facilities, schools, seniors' residences, and the Historic Indigenous Village Site<sup>59</sup>, directly across the river from the site - remain below CAAQS and MVAAQO 2025 under the mitigated scenario for the 90th and 75th percentiles.</p> <p>Air quality is expected to return to pre-project conditions after decommissioning; however, some health and environmental effects associated with air-quality changes may persist when using the 98<sup>th</sup> percentile. Indigenous knowledge shared during consultation highlights the interconnected nature of air quality, health, and culturally significant areas, underscoring that reversibility cannot be considered in isolation. Considering these</p> |

<sup>58</sup> Impacts to air quality can affect human health; however, potential health effects are addressed separately in [section 7.15 \(Human Health\)](#) of the Revised Application.

<sup>59</sup> See Section 3.1 for naming and jurisdictional context regarding the Historic Indigenous Village Site.

| Residual Effect                                                      | Assessment Rating*                                                                                                                                                                                                                                                                                                                                      | Rationale                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|                                                                      |                                                                                                                                                                                                                                                                                                                                                         | <p>factors, the effect on air quality is rated as partially reversible. See <a href="#">Section 7.15 (Human Health)</a> of the Revised Application for further discussion.</p> <p>While the long-term operational air quality is expected to affect the general population evenly, those in the immediate vicinity; such as onsite workers and people fishing in the river directly adjacent to the site, will be exposed to the highest predicted concentrations and deposition levels.</p> <p>Likelihood of an increase in NO<sub>2</sub> is medium, reflecting that mitigation is expected to be effective but final design and permitting are pending. Consequence is rated as moderate due to the medium-term operational duration, negligible to low magnitude impacts and limited geographical extent after mitigation. These two factors result in an overall moderate risk rating.</p> <p>Uncertainty is moderate to high because modelling was completed for both mitigated and unmitigated scenarios and base case conditions are well quantified, but the exact location of exceedances depends on meteorological conditions. Uncertainty remains due to dispersion modelling being used to characterize baseline conditions, rather than real-time monitoring and because Project-case predication are based on mitigations that have not yet been finalized; however, technical advisors expect significant reductions if best available technology is applied.</p> <p>Importance is high because air quality is a top concern for First Nations and regulatory agencies and its link to human health.</p> |
| Increase in SO <sub>2</sub> concentrations during project Operation. | <p>Context (resilience): Moderate</p> <p>Magnitude: Low</p> <p>Extent: Local</p> <p>Duration: Medium-term</p> <p>Reversibility: Partially Reversible</p> <p>Frequency: Continuous</p> <p>Affected Populations: Evenly/Disproportionate.</p> <p>Risk (likelihood and consequences): Low</p> <p>Uncertainty: Moderate to High</p> <p>Importance: High</p> | <p><b>Not significant</b></p> <p>The airshed near Tilbury Phase 2 has moderate resilience to imposed stresses given the low existing ambient SO<sub>2</sub> concentrations that have been declining.</p> <p>The EAO agrees with the Revised Application's conclusion that SO<sub>2</sub> magnitude is low because, under the mitigated design, predicted concentrations remain below the 2025 CAAQS and MVAAQO at all percentiles, with increases of less than 10 % from Base Case levels. At the same time, EAO acknowledges Indigenous knowledge shared during consultation, which emphasizes that even small increases can have cultural and health implications given the interconnected nature of air quality and health.</p> <p>See rationale for reversibility and affected populations in NO<sub>2</sub> section above.</p> <p>Likelihood is medium, reflecting that mitigation is expected to be effective but final design and permitting are pending. Consequence is rated as minor due to the long operational duration and low magnitude effect after mitigation, resulting in an overall low risk rating.</p> <p>See uncertainty discussion in the NO<sub>2</sub> section above.</p> <p>Importance is high because air quality is a top concern for First Nations and regulatory agencies and its link to human health.</p>                                                                                                                                                                                                                                                                                |
| Increase in CO, PM, VOCs concentrations during project Operation.    | <p>Context (resilience): Moderate</p> <p>Magnitude: Negligible</p> <p>Extent: Local</p> <p>Duration: Medium-term</p> <p>Reversibility: Partially Reversible</p> <p>Frequency: Continuous</p> <p>Affected Populations: Evenly/Disproportionate</p>                                                                                                       | <p><b>Not significant</b></p> <p>The airshed near Tilbury Phase 2 has moderate resilience to imposed stresses given the low existing ambient CO, PM, and VOCs concentrations.</p> <p>The Revised Application rates the magnitude of PM, CO, and VOCs as negligible because predicted increases during operation remain well below CAAQS and MVAAQO under both mitigated and unmitigated scenarios. EAO acknowledges Indigenous knowledge shared during consultation that while thresholds are not exceeded Tilbury Phase 2 combined with Base Case conditions represents a measurable increase from existing levels, contributing to effects identified by First Nations as a concern.</p> <p>See rationale for reversibility and affected populations in NO<sub>2</sub> section above.</p> <p>Likelihood is medium, reflecting that mitigation is expected to be effective but final design and permitting are pending. Consequence is rated as moderate due to the long</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Residual Effect                                                                          | Assessment Rating*                                                                                                                                                                                                                                                                                 | Rationale                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|                                                                                                                                 |                    | Importance is rated as high because flaring and abnormal air emissions were consistently identified by First Nations, health authorities, and regulatory agencies as a key concern due to their potential implications for human health, culturally important areas, and overall air-quality management. |
| Note: Criteria and assessment ratings are defined in <a href="#">Appendix 3 - Residual Effects Characterization Definitions</a> |                    |                                                                                                                                                                                                                                                                                                          |

### 17.1.8 Cumulative Effects Assessment

The assessment of a designated project must consider any cumulative effects that are likely to result from Tilbury Phase 2 in combination with other physical activities that have been or will be carried out. The following effects pathway was carried forward for CEA on air quality:

- Increase in ambient CAC concentrations during construction;
- Increase in ambient concentrations of NO<sub>2</sub> during operation;
- Increase in ambient concentrations of SO<sub>2</sub> during operation; and
- Increase in ambient concentrations of CO, PM, and VOCs during operation.

As per [Section 7.2.5.3](#) of the Revised Application, five existing and reasonably foreseeable projects and activities that have the potential for overlapping air quality effects with the Tilbury Phase 2 during their respective operation phases. These reasonably foreseeable projects and activities were considered in the CEA for the air quality VC, along with existing conditions expected to persist into the future. Of these, the Proponent included only two in the cumulative effects modelling; the remaining three were addressed qualitatively. Table 7.2-14 of the Revised Application provides a full accounting for all the projects and activities considered in the CEA. A summary follows:

- **T1B:** Included in the cumulative modelling. involves the construction and operation of facilities to increase the LNG production, storage, and distribution capacity at the existing Tilbury facility;
- **TMJ:** Included in modelling due to proximity. TMJ, based on outdated information, is a major contributor to cumulative impacts, with predicted 1-hour NO<sub>2</sub> levels conservatively calculated to exceed objectives by approximately 164%<sup>60</sup>;
- **Delta Grinding Facility:** Located within the Regional Assessment Area. Identified as having limited potential for overlapping effects (PM, DPM, NO<sub>x</sub>, CO) but not modelled due to insufficient public data;

- **Roberts Bank Terminal 2 (RBT2):** About 16 km southwest of Tilbury Phase 2. Expected localized impacts; overlap with Tilbury Phase 2 is unlikely, so not modelled; and
- **Vancouver Airport Fuel Delivery (VAFD):** Under construction ~2 km west of Tilbury Phase 2. Expected result in a decrease<sup>61</sup> in NO<sub>x</sub> emissions when compared to replacement of trucking associated with the current facility; not included in modelling.

The cumulative case includes emissions from the mitigated Application Case (Project + Base Case) and the T1B and TMJ project. Tilbury Phase 2's incremental contribution is small—about 1% (0.86 µg/m<sup>3</sup>) for 1-hour NO<sub>2</sub> and 7% (1.36 µg/m<sup>3</sup>) for annual NO<sub>2</sub>.

Under the mitigated cumulative scenario, 1-hour NO<sub>2</sub> concentrations were modelled to be high magnitude or double (161 µg/m<sup>3</sup>), the CAAQS and MVAAQO 2025 (79 µg/m<sup>3</sup>) using the 98<sup>th</sup> percentile background, and 147 µg/m<sup>3</sup> and 136 µg/m<sup>3</sup> at the 90<sup>th</sup> and 75<sup>th</sup> percentile background respectively. This indicates a persistent tendency for 1-hour concentrations to exceed the regulatory objective across a wide range of background conditions, rather than only during rare or extreme circumstances.

Exceedances are expected 346 days per year using 98<sup>th</sup> percentile background level, and 276 and 185 days per year using the 90<sup>th</sup> and 75<sup>th</sup> background percentile respectively, which means exceedances of the 1-hour NO<sub>2</sub> objective are predicted to occur frequently, on the majority of days in a typical year, rather than being limited to occasional or rare events. This means the 1-hour NO<sub>2</sub> limit would be exceeded most days, not just during unusual or extreme conditions.

The modelling indicates that the spatial extent of 1-hour NO<sub>2</sub> exceedances under the mitigated cumulative scenario is concentrated in a defined hotspot area associated with TMJ emissions, with the footprint becoming progressively smaller as lower background percentile values are applied. Furthermore, elevated concentrations occur at several residential and business receptors and at the Historic Indigenous Village Site within approximately 1–3 km of Tilbury Phase 2. The modelling further notes that little to no exceedances are observed south of River Road under the mitigated scenario.

Annual NO<sub>2</sub> exceedances are limited to a small area near the TMJ berth over water, with predicted concentrations of 22.7 µg/m<sup>3</sup> compared to the 22.6 µg/m<sup>3</sup> standard.

SO<sub>2</sub>, cumulative 1-hour concentrations remain below regulatory standards, with Tilbury Phase 2 contributing only 4.46 µg/m<sup>3</sup> of the cumulative total (120 µg/m<sup>3</sup>). Increases are localized near Tilbury Phase 2 site and adjacent business areas. Other contaminants (CO, PM<sub>2.5</sub>, PM<sub>10</sub>, VOCs) assessed in the unmitigated cumulative scenario remain well below 1-hour and annual standards, with Tilbury Phase 2's contribution minimal.

There is meaningful uncertainty in the cumulative air quality results. The modelling intentionally incorporates conservative assumptions, so even the 75<sup>th</sup> and 90<sup>th</sup> percentile background cases represent upper bound conditions rather than average or typical conditions. Notably, most of the predicted NO<sub>2</sub> and SO<sub>2</sub> increases come from TMJ, and it is unclear how representative the TMJ modelling assumptions remain, as they were based on an older, conservative assessment using large diesel-powered LNG carriers and high activity levels; actual emissions could be lower if LNG powered or hybrid vessels are used or if peak operations occur infrequently. Results also vary with changing weather conditions, and some sources (such as Delta Grinding) were only qualitatively characterized. Overall, these results should be viewed as deliberately conservative estimates, not precise forecasts of future air quality.

<sup>61</sup> The reduction is driven primarily by eliminating daily tanker-truck fuel deliveries and shortening marine vessel transit distances, which together significantly lower regional NO<sub>2</sub>/NO<sub>x</sub> emissions [Assessment Report and Appendices for the Vancouver Airport Fuel Delivery Project dated Dec 14, 12.pdf](#).

Provincial conditions for both approved TMJ and proposed Tilbury Phase 2, along with Metro Vancouver permitting for Tilbury Phase 2, and federal TMJ requirements (e.g., Idle limits, vessel limits, boil-off gas controls) all play an important role in ensuring compliance and managing air emissions within the airshed. Tilbury Phase 2 will be subject to enforceable emission limits, stack testing, and monitoring under Metro Vancouver's Air Quality Management Bylaw. Regional monitoring indicates NO<sub>2</sub> levels have declined over the past decade despite population growth, and SO<sub>2</sub> remains very low mainly due to marine fuel Sulphur limits and limited LNG/electric vessel adoption.

Taking these factors into account, the cumulative assessment indicates that ambient NO<sub>2</sub> concentrations within the airshed may remain elevated under certain modelling scenarios driven primarily by other existing or reasonably foreseeable activities. However, the residual emissions from Tilbury Phase 2 are predicted to be negligible to low in magnitude, and Tilbury Phase 2's incremental contribution to cumulative concentrations is small relative to other sources. Accordingly, Tilbury Phase 2 is not anticipated to measurably alter cumulative air quality conditions within the Regional Assessment Area and is therefore not expected to result in an adverse cumulative effect on the air quality VC.

#### 17.1.9 Conclusion

The EAO is satisfied that Tilbury Phase 2 would not have significant adverse residual or cumulative effects on the air quality VC. The extent of significance for federal effects the health, social, and economic conditions of Indigenous peoples (which considers Tilbury Phase 2's potential effects to air quality) is found in [Appendix 15](#). This conclusion considers the information and analysis presented in this section; the views of the TAC, First Nations, and FortisBC; the proposed Mitigation Measures identified in the provincial Table of Conditions including Condition 12 (CEMP) and Condition 14 (Air Quality Management Plan); and federal Key Mitigation Measures and Follow-up Programs under the *Impact Assessment Act* (IAA) for the air quality VC as it may pertain to the health, social, and economic conditions of Indigenous peoples ([Appendix 2](#)).

## 17.2 Acoustic

### 17.2.1 Summary

Acoustic was selected as a VC for the Tilbury Phase 2 environmental assessment as it can affect human health, disrupt wildlife behavior and habitat use, and interfere with cultural and land-based activities. Indicators for the acoustic VC considered as part of the assessment include audible noise, low-frequency noise, and vibration.

The Project is on private land in Tilbury Industrial Park, Delta, B.C.—a medium- to high-impact industrial zone with ongoing development and infrastructure. Ambient sound levels are shaped by nearby industrial, marine, road, rail, and air traffic activity. Since the 1970s, the area's shift from farmland to sawmills and gas facilities has raised noise levels, with some receptors exceeding Health Canada's thresholds for sleep disturbance and speech intelligibility. As part of the assessment receptors were considered at a range of location including the nearest homes, a pathway adjacent to the Project Footprint, the nearby animal shelter, and the Historic Indigenous Village Site<sup>62</sup> on directly across the river on what is known as Lulu Island.

Key issues raised by reviewers included Existing Conditions and modeling assumptions, concerns regarding increased noise levels, and the effectiveness of mitigation measures response processes.

In response to the issues raised, the EAO has proposed that if a Certificate is issued, the Certificate should include Condition 12 requiring approval of a CEMP before construction, and Condition 13 for an OEMP, both of which must address acoustic effects and include the implementation of a noise monitoring program. The effectiveness of these plans and their mitigation measures will be evaluated under Condition 1 (Document Review). A separate Condition 10 (Community Feedback Process) will require a process to track and respond to community concerns, including noise disturbances, during Construction and Operation.

The EAO concludes that the Project is not expected to result in significant adverse residual effects on the acoustic VC. Similarly, the EAO finds no significant cumulative effects on the acoustic VC from Tilbury Phase 2 when assessed in combination with other past, present, and reasonably foreseeable future projects.

### 17.2.2 Assessment Boundaries

The spatial boundaries for the Acoustic assessment included:

- The Project Footprint: defined as the area directly disturbed by Project activities;
- The Local Assessment Area (LAA): the Project Footprint plus a 1.5 km buffer; and
- The Regional Assessment Area (RAA): a 3-km-wide zone around the perimeter of the Project Footprint.

The temporal boundaries used in the assessment of acoustics include the Construction (3–6 years), Operation (40 plus years), and Decommissioning (2 years) phases of the Project.

Project components and anticipated duration of activities are described in detail in [Section 1.2](#) (Project Description and Schedule) of this Report.

### 17.2.3 Existing and Future Conditions by Proponent

FortisBC (Proponent) assessed existing acoustic conditions in [Section 7.3.4](#) and [Appendix C \(Noise and Vibration Technical Data Report\)](#) of the Revised Application.

The assessment considered two noise scenarios:

- Existing Ambient Sound Level: This is the current noise in the area without sound from the existing Tilbury Phase 1A facility or the Project. This scenario includes general background noise from sources such as traffic,

---

See Section 3.1 for naming and jurisdictional context regarding the Historic Indigenous Village Site.

marine activity, and nearby businesses. It helps show what the area sounds like without project-related noise and is used to assess impacts like sleep disturbance or changes from normal conditions; and

- **Expected Future Conditions:** This includes noise from the existing Phase 1A facility and other nearby approved soon to be built projects (like T1B, TMJ, and the base plant demolition vibrations, but not the Project itself.) It's used to figure out how much additional noise the Project would create and to understand the total future noise level when all nearby developments are considered.

### 17.2.3.1 Historic Context

The Fraser River and Tilbury Island have long been used by Indigenous peoples for cultural practices, including transportation, hunting, fishing, and gathering. These traditional activities are deeply connected to the land and remain culturally significant.

Over time, the area has been heavily industrialized, with Tilbury Island transitioning from agricultural use to sawmills and natural gas facilities starting in the 1970s, leading to increased noise levels. The Project is located within this industrial zone on FortisBC-owned land. Ongoing industrial activity, including marine traffic on the Fraser River, contributes to an already elevated noise environment, which may further affect Indigenous use of the area, particularly activities sensitive to changes in acoustic conditions.

### 17.2.3.2 Existing Ambient Sound Level

Existing Ambient Sound Levels occur from dominant sound sources in the LAAs and RAAs include marine, road, rail, and air transportation; as well as industrial and commercial operations.

Baseline noise levels at the site, located in a heavily industrialized coastal area, range from 46.6 to 57.1 A-weighted decibels (dBA) during the daytime - comparable typical background noise in an office (45 dBA) and typical background noise in a large department store (60 dBA).

The Proponent assessed ground-borne vibration, which refers to vibrations from sources like traffic or industrial activity that travel through the ground.

See Figure 9 below that shows the location of specific receptors that were used to assess current and future acoustic impacts.

#### Receptor-specific conditions

- **R1 (a home in Delta, 500 meters from the site), R3 (Historic Indigenous Village Site ~700 metres across the Fraser River) and R4 (A home in Richmond, 1,800 metres away)** nighttime noise was 53.1, 50.3, and 45.7 dBA respectively - above the World Health Organization's (WHO) recommendation for an average annual nighttime sound level of 40 dBA as referenced in the Health Canada Noise Guideline;
- Day time noise at **R1** (57.1 dBA) was above the Health Canada recommended outdoor speech intelligibility threshold of 55 dBA;
- **R2 (Delta Community Animal Shelter ~220 metres away)** outdoor animal areas exposed to daytime noise just below the 55 dBA speech intelligibility threshold;
- **R3 –Historic Indigenous Village Site: ~700 metres across the Fraser River;** used for traditional purposes by multiple First Nations. Noise levels for daytime are below Health Canada speech intelligibility threshold of 55 dBA; and

- **R5 (Informal pathway ~5 metres from the Project Footprint)** Daytime noise (56.5 dBA) exceeded thresholds for speech interference and annoyance. Evaluated for context but not formally assessed against regulatory guidelines.

Figure 9: Location of Receptors Used in Assessing Current and Future Project Related Acoustic Effects

#### 17.2.4 Potential Project Effects by Proponent

The Proponent assessed the potential Project effects with the activities associated with Construction and Operation of Tilbury Phase 2 that have the potential to interact directly or indirectly with the acoustic VC in [Section 7.03](#) of the Revised Application. This section focuses on Construction and Operation, as Decommissioning noise levels will be similar to Construction.

Results of the expected future conditions for Construction and Operation can be found in *Table 7.3-6* and *Table 7.3-7* of the Revised Application and are discussed below.

##### 17.2.4.1 Key Findings for Noise during Construction:

For the Construction phase of the Project, the expected future condition includes the summation of noise from the existing ambient condition, existing Phase1A facility, predicted future TMJ facility.

Overall Noise Levels (Annoyance and Speech Intelligibility):

- For receptors R1, R2, R3, and R4, the predicted increase in community annoyance (% Highly Annoyed or %HA) due to the Project's Construction is less than the Health Canada threshold of 6.5% change, when compared to either baseline;

- For R5, an informal pathway receptor located very close to the site, the predicted increase in annoyance is significantly greater than 6.5%; and
- Regarding speech intelligibility (ability to hold a conversation outdoors), the Health Canada threshold is 55 dBA (during the day). The predicted cumulative noise levels during Construction are expected to be above 55 dBA at receptors R1, R2, and R5 (R5 exceeds by 18.9dBA). At R3 and R4, the levels are predicted to be below this threshold. Note that the measured Existing Ambient Condition already exceeded 55 dBA LD at R1 and was just below it at R2.

#### Sleep Disturbance

- The measured existing nighttime noise levels (Ambient Sound Level LN) at some receptors (R1, R3 and R4) already exceed WHO's recommendation for an average annual nighttime sound level of 40 dBA outdoors for good sleep as referenced in the Health Canada Noise Guideline;
- The predicted increase in average nighttime noise caused by the Project's Construction, even in the "worst-case," is relatively small. Compared to the Ambient Sound Level, the predicted increase is 1.7 decibels (dB) or less at the assessed receptors (R1, R3, R4). Compared to the "Construction Expected Future Condition" (which includes noise from other nearby facilities), the increase is less than 1 dB at these receptors; and
- While average noise increases are small, sudden, loud "sporadic" noise events (like alarms, material dropping, or hammering) from Construction could potentially cause sleep disturbance by exceeding Health Canada's criteria for individual events.

#### Low-Frequency Noise (LFN)

- LFN refers to deep sounds, like rumbling, that you might feel more than hear. These can sometimes cause buildings to shake or rattle. The assessment found LFN is expected during loud construction phases. More detailed analysis will happen in the design stage; and
- For extremely low frequencies (called infrasound), anything over 70 z-weighted decibels (dBZ) may cause building rattles.

#### Ground-borne Vibrations

- From R1 through to R4, vibration is expected to be too low to feel or cause damage.
- At R5 (a pathway very close to construction), people might feel some vibration, especially during heavy activities like stone column work;
- Vibration strong enough to risk damage is only possible if the work is happening very close to a building - within 17 to 23 metres. No buildings are that close, so damage is unlikely; and
- Overall, vibration impacts are expected to be low, temporary, and not harmful to structures.

#### 17.2.4.2 Key Findings for Noise during Operation:

For the Operation phase of the Project, the expected future condition includes the summation of noise from the existing ambient condition, existing Phase1A facility, predicted future T1B facility and TMJ facility.

#### Annoyance

- The BCER noise guideline provides permissible sound levels (PSL) for energy facilities in B.C. at occupied dwellings which for this study include R1 and R4. The study predicts that noise levels at these dwellings will comply with BCER's PSLs, meaning the noise shouldn't significantly disturb people living there;
- Using Health Canada's metric for annoyance (%HA), the predicted increase in annoyance from the Project is below the 6.5% threshold at R1, R2, R3, and R4 - so no major concern is expected at those spots; and

- At R5 (a pathway right next to the site), the predicted %HA increase is above 6.5%, suggesting possible high annoyance. But because R5 isn't a home or formal receptor, no mitigation is required but FortisBC will work with a Qualified Professional (QP) to manage these potential changes during Operation.

#### Speech Intelligibility

- Health Canada recommends keeping daytime noise below 55 dBA so people can talk comfortably outside. The predicted noise from the Project is above that level at R1, R2, R3, and especially at R5, where the exceedance is more noticeable; and
- The Project's noise increase is small (3 dBA or less, within the modelling uncertainty) and, based on conservative estimates, is unlikely to significantly affect speech intelligibility.

#### Sleep Disturbance

- Existing nighttime noise is already high at the receptors assessed (R1, R3 and R4), above WHO's recommendation for an average annual nighttime sound level of 40 dBA for good sleep as referenced in the Health Canada Noise Guideline;
- The Project will add a small increase in nighttime noise—between 1.4 and 4 dB depending on the location. Compared to future noise without the Project, the increase is less than 2-3 dB; and
- No sudden, loud noise events (like alarms or bangs) are expected from Project Operation that could disturb sleep.

#### Low Frequency Noise

- Low Frequency Noise (LFN) includes deep sounds below 100 Hz, like rumbles or vibrations, you might feel more than hear. These sounds can sometimes cause buildings to vibrate or "rattle." LFN from the Project are predicted to be above the Health Canada guidance at R1,3,4, and 5 but below BCER's threshold for at R1 and R4 receptors.

### 17.2.5 Proposed Mitigation Measures by Proponent

The Proponent identified the following relevant mitigation measures to reduce potential effects on acoustic:

- During Construction, develop and implement a vehicle idle reduction policy that focuses on reducing noise and vibration emissions from construction vehicles. These measures are to be incorporated into the CEMP;
- During Construction and Operation of the project, develop mitigation and contingency measures through engagement with a QP to manage acoustic disturbance to human and wildlife receptors, and incorporate these measures into the CEMP and OEMP;
- Receive, record, investigate, and follow-up on noise complaints from First Nations, the public, and adjacent businesses;
- Conceptual engineered noise mitigation measures for project equipment during Operation are based on preliminary project design and are outlined in the Noise and Vibration Technical Data Report (TDR) (Appendix C of the Revised Application). Final noise mitigation measures for project equipment will be engineered based on detailed noise specifications and incorporated into the Project;
- All compressors will be enclosed to attenuate noise to a level consistent with the BCER noise regulations;
- Use of Totally Enclosed Ground Flare (TEGF) technology to reduce noise and light from flaring; and
- No waterborne deliveries of modular components or construction materials to the project site - no MOF will be required.

As part of the substituted process, the EAO has identified KMMs for effects within federal jurisdiction to inform the IAAC's draft potential federal conditions. The KMMs for the acoustic VC as it may pertain to Indigenous health under the IAA are outlined in [Appendix 2](#).

### 17.2.6 Key Issues Raised

Based on a review of the Revised Application and with feedback from the TAC, IAAC, participating Indigenous nations, Metis and the public, the following key issues related to the assessment of the acoustic VC for Tilbury Phase 2 were identified.

#### 17.2.6.1 Existing Conditions and Modelling Assumptions

Health Canada, xʷməθkʷəy̓əm, and Quw'utsun Nation raised concerns about the Existing Conditions used for noise assessment, the assumptions and uncertainties in noise modelling, and the completeness of cumulative effects analysis. Their concern arises from the lack of consistency in the use of pre-project Ambient Sound Level as a baseline across all scenarios. Health Canada recommended an additional LFN study be completed based on final engineering design as this detailed analysis is considered the best method to develop noise mitigation controls. See LFN in [Section 17.2.4](#) (Potential Project Effects by Proponent) above.

In response FortisBC noted that the “expected future condition” baseline helps isolate the Project's incremental contribution. Computer programs were used to model sound levels, following guidelines, which typically carry a  $\pm 3$  dB uncertainty. Vancouver Airport Fuel Delivery Project (VAFD) and Heidelberg Cement operations were active during the ambient noise monitoring period.

The EAO has identified that noise is a consideration by the BCER as part of the LNG Facility Permit process. Under Section 15 of the LNG Facility Regulation the permit holder must ensure that construction and normal operations of the LNG facility do not cause excessive noise or emanation of light on human and wildlife receptors. Permit holders should ensure that mitigation measures are built into the design and operating procedures using the B.C. Noise Control Best Practices Guideline<sup>63</sup>. B.C. Noise Control Best Practices Guideline outline the BCER's expectations for noise impact assessments and best practices and include consideration of LFN.

#### 17.2.6.2 Increased Noise Levels

BCER, Health Canada, xʷməθkʷəy̓əm, and Quw'utsun Nation raised concerns about noise impacts during Construction, Operation, and Decommissioning — including from truck traffic, overlapping phases, and effects on nearby communities and the environment. Quw'utsun Nation also noted that increased operational noise could affect their intended future cultural and residential use of Tl'uq̓tinus.

FortisBC acknowledged the potential for overlapping Construction (Phase 1B and Phase 2) and committed to updating modelling if needed. They stated that predicted operational noise levels remain below perceptible thresholds (<3 dB) and agreed to revisit modelling and mitigation during final design if warranted.

xʷməθkʷəy̓əm, Quw'utsun Nation, and Ts'uubaa-asatx expressed that Indigenous Knowledge and perspectives were not sufficiently considered, particularly regarding effects on the Historic Indigenous Village Site and members exercising rights or undertaking cultural practices near the Project.

FortisBC stated that receptor locations, including the Historic Indigenous Village Site or “R3”, were selected based on Indigenous Knowledge and Health Canada guidance. They acknowledged differing perspectives, noting that although regulatory thresholds were not exceeded, culturally important sites could still experience sensory disruption. FortisBC committed to working with First Nations on mitigation planning and evaluation.

<sup>63</sup> BC Noise Control Guidelines version 2.4 (June 2024), BCER. [https://www.bc-er.ca/files/operations-documentation/Oil-and-Gas-Operations-Manual/Supporting\\_Documents/BC-Noise-Control-Best-Practices-Guideline.pdf](https://www.bc-er.ca/files/operations-documentation/Oil-and-Gas-Operations-Manual/Supporting_Documents/BC-Noise-Control-Best-Practices-Guideline.pdf). Accessed on June 17, 2025

The EAO determined that the magnitude of impact of increased noise levels is low, based on minor exceedances of Health Canada's speech intelligibility threshold at the Historic Indigenous Village Site, exceedances that may or may not result in perceptible changes to experience or use. The EAO also identified that the LNG Facility Permit amendment must consider operational noise effects, including at receptors beyond the facility boundary, and align with B.C. Noise Control Best Practices, Health Canada guidance, or applicable municipal bylaws.

If issued, the EAO proposes that the Certificate includes Conditions 12 (CEMP) and 13 (OEMP). Both conditions would require an outline of how the mitigation measures proposed in the Revised Application will be implemented, will require consultation with First Nations, and will require approval from the EAO prior to the commencement of Construction and Operation. The conditions also require the Holder to implement a noise monitoring program that takes into account Health Canada Guidance for Evaluating Human Health Effects in Impact Assessment: Noise and British Columbia Noise Control Best Practices Guideline.

### 17.2.6.3 Effectiveness of Mitigation Measures

x̣ṃəθḳẉəỵəm, Quw'utsun Nation, and Ts'uubaa-asatx raised concerns about the effectiveness of the proposed mitigation measures. There were also concerns raised, including from Health Canada, regarding the need for robust complaint mechanisms, clear timelines for issue resolution, and detailed operationalization of noise control strategies.

Specifically, Health Canada recommended the development of a robust noise complaint resolution plan with clear communication pathways and service standards for addressing community concerns.

x̣ṃəθḳẉəỵəm additional details on acoustic mitigation, including key receptors, noise controls (e.g., mufflers, barriers), and monitoring protocols. x̣ṃəθḳẉəỵəm and Quw'utsun Nation noted the importance of reviewing the CEMP and the OEMP prior to approval, to ensure cultural and technical adequacy.

The EAO has proposed Certificate Condition 10 (Community Feedback Process) requiring a process to track and respond to community feedback regarding project effects. The EAO has also proposed as part of Condition 3 (Document Development), which includes mitigation effectiveness, evaluation requirements that would apply to Condition 12 (CEMP) and Condition 13 (OEMP). Consultation requirements are included as part of Conditions 12 (CEMP) and 13 (OEMP).

### 17.2.7 The EAO's Characterization of Residual Effects

After considering the proposed mitigation measures and conditions proposed, the information contained in [the Joint Permitting/Regulatory Coordination Plan](#) and the [Regulatory Coordination Issues Tracking Table](#), the EAO concludes that the Project would result in the following residual adverse effects on the acoustic VC:

- Increase in noise levels during Construction of the Tilbury Phase 2 facility and associated infrastructure, including from truck traffic, equipment operation, and daytime/nighttime Construction activities;
- Increase in ground-borne vibration during Construction activities, particularly from stone column installation and other heavy construction methods, with perceptibility expected within 14–179 metres of the site; and
- Increase in noise levels during long-term Project Operation, including from enclosed compressors, flare stacks, and other facility components that may contribute to perceptible changes at nearby receptors.

The EAO's characterization of the expected residual effects of the Project on acoustic is summarized below, as well

as the EAO's level of confidence in the effects determination (including their likelihood and significance).

Table 52: Summary of Residual Effects for Acoustic VC

| Residual Effect                                  | Assessment Rating*                                                                                                                                                                                                                                                            | Significance and Rationale                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Increase in noise levels during Construction     | Context (resilience): Moderate<br>Magnitude: Low<br>Extent: Local<br>Duration: Short-Term<br>Frequency: Regular<br>Reversibility: Fully Reversible<br>Affected Populations: Disproportionate<br>Risk: Moderate<br>Uncertainty: Moderate<br>Importance: High                   | <p><b>Not Significant</b></p> <p>The area has a history of industrial noise exposure. Since some receptors already exceed sleep disturbance and speech thresholds, there is limited capacity to absorb more noise. Overall, the environment has moderate acoustic resiliency, reflecting its industrial context but limited tolerance for further impact.</p> <p>During the expected future condition, noise levels are expected to stay within Health Canada's annoyance criteria and increase by less than 3 dBA at night. While thresholds for speech intelligibility and sleep disturbance are already exceeded, the Project's incremental contribution is minor and may not be noticeable. Magnitude is rated as low.</p> <p>Effects will be concentrated within the LAA (up to 1.5km from the Project Footprint) for onsite activities.</p> <p>The effects will be short-term and regular. Effects will cease and be fully reversible at the end of Construction.</p> <p>Noise-sensitive groups, like residents near R1 and Indigenous users near the Historic Indigenous Village Site, may face higher impacts, making the affected population disproportionate.</p> <p>The likelihood of the effect is high, with moderate consequences due to the temporary but frequent exceedance of Health Canada thresholds for sleep disturbance and speech intelligibility at nearby receptors. Therefore, the risk is rated as moderate.</p> <p>Despite conservative modelling, the specific nature of the disturbance and how it will be perceived leads to a rating of moderate uncertainty.</p> <p>Construction noise during Operation could disrupt rest and sensory awareness in people and wildlife, particularly affecting First Nations' use of the Fraser River and the Historic Indigenous Village site. These concerns were also raised by regulators and the public. Due to cultural significance, health implications, and ecological sensitivity, the residual effect is rated as high in importance.</p> |
| Increase in vibration levels during Construction | Context (resilience): Moderate<br>Magnitude: Negligible (R1-4) to Low (R5)<br>Extent: Local<br>Duration: Short-Term<br>Frequency: Irregular<br>Reversibility: Fully Reversible<br>Affected Populations: Disproportionate<br>Risk: Low<br>Uncertainty: Low<br>Importance: High | <p><b>Not Significant</b></p> <p>The area's long-standing industrial use and routine exposure to mechanical activities suggest a high capacity to absorb additional vibration without lasting disruption. A moderate resilience rating reflects this tolerance,</p> <p>Vibration will be noticeable at times (especially at R5) but remains below structural damage thresholds. While annoyance may occur up to 179 metres away, the effect is intermittent and localized, with no critical receptors in high-risk areas, supporting a low magnitude rating.</p> <p>Effects will be irregular, short term, and fully reversible. They are temporary and episodic, and limited to Construction.</p> <p>Noise-sensitive groups, like residents, trail and river users, or Indigenous peoples who exercise cultural practices on the Fraser River and the Historic Indigenous Village Site, may face higher impacts from vibrations during Construction, making the affected population disproportionate.</p> <p>There is a low level of risk associated due to the magnitude, duration, and location of the expected effects.</p> <p>There is a low level of uncertainty due the acoustic modeling using conservative assumptions based on worst-case Construction scenarios and well understood relationships between Construction activities and acoustic effects.</p> <p>First Nations identified vibration as highly important due to its potential to disrupt Historic Indigenous Village Site (R3) along with impacting Fraser River fishing sites and land-based experiences. This was also identified as a key concern by Health Canada, BCER, local governments,</p>                                                                                                                                                                                                                                                                                                                                             |

| Residual Effect                                                                                                                   | Assessment Rating*                                                                                                                                                                                                                                                            | Significance and Rationale                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Increase in noise levels during Operation                                                                                         | Context (resilience): Moderate<br>Magnitude: Negligible to Low<br>Extent: Local<br>Duration: Medium-Term<br>Frequency: Continuous<br>Reversibility: Fully reversible<br>Affected Populations: Disproportionate<br>Risk: Moderate<br>Uncertainty: Moderate<br>Importance: High | <p><b>Not significant</b></p> <p>The area has a history of industrial noise exposure. Since some receptors already exceed sleep disturbance and speech thresholds, there is limited capacity to absorb more noise. Overall, the environment has moderate acoustic resiliency, reflecting its industrial context but limited tolerance for further impact.</p> <p>During the expected future condition, magnitude is rated low due to minor exceedances (3 dBA or less) of Health Canada's speech intelligibility threshold (criteria) at the Historic Indigenous Village Site. Negligible magnitude rating is for the other receptors where exceedance of thresholds is not expected.</p> <p>Effects will be continuous throughout Operation which is a medium-term activity. The effects will be fully reversible, as they will cease following Decommissioning of the Project.</p> <p>The affected population rating is considered disproportionate due to the heightened sensitivity of Indigenous cultural users near the Historic Indigenous Village Site to sensory disturbances. Activities such as fishing, gathering, and ceremonial practices may be more acutely impacted by continuous noise, even when levels remain below established thresholds.</p> <p>The risk is rated moderate due to the high likelihood of continuous operational noise and moderate consequences from potential sensory impacts at culturally sensitive sites. Although some noise levels are within regulatory limits, constant exposure and cultural sensitivity elevate the risk.</p> <p>While potential adverse acoustic effects are well understood, predictive noise modelling was completed based on preliminary design, and therefore there is a moderate level of uncertainty.</p> <p>Concerns raised by First Nations highlighted the potential effects to the acoustic environment affecting cultural practices, sense of place, and knowledge transfer, therefore the importance was considered high. Sustained exceedances of BCER, Health Canada and WHO guidelines at key receptors such as residential areas and the Historic Indigenous Village Site support this rating.</p> |
| * Note: Criteria and assessment ratings are defined in <a href="#">Appendix 3 - Residual Effects Characterization Definitions</a> |                                                                                                                                                                                                                                                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

### 17.2.8 Cumulative Effects Assessment

Cumulative effects must be considered where a designated project may interact with other past, present, or reasonably foreseeable physical activities.

For acoustic effects, the Revised Application (Section 7.3.6) assessed the following cumulative pathways:

- Increase in noise levels during Construction;
- Increase in vibration levels during Construction; and
- Increase in noise levels during Operation.

As described in Section 1.1.3, the noise assessment considered known projects within the LAA, including; Phase 1A and 1B, TMJ, and the storage tank expansion facility.

Two additional projects were also considered; Delta Grinding Facility and VAJD.

Both are expansions of existing operations. Ambient sound measurements used in FortisBC's acoustic assessment implicitly included noise from these two facilities, as they were assumed to be operating during monitoring.

A detailed noise assessment for the VAFD project identified one shared receptor (R4). At this location, predicted noise from the Project is substantially lower than from VAFD, and is therefore not expected to meaningfully influence cumulative noise levels.

The Delta Grinding Facility did not include a noise assessment. While FortisBC did not provide a qualitative evaluation, the EAO conservatively assumed some potential overlap in noise effects, though the magnitude remains uncertain.

Cumulative acoustic effects from the six projects listed above, along with existing ambient conditions, are expected to span all Project phases.

Key considerations informing the EAO's conclusion on cumulative effects include:

- Potential overlap with future projects in the area;
- Existing background noise levels (46.6–57.1 dBA), already elevated due to industrial, marine, rail, and air traffic, and exceeding regulatory thresholds in some locations;
- Regulatory requirements under the LNG Facility Regulation further consider noise through engineering design and require that an LNG facility permit holder must ensure that the construction of and normal operations at the LNG facility do not cause excessive noise which reduces the likelihood of changes to cumulative effect conditions at shared receptors;
- Residual noise effects from Tilbury Phase 2 are expected to be of low to negligible magnitude;
- The logarithmic nature of sound, where multiple sources do not add linearly: two equally loud sources increase total noise by ~3 dB, and adding a quieter source contributes minimally; and
- Predicted noise increases from Tilbury Phase 2 are generally below 3 dBA.

Taking these factors into account, cumulative acoustic conditions within the LAA reflect an already elevated industrial sound environment influenced by multiple existing and reasonably foreseeable projects (see Section 17.2.3, Existing and Future Conditions by Proponent). While some overlap in noise emissions may occur, predicted increases attributable to Tilbury Phase 2 are generally below 3 dBA and are not expected to materially influence cumulative noise levels at shared receptors. Accordingly, Tilbury Phase 2's incremental contribution to cumulative acoustic conditions is expected to be negligible to low and is not anticipated to measurably alter the existing cumulative acoustic environment. As such, the Project is not expected to result in an adverse cumulative acoustic effect when considered in combination with past, present, and reasonably foreseeable future projects and activities.

### 17.2.9 Conclusion

The EAO is satisfied that Tilbury Phase 2 would not have significant adverse residual or cumulative effects on the acoustic VC. This conclusion considers the information and analysis presented in this section; the views of the TAC, First Nations, and FortisBC; the proposed mitigation measures identified in the provincial Table of Conditions including, Condition 1, 3, 10, 12, and 13; and federal Key Mitigation Measures and Follow-up Programs for the acoustic VC as it may pertain to Indigenous health under the IAA ([Appendix 2](#)).

## 17.3 Surface Water

### 17.3.1 Summary

Surface water was selected as a VC due to its important ecological functions for both aquatic and terrestrial species. Project activities are expected to interact with surface water quality and quantity, with the potential to affect vegetation, wildlife, and fish.

The surface water assessment considered potential effects of Tilbury Phase 2 on surface water quality and quantity. The key issues raised by reviewers included erosion and sedimentation, hydrostatic testing of the LNG storage tank, 6-PPDQ (a tire wear contaminant), and water quality impacts to the Tilbury Slough and the Fraser River.

In consideration of issues raised, the EAO has proposed Condition 12 (CEMP) and Condition 13 (OEMP) that will require the implementation measures to address erosion and sediment control and surface water quality and quantity during Construction and Operation. Condition 12 (CEMP) that will also include requirements for a LNG Storage Tank Hydrostatic Testing Plan during Construction, and Condition 17 (Dry Street Sweeping Report) to require a report on a potential mitigation measure to address effects associated with 6-PPDQ.

After considering the proposed mitigation, the EAO concluded there would be no significant residual effects on surface water. No cumulative effects were identified, given the lack of interaction with other projects and adherence to existing regulatory requirements. Overall, the EAO is satisfied that the Project will not result in significant adverse residual or cumulative effects on surface water.

### 17.3.2 Assessment Boundaries

The spatial boundaries for the surface water assessment included:

- The Project Footprint includes the area directly disturbed by Project activities;
- The Local Assessment Area (LAA) includes the section of water extending 100 meters upstream and 200 metres downstream of the Project Footprint. It also covers 100 metres upstream and 200 metres downstream within Tilbury Slough, starting from the Delta stormwater outlets that discharge runoff from the Project area and surrounding properties; and,
- The Regional Assessment Area (RAA) includes a broader portion of the lower Fraser River, extending 500 metres upstream and 1,000 metres downstream of the Project Footprint. It also encompasses Tilbury Slough for 500 metres upstream and 1,000 metres downstream of the Delta stormwater outlets that receive stormwater from the Project site and adjacent lands. The temporal boundaries for surface water include the Construction (3-6 years), Operation (40 plus years), and Decommissioning (2 years) phases of Tilbury Phase 2.

Project components and anticipated duration of activities are described in detail in [Section 1.2](#) (Project Description and Schedule) of this Report.

### 17.3.3 Existing Conditions by Proponent

The existing surface water conditions in the region were assessed in [Section 7.04](#) of the Revised Application by FortisBC and summarized here.

Surface water refers to water that collects on the ground surface, such as precipitation or runoff. Currently, surface water is routed to onsite drainage ditches, which flow into the stormwater network, municipally managed by Delta, and ultimately discharge into Tilbury Slough.

Contact water is defined as precipitation or surface runoff that comes into contact with process equipment or other surfaces with potential for contamination. The Proponent proposes to direct the contact water to concrete

containment sumps below project-related infrastructure for testing and/or treatment before being released to the stormwater system.

#### **17.3.3.1 Habitat, Landscape and Surface Water Quality**

The Project Footprint covers approximately 18 hectares, consisting of about 70% gravel and the remaining area being structures, and concrete. There are no natural water courses or intermittent streams on the property site.

The Fraser River is an adjacent body of water, which conveys approximately 17 million tonnes of sediment per year, consisting of silt, sand, and clay.

Existing sediment samples within the LAA showed metal concentrations mostly at or below the B.C. Sediment Quality guidelines or within ambient conditions. While exceedances for arsenic, chromium, copper, iron, manganese, and nickel were noted, these were considered representative of ambient conditions. Polychlorinated Biphenyls (PCBs), Volatile Organic Compounds (VOCs), and phenols in sediment were below detection limits or guidelines. Most Polycyclic Aromatic Hydrocarbons (PAH) concentrations were below guidelines, with approximately 90% of samples not exceeding applicable guidelines. Only a few samples (4 out of 32) exceeded applicable guidelines for individual PAHs, considered localized findings.

Water quality in the Fraser River is influenced by erosion of natural sources of metals, agricultural runoff, and remobilization of sediments during high flow periods. Water quality data in the LAA show exceedances of provincial and federal standards<sup>1</sup> for the protection of aquatic life, irrigation, or wildlife for several metals, including aluminum, beryllium, cadmium, cobalt, copper, iron, and zinc, as well as phosphorus.

#### **17.3.3.2 Tilbury Slough**

Tilbury Slough's water levels and quality are shaped by both natural and man-made hydrological controls linked to its connection with the Fraser River.

Upstream of MacDonald Road, water levels are primarily controlled by a flood box (tidal gate) and the Delta pump station, which discharges to the Fraser River during high-water conditions. This infrastructure limits connectivity with the Fraser River, resulting in stagnant conditions and a lack of response to river level changes. As a result, this upper section of the slough is shallow, low-velocity, and largely stagnant—fed mainly by stormwater runoff and local groundwater seepage.

Downstream of MacDonald Road, water levels fluctuate directly with Fraser River tides—a key distinction from the upstream section. The channel width ranges from about 10 metres at high tide to 1.5 metres at low tide. While the slough is generally freshwater, it becomes brackish near the MacDonald Road flood box due to tidal influence.

Water quality in Tilbury Slough is generally characterized by low dissolved oxygen and low pH (measure of acidity or alkalinity), a reflection of its backwater, low-flow nature.

Further upstream, near Huston Road, another flap gate restricts flow from the Fraser River. In the section between Hopcott Road and Huston Road, the slough is approximately 25 metres wide, with a maximum depth of 1.5 metres. Like the area upstream of MacDonald Road, this stretch is not directly influenced by Fraser River levels, contributing to persistently stagnant water conditions.

#### **17.3.4 Potential Project Effects by Proponent**

The Revised Application identified the following potential effects to surface water during the Construction, Operation and Decommissioning of Tilbury Phase 2.

The following effects to the Tilbury Slough were considered:

- Change in water quality from sediment-laden runoff during site clearing and grading in Construction;
- Change in water quality from sediment-laden runoff during Operation;

- Change in water quality from contaminated runoff (e.g., contact water) entering the Delta storm sewer during Operation;
- Erosion at stormwater outlets from increased surface runoff rates during Construction and Operation and from hydrostatic test water discharge;
- Change in water level due to hydrostatic test water discharge to the Delta storm sewer;
- Decrease in pH in Tilbury Slough from acid deposition related to air emissions; and
- Eutrophication in Tilbury Slough due to nitrogen deposition from air emissions.

The following effects to the Fraser River were considered:

- Decrease in pH in the Fraser River from acid deposition related to air emissions; and
- Eutrophication in the Fraser River due to nitrogen deposition from air emissions.

The following ecosystem effect was considered:

- Changes in water quality and quantity could harm fish, fish habitat, wildlife and wildlife habitat, affecting traditional practices like fishing and hunting.

### 17.3.5 Proposed Mitigation Measures by Proponent

The Proponent identified the mitigation measures, outlined in [Table 7.4-9](#) of the Revised Application, related to surface water which include:

- Develop erosion and sediment-control measures to manage surface water in consultation with Indigenous nations and a QP and incorporate them into the CEMP to reduce sediment deposition into watercourses or storm sewers;
- Collect contact water with the use of containments and impoundments. Contact water captured in sumps will be tested for contaminants prior to being released to the onsite drainage ditches that flow into the Delta storm sewer;
- Design site to promote drainage toward the Delta storm sewer system. Stormwater draining from paved parking areas will be captured and treated in oil-water separators to remove sediments and oil or grease before discharge into the Delta storm sewer;
- Conduct testing and treatment of hydrostatic test water prior to discharge to Delta's storm sewer, if required. Discharge procedure requirements of hydrostatic test water will be described in the CEMP; and
- Manage runoff rate to the Delta storm sewer through project engineering controls.

As part of the substituted process, the EAO has identified KMMs for effects within federal jurisdiction to inform IAAC's draft potential federal conditions. The KMMs related to the surface water VC as it relates to fish and fish habitat under the IAA are outlined in [Appendix 2](#).

### 17.3.6 Key Issues Raised

Based on a review of the Revised Application and with feedback from the TAC, participating Indigenous nations, and the public, the following key issues related to the assessment of the surface water VC for Tilbury Phase 2 were identified.

### 17.3.6.1 Sediment Controls for Fraser River & Tilbury Slough

BCER recommended the erosion and sediment control measure be implemented to reduce the potential of sediment entering into the Tilbury Slough and Fraser River during post-construction due to the site design that promotes drainage towards the Delta storm sewer system.

FortisBC responded that erosion and sediment control mitigation will be implemented as part of the Project's CEMP and OEMP, with permanent controls in place for the duration of the Project's lifespan. These controls are intended to reduce the potential for excess sediment to enter nearby watercourses.

The EAO will recommend that the Certificate will include Condition 12 (CEMP) and Condition 13 (OEMP) that will require the implementation of erosion and sediment control measures during Construction and Operation. The Holder would be required to consult with First Nations on the CEMP and OEMP prior to submitting it to the EAO for approval prior to Construction and Operation.

### 17.3.6.2 Hydrostatic Testing

ECCC and Tsawwassen First Nation requested additional information on the hydrostatic testing of the LNG Storage Tank, such as testing or treatment procedures, the potential impacts of the contaminants of potential concern in the effluent, and applicable provincial or local guidelines.

FortisBC confirmed the volume of the hydrostatic testing effluent (94,580 m<sup>3</sup>) and location of discharge approximately 200 metres upstream of the flood box, released over six days into the stormwater system. Discharges into the stormwater system must meet the requirements under the Delta Waterways Protection Bylaw No. 1615, which prohibit pollution being released into the stormwater system. FortisBC plans to conduct field testing of the potentially contaminated water and properly treat the contaminated water as required. FortisBC plans to monitor contaminants of potential concern in the Tilbury Slough.

The EAO will recommend that the Certificate include Condition 12 (CEMP) include an LNG Storage Tank Hydrostatic Testing Plan. The LNG Storage Tank Hydrostatic Testing Plan will outline where water will be sourced, filling procedures, testing, and how water used for hydrostatic testing will be discharged.

### 17.3.6.3 Water Quality – Tilbury Slough & Fraser River

Quw'utsun Nation requested clarity on sediment accumulation in Tilbury Slough and how it might affect water depth over time.

FortisBC responded to this, confirming that there is no expected change in the quality of the site's surface water that discharges to the City of Delta's stormwater system and there is no expected change to sediment quality or quantity being discharged to the stormwater system.

Quw'utsun Nation emphasized that with Construction, Operation, and Decommissioning spanning multiple years, the environmental assessment should include a discussion on how climate change could affect surface water runoff, groundwater recharge, and overall water quality over time.

FortisBC stated that the post site redevelopment peak runoff draining to the stormwater system is expected to be less than the current peak runoff rate and total volume of runoff may increase by 1 percent and this percentage is not expected to change as a result of potential climate change.

The EAO notes, while the potential increases in precipitation and storm intensity can result in changes to infiltration, the percentage of precipitation that infiltrates are expected to remain similar to post-Project infiltration rates under current climate conditions. Importantly, the EAO also noted that the Condition 12 (CEMP) and Condition 13 (OEMP) will require measures to control and treat stormwater and contact water, including containment systems, oil-water separators, erosion and sediment controls, and spill prevention and response measures for hydrocarbons and other contaminants.

These plans will also require testing and monitoring of discharges to verify compliance with applicable municipal bylaws and provincial or federal water quality guidelines. These will help address potential future impacts from climate change or unforeseen circumstances, ensuring that water quality and hydrological performance can be monitored and managed over time.

#### 17.3.6.4 Water Quantity

Tsawwassen First Nation, along with ECCC, the BCER, and other reviewers, raised concerns regarding potential changes to surface water quantity associated with hydrostatic testing discharges and changes in runoff and infiltration resulting from Project site modifications. Specifically, reviewers questioned whether the volume and discharge rate of hydrostatic test water, increased impervious surfaces, and altered infiltration patterns could result in temporary changes to water levels or flow conditions in Tilbury Slough.

FortisBC stated that hydrostatic testing would involve a one-time, controlled discharge to the City of Delta's stormwater system during dry conditions, and that the Delta pump station and flood box at MacDonald Road would operate to manage flows and maintain stable water levels in the slough. FortisBC also indicated that while total runoff volume may increase slightly following site redevelopment, post-development peak runoff rates are expected to be less than existing conditions and changes to infiltration are not expected to result in measurable effects on surface water quantity.

The EAO considered these responses and determined that potential effects on surface water quantity would be negligible. The EAO will recommend that the Certificate include requirements under Condition 12 (CEMP) and Condition 13 (OEMP) to manage runoff and hydrostatic test water discharges, monitor and document stormwater and effluent discharges, and apply adaptive management if monitoring demonstrates that Project effects differ from those predicted.

#### 17.3.6.5 6PPD-Quinone

Comments were received from various First Nations and technical advisors regarding 6-PPDQ (a chemical found in tire wear that has the potential to effect fish), and how potential effects of 6-PPDQ could be managed in relation to the Project. This topic is discussed in further detail in [Appendix 6, Section 17.08](#) (Fish and Fish Habitat) of this Report as part of the fish and fish habitat VC.

### 17.3.7 The EAO's Characterization of Residual Effects

After considering the proposed mitigation measures and conditions proposed, the information contained in the [Joint Permitting/Regulatory Coordination Plan](#) and the [Regulatory Coordination Issues Tracking Table](#), the EAO concludes that the Project could cause the following potential residual effects to surface water VC:

- Change in water quality in Tilbury Slough; and
- Changes to water-based cultural landscapes and visual/cultural integrity of Tilbury Slough.

The EAO's characterization of the potential residual effects of the Project on the surface water VC is summarized below in Table 53 as well as the EAO's level of confidence in the effects determination (including likelihood and significance).

Table 53: Summary of Residual Effects for Surface Water

| Residual Effect                                                                                                                   | Assessment Rating*                                                                                                                                                                                                                                             | Significance and Rationale                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Changes in Water Quality in Tilbury Slough                                                                                        | Context (resilience): High<br>Magnitude: Negligible<br>Extent: Local<br>Duration: Medium-Term<br>Frequency: Regular<br>Reversibility: Partially reversible<br>Affected Populations: Disproportionate<br>Risk: Low<br>Uncertainty: Moderate<br>Importance: High | <b>Overall Significance: Not Significant</b><br><br>Project activities will discharge negligible magnitude treated stormwater, contact water, and hydrostatic test water into the Delta storm sewer, which drains directly into Tilbury Slough. The Tilbury Slough is an already degraded, stagnant waterbody characterized by low dissolved oxygen, low pH, and guideline exceedances for metals, PAHs, chloride, and nutrients.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Change in Tilbury Slough water quantity                                                                                           | Context (resilience): high<br>Magnitude: Negligible<br>Extent: Local<br>Duration: Medium-Term<br>Frequency: Regular<br>Reversibility: Partially reversible<br>Affected Populations: Disproportionate<br>Risk: Low<br>Uncertainty: Moderate<br>Importance: High | <b>Overall Significance: Not significant</b><br><br>The Project is expected to have a negligible effect on the quantity of water entering Tilbury Slough. Even though the site will have slightly more paved or hard surfaces, the increase in runoff is extremely small, about 0.2% of change compared to all the water already flowing into the Tilbury Slough from surrounding industrial areas. Stormwater, contact water, and hydrostatic test water will all be treated and tested so they meet regulatory standards before entering the Delta storm sewer. When hydrostatic test water is released, the existing pump station and flood box at MacDonald Road will automatically adjust flows to keep water levels stable. Because of these controls and the very small change in runoff, no measurable change in water quantity in Tilbury Slough is expected |
| * Note: Criteria and assessment ratings are defined in <a href="#">Appendix 3 - Residual Effects Characterization Definitions</a> |                                                                                                                                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

### 17.3.8 Cumulative Effects Assessment

The assessment of a designated project must consider cumulative effects that may result from Tilbury Phase 2 in combination with past, present, and reasonably foreseeable projects and activities. For the surface water VC, the following residual pathways were carried forward: changes in water quality and quantity in the Tilbury Slough. Reasonably foreseeable projects in the assessment areas include the Tilbury Marine Jetty (TMJ), the Fraser River Tunnel Project (FRT), and the Delta Grinding Facility (DGF).

Tilbury Phase 2's interactions with surface water are limited to treated stormwater, contact water, and a one-time hydrostatic test discharge of approximately 95,000 m<sup>3</sup>, all of which must meet municipal and provincial water quality requirements before entering the Delta storm sewer. These discharges flow into Tilbury Slough, a waterbody already marked by low dissolved oxygen, low pH, limited flushing, and frequent exceedances of aquatic life guidelines for metals, phosphorus, PAHs, VOCs, and chloride.

Considering the negligible magnitude of these residual effects, the existing degraded cumulative baseline of Tilbury Slough, and the mitigation controls applied across projects in the area, the EAO concludes that Tilbury Phase 2 is not predicted to cause adverse cumulative effects on surface water quality or on quantity.

### 17.3.9 Conclusion

The EAO is satisfied that Tilbury Phase 2 would not have significant adverse residual or cumulative effects on the surface water VC. This conclusion considers the information and analysis presented in this section; the views of the TAC, First Nations, and FortisBC; the proposed mitigation measures identified in the provincial Table of Conditions including the Conditions 12, 13 and 18.

## 17.4 Groundwater

### 17.4.1 Summary

A clean and abundant groundwater system supports ecosystems, including vegetation and wildlife habitat.

To assess groundwater conditions and potential effects of the Tilbury Phase 2 LNG Expansion Project (Tilbury Phase 2 or Project), FortisBC (Proponent) used desktop reviews, field studies, and expert input. Existing groundwater conditions within the Project area include Aquifer 42, a moderately productive aquifer. The area acts as a groundwater recharge zone, discharging into Tilbury Slough and the Fraser River.

Potential project effects on groundwater include contamination risks from surface infiltration and dewatering activities, and changes in groundwater recharge from a change in land cover type.

To mitigate these risks, FortisBC proposed measures such as capturing, testing, and offsite disposal (as applicable) for contact water and treating stormwater from parking lots using an oil water separator, implementing best management practices through a CEMP. The development and implementation of a CEMP is proposed by the EAO to be Condition 12 of the Certificate.

Key issues raised by reviewers included requests for clarification on groundwater flow, water quality monitoring, and contamination risks. FortisBC provided further data and clarifications.

After considering proposed mitigations, the EAO concluded there would be no significant residual effects on groundwater. No cumulative effects were identified, given the lack of interaction with other projects and adherence to existing regulatory requirements. Overall, the EAO is satisfied that the Project will not result in significant adverse residual or cumulative effects on groundwater.

### 17.4.2 Assessment Boundaries

The spatial boundaries for the groundwater assessment included:

- The Project Footprint, defined as the area directly disturbed by project activities;
- The Local Assessment Area (LAA) defined as the terrestrial footprint of the Project; and
- The Regional Assessment Area (RAA) defined as the mapped extent of the aquifer that is within the proposed Project footprint.

The temporal boundaries for groundwater include the Construction (3-6 years), Operation (40 years), and Decommissioning (2 years) phases of Tilbury Phase 2.

Project components and anticipated duration of activities are described in detail in [Section 1.2](#) (Project Description and Schedule) of this Report.

### 17.4.3 Existing Conditions by Proponent

Existing groundwater conditions, assessed in [Section 7.05](#) of the Revised Application, consider soil composition, Aquifer 42, and historical land use. The subsurface features a shallow sand and gravel layer with minor silt, clay, and organic material over native alluvial sediments, underlain by a silt and clay layer that coarsens with depth into silty sand and sand. These layers occur throughout the LAA, except in the northeast.

Aquifer 42 is located within the RAA and the Project Footprint. It spans ~143 square km (km<sup>2</sup>), has moderate productivity due to light demand, high vulnerability to surface contamination, and low well density (fewer than four wells/km<sup>2</sup>). It may support local drinking water supplies.

The western LAA was previously occupied by a sawmill (1974–2008). Following remediation, the area met the B.C. Contaminated Sites Regulation (CSR) standards of the time. However, due to updates to the CSR and changing standards, the contaminated soil will be excavated and disposed of offsite prior to Construction of the Project.

The Project area is considered a groundwater recharge area, and both the slough and the Fraser River receive groundwater discharge. See Figure 1 below.

Figure 10: Conceptual Site Hydrogeological Model

#### 17.4.4 Potential Project Effects by Proponent

To assess groundwater conditions and potential effects, FortisBC used desktop reviews, field studies, and expert input. Two key site investigations looked at historical land use, potential contamination, geology, and water flow. The second investigation included drilling, sampling, and installing 11 monitoring wells. Data from nearby projects and the B.C. aquifer database supported the assessment. Groundwater levels were tracked over a year, and seasonal water quality sampling in 2022 and 2023 confirmed the presence of expected contaminants. All findings followed provincial environmental guidelines.

Potential project impacts on groundwater include:

- Changes to quality from contaminated surface water infiltrating into the ground during construction or operation, and from mobilization of existing contamination due to dewatering; and
- Changes to quantity could also be affected by change to land cover type, altering infiltration, and by temporary groundwater pumping during excavation, which may lower water levels nearby.

#### 17.4.5 Proposed Mitigation Measures by Proponent

The Proponent identified the following relevant mitigation measures to reduce potential effects on groundwater:

- Collect contact water with the use of containments and impoundments. Contact water captured in sumps will be measured for field parameters prior to being released to the onsite drainage ditches that flow into Delta storm sewer;
- Design site to promote drainage toward the Delta storm sewer system. Stormwater draining from paved parking areas will be captured and treated in oil-water separators to remove sediments and oil or grease before discharge into the Delta storm sewer;
- Conduct testing and treatment of hydrostatic test water prior to discharge to Delta's storm sewer, if required. Discharge procedure requirements of hydrostatic test water will be described in the CEMP; and
- Incorporate best management practices into the CEMP to manage groundwater.

As part of the substituted process, the EAO has identified KMMs for effects within federal jurisdiction to inform IAAC's draft potential federal conditions. The KMMs related to groundwater VC are outlined in [Appendix 2](#).

#### 17.4.6 Key Issues Raised

Based on the Revised Application and input from the TAC, First Nations, and the public, no key issues were identified regarding the assessment of the groundwater VC for Tilbury Phase 2.

#### 17.4.7 The EAO's Characterization of Residual Effects

After considering the proposed mitigation measures and conditions proposed, the information contained in the [Joint Permitting/Regulatory Coordination Plan](#) and the [Regulatory Coordination Issues Tracking Table](#), the EAO concludes that the Project would not result in residual effects on groundwater for the following reasons:

- The extent of the interactions between the Project and groundwater; and,
- The mitigation measures identified for implementation in the Revised Application.

#### 17.4.8 Cumulative Effects Assessment

The Revised Application and the EAO's assessment determined that the Project would not result in residual adverse effects to groundwater. As no residual effects were identified for the groundwater VC, a cumulative effects assessment was not warranted.

#### 17.4.9 Conclusion

The EAO is satisfied that Tilbury Phase 2 would not have significant adverse residual or significant cumulative effects on the groundwater VC. This conclusion considers the information and analysis presented in this section; the views of the TAC, First Nations, and FortisBC; the proposed mitigation measures identified in the provincial Table of Conditions, including Conditions 12 (CEMP), 13 (OEMP), and 17 (Dry Street Sweeping Report).

## 17.5 Soil

### 17.5.1 Summary

Healthy soils support healthy ecosystems including vegetation and wildlife. Terrain, including slopes and contouring, further influence an area's drainage, stability, vegetation, and use. The soil VC includes the subcomponents of terrain, soil quality, and soil quantity. The key indicators for assessment include terrain instability, changes to soil quality, and reduction in soil quantity.

FortisBC (Proponent) conducted desktop and field studies to characterize the existing site conditions. Located in the Fraser River delta, the Project Footprint is generally flat, and soils have been heavily disturbed by industrial uses. The entire Project Footprint is either covered with gravel (70%) or is otherwise occupied by structures, asphalt and concrete (30%) – little to no topsoil remains on-site.

FortisBC identified one area of existing arsenic-contaminated soil, and otherwise soil contaminants were not found on-site. The arsenic-contaminated area will be excavated and disposed of prior to Construction. The primarily river sediment-based soils (e.g. silt and sand) are not conducive to metal leaching and acid rock drainage. The risk of soil loss due to water or wind erosion is considered low.

Key issues raised by reviewers relate to on-site soil management to prevent drainage, erosion, and contamination impacts, including for stockpiles and imported soils. To address key issues, the EAO has proposed in Condition 12 the requirement that the Holder develop and implement a CEMP including measures to address erosion and sediment control measures, and soil management.

The EAO is satisfied that there are no residual or cumulative effects associated with the soil VC. Proposed mitigation measures and regulatory requirements adequately address/resolve key issues raised.

### 17.5.2 Assessment Boundaries

The spatial boundaries for the soil assessment included the Project Footprint, defined as the area directly disturbed by project activities, and a LAA and RAA defined below: Project Footprint

- Project footprint: the area directly disturbed by project activities;
- Local Assessment Area (LAA): the Project footprint, plus a 100 metres buffer around the Project footprint, with an additional 50- metres buffer around truck routes between Highway 17 and the Project footprint; and,
- Regional Assessment Area (RAA): the area of the LAA.

The temporal boundaries for Soil include the Construction (3-6 years), Operation (40+ years), and Decommissioning (2 years) phases of Tilbury Phase 2.

Project components and anticipated duration of activities are described in detail in [Section 1.2](#) (Project Description and Schedule) of this Report.

### 17.5.3 Existing Conditions by Proponent

The Proponent assessed baseline soil conditions in [Section 7.6](#) of the Revised Application, summarized here.

#### Context & Overview

The area's soil has been heavily disturbed by past agricultural and industrial use and is highly developed. Some undisturbed areas near the riparian zone and Tilbury Slough remain but lie outside the Project Footprint. Various activities, such as gas and utility developments, transportation, infrastructure, housing, natural resource development, farming, and recreational use, have contributed to past and ongoing changes in the soil and terrain.

These activities typically impact the land through grading, excavation, soil compaction, engineered slopes, and changes in land contours for drainage.

The 13-hectare Project Footprint, a rectangular area along the Fraser River, includes the Tilbury LNG facility to the east and a mostly vacant former sawmill to the west. Approximately 70 percent of the site is gravel-covered, with the remainder consisting of buildings, asphalt, and concrete.

Due to past disturbances, little natural topsoil remains. The northern riparian area, previously disturbed by a dock installation and removal, has little native soil left and is not within the Project Footprint.

#### Terrain

The Project Footprint in the Fraser Valley lowlands, is mostly flat at two to three metres above sea level. Terrain stability depends on rock and soil type, land shape, drainage, vegetation, and soil distribution. Sloped areas are more prone to erosion, but even flat ground can be affected by underlying bedrock. The site sits on the Kitsilano Formation, composed of sedimentary rock, sandstone, shale, lesser basalt flows, sills, and minor pyroclastics. The topsoil consists of Fraser River sediments, with silt clay loam over deep sand and silt layers. Borehole logs confirmed these layers and noted some organic material.

Earthquakes pose a risk, particularly soil liquefaction, where saturated soil loses strength. The site has a moderate to high liquefaction risk, especially in Fraser Delta sediments, but strong ground movement from subduction zone earthquakes may be a greater concern.

#### Soil Quality

Acid rock drainage (ARD) occurs when sulphur-bearing rocks react with air and water, producing acidic runoff that can release metals. While metal leaching can occur independently, the two often coincide. At the Project Footprint, bedrock is 200 metres deep, with no evidence of ARD or metal leaching. Soil pH (measure of acidity or alkalinity) tests showed neutral to alkaline conditions, and groundwater had low sulphur levels, indicating ARD is unlikely from excavation.

Arsenic was the only contaminant found above B.C. standards, located in the western LAA at a former sawmill site (1974–2008). This soil will be excavated and safely disposed of before Construction in accordance with Contaminated Sites Regulation (CSR) standards, including confirmatory sampling.

Most native soil has been disturbed or covered by gravel and pavement, limiting plant growth.

#### Soil Quantity

Wind erosion risk in the Project Footprint is unrated, but available mapping suggests a low overall risk of soil loss due to the combined effects from wind, water and tillage.

Water erosion risk depends on factors like soil texture, moisture, organic content, ground cover, slope, and rainfall. Moderate water erosion risk is usually linked to fine-textured soil on slopes steeper than 5% and given the Project Footprint is mostly flat, the risk of water erosion on site is considered low.

### 17.5.4 Potential Project Effects by Proponent

In the Revised Application, the Proponent identified the following potential effects during the Construction, Operation, and Decommissioning of Tilbury Phase 2:

#### Changes to Terrain

The terrain at the Project Footprint could be affected by activities like grading, excavation, backfilling, leveling and recontouring during Construction and Decommissioning. Changes could also result from vehicle and equipment traffic throughout the Project and from ground settling (subsidence) over time.

Terrain stability could be impacted by planning and engineering decisions, vegetation clearing and ground disturbance (such as clearing, grubbing, grading, excavation, backfilling, and cleanup) during construction and decommissioning, equipment and vehicle movement, Construction and Decommissioning (such as drilling and piling), ground stability issues during all Project phases, and natural hazards.

The Tilbury facility site has already been disturbed, so there is no undisturbed natural terrain left within the existing facility. Any terrain changes from the Project will be limited to the facility site and will not affect the surrounding landscape.

#### Changes to Soil Quality

Various Project activities could impact soil quality at the site. Erosion may reduce soil capability by admixing and loss of mineral soils, seed banks, and organic matter. Wind erosion occurs more likely in sandy soils, while water erosion affects clay-heavy soils with poor absorption. Vehicles could carry soil away from the site, potentially affecting nearby agricultural lands, although, the site's sandy fill makes this unlikely, and extra dust from the Project could blend with existing traffic dust.

Soil contamination could result from digging in contaminated areas or hazardous material spills, reducing soil quality. Finally, subsidence, or ground settling, may occur after grading, especially following heavy rainfall during Construction, Operation, and Decommissioning.

#### Reduction in Soil Quantity

Soil quantity may be impacted by wind and water erosion, resulting in reduced soil capability. However, given that there is no existing topsoil and that the site is dominantly paved or gravelled, additional disturbance is unlikely to reduce soil quantity and effects are considered negligible.

### 17.5.5 Proposed Mitigation Measures by Proponent

The Proponent identified the following relevant mitigation measures to reduce potential effects on soil:

- Establish a refuelling and spill response plan. The measures will be incorporated into the CEMP;
- Develop erosion and sediment control measures to manage surface water in consultation with Indigenous nations and a QP and incorporate them into the CEMP to reduce sediment deposition into watercourses or storm sewers; and
- Avoid or manage known areas of contaminated soil by implementing contingency measures outlined in the CEMP in the event that contaminated sediments are discovered during Construction.

### 17.5.6 Key Issues Raised

Based on a review of the Revised Application and with feedback from the TAC, participating Indigenous nations, the CAC, and the public, the following key issues related to the assessment of the Soil VC for Tilbury Phase 2 were identified.

#### 17.5.6.1 On-site soil management

The BCER, Richmond, xʷməθkʷəyám, and the IAAC provided comments related to on-site soil management practices to mitigate negative impacts associated with drainage, erosion, and contamination – including for stockpiles and soils brought to the site. The existing area of arsenic contaminated soil will be excavated and disposed of offsite prior to Construction, and no other areas of existing contamination were identified. TAC members identified the need to manage potential contaminants through methods such as monitoring and testing, covering stockpiles, and contingency measures.

If issued, the Certificate will include Condition 12 for a CEMP that must be approved prior to Construction. The CEMP will include measures to address soil management, including soil transportation, erosion and sediment control measures, and soil handling, spill prevention and response related to hydrocarbon storage and leaks or other accidental emissions from machinery or equipment.

Additionally, the Proponent must also comply with all requirements prescribed by the CSR and any permits associated with soil management. To verify that remediation has met the prescribed numerical or risk-based standards for soil and groundwater quality, the Proponent may obtain a Certificate of Compliance (COC) under the EMA, verifying that remediation has met the standards prescribed in the *Contaminated Sites Regulation*.

#### 17.5.6.2 End land use soil condition

In the Revised Application, the Proponent stated that the end land use, which is currently designated as industrial, does not warrant soil quantity or quality that supports vegetation. xʷməθkʷəyám and Quw'utsun Nation noted the cultural importance of the area, and that re-vegetation will be important for restoring traditional use.

The EAO notes that the Project requires an LNG Facility Permit; or an amendment to the current LNG Facility Permit held for the existing facility. The [Section 21](#) of the LNG Facility Regulation has requirements for site restoration after the closure of a facility, including requirements related to soil.

#### 17.5.7 The EAO's Characterization of Residual Effects

After considering the proposed mitigation measures and conditions proposed, the information contained in the [Joint Permitting/Regulatory Coordination Plan](#) and the [Regulatory Coordination Issues Tracking Table](#), the EAO concludes that the Project would not result in residual effects on the soils VC for the following reasons:

- The Project does not pose significant changes to the terrain from current conditions;
- Soil samples detected an area of existing arsenic-contaminated soil. This contaminated soil will be removed and disposed of prior to Construction in a manner consistent with the Contaminated Sites Regulation. No other contaminated soils were found on-site;
- The Project is subject to requirements under the ERAA and its regulations associated with site and soil conditions after the closure of an LNG facility; specifically, the deactivation, decommissioning, and land reclamation phases are overseen by the BCER through its established permitting and closure processes, including the final issuance of a Certificate of Restoration; and
- If issued, the Certificate will require the Proponent to develop and implement a CEMP including soil handling and management associated with contamination, erosion, and drainage.

#### 17.5.8 Cumulative Effects Assessment

The Revised Application and the EAO's assessment determined that the Project would not result in residual adverse effects to terrain, soil quality, or soil quantity. As no residual effects were identified for the Soil VC, a cumulative effects assessment was not warranted.

#### 17.5.9 Conclusion

The EAO is satisfied that Tilbury Phase 2 would not have significant adverse residual or significant cumulative effects on the Soil VC. The extent of significance for federal effects are found in [Appendix 15](#). This conclusion considers the information and analysis presented in this section; the views of the TAC, First Nations, and FortisBC; and the proposed conditions identified in the provincial Table of Conditions including the Condition 12 (CEMP).

## 17.6 Vegetation

### 17.6.1 Summary

Vegetation was selected as a VC to support analyses of potential Tilbury Phase 2 LNG Expansion Project (Tilbury Phase 2 or Project) interactions with plant species and ecosystems and other VCs. The vegetation subcomponents assessed are plant species of interest, ecological communities of interest including wetlands, and riparian ecosystems.

Tilbury Phase 2 is located within a largely industrial and previously disturbed area; therefore, vegetation is already heavily impacted. Riparian zones along the Fraser River and Tilbury Slough have been degraded by infrastructure and industrial activities.

Key concerns raised by reviewers included the spread and management of invasive species and the potential impacts to culturally significant species.

Residual effects, including the introduction or spread of invasive plant species, may occur during all phases of the Project. While mitigation measures will be implemented to minimize these residual effects, invasive plant species could still spread within and around the Project footprint or be introduced to the Project site from external sources. This will be managed through regulatory requirements and Condition 12, the CEMP.

The residual effect of the introduction or spread of invasive species is expected to be not significant. The EAO concludes that the Project is expected to result in not significant cumulative effects to vegetation from interactions with other past, present, or reasonably foreseeable projects and activities.

### 17.6.2 Assessment Boundaries

The spatial boundaries used in the assessment of vegetation included:

- The Project Footprint – defined as the area directly disturbed by project activities;
- The Local Assessment Area (LAA) - defined as the Project site plus a 100 meters buffer around the site, which includes both aquatic habitat in the Fraser River, and terrestrial habitat on Tilbury Island. The LAA also includes 100 metres upstream and 200 metres downstream within the Tilbury Slough from the culvert outlet that drains stormwater from the Project site, located at the south end of the Project site; and
- The Regional Assessment Area (RAA) - defined as the LAA and a 1,000 metres buffer around the site, including aquatic and terrestrial habitats.

The temporal boundaries use in the assessment of vegetation include Construction (approximately 3-6 years); Operation (40+ years); and Decommissioning (approximately 2 years) phases.

Project components and anticipated duration of activities are described in detail in [Section 1.2](#) (Project Description and Schedule) of this Report.

### 17.6.3 Existing Conditions by Proponent

The existing conditions for vegetation were assessed by the Proponent in [Section 7.7.3](#) and [Appendix D \(Terrestrial Biophysical Technical Data Report\)](#) of the Revised Application and are summarized here.

The Project site is located within the Coastal Douglas-fir (CDF) biogeoclimatic zone and the Pacific Temperate Wetland Region. The Project site is located on Tilbury Island, in the Fraser River. Tilbury Island is largely an industrial area, and the Project is an expansion of an existing operational LNG facility and surrounded by other industrial activity. Tilbury Island and the Project site have been heavily disturbed by past and present industrial activities and are largely cleared of natural forest and vegetation.

### Plant species of interest

The Revised Application identified existing conditions for plant species of interest within the Project Footprint, Local and RAAs.

No species of interest were identified within the Project Footprint, which is comprised primarily of paved and gravel areas.

Species noted within LAAs and RAAs include a mix of invasive species and provincially listed species.

Invasive species include Himalayan blackberry (*Rubus armeniacus*), Japanese knotweed (*Reynoutria japonica*), and Scotch broom (*Cytisus scoparius*).

Provincial listed species at risk that had previously been documented include blue-listed: Henderson's checker-mallow (*Sidalcea hendersonii*) and Vancouver Island beggarticks (*Bidens amplissima*), but no recent observations were made during field surveys for this Project.

Critical habitat for federally listed plant species at risk was not reported within the LAAs and RAAs.

### Ecological communities of interest including wetland ecosystems

Wetlands provide habitat, hydrological, and water quality functions. Wetland ecosystems in the area include marshes, estuarine marshes, and swamps. Wetlands and riparian habitats are limited due to urbanization, industrial development, and agriculture in the area.

Wetlands make up about 4 percent of the LAA with 17 distinct wetlands located in the RAA. Five occur within the LAA, four of which are ecological communities of conservation concern.

The Tilbury Slough is a wetland area within the LAA. It includes open water and cattail marshes that are considered sensitive (Blue Listed) in B.C. Cattail is culturally important to First Nations who use it for weaving and medicine. The wetland has been reduced over time due to nearby industrial development and roads, which have also damaged the natural buffer (riparian area) and may affect how well the wetland filters water and stores runoff.

Despite these impacts, the wetland still supports habitat, water flow, and nutrient cycling functions. Open water with dense vegetation and diverse plant types likely helps with water purification. The wetland and riparian areas support wildlife, including birds, mammals, amphibians, and reptiles.

Some wetland ecosystems and ecological communities are present along the Fraser River shoreline. However, because FortisBC (the Proponent) removed barge deliveries and the proposed MOF from the Project, this area was excluded from the EAO's assessment in this section. See Section 7.7.3 of the Revised Application for more information.

### Riparian ecosystems

Riparian ecosystems support a wide range of species and are key areas for biodiversity. The Revised Application notes that riparian areas within the Project Footprint are fragmented and degraded due to past and ongoing industrial activity. These zones are mainly found along the Fraser River and Tilbury Slough within the LAA and overlap with wetlands discussed above.

Much of the riparian habitat has been altered by infrastructure, dikes, and urban development, with natural vegetation replaced by human-made surfaces. Riparian ecosystems make up approximately seven percent of the vegetation LAA and 6.5 percent of the RAA.

Riparian vegetation near the Project is sparse, consisting mostly of young forest and wetland-associated plants. Many areas are dominated by invasive species such as Himalayan blackberry and Japanese knotweed. Some riparian zones still support culturally important plants like red alder, salmonberry, and skunk cabbage, which are used by Indigenous communities for traditional practices.

#### 17.6.4 Potential Project Effects by Proponent

The activities associated with the Construction, Operation, and Decommissioning phases of Tilbury Phase 2 have the potential to interact directly and indirectly with the subcomponents of the vegetation VC, including plant species, ecological communities of interest, wetlands, and riparian ecosystems.

Table 58 below summarizes the five potential effects and effects pathways by project phase identified in the Revised Application. For a detailed breakdown of these anticipated effects, see [Section 7.7.4](#) of the Revised Application. Out of the potential effects identified after the application of mitigation measures, an adverse residual effect is predicted for introduction or spread of invasive plant species.

Table 54: Potential Effects, Indicators and Effect Pathways for Vegetation identified by the Proponent Revised Application

| Potential Effect                                     | Effect Indicator                                          | Project Phase                 | Potential Effects and Effect Pathways                                                                                                                     |
|------------------------------------------------------|-----------------------------------------------------------|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| Loss of plant species of conservation concern        | Number or known locations of affected plant species       | Construction, Decommissioning | Vegetation clearing and ground disturbance may damage or remove species of conservation concern.                                                          |
| Introduction or spread of invasive plant species     | Presence and distribution of invasive plant species       | All phases                    | Vegetation clearing, ground disturbance, and movement of materials can introduce or spread invasive species, including Noxious weeds.                     |
| Loss of culturally important traditional use species | Number or known locations of culturally important species | Construction, Operation       | Vegetation clearing and ground disturbance may reduce the number or locations of culturally significant plants.                                           |
| Alteration or loss of wetland ecological communities | Area (hectare) of affected wetland ecological communities | Construction, Operation       | Infrastructure placement and Construction activities can cause habitat loss or alteration in wetlands, impacting hydrologic and biogeochemical functions. |
| Alteration or loss of riparian ecosystems            | Area (hectare) of affected riparian ecosystems            | Construction, Operation       | Clearing, ground disturbance, and infrastructure placement may result in the alteration or permanent loss of riparian ecosystems.                         |

#### 17.6.5 Proposed Mitigation Measures by Proponent

Mitigation measures identified by the Proponent in their Revised Application were based on current regulations, professional judgment, engagement with First Nations and regulatory agencies, as well as lessons learned during Operation of the existing Tilbury LNG facility.

The mitigation measures identified by the Proponent in the Revised Application are:

- The development and implementation of soil-management and soil-handling practices that are effective at managing the introduction and spread of invasive noxious plant species, as required under provincial regulations and municipal bylaws. These measures will be incorporated into the CEMP, that will be developed by qualified professionals through engagement with regulators and Indigenous nations.

The mitigation measures are expected to avoid or reduce the potential effects of Construction and Operation activities on the vegetation VC.

### 17.6.6 Key Issues Raised

Based on a review of the Revised Application and with feedback from the TAC, participating Indigenous nations, and the public, the following key issues related to the assessment of the vegetation VC for Tilbury Phase 2 were identified: the spread and management of invasive species, and impacts to culturally important vegetation species.

#### 17.6.6.1 Invasive species

Quw'utsun Nation and xʷməθkʷəyám indicated concern about invasive species causing adverse impacts or displacement to cultural vegetation in the area. FortisBC stated that mitigation measures that manage the introduction and spread of invasive noxious plant species will be incorporated into the CEMP. BCER noted that FortisBC will be required to maintain invasive plant compliance record as part of the LNG Facility Regulation requirements and manage the site in accordance with [Section 15](#) of the ERAA. There are also requirements under the [Weed Control Act](#) and [Integrated Pest Management Act](#) regarding the safe use of pesticides.

FortisBC confirmed that the maintenance of existing landscaping and vegetation will be managed by the existing facility and not part of the scope of Tilbury Phase 2, yet it will be carried out for the duration of the Project in accordance with relevant noxious weed and invasive species regulations/guidelines. This maintenance would ensure that noxious weeds and invasive species are treated properly to maintain wetland health and growth of vegetation important to Indigenous nations.

Invasive species prevention and management are explicitly required under Mitigation Measure M-60 in Appendix A of the Revised Application. This measure requires the development and implementation of soil management and soil-handling practices to prevent the introduction and spread of invasive noxious plant species during both Construction and Operation, in accordance with provincial and municipal requirements. Implementation of this measure will be carried out through the CEMP and the OEMP, should a Certificate be issued. The Holder would be required to consult with First Nations on the CEMP prior to submitting it to the EAO for approval prior to Construction.

#### 17.6.6.2 Culturally important species

First Nations indicated concern regarding impact to or loss of culturally important species due to removal of vegetation both historically and for the Project, as well as the displacement of culturally important species by invasive species.

Quw'utsun Nation raised the issue of the loss of culturally important species due to historic land use change and development on Tilbury Island. Quw'utsun Nation also suggested the loss of culturally important plant species be compensated for. Ts'uubaa-asatx indicated that ongoing and cumulative effects on vegetation in an already disturbed environment would result in impacts to Ts'uubaa-asatx's rights, including to the health and availability of instream and riparian vegetation, and plant harvesting, and thus to Ts'uubaa-asatx's harvesting-based livelihoods.

FortisBC indicated that no vegetation clearing will occur for the development of Tilbury Phase 2, and the Project will not adversely affect or result in a loss of vegetation, including culturally important plants. The removal of the MOF from the Project will eliminate any potential effects to instream or riparian vegetation along the Fraser River. In FortisBC's view, there are no anticipated interactions with vegetation due to the Project.

EAO notes that Project Footprint must be restored following the cessation of Project Operation, in accordance with [Section 21](#) of the LNG Facility Regulation.

### 17.6.7 The EAO's Characterization of Residual Effects

After considering the proposed mitigation measures and conditions, the information contained in the [Joint Permitting/Regulatory Coordination Plan](#) and the [Regulatory Coordination Issues Tracking Table](#), the EAO concludes that the Project would result in the following residual adverse effects on vegetation:

- Introduction or spread of invasive plant species that may occur during all phases of the Project.

The EAO's characterization of the expected residual effects of the Project on vegetation is summarized below in Table 55, as well as the EAO's level of confidence in the effects determination (including their likelihood and significance).

Table 55: Summary of Residual Effects for Vegetation

| Residual Effect                                                                                                                   | Assessment Rating*                                                                                                                                                                                                                                                                                         | Significance and Rationale                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Introduction or spread of invasive plant species                                                                                  | Context (resilience): Low<br>Magnitude: Negligible to low<br>Extent: Limited or Local<br>Duration: Medium-term<br>Frequency: Infrequent<br>Reversibility: Reversible<br>Affected Populations: Disproportionate<br>Risk (likelihood and consequences): Moderate<br>Uncertainty: Low<br>Importance: Moderate | <p><b>Not significant</b></p> <p>Vegetation on Tilbury Island has been severely altered by long-standing industrial development, with native and traditional plant communities largely displaced and invasive species already established within the Project Footprint and LAA. These species are already spreading under current conditions, including at the existing Tilbury LNG facility, and must be managed under applicable requirements of the ERAA. Given the highly disturbed setting, vegetation resilience is low, and additional disturbance from the Project is unlikely to meaningfully change existing ecological conditions.</p> <p>The magnitude of the residual effect is expected to be mostly adjacent to existing disturbance and is of negligible to low magnitude.</p> <p>Effects are considered reversible by implementing noxious weed management.</p> <p>Effects on traditional use plants would be disproportionately experienced by First Nations.</p> <p>The introduction or spread of invasive plant species is limited to the vegetation LAA and is medium-term in duration, as effects are expected to be reversible, and the site is expected to be rehabilitated after Decommissioning.</p> <p>Because the mitigations are considered to be effective, there is a medium likelihood of the effect occurring, with moderate consequences due to its low magnitude. Therefore, the risk is rated as moderate.</p> <p>The introduction or spread of invasive species is of interest to First Nations and provincial, regional, and municipal groups.</p> |
| * Note: Criteria and assessment ratings are defined in <a href="#">Appendix 3 - Residual Effects Characterization Definitions</a> |                                                                                                                                                                                                                                                                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

### 17.6.8 Cumulative Effects Assessment

The assessment of a designated project must consider any cumulative effects that are likely to result from the Project in combination with other physical activities that have been or will be carried out.

The following pathway was carried forward for cumulative effects assessment on vegetation, as detailed in [Section 7.7.5](#) of the Revised Application:

- Introduction or spread of invasive plant species.

Several factors contribute to cumulative impacts on vegetation:

- Projects like the Tilbury Phase 1 LNG Expansion and the Tilbury Marine Jetty (TMJ) project may increase the spread of invasive plant species;
- Natural hazards such as flooding can further exacerbate this issue; and
- Climate-related changes in temperature, Carbon Dioxide (CO<sub>2</sub>) levels, rainfall, drought, and sea level are altering vegetation patterns. These shifts favor invasive species, which are more resilient to heat and drought.

See [Table 7.7-9](#) of the Revised Application for a full accounting for all the projects and activities considered in the cumulative effects assessment.

Tilbury Phase 2 is situated within heavily disturbed industrial lands where invasive plant species are already widespread and expected to persist due to long-standing land use patterns and limited functional habitat (see [Section 17.6.3](#) Existing Conditions by Proponent). Ongoing and reasonably foreseeable activities in the area, together with climate-related changes that favour invasive species, contribute to continued regional pressures on vegetation communities. Given the Project's small footprint, limited disturbance, and implementation of mitigation measures, the residual invasive-species pathway is expected to be negligible to low in magnitude and confined to the footprint and immediate surroundings. As invasive plants are already established under current conditions, Tilbury Phase 2 is not anticipated to measurably alter cumulative vegetation conditions at the Local or Regional Assessment Area scale and is therefore not expected to result in an adverse cumulative effect on the Vegetation VC.

#### 17.6.9 Conclusion

The EAO is satisfied that Tilbury Phase 2 would not have significant adverse residual or cumulative effects on the vegetation VC. This conclusion considers the information and analysis presented in this section; the views of the TAC, First Nations, and FortisBC; and the mitigation measures identified in the provincial Table of Conditions including Condition 12 (CEMP).

## 17.7 Wildlife and Wildlife Habitat

### 17.7.1 Summary

Wildlife and wildlife habitat is important to the function of natural ecosystems, maintains biodiversity, and supports human activities such as traditional hunting. First Nations involved indicated the importance of a variety of wildlife species connected to their cultural practices, such as harvesting of wildlife.

Key issues related to the wildlife and wildlife habitat VC raised by reviewers include wildlife mortality risk reporting, effects to birds and bats including associated mitigation measures, mitigation effectiveness, and habitat enhancements.

If issued, the Certificate will include Condition 12 requiring the approval and implementation of a CEMP and Condition 13 for an OEMP. These plans include requirements to address concerns related to wildlife and habitat throughout the Tilbury Phase 2 LNG Expansion Project's lifecycle.

The EAO is satisfied that though there are negligible to low residual effects associated with the wildlife and wildlife habitat VC, there are no significant adverse residual effects. The EAO concludes cumulative effects to the wildlife and wildlife habitat VC from Tilbury' Phase 2's interactions with other past, present, or reasonably foreseeable projects and activities are not significant.

### 17.7.2 Assessment Boundaries

The spatial boundaries for the wildlife and wildlife habitat VC assessment include the following:

- Project Footprint – defined as the area directly disturbed by project activities;
- Local Assessment Area (LAA) - defined as the Tilbury Phase 2 Project Footprint plus a 300 metres buffer around the Tilbury Phase 2 Project Footprint; and
- Regional Assessment Area (RAA) - defined as the Tilbury Phase 2 Project Footprint plus a 500 metres buffer, extending along the Fraser River 300 metres upstream and 2 km downstream, with a 50 metres buffer from the high-water mark on both banks.

The temporal boundaries use in the assessment of the wildlife and wildlife habitat VC include Construction (3-6 years); Operation (40+ years); and Decommissioning (2 years) phases.

Project components and anticipated duration of activities are described in detail in [Section 1.2](#) (Project Description and Schedule) of this Report.

### 17.7.3 Existing Conditions by Proponent

Fortis BC (Proponent) assessed wildlife and wildlife habitat conditions in [Section 7.8](#) and [Appendix D \(Terrestrial Biophysical Technical Data Report\)](#) of the Revised Application, which includes a full list of species at risk in Section 3.1.2.3 of Appendix D.

Existing conditions were characterized through a desktop review, 2021 and 2022 field studies, Indigenous Knowledge and Traditional Use Knowledge, literature review, engagement, expert opinion, and data from previous studies in the area.

The Local and RAAs have a long history of Indigenous use for transportation, harvesting (for example, hunting, trapping, fishing).

### Habitat and Landscape:

The Project Footprint is characterized by very limited habitat value for wildlife due to its highly disturbed and industrialized condition; however, the Local and RAAs include portions of a broader ecologically important landscape associated with the Fraser River, where habitat value varies and includes riparian and estuarine areas that support wildlife, including migratory birds and species at risk.

Water quality in Tilbury Slough is poor, with low oxygen and pH levels, and elevated contaminants from surrounding runoff, which can negatively impact sensitive species such as amphibians. While some generalist species (e.g., mallards, Canada geese, beavers, and bats) utilize the area, habitat quality is suboptimal for sensitive or specialist species.

The Project Footprint lacks suitable foraging and nesting habitat for migratory and resident birds, as it is sited entirely within the existing Tilbury site (i.e. paved and gravelled surfaces). However, some bird species are known to utilize gravelled or otherwise disturbed areas, and anthropogenic structures, for nesting. For example, species such as killdeer and common nighthawk may nest on gravelled surfaces, and swallows (including barn swallow) may nest on built structures. Evidence of this use has been documented within the Project Footprint, including a cliff swallow nest colony previously identified under an existing dock structure. Outside the Project Footprint, there are small patches of shrub and young forest that could provide suitable foraging and nesting habitat but are fragmented and subject to disturbance.

### Wildlife Populations:

Wildlife populations in the area are predominately composed of mid-level predators (such as raccoons and skunks) and species at lower trophic levels (such as mice, rats, rabbits), with apex predators mainly consisting of birds of prey. Large native carnivores such as lynx, foxes, wolverines, wolves, and bears are no longer found in the area. Land mammals such as deer and beavers are still present and could be found in the LAA. Bird and amphibian populations within the LAA have a high abundance of invasive species, including green frog, European starlings, and house sparrows.

### Species at Risk:

To meet EA substitution requirements, the EAO has assessed the potential effects of Tilbury Phase 2 on wildlife species listed under SARA and/or the *Committee on the Status of Endangered Wildlife in Canada* (COSEWIC) as required under the IAA, which were also further assessed in Appendix 15. These species are listed in *Table 56* below. For a complete list of species assessed please see Section 3.1.2.3 in [Appendix D \(Wildlife and Wildlife Habitat Technical Data Report\)](#) of the Revised Application. While not all these species were identified during field surveys, it is likely they are either present in the RAA already, or that parts of the RAA represent appropriate ecosystems where these species could potentially occur.

Table 56: Wildlife Species Listed Under the SARA and/or the COSEWIC

| Species name                                                      | Species Group Assessed                          | Federal Species at Risk Status                 |
|-------------------------------------------------------------------|-------------------------------------------------|------------------------------------------------|
| Great blue heron, fannini ssp. ( <i>Ardea herodias fannini</i> )* | Birds (wading birds and shorebirds)             | Special Concern                                |
| Horned grebe ( <i>Podiceps auritus</i> )*                         | Birds (waterbirds)                              | Special Concern                                |
| Western grebe ( <i>Aechmophorus occidentalis</i> )*               | Birds (waterbirds)                              | Special Concern                                |
| Barn owl ( <i>Tyto alba</i> )                                     | Birds (species adapted to human infrastructure) | Threatened                                     |
| Barn swallow ( <i>Hirundo rustica</i> )*                          | Birds (species adapted to human infrastructure) | Threatened (SARA)<br>Special Concern (COSEWIC) |

| Species name                                                                       | Species Group Assessed                          | Federal Species at Risk Status                  |
|------------------------------------------------------------------------------------|-------------------------------------------------|-------------------------------------------------|
| Peregrine falcon, <i>anatum</i> ssp. ( <i>Falco peregrinus anatum</i> )            | Birds (species adapted to human infrastructure) | Special Concern (SARA)<br>Not At Risk (COSEWIC) |
| Little brown myotis ( <i>Myotis lucifugus</i> )                                    | Mammals                                         | Endangered                                      |
| Pacific water shrew ( <i>Sorex bendiri</i> )                                       | Mammals                                         | Endangered                                      |
| Red-legged frog ( <i>Rana aurora</i> )                                             | Amphibians and reptiles                         | Special Concern                                 |
| Western painted turtle, Pacific Coast population ( <i>Chrysemys picta bellii</i> ) | Amphibians and reptiles                         | Threatened                                      |
| Western toad ( <i>Anaxyrus boreas</i> )                                            | Amphibians and reptiles                         | Special Concern                                 |

Migratory birds, protected under the Migratory Birds Convention Act (1994), have been identified with an asterisk in this table and further assessed in [Appendix 15](#) of this Report as a requirement under the IAA. The proponent did not assess migratory birds separately, grouping them according to the bird community categories listed in this table.

#### 17.7.4 Potential Project Effects by Proponent

The Proponent has evaluated the potential effects of the Construction, Operation, and Decommissioning activities of Tilbury Phase 2 that may directly or indirectly interact with the wildlife and wildlife habitat VC in [Section 7.8.4](#) of the Revised Application.

Three potential effects were identified in the Revised Application:

##### 17.7.4.1 Loss or Alteration of Wildlife Habitat:

Construction, Operation, and Decommissioning of the Project will create noise, vibration, and artificial light. These disturbances may make nearby habitat less suitable for wildlife, especially sensitive species or those at risk. For example, birds might avoid nesting or feeding near loud or brightly lit areas, and bats could have trouble finding food if noise interferes with how they hunt insects. Some animals might adjust to these conditions, and in some cases certain species may utilize lit areas where prey is concentrated; however, artificial light can also disrupt predator-prey relationships, alter behaviour, and lead to avoidance by light sensitive species, including bats.

These effects are temporary during Construction and Decommissioning but could continue to some degree during Operation. However, because the Project is in an already industrialized area, increase in lighting and noise levels compared to existing conditions are expected to be negligible to low magnitude. Still, the disturbances could affect how often some wildlife, including culturally important species like ducks, geese, and eagles, use nearby habitat.

While the habitat is planned to stay physically intact, the added disturbance from the Project could reduce how effective it is for wildlife—at least during certain times of year like nesting or migration for birds.

##### Changes to Wildlife Movement

Tilbury Phase 2 is not expected to affect wildlife movement. The existing fenced facility already restricts animal access, and the Project avoids major disturbances through the removal of the MOF, barging and any related activities such as dredging;

##### 17.7.4.2 Increased Wildlife Health and Mortality Risk

The Project may increase wildlife health risks and mortality due to land-based activities during Construction, Operation, and Decommissioning. Potential sources of increased risk include:

- **Vehicle Collisions & Human-Wildlife Conflict:** Increased traffic during Construction may slightly elevate collision risk, particularly for barn owls that forage along roads. There is no predicted interaction with wildlife mortality risk from vehicle collisions during Operation of the project, as traffic levels are anticipated to be the same as the existing levels. Odour from waste may attract urban wildlife like coyotes or raccoons, increasing human-wildlife encounters and mortality risk;
- **Habitat Disturbance:** Disturbance of occupied habitat features during construction site preparation activities has the potential to cause accidental mortality to wildlife. However, with the removal of the MOF and no barging of construction materials, no physical habitat disturbance is predicted;
- **Sensory Disturbance:** Project-related noise, lighting, and activity may disturb nesting birds and increase mortality risk. However, given the industrial setting, most wildlife in the area is already habituated. Lighting may also increase bird collision risk, particularly during migration. Noise can negatively affect bats and their foraging abilities and navigation of an industrial setting;
- **Flaring:** Use of a TEGF (low-noise, totally enclosed ground flare) is expected to minimize risks, though heat plumes and low-visibility conditions could still pose a limited collision or injury risk to birds;
- **Deleterious Substances:** With the removal of the MOF and no instream works, there is no potential for remobilizing legacy contaminants or sedimentation in the Fraser River Historical soil contamination within the existing Tilbury site won't be disturbed; any within the Project Footprint will be contained and removed before construction. Runoff is diluted before reaching Tilbury Slough, and any sediment mobilization would be negligible. No water quality or wildlife impacts are expected. The Project's normal operation is not expected to have a significant effect on air quality, plants or animals. Dust from construction might affect air quality nearby but will be controlled and is predicted to cause minimal impact; and
- **Pest Control:** Rodenticides may harm raptors (e.g., barn owls) through secondary poisoning.

#### 17.7.5 Proposed Mitigation Measures by Proponent

The Proponent included a list of all proposed mitigation measures for the wildlife and wildlife habitat VC in [Table 7.8-6](#) of the Revised Application.

The Proponent identified the following relevant mitigation measures to reduce potential effects on the wildlife and wildlife habitat VC:

- Complete wildlife surveys prior to construction to identify habitat features that warrant site-specific mitigation measures to reduce potential project effects to wildlife and wildlife habitat. Where practical, plan Construction activities within wildlife habitat or buffers of identified wildlife habitat features during the least-risk timing windows for applicable species;
- For any work within the buffer zone during a sensitive timing window, consult with Indigenous nations and a wildlife QP and the appropriate regulatory agencies to determine whether additional feature-specific mitigation is required to be incorporated into the CEMP;
- Develop and implement soil-management and soil-handling practices that are effective at managing the introduction and spread of invasive noxious plant species, as required under provincial regulations and municipal bylaws. These measures will be incorporated into the CEMP;
- Lighting for the project will be designed in a manner that is consistent with the BCER's Light Control Best Practices Guideline;

- Develop mitigation and contingency measures in consultation with Indigenous nations and a QP to reduce the potential for adverse interactions with wildlife and wildlife habitat (such as human wildlife conflict, vehicle collisions, and sensory disturbance) and incorporate these measures into the CEMP;
- During Construction and Operation of the Project, develop mitigation and contingency measures through engagement with a QP to manage acoustic disturbance to human and wildlife receptors, and incorporate these measures into the CEMP and OEMP;
- Establish a refuelling and spill response plan, which will be incorporated into the CEMP;
- Develop dust-control measures to be described in the CEMP to limit particulate matter emission during the construction phase;
- If rodent population control is needed at the Project site, employ best practices to manage rodent populations onsite during Construction and Operation and these measures will be included in the CEMP; and
- Monitor and report wildlife incidents associated with transportation (i.e. vehicle strikes) within the project Footprint.

As part of the substituted process, the EAO has identified KMMs for effects within federal jurisdiction to inform IAAC's draft potential federal conditions. The KMMs related to wildlife and wildlife habitat VC as it relates to migratory birds, species at risk, or species of cultural importance under the IAA are outlined in [Appendix 2](#).

### 17.7.6 Key Issues Raised

Based on a review of the Revised Application and with feedback from the TAC, participating Indigenous nations, the CAC, and the public, the following key issues related to the assessment of the wildlife and wildlife habitat VC for Tilbury Phase 2 were identified.

#### 17.7.6.1 Migratory Birds, Bats, and Mitigation Measures

Cheam First Nation, x̱m̱əθḵ'əyám, Quw'utsun Nation, and ECCC provided comments relating to birds, bats, and potential mitigation measures.

Cheam raised concerns about migratory waterbirds and the Boundary Bay-Roberts Bank-Sturgeon Bank Important Bird Area (IBA). The IBA habitat supports species that are traditionally hunted, such as ducks and geese that are of cultural importance, and raised concerns that localized impacts could reduce bird populations further up the Fraser River. Quw'utsun Nation, and other reviewers, indicated that additional detail on how bald eagle nest monitoring would take place and if a qualified environment professional would conduct the monitoring, and how the effectiveness of the proposed mitigation measures applicable to the wildlife and wildlife habitat VC would be determined.

FortisBC stated that, with the implementation of proposed mitigation, no adverse residual effects are expected on waterbirds as the Project is occurring in an existing brownfield site with limited vegetation and generally low-quality wildlife habitat, although some anthropogenic structures may be used by certain species (birds and bats) for nesting or roosting. No clearing of vegetation will occur for the Project, and no work will occur in or directly adjacent to the Fraser River, where the IBA overlaps the wildlife and wildlife habitat LAA.

FortisBC also stated that species-specific mitigation measures will be developed by a QP as part of the CEMP and OEMP, which will consider the applicability and effectiveness of least risk timing windows for applicable species. A QP will provide expert advice regarding protective buffers that are needed for specific species of birds and their nests, including bald eagles.

Where appropriate and practical, protective buffers may be applied, depending on factors including the wildlife species and habitat feature, degree of tolerance of the species, life stage of the wildlife species, surrounding conditions and landscape context, timing (such as overlap with peak activity period within a sensitive timing window), and the potential for planned construction activities to cause disturbance. FortisBC noted that the evaluation of implemented mitigation measure success, such as through post-construction monitoring, will be considered in the development of the CEMP and OEMP.

x̣ṃəθḳəỵəm and ECCC proposed specific mitigation and enhancement measures to reduce potential effects of artificial lighting on birds and bats. For instance, mitigation measures could include the use of specific lighting types (strobe, LED), consider the direction and intensity of lighting (automatic sensor lighting and down shielding) and the periods of its usage (avoiding wildlife sensitive periods).

FortisBC stated that species-specific mitigation measures to reduce potential effect to bats and migratory birds from artificial lighting will be developed as part of the CEMP, as recommended by a QP.

If issued, the EAO proposes that the Certificate should include Conditions 12 (CEMP) and 13 (OEMP) that would require a Holder to outline how the mitigation measures applicable to wildlife would be implemented during Construction and Operation. The consultation will be required with First Nations and agencies on the development of the CEMP and OEMP prior to approval. Both plans would also be required, under the proposed Condition 3 (Document Development), to outline how adaptive management will be implemented, and how the effectiveness of any mitigation measures will be evaluated including the schedule(s) for evaluating effectiveness.

#### 17.7.6.2 Wildlife Mortality Reporting

Tsawwassen First Nation (TFN) and the Ministry of Transportation and Transit (TRAN) provided comments related to wildlife mortality reporting. TFN recommended that wildlife mortality monitoring should occur during Operation, while TRAN recommended reporting associated with vehicle strikes during Construction.

FortisBC stated that detailed mitigation and monitoring plans will be developed through the CEMP and OEMP, in consultation with regulators and Indigenous nations.

The EAO noted that wildlife incidents must be reported under Section 75 of the *Wildlife Act*. To support holistic monitoring of the Project, the EAO has proposed EAC Conditions 12 (CEMP) and 13 (OEMP) which would require wildlife mortality reporting during Construction and Operation.

#### 17.7.6.3 Habitat Enhancements

Snuneymuxw First Nation asked how the Project could support and improve surrounding habitat areas, such as riparian zones, habitat corridors, parks, and conservation areas (e.g., Fraser River riparian habitat, Tilbury Slough riparian habitat, Burns Body Ecological Conservancy Area, and Deas Island Regional Park). Snuneymuxw First Nation raised that enhancement measures for wildlife habitat could mitigate potential impacts to Snuneymuxw's rights to hunt and harvest species.

FortisBC noted that no anticipated habitat clearing or riparian impacts due the current project design and committed to exploring native vegetation planting and voluntary water quality measures in collaboration with Snuneymuxw.

### 17.7.7 The EAO's Characterization of Residual Effects

After considering the proposed mitigation measures and conditions proposed, the information contained in the [Joint Permitting/Regulatory Coordination Plan](#) and the [Regulatory Coordination Issues Tracking Table](#), the EAO concludes that the Project would result in the following residual adverse effects on the wildlife and wildlife habitat VC:

- Loss or alteration of wildlife habitat; and

- Increased wildlife health and mortality risk.

The EAO's characterization of the expected residual effects of the Project on wildlife and wildlife habitat is summarized below, as well as the EAO's level of confidence in the effects determination (including their likelihood and significance).

Table 57: Summary of Residual Effects for Wildlife and Wildlife Habitat VC

| Residual Effect                              | Assessment Rating*                                                                                                                                                                                                                                                              | Significance and Rationale                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Loss or Alteration of Wildlife Habitat       | Context (resilience): Low<br>Magnitude: Negligible to Low<br>Extent: Local<br>Duration: Medium-term<br>Frequency: Continuous<br>Reversibility: Fully reversible<br>Affected Populations: N/A<br>Risk (likelihood and consequences): Low<br>Uncertainty: Low<br>Importance: High | <p><b>Not significant</b></p> <p>The receiving environment is already stressed from industrial development and fragmentation, which suggests lower resilience to further habitat loss or alteration, especially for species at risk. This supports a rating of low resilience. While some species may be adapted to the existing disturbance, the degraded state of the habitat overall and the presence of vulnerable species suggest that the environment would not easily adapt to additional stresses.</p> <p>The Project Footprint contains little natural wildlife habitat, as it lies entirely within an existing fenced industrial site. While the site does not provide high-quality or diverse habitat, it may be used opportunistically by some wildlife (particularly birds) for activities such as overflight, perching, resting, or short-term use of existing or Project-related infrastructure. In addition, wildlife habitat immediately adjacent to the Project Footprint, including shoreline or industrial-edge areas, may be exposed to Project-related noise, light, vibration, and human activity during Construction, Operation, and Decommissioning. Effects are expected to be negligible for most wildlife species, given the limited number and nature of interactions expected with the implementation of wildlife specific mitigation measures, with a low rating applied to species at risk due to their lower resilience and recovery status'. This reflects the Project's minor contribution to potential effects on wildlife and wildlife habitat and the expected effectiveness of mitigation measures.</p> <p>Since potential residual effects to wildlife habitat are limited to the LAA, the extent is rated as local.</p> <p>Duration is expected to be medium-term as the residual effect will be felt during all the project phases until Decommissioning of the Project.</p> <p>The residual effect frequency will be continuous.</p> <p>Effects are considered reversible because the habitat is expected to recover to its pre-project state after the project is decommissioned and the infrastructure is removed.</p> <p>Following mitigation measures, there is a medium likelihood of effects occurring, and a low level of consequence given there is limited habitat and low magnitude, therefore overall risk is rated as low.</p> <p>Uncertainty is low, as the effect characterization is based on good understanding of cause effect relationships, the known effectiveness of mitigation measures, and data pertinent to the Project area.</p> <p>Loss or alteration of wildlife habitat is a key concern for Indigenous nations and government agencies, so its importance is rated as high.</p> |
| Increased wildlife health and mortality risk | Context (resilience): Low<br>Magnitude: Negligible to Low<br>Extent: Local<br>Duration: medium-term                                                                                                                                                                             | <p><b>Not significant</b></p> <p>The existing industrial setting suggests some wildlife habituation, but ongoing stress and the presence of vulnerable species reduce the species and area's ability to absorb further impacts. A low resilience rating reflects this limited capacity to adapt to increased health and mortality risks.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Residual Effect                                                                                                                   | Assessment Rating*                                                                                                                                                | Significance and Rationale                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|                                                                                                                                   | Frequency: Irregular<br>Reversibility: Reversible<br>Affected Populations: N/A<br>Risk (likelihood and consequences): Low<br>Uncertainty: Low<br>Importance: High | <p>Given the project's scope and planned mitigation, residual effects are expected to be negligible for most wildlife. However, due to the lower resilience of species at risk (e.g. barn owl and Little Brown Myotis), a precautionary low magnitude rating is applied to reflect their increased vulnerability.</p> <p>Residual effects are limited to the LAA.</p> <p>As effects end after Decommissioning, the duration of residual effects is considered medium-term.</p> <p>Effects on wildlife health and mortality risk occur year-round but may increase seasonally (e.g. during bird nesting or amphibian breeding), so frequency is rated as irregular.</p> <p>Effects are considered reversible because the habitat is expected to recover to its pre-project state after the project is decommissioned.</p> <p>The likelihood of the effect is medium, but with minor consequences due to its low magnitude and local extent, the overall risk is rated as low.</p> <p>Uncertainty is low as the effect characterization is based on good understanding of cause-effect relationships and data pertinent to the Project area.</p> <p>Increased wildlife health and mortality risk has been a consistent priority raised by Indigenous nations and government agencies during engagement, so importance is rated as high.</p> |
| * Note: Criteria and assessment ratings are defined in <a href="#">Appendix 3 - Residual Effects Characterization Definitions</a> |                                                                                                                                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

### 17.7.8 Cumulative Effects Assessment

The assessment of a designated project must take into account any cumulative effects that are likely to result from the Project in combination with other known, past, present or reasonably foreseeable physical activities that have been or will be carried out.

There are four reasonably foreseeable projects and activities that have the potential to act cumulatively with Tilbury Phase 2, as described in [Section 7.8.5](#) of the Revised Application. These include Tilbury Phase 1 LNG Expansion Project, Tilbury Marine Jetty Project, natural hazards (e.g. flooding), and climate change.

The key cumulative effects assessment results are summarized in [Table 7.8-9](#) of the Revised Application, with two residual effects carried forward to the assessment:

- Loss or alteration of wildlife habitat; and,
- Risk to wildlife health and mortality.

The wildlife and wildlife habitat RAA is subject to extensive cumulative effects from past and ongoing industrial and urban development, including habitat loss and degradation and ongoing pressures on wildlife health and mortality (See Section 1.1.3 Existing Conditions). These conditions are expected to continue under current and reasonably foreseeable land use patterns. Tilbury Phase 2 is located within the existing Tilbury LNG facility, a long-established and already disturbed brownfield site with limited wildlife habitat value. After mitigation measures and conditions are applied, Tilbury Phase 2's incremental contribution to cumulative effects on wildlife and wildlife habitat is characterized as negligible for non-listed species and low for species at risk for both habitat loss/alteration and health/mortality risk.

Accordingly, Tilbury Phase 2 is not anticipated to measurably alter cumulative wildlife or wildlife habitat conditions at the RAA scale and is not expected to result in an adverse cumulative effect on the wildlife and wildlife habitat VC when considered in combination with past, present, and reasonably foreseeable future projects and activities.

### 17.7.9 Conclusion

The EAO is satisfied that Tilbury Phase 2 would not have significant adverse residual or significant cumulative effects on the wildlife and wildlife habitat VC. The extent of significance for federal effects to migratory birds are found in [Appendix 15](#). This conclusion considers the information and analysis presented in this section; the views of the TAC, First Nations, and FortisBC; the proposed Mitigation Measures identified in the provincial Table of Conditions including, Conditions 12 (CEMP), 13 (OEMP) and 3 (Document Development), and identified and where appropriate recommended federal Key Mitigation Measures and Follow-up Programs for the wildlife and wildlife habitat VC as it may pertain to migratory birds, species at risk, and Indigenous use of traditional lands and resources under the IAA ([Appendix 2](#)).

## 17.8 Fish and Fish Habitat

### 17.8.1 Summary

The fish and fish habitat VC was selected and assessed due to the potential for the Tilbury Phase 2 LNG Expansion Project (Tilbury Phase 2 or Project) to adversely affect fish and fish habitat, including changes in habitat, fish movement, and mortality risk. Fish and fish habitat are integral to functioning aquatic and terrestrial ecosystems, and provide economic, sustenance, and cultural value and the exercising of Section 35 rights, especially for Indigenous fisheries.

The key issues raised by reviewers related to fish and fish habitat are the potential water quality effects on the Tilbury Slough and concerns related to 6-PPDQ from increased truck traffic and potential effects on fish.

Because of issues raised, the EAO has proposed Condition 12 (CEMP) and Condition 13 (OEMP) that would require the implementation of erosion and sediment control measures, measures to address spill prevention and response related to hydrocarbon storage and leaks or other accidental emissions from machinery or equipment, and measures to address surface water quality and quantity including testing requirements for discharge into the City of Delta's stormwater system. The EAO also proposed as part of Condition 12 (CEMP) will also include requirements for an LNG Storage Tank Hydrostatic Testing Plan during Construction, and as part of Condition 17 the submission of a report on the effectiveness of Dry Street Sweeping as a mitigation measure related to 6-PPDQ.

The EAO concluded that there would be negligible magnitude effects related to the fish and fish habitat VC due to the removal of all in water works from the scope of the Project's assessment, and that no water releases from the Project into the environment are expected to exceed thresholds that would cause harm to fish or fish habitat. Therefore, the EAO concludes that after a review of the proposed mitigation measures and conditions there is a negligible magnitude effect and no significant cumulative effects to fish and fish habitat that is expected to result from the Project interacting with the effects of other past, present and reasonably foreseeable future projects and activities.

### 17.8.2 Assessment Boundaries

The spatial boundaries for the fish and fish habitat assessment included:

- Project Footprint – defined as the area directly disturbed by project activities;
- Local Assessment Area (LAA) for fish - defined as the lower Fraser River for 1,000 meters upstream and downstream of the Project's Footprint;
- Local Assessment Area (LAA) for fish habitat - defined as the lower Fraser River for 100 metres upstream and 200 metres downstream of the Tilbury Phase 2 Project Footprint. The fish habitat LAA also includes the Tilbury Slough for 100 metres upstream and 200 metres downstream of Delta stormwater outlets that drain stormwater from the Project's Footprint and adjacent properties;
- Regional Assessment Area (RAA) for fish and fish habitat includes the lower Fraser River for 2,000 metres upstream and downstream of the Project's Footprint and adjacent properties.

The temporal boundaries for fish and fish habitat include the Construction (3-6 years), Operation (40+ years), and Decommissioning (2 years) phases of Tilbury Phase 2.

Project components and anticipated duration of activities are described in detail in [Section 1.2](#) (Project Description and Schedule) of the Assessment Report.

### 17.8.3 Existing Conditions by Proponent

The Proponent assessed fish and fish habitat conditions in [Section 7.9](#) of the Revised Application, which includes an assessment of existing conditions for the fish and fish habitat VC and in [Appendix E Aquatic Biophysical Technical Data Report](#).

The existing conditions at the Project Footprint, located within the Tilbury LNG facility, are characterized by a heavily industrialized area that does not include fish habitat. The site is a long-standing brownfield consisting of about 70 percent gravel and the remaining area being the existing infrastructure, and equipment laydown areas. The suitability of fish habitat in the Fraser River is described as a tidally influenced ecological transition zone, highly biodiverse, and subject to saltwater wedge intrusion.<sup>1</sup> Fish habitat in the lower reach of Tilbury Slough below MacDonald Road has potential to support a wide range of fish species. Although a tidal gate at MacDonald Road restricts fish access to upstream sections of the slough, some non-anadromous species are known to inhabit these waters

The lower Fraser River has been subject to anthropogenic activity since settlers arrived, with modifications such as dike and jetty construction, dredging, and water diversions occurring since the 1900's. Dike construction along the Fraser River has occurred over decades with varying standards in response to flood events. Until 1985, a dike extended along the Fraser River, protecting the entire reach of the Tilbury Slough. In 1985, the diking area was partly reclaimed by breaking a portion of the dike and excavating a tidal channel system to improve tidal flushing up to MacDonald Road.

Shallow waters around Tilbury Island were previously used by Indigenous people to harvest eulachon as these waters provide excellent spawning habitat for eulachon. White Sturgeon has been identified as a fish species with ecological importance because they are vulnerable to habitat disturbances. A traditional and integral fishing site was located on the Fraser River beside Tilbury Island opposite the historic Indigenous village site where Indigenous people would spear sturgeon and conduct drift- and set-netting along the shoreline for salmon. Salmon are of particular importance to Indigenous Nations in the Fraser River region, serving as a key source of sustenance, cultural practice, and knowledge transmission, and are closely tied to social, ceremonial, and governance systems. As such, access to and the health of salmon populations are central to maintaining cultural continuity and relationships with the river.

A desktop review of literature, environmental data, government studies, and technical reports was completed to identify fish presence, sensitive habitats, local biodiversity, and species at risk. Field studies, in 2021, surveyed riparian and intertidal fish habitat along the Fraser River foreshore and assessed Tilbury Slough, including 100 metres upstream and 200 metres downstream of the Delta stormwater outlet that are within the vicinity of the Project Footprint.

#### The Lower Fraser River:

The lower Fraser River is a tidally influenced, ecologically diverse, transition zone with saltwater intrusion. The lower Fraser River provides habitat for various fish species, which includes intertidal marsh, mudflats, and riparian vegetation that are important for fish rearing and foraging. The mainstem channel of the lower Fraser River serves as migratory habitat for Pacific salmon, while nearshore areas provide rearing habitat for salmonids. Juvenile white sturgeon are believed to use habitat in the lower Fraser River and Tilbury Slough adjacent to the Project Footprint; however, shallow water conditions and elevated salinity levels during periods of low flow may reduce its suitability. Adult white sturgeon are also known to inhabit this reach of the Fraser River, typically utilizing deeper nearshore habitats associated with higher flow conditions. The shallow waters around Tilbury Island provide spawning habitat and harvesting potential for eulachon, however there are limitations within the lower Fraser River including brackish conditions, sediment deposition, and a lack of small gravels.

Sediment quality in the lower Fraser River is influenced by local scour and deposition, with some guideline exceedances for metals within the range measured in the lower Fraser River south arm. Existing ambient underwater noise levels are influenced by shipping traffic and machinery in the lower Fraser River. The Project Footprint is adjacent to the Seaspan Ferry terminal, which has frequent vessel movements. Fish species found in the lower Fraser River are:

- Pacific salmon species
- White sturgeon
- Eulachon
- Estuarine/brackish species
- Freshwater resident species
- Benthic invertebrates
- Seals and sea lions may also occur within the LAA.

#### The Tilbury Slough:

Tilbury Slough provides limited fish habitat suitability due to a combination of physical barriers and degraded water quality. The upstream and downstream tidal flood gates restrict tidal exchange with the lower Fraser River, resulting in stagnant water conditions when closed; additionally, the railway crossing on the eastern side of the Island further constrains hydrological connectivity by limiting water movement from the upstream gate. The tidal gate at MacDonald Road does not allow fish passage, effectively isolating upstream habitat from migratory species such as Pacific salmon. Habitat upstream of the gate is characterized by low flows, abundant instream vegetation, and marginal water quality, which limits suitability to species tolerant of low dissolved oxygen, elevated temperatures, and variable conditions (such as, threespine stickleback and brassy minnow). The lower reach of Tilbury Slough below the tidal gate benefits from tidal exchange and supports more productive fish habitat, including rearing areas for several salmonid species. Water from the isolated upper section of the Tilbury Slough, which may be of lower quality, is periodically discharged into the lower reach, influencing habitat conditions.

Baseline water quality monitoring conducted in 2021 and 2023 revealed seasonal stressors that further constrain habitat suitability upstream of the tidal gate. Dissolved oxygen levels were found to be variable and reached stressfully low levels throughout much of the year, while water temperatures exceeded thresholds for salmonid health during summer months. Salinity remained freshwater upstream but became brackish near and downstream of the gate during high tides. Elevated concentrations of metals (including iron, aluminum, copper, and zinc) were detected. Iron levels exceeded provincial guidelines by up to two orders of magnitude, posing risks to fish health. High phosphorus levels likely contributed to eutrophication and algal growth. Turbidity was also elevated and variable, influenced by sediment-rich conditions and runoff from adjacent industrial areas (see Figure 11).

First Nations expressed the potential of Tilbury Slough as habitat for juvenile chum and Chinook salmon, culturally significant species, especially under current restoration efforts to restore connectivity between fish spawning and rearing habitat. For example, TWN highlights that the Tilbury Slough has been identified as a high-priority site for restoration under the Resilient Waters Program, aimed at restoring the connection between fish spawning and rearing habitat. The fish and fish habitat Local and RAAs do not overlap with any known occurrences of Critical Habitat for federally-listed fish species at risk or provincially defined fisheries sensitive watersheds. Brassy minnow occur in Tilbury Slough within the LAA, and are a species listed as Special Concern by the COSEWIC and in consideration for listing under SARA.

Figure 11: Map of Tilbury Slough

Figure 12: Image of Tilbury Slough

#### 17.8.4 Potential Project Effects by Proponent

The Proponent assessed potential effects on fish and fish habitat, including marine mammals (as defined under the *Fisheries Act*), focusing on changes to habitat, movement, and mortality risk from direct and indirect pathways during construction, operation, and decommissioning.

Potential effects considered by the Proponent include changes to the following:

- **Fish Habitat Availability:** refers to the available habitat that can support fish species in the LAAs and RAAs of the Project's Footprint. FortisBC stated in the Revised Application that there is no projected project activities or interaction with fish habitat availability. This is mainly due to the removal of all in-water works and construction of the MOF, which was in response from First Nations who stated concerns with the delivery of modular components and bulk construction materials being delivered to the Project Footprint during construction and the potential impacts to the lower Fraser River from in-water works, fishing practices, accidents and malfunctions, or effects to species of cultural importance.
- **Fish Habitat Quality:** refers to the measurable environmental parameters that determine the suitability and health of aquatic environments for fish and other aquatic species. During operation, the Project's air emissions may contribute to acid rain and nitrogen deposition in the lower Fraser River. Emissions such as nitrogen dioxide (NO<sub>2</sub>), carbon monoxide, sulphur dioxide, and fine particulate matter can increase nitrogen inputs to the aquatic environment, potentially leading to eutrophication and degraded water quality. The Project is not expected to cause exceedances of air quality standards (during steady state Operation conditions) and is anticipated to have a negligible effect on air quality compared to existing conditions. Artificial lighting during nighttime Construction and Operation is expected to have a limited and incremental effect on fish habitat quality due to its localized nature, the high turbidity of the Fraser River, and the presence of light sources from adjacent industrial activities. Underwater noise generated during Construction and Operation is not expected to exceed thresholds that would reduce fish habitat quality. Potential impacts to riparian habitat and benthic invertebrates have been mitigated through the removal of all in-water works and construction of the MOF. The Proponent also considered the risk of deleterious substances entering the Delta stormwater system via spills and runoff, which could alter water quality and affect fish habitat in Tilbury Slough and downstream in the Fraser River.
- **Fish Health, Injury, and Mortality:** Underwater noise and vibrations from Construction activities and Operation have the potential to adversely affect fish health by causing hearing loss, ruptures in the swim bladder, and other tissue damage, which may result in internal bleeding and mortality. However, with the removal of the MOF from the Project plans, all underwater noise will originate from land-based sources and is not expected to exceed regulatory thresholds for the protection of fish and marine mammals. Stormwater runoff into the Tilbury Slough could result in potential changes in water quality, which could harm fish. Increased air emissions during project Operation may introduce constituents such as NO<sub>2</sub>, which can contribute to acid deposition and elevated nitrogen inputs in the lower Fraser River and Tilbury Slough. These inputs have the potential to degrade water quality through eutrophication, where excessive algal growth can reduce dissolved oxygen levels and create unsuitable conditions for many aquatic species. Acid deposition may also lower pH levels, further impairing fish habitat quality. However, under steady-state operational conditions, the Project is not expected to exceed applicable air quality standards and is anticipated to have a negligible impact on ambient air quality relative to existing conditions.
- **Fish Distribution and Abundance:** refers to the potential changes in fish species presence, absence, and relative abundance resulting from temporary and longer-term habitat effects due to project activities. With the removal of all in-water works, the potential project effects on fish distribution and abundance were determined by the Proponent to be negligible.

### 17.8.5 Proposed Mitigation Measures by Proponent

The Proponent identified the following relevant mitigation measures to reduce potential effects on fish and fish habitat including:

- Develop erosion- and sediment-control measures to manage surface water in consultation with First Nations and a QP and incorporate them into the CEMP to reduce sediment deposition into watercourses or storm sewers.

- Establish a refuelling and spill response plan.
- Collect contact water with the use of containments and impoundments. Contact water captured in sumps will be measured for field parameters prior to being released to the onsite drainage ditches that flow into the Delta storm sewer.
- Design site to promote drainage toward the Delta storm sewer system. Stormwater draining from paved parking areas will be captured and treated in oil-water separators to remove sediments and oil or grease before discharge into the Delta storm sewer.
- Conduct testing and treatment of hydrostatic test water prior to discharge to Delta's storm sewer, if required. Discharge procedure requirements of hydrostatic test water will be described in the CEMP.
- Lighting for the project will be designed in a manner that is consistent with the BCER's Light Control Best Practices Guideline.

As part of the substituted process, the EAO has identified KMMs for effects within federal jurisdiction to inform the Impact Assessment Agency of Canada's draft potential federal conditions.

### 17.8.6 Key Issues Raised

Based on a review of the Revised Application and with feedback from the TAC, participating First Nations, the CAC, and the public, the following key issues related to the assessment of fish and fish habitat VC for Tilbury Phase 2 were identified.

#### 17.8.6.1 Sediment Controls & Water Quality

The key issues raised for stormwater runoff and Tilbury Slough water quality are discussed in [Section 7.4](#) of the Revised Application, key issues raised, Section 7.4.6.1 (Sediment Controls for the lower Fraser River & Tilbury Slough) and Section 7.4.6.3 (Water Quality – Tilbury Slough & the lower Fraser River).

#### 17.8.6.2 6PPD-Quinone

TWN, Tsawwassen First Nation, the STSA, Ts'uubaa-asatx, Qu'wutsun Nation, xʷməθkʷəy̓əm, and kʷikʷəłəm First Nation raised concerns about the potential effects of truck traffic on fish and fish habitat due to the emerging chemical 6-PPDQ. 6-PPDQ is an emergent contaminant contained in the rubber of vehicle tires that can be lethal for fish species, especially salmonoids, like coho and chinook salmon and steel head trout.

The Proponent stated that since 6-PPDQ is an emerging contaminant, with minimal information available, they have committed to conducting a street sweeping study to contribute to the body of knowledge on 6-PPDQ.

The EAO requested information on potential mitigation measures or follow-up programs identified by the Proponent, First Nations, or TAC members to address the effects of 6-PPDQ and the associated study that FortisBC (the Proponent) committed to conducting. Further to this, there were measures, such as experimental bioswales<sup>3</sup>, proposed by TAC members to reduce or eliminate these potential effects; however, the overall impact specifically from Tilbury Phase 2 is minimal in comparison to the truck traffic in the area from other industrial activities that require transport trucks in daily operations.

The EAO has recommended that if an EA Certificate is issued that it includes Condition 17 which would require the submission of a report on the effectiveness of dry street sweeping as potential mitigation measures within eighteen months of a certificate being issued. If dry street sweeping is determined to be an effective mitigation measure, then an update would be required to the CEMP to implement it during Construction.

The EAO has also recommended as part of Condition 12 (CEMP) and Condition 13 (OEMP) which require both management plans include measures to address surface water quality and quantity. For Construction, this would include how discharges into the storm water system would be monitored. Consultation would be required on the substances to be tested for.

### 17.8.7 The EAO's Characterization of Residual Effects

After reviewing FortisBC's assessment, the proposed mitigation and conditions, and information in the [Joint Permitting/Regulatory Coordination Plan](#) and [Regulatory Coordination Issues Tracking Table](#), the EAO concludes Tilbury Phase 2 could cause the following negligible adverse effects:

- Reduced fish habitat quality
- Increased risk to fish health, injury, and mortality
- Changes in fish distribution and abundance

For the purposes of this assessment, a negligible magnitude residual effect is one that does not result in a measurable change from existing conditions, or results in no observable change at all at the scale of the LAA or RAA.

The Project is not expected to reduce fish habitat availability because all in-water works were removed from the project scope, which eliminates any potential interaction with existing fish habitat in the Fraser River. As the Project footprint is entirely upland within a longstanding industrial area that contains no riparian, intertidal, or subtidal habitat, no residual effects on fish habitat availability are expected.

The EAO's characterization of the potential residual effects of the Project on Fish and Fish Habitat VC is summarized below in Table 62, as well as the EAO's level of confidence in the effects determination (including their likelihood and significance).

Table 58: Summary of Residual Effects for Fish and Fish Habitat

| Residual Effect              | Assessment Rating*                                                                                                                                                                                                                                          | Significance and Rationale                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Reduced Fish habitat quality | Context (resilience): Low<br>Magnitude: Negligible<br>Extent: Local<br>Duration: Medium-Term<br>Frequency: Irregular<br>Reversibility: Fully Reversible<br>Affected Populations: Disproportionate<br>Risk: Low<br>Uncertainty: Moderate<br>Importance: High | <p><b>Overall Significance: Not Significant</b></p> <p><b>Context:</b> The receiving environment is characterized by degraded conditions, including elevated turbidity, reduced water quality, and ongoing industrial influences, indicating low resilience to additional stressors.</p> <p><b>Magnitude:</b> Tilbury Phase 2 is anticipated to have no direct effects on fish habitat quality in the Fraser River, as all in-water works have been removed from the Project scope, eliminating primary pathways such as instream disturbance, turbidity generation, scour, and habitat alteration. Remaining pathways, including discharge or hydrostatic testing water, dewatering during construction, release of contact water and surface water are indirect and controlled through engineered systems, including mitigations and conditions as discussed above, regulatory requirements, and are not expected to result in measurable changes to surface water quality or fish habitat function, health or mortality and therefore rated as negligible.</p> <p><b>Extent, Duration, and Frequency:</b> Potential interactions are limited to localized areas near stormwater discharge points and the immediate shoreline. Effects may occur intermittently during construction and operation phases but are not expected to persist beyond decommissioning.</p> <p><b>Reversibility:</b> No permanent physical alteration of aquatic habitat or sustained contaminant loading is expected. Any minor, temporary changes to environmental conditions are anticipated to diminish following cessation of Project activities,</p> |

| <p>* Note: Criteria and assessment ratings are defined in <a href="#">Appendix 3 - Residual Effects Characterization Definitions</a></p> |                                                                                                                                                                                                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

### 17.8.8 Cumulative Effects Assessment

The assessment of a designated project must consider cumulative effects that may result from Tilbury Phase 2 in combination with other past, present, and reasonably foreseeable future projects and activities.

For the Fish and Fish Habitat VC, the reasonably foreseeable projects with potential to interact cumulatively with Tilbury Phase 2 include the Tilbury Marine Jetty (TMJ), the Fraser River Tunnel Project (FRTTP), and the Delta Grinding Facility (DGF), based on their proximity to the lower Fraser River and their potential to contribute to shared pathways affecting aquatic conditions (e.g., shoreline disturbance, surface water quality changes, lighting, noise, and stormwater discharge).

Residual effects of Tilbury Phase 2 on Fish and Fish Habitat are limited to stormwater quality interactions in Tilbury Slough, localized artificial lighting along the shoreline, negligible air-deposition pathways, and upland construction noise. These occur within an area already characterised by high turbidity, poor water quality in Tilbury Slough, industrial shoreline development, and elevated ambient noise and lighting in the lower Fraser River system. Residual effects are negligible in magnitude, localized, and medium-term, and fully reversible with prescribed mitigation and adaptive management measures such as erosion and sediment control, oil–water separation, lighting design, and stormwater monitoring.

The cumulative effects assessment examines whether these negligible residual effects may interact with similar pathways generated by TMJ, FRTTP, and DGF such that they would materially alter the future condition of the Fish and Fish Habitat VC. The RAA already experiences long-standing industrial and transportation pressures. These existing conditions reflect historical and ongoing cumulative pressures on aquatic habitat function, fish species, and water quality (see Section 17.8.3 Existing Conditions by Proponent).

Mitigation and management measures under the CEMP and OEMP, such as erosion and sediment control, stormwater treatment, lighting management, and the proponent's commitment to conduct a 6-PPDQ street-sweeping study, further limit the Project's incremental contribution to cumulative aquatic effects. Continued engagement with Indigenous Nations provides additional opportunities to identify concerns related to culturally important fish species and cumulative aquatic health.

Indigenous Nations have described long-standing cumulative pressures on fish populations, water quality, and access to fisheries throughout the lower Fraser River. These broader cumulative conditions are acknowledged and addressed in Section 11 of the Assessment Report. At the scale of the Fish and Fish Habitat VC, however, Tilbury Phase 2's residual effects are too small, localized, and reversible to meaningfully influence the cumulative state of aquatic conditions in the RAA.

Accordingly, based on the highly industrialized existing setting, degraded existing conditions in Tilbury Slough, and the negligible magnitude of Project residual effects, Tilbury Phase 2 is not predicted to result in an adverse cumulative effect on the Fish and Fish Habitat VC when considered in combination with past, present, and reasonably foreseeable future projects and activities.

### 17.8.9 Conclusion

The EAO is satisfied that Tilbury Phase 2 would not have significant adverse residual or cumulative effects on the fish and fish habitat VC. The extent of significance for federal effects to fish and fish habitat are found in [Appendix 15](#). This conclusion considers the information and analysis presented in this section; the views of the TAC, First Nations, and FortisBC; the proposed mitigation measures identified in the provincial Table of Conditions including the Condition 12 (CEMP), Condition 13 (OEMP), and Condition 17 (Dry Street Sweeping Report), and federal Key Mitigation Measures and Follow-up Programs under the IAA for the fish and fish habitat VC in [Appendix 2](#).

## 17.9 Employment and Economy

### 17.9.1 Summary

A strong economy and high employment support a healthy standard of living and contribute to overall community well-being. Employment and the economy are directly related to [Appendix 6, Section 17.11](#) (Infrastructure and Services) as they shape demand for, and availability of, tax revenue to support infrastructure and services depended on by all British Columbians.

In the Revised Application, FortisBC assessed how Tilbury Phase 2 LNG Expansion Project (Tilbury Phase 2 or Project) could impact employment and the economy (including wages, skills development, training, access to opportunities, revenues, and Gross Domestic Product (GDP)). FortisBC's (the proponent) assessment found that the project could generate positive regional effects, such as more jobs, higher incomes, and increased revenues for businesses and governments. FortisBC also outlined measures to enhance these benefits and minimize potential negative effects.

Reviewers raised concerns about how Indigenous peoples and underrepresented groups would access these opportunities, as well as the potential impacts on traditional economic activities and associated indigenous rights and interests. In response, the EAO proposed Certificate Condition 17 (First Nations and Local Economic Inclusion and Monitoring Plan) to enhance benefits associated with the Project and assist in First Nation and Provincial government planning.

The EAO considered FortisBC's assessment, the positive regional and national effects to employment and economy generated, the proposed mitigation and enhancement measures, as well as the draft Certificate condition.

The EAO is satisfied that though there are no adverse residual effects associated with the employment and economy VC, there are no significant adverse effects. Proposed conditions, mitigation measures and regulatory requirements adequately address the key issues raised.

### 17.9.2 Assessment Boundaries

The spatial boundaries for the employment and economy assessment include:

- The Project footprint defined as the area directly disturbed by project activities;
- The Local Assessment Area (LAA): Metro Vancouver (METRO VAN), with a focus on Delta, Richmond, and Tsawwassen Lands; and
- The Regional Assessment Area (RAA): METRO VAN.

The assessment also considered some effects beyond METRO VAN, as applicable (e.g. economic benefits may be applicable to B.C. or Canada).

The temporal boundaries for employment and economy include the Construction (3-6 years), Operation (40+ years), and Decommissioning (2 years) phases of Tilbury Phase 2.

Project components and anticipated duration of activities are described in detail in [Section 1.2](#) (project description and schedule) of this Report.

### 17.9.3 Existing Conditions by Proponent

An overview of existing employment and economic conditions is provided in [Section 7.10](#) of the Revised Application. Information was collected through publicly available data, engagement activities, and project-specific studies.

The Revised Application notes that METRO VAN, including Delta and Richmond, face significant housing pressures due to population growth and land-use constraints. Rising property values have exacerbated housing affordability challenges, particularly for lower-income and marginalized groups.

The Revised Application highlights that METRO VAN faces socio-economic challenges that disproportionately impact specific populations:

- Economic and social inequity is a key long-term issue;
- Marginalized populations experience systemic barriers, discrimination, and oppression;
- Indigenous communities are particularly vulnerable to economic shifts that deepen existing disadvantages, including higher unemployment and poverty rooted in settler colonialism;
- Racialized communities experience disparities in income, employment, and commuting, with lower median incomes and higher rates of part-time or seasonal work; and
- New immigrants face employment barriers, including discrimination, lack of familiarity with Canadian labor practices, and difficulties in recognizing foreign qualifications.

Historically, the regional economy transitioned from traditional Indigenous trade networks to an export and service-based economy following colonization. Indigenous Peoples have long relied on the Fraser River for harvesting, transportation, and trade. Specific First Nations, including the xʷməθkʷəyám, Tsawwassen First Nation, TWN, Squamish Nation, Semiahmoo First Nation, and Quw'utsun Nation, have historically used the Fraser River and surrounding lands for economic and trade purposes. The Fraser River and surrounding lands continues to be utilized by First Nations for a range of purposes.

#### 17.9.4 Potential Project Effects by Proponent

According to the Revised Application, Tilbury Phase 2 LNG Expansion Project is anticipated to generate both positive and adverse economic effects during Construction, Operation, and Decommissioning phases.

Table 59 below summarizes potential effects and effects pathways by project phase, as identified in the Revised Application. For a detailed breakdown of these anticipated effects see [Section 7.10.4](#) of the Revised Application.

Table 59: Potential Effects, Indicators and Effect Pathways for Employment and Economy Identified in the Revised Application

| Potential Effect                                                          | Effect Indicator                                                                                        | Project Phase                            | Effect Pathways as Identified in the Revised Application                                                                                                                                              |
|---------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Increase in employment</b>                                             | FTE Jobs created<br>Unemployment rate and increase in labour force participation rate (%)               | Construction, Operation                  | Construction and Operation activities will generate direct, indirect, and induced employment.                                                                                                         |
| <b>Increase in income</b>                                                 | FTE Jobs created<br>Income (median and mean [\$])                                                       | Construction, Operation                  | The increase in employment opportunities is expected to increase labour income, in turn, increasing living standards for workers and families.                                                        |
| <b>Enhancement of the workforce</b>                                       | Level of education<br>Job market and skills<br>Employment, education, and skills for Indigenous peoples | Construction, Operation                  | Tilbury Phase 2 activities may influence demand for specific skills and training programs, in turn encouraging more participation in the skilled trades.                                              |
| <b>Increase in contracting and procurement opportunities</b>              | Unemployment rate (%)<br>Labour force Participation rate (%)                                            | Construction, Operation, Decommissioning | Tilbury Phase 2 is expected to provide bidding opportunities for contracts and procurement of goods and services in the local and RAAs.                                                               |
| <b>Economic benefits to local, regional, B.C., and Canadian economies</b> | GDP                                                                                                     | Construction, Operation                  | Tilbury Phase 2 activities will contribute to the provincial and Canadian GDPs.                                                                                                                       |
| <b>Increase in government revenues</b>                                    | Municipal and regional Government revenues, including property tax revenue and total revenue            | Construction, Operation                  | Tilbury Phase 2 will generate tax revenues at municipal, provincial, and federal levels.                                                                                                              |
| <b>Increase in business revenue</b>                                       | Consumer expenditures (\$)<br>Business revenue (\$)                                                     | Construction                             | Construction activities will indirectly interact with local businesses through worker spending.                                                                                                       |
| <b>Decrease in business revenue</b>                                       | Consumer expenditures (\$)<br>Business revenue (\$)                                                     | Construction                             | Construction activities will generate traffic on roads, causing delays, disruptions and dust, which could impact agricultural operations and other local businesses, contributing to economic losses. |
| <b>Decrease in labour availability in other industries</b>                | Unemployment rate (%)<br>Labour force participation rate (%)<br>Job market and skills                   | Construction, Operation                  | Tilbury Phase 2 activities may indirectly create a labour shortage for other industries. Some professional or skilled trades workers may need to be sourced from outside the RAA.                     |
| <b>Change to property values</b>                                          | Business revenue (\$)                                                                                   | Operation                                | Tilbury Phase 2 may adversely affect adjacent land values.                                                                                                                                            |
| <b>Decrease in opportunities for traditional economic activities</b>      | Employment, education, and skills for Indigenous peoples                                                | Construction, Operation                  | Tilbury Phase 2 may adversely affect the ability of Indigenous peoples to practice traditional economic activities.                                                                                   |

| Potential Effect                | Effect Indicator                                                     | Project Phase           | Effect Pathways as Identified in the Revised Application                                                                                                                                                                                                           |
|---------------------------------|----------------------------------------------------------------------|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Change to Cost of Living</b> | Cost of living<br>Availability and cost of housing and accommodation | Construction, Operation | The construction and operation phases will involve a large workforce and high demand for specialized trades and skills, which may increase pressure on local infrastructure and services, especially housing, resulting in higher housing prices and living costs. |

Tilbury Phase 2 would provide jobs for Direct, Indirect, and Induced jobs during all Project Phases. For information regarding expected jobs during Construction and Operation, see Table 60.

Table 60: Expected direct, indirect, and induced jobs from Tilbury Phase 2

| Phase                     | Job Type                  | Number of Jobs (FTE)* | Description                                                                        |
|---------------------------|---------------------------|-----------------------|------------------------------------------------------------------------------------|
| <b>Construction Phase</b> | Direct Jobs               | 6,200                 | Jobs directly involved in construction activities on-site over six years.          |
|                           | Indirect Jobs             | 4,800                 | Jobs in industries supporting the project (e.g., suppliers, logistics).            |
|                           | Induced Jobs              | 2,300                 | Jobs created by spending from construction workers and suppliers.                  |
|                           | <b>Total (Cumulative)</b> | <b>13,300</b>         | Total employment impact during Construction.                                       |
| <b>Operation Phase</b>    | Direct Jobs               | 100                   | Jobs at the LNG facility, including skilled trades, professionals, and management. |
|                           | Indirect Jobs             | 400                   | Support industry jobs (e.g., maintenance, operations-related suppliers).           |
|                           | Induced Jobs              | 100                   | Jobs created by spending from employees and supporting businesses.                 |
|                           | <b>Total (Annual)</b>     | <b>600</b>            | Sustained annual employment during operation.                                      |

\*Full-Time Equivalent 6,200 FTEs during Construction means the equivalent of 6,200 net new full-time jobs spread over the entire 6-year Construction phase. It could include combinations of part-time or shorter-term roles adding up to that total.

According to the Revised Application, the project will increase tax revenues at municipal, provincial, and federal levels, while also contributing to GDP through economic activity generated during both Construction and Operation phases. These effects are summarized in Table 61 (Expected GDP contribution, labour income, and tax revenue resulting from Tilbury Phase 2). Section 2.5 (Project Anticipated Expenditures) of the Report describes project expenditures, which for Construction are currently estimated at between \$3 to \$3.5 billion.

Table 61: Expected GDP contribution, labour income, and tax revenue resulting from Tilbury Phase 2

| Phase                     | Category         | Amount (CAD)             | Description                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------|------------------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Construction Phase</b> | GDP Contribution | \$1.7 billion (total)    | Contribution to B.C.'s GDP, including \$699M in direct effects, \$625M in indirect effects, and \$405M in induced effects over 6 years. This represents the value added to the economy, calculated as the difference between the value of final goods and services produced and the cost of the inputs used in the production process.                                         |
|                           | Tax Revenues     | \$308.9 million (total)  | Tax revenues for B.C. governments from direct, indirect, and induced effects (\$152M from provincial taxes, \$46M from municipal taxes, \$22M from corporate income tax and \$89M from personal income tax). <sup>64</sup>                                                                                                                                                     |
|                           | Labour Income    | \$1.2 billion (total)    | Total wages earned by workers across direct, indirect, and induced jobs.                                                                                                                                                                                                                                                                                                       |
| <b>Operation Phase</b>    | GDP Contribution | \$499.5 million (annual) | Contribution to B.C.'s GDP from direct and indirect economic effects related to the Tilbury facility's LNG production and associated upstream natural gas purchases. This represents the value added to the economy, calculated as the difference between the value of final goods and services produced and the cost of the inputs used in the production process.            |
|                           |                  | \$594.6 million (annual) | Contribution to the Canadian GDP from direct and indirect economic effects related to the Tilbury facility's LNG production and associated upstream natural gas purchases. This represents the value added to the economy, calculated as the difference between the value of final goods and services produced and the cost of the inputs used in the production process.      |
|                           | Tax Revenues     | \$63.8 million (annual)  | Direct, indirect, and induced B.C. governments tax revenues, including \$43M from LNG production (\$12M from provincial taxes, \$8M from municipal taxes, \$11M from corporate income tax, \$5M from personal income tax and \$7M from royalties) and \$21M from natural gas (\$11M from provincial taxes, \$6M from corporate income tax, and \$4M from personal income tax). |
|                           |                  | \$144.8 million (total)  | Direct, indirect, and induced Federal government tax revenues (\$87M from LNG production and \$58M from natural gas).                                                                                                                                                                                                                                                          |
|                           | Labour Income    | \$122 million (annual)   | Wages across direct, indirect, and induced employment annually during Operation.                                                                                                                                                                                                                                                                                               |

### 17.9.5 Proposed Mitigation Measures by Proponent

FortisBC identified the mitigation and enhancement measures, in [Table 7.10-14 of the Revised Application](#), related to employment and economy which include:

- Implement cultural awareness programs, which may include training, to acknowledge, respect and understand that Indigenous nations, employees, consultants, and contractors have unique histories, cultures, protocols, values, beliefs, and governments;

<sup>64</sup> For additional information on the expected tax revenue please see [Section 7.10 of the Revised Application](#), and [Tilbury Phase 2 Memo 3 PwC Economic and GHG Analysis – 2021-04-13](#).

- Engage with potentially affected Indigenous nations for the purpose of outlining work packages that are available for Indigenous-affiliated companies to undertake, as well as the skills necessary for the work. These discussions will take place well in advance of when the work needs to be done, to provide Indigenous nations with opportunities to qualify and bid for the work. Encourage Indigenous businesses to prequalify for medium- and high-risk work when businesses can gain experience working on construction or operation of components of the project, or on other contracting opportunities in advance of the project. Specific commitments in confidential agreements with individual Indigenous nations may also include information for nation owned or affiliated companies wishing to participate in contracting for the project;
- Continue to work with Indigenous nations to identify economic opportunities, to identify current capacity, and to identify how Indigenous groups and nations may be included in project construction, operation, and decommissioning. Efforts will be made with advanced notice to allow for the Indigenous nations to address these needs and opportunities;
- Prohibit the collection of heritage resources by project personnel and implement the site-specific Archaeological Chance Find Management Guide through engagement with participating Indigenous nations should resources be identified during construction;
- Encourage the use of local and regional human resources in design, planning, Construction, restoration, and Operation, to the extent practical;
- Promote awareness of local and regional business opportunities through the timely dissemination of information regarding project service and supply requirements. Continue communications with community stakeholders;
- Engage with potentially affected Indigenous nations to outline available work packages for Indigenous-affiliated companies and the skills necessary for the work, well in advance of when the work needs to be done;
- Support local training initiatives and opportunities to support the development of project-relevant skills;
- Implement FortisBC's Human Resource Policy to recruit workers for the project, targeting groups that are traditionally underrepresented in the construction labour force, including women, Indigenous workers, and new immigrants;
- Receive, record, investigate, and follow-up on complaints from Indigenous nations, the public, and adjacent businesses regarding project-related disturbances;
- Communicate project activities, safety measures, and emergency response measures to Indigenous nations, the public, and stakeholders through different media and forums;
- Implement the construction-related mitigations listed in the CEMP to ensure project effects are managed throughout the construction phase; and
- Develop and implement a Net-Zero Plan that utilizes Best Available Technology (BAT) to ensure the project's direct operational GHG emissions follow government policies and regulations.

These measures are intended to maximize positive outcomes, such as increased employment and revenue, while minimizing any potential negative impacts on the local and regional economy and labour force.

As part of the substituted process, the EAO has identified KMM for effects within federal jurisdiction to inform the IAAC's draft potential federal conditions. The KMM related to employment and economy VC are outlined in [Appendix 2](#).

### 17.9.6 Key Issues Raised

Based on a review of the Application and with feedback from the TAC, participating Indigenous nations (PINS), and the public, the following key issues related to the assessment of the employment and economy VC for Tilbury Phase 2 were identified.

#### 17.9.6.1 Impacts on Indigenous and Underrepresented Groups Employment and Economic Opportunities

Richmond, Quw'utsun Nation, Employment and Social Development Canada, IAAC, TWN, Tsawwassen First Nation, x̣ṃəθḳẉəỵəm, Snuneymuxw First Nation, Ts'uubaa-asatx, and the Ministry of Post-Secondary Education and Future Skills (PSFS), requested more information on how the Tilbury Phase 2 would benefit First Nations and underrepresented communities through employment, training, and economic opportunities. While there were shared concerns about fair access to jobs, targeted training programs, and procurement opportunities, many Nations emphasized issues specific to their own communities.

For example, Quw'utsun Nation sought clarity on how Tilbury Phase 2 would impact their ongoing economic practices, such as fishing, within the LAA. TWN and x̣ṃəθḳẉəỵəm raised concerns about protecting and engaging in traditional economic activities, such as fishing, and ensuring project activities would not negatively affect their rights and interests. x̣ṃəθḳẉəỵəm requested the proponent consider how Tilbury Phase 2 could affect fishing rights, particularly in terms of ensuring people have the time and opportunity to participate in this traditional economy. They proposed a cultural leave policy to support their request. Tsawwassen First Nation and Snuneymuxw First Nation highlighted the need for targeted training programs that align with their workforce development goals. Quw'utsun Nation and Snuneymuxw First Nation specifically questioned whether Indigenous People would receive priority for training and employment and how barriers to workforce participation would be addressed. Additionally, cultural competence among hiring managers was identified as essential to fostering an inclusive and supportive work environment.

In response, the FortisBC acknowledged that past projects and activities have constrained Indigenous peoples' ability to use the land and water in the local assessment area. It is the proponent's view that the negligible or low magnitude changes to noise and other sensory conditions are not expected to affect indigenous rights to fish. The proponent reiterated that the removal of the Marine Offloading Facility from Phase 2 will result in no in-river work occurring in the Fraser River, reducing impacts to Indigenous economic practices and rights related to fishing and activities on the water. Nations have requested continued engagement with the Proponent to ensure that potential impacts on Indigenous rights and economic interests are understood and addressed through effective, proactive, and culturally appropriate mitigation measures.

FortisBC used GBA Plus to assess how Tilbury Phase 2 may disproportionately affect underrepresented groups, including Indigenous peoples, women, racialized communities, newcomers, and people with disabilities. The analysis acknowledged that systematic inequalities, such as those rooted in settler colonialism, social exclusion, and economic marginalization, can compound vulnerabilities and influence access to employment and economic opportunities. The proponent identified that racialized communities in METRO VAN experience lower median incomes and higher rates of part-time or seasonal work; newcomers face barriers such as credential recognition and discrimination; and women are overrepresented in lower-wage sectors and face advancement barriers. Tilbury Phase 2 may also contribute to increased housing demand, which could disproportionately affect low-income households. While these effects were acknowledged, Quw'utsun Nation raised concerns that the analysis did not sufficiently reflect the lived realities and intersectional experiences of Indigenous peoples, particularly in relation to identity, place, and cultural context. Quw'utsun Nation and FortisBC also recognized that there are some data gaps, particularly detailed data for First Nation communities, and that benefits may not be evenly experienced by all First Nations and residents near the project.

FortisBC has committed to engaging and working with indigenous and local communities to create fair and accessible employment and training opportunities, including the development of indigenous participation plans with project contractors. FortisBC also committed to work collaboratively with SkilledTradesBC to identify educational and training opportunities on Tilbury Phase 2, with programming specifically for Indigenous communities in trades.

In consideration of these issues and FortisBC's commitments, the EAO has proposed Condition 17 (First Nation and Local Economic Inclusion and Monitoring Plan) to support access to employment and training associated with the project by members of First Nations and local communities. This includes seeking to recruit workers that are traditionally underrepresented in the construction labour force, including women, Indigenous workers, and new immigrants.

The EAO notes that disproportionate effects on distinct human populations, including underrepresented groups, such as Indigenous communities, women and immigrants, are further assessed in [Appendix 8 – Human and Community Well-Being](#).

#### **17.9.6.2 Workforce Availability Impacts on Housing Costs and Availability**

Employment and Social Development Canada (ESDC), x̣ẉməθḳẉəỵəm, and Quw'utsun Nation raised concerns that professional or skilled trades workers may need to be sourced from outside the RAA and the possibility of this affecting already high housing costs and availability.

FortisBC committed to prioritizing and supporting hiring local labour for Tilbury Phase 2. They anticipate that most of the required workers can be sourced within the region, with only a small percentage of the construction workforce expected to come from outside the RAA due to a local skilled trades shortage.

According to ESDC, if more than the anticipated amount of labour comes from outside of the region, and the additional labour force relocates for employment, it could create additional strain on services such as early learning and child care (ELCC). Already characterized by limited spaces and long waitlists, additional populations may not be able to be served by the ELCC system. ESDC further notes that the temporary/cyclical nature of work rotations for project workers, the lack of child care options may prevent some tradespeople, especially women, from becoming and staying employed for the duration of this project. ESDC indicates that increasing the number of spaces through the Canada-wide Early Learning and Child Care system would help alleviate this pressure and that communities surrounding the project may also want to consider increasing access to flexible child care for shift work (e.g., overnight and non-standard hours).

The EAO notes that the assessment of potential project effects on “Housing and Accommodation” has been considered as part of [Appendix 6.11, Section 17.11](#) (Infrastructure and Services). The EAO has proposed Condition 17 (First Nation and Local Economic Inclusion and Monitoring Plan) which directly relates to the issue by enhancing First Nations and Local Employment.

#### **17.9.7 The EAO's Characterization of Residual Effects**

After considering FortisBC's assessment, the proposed mitigation measures and conditions proposed, the information contained in the [Joint Permitting/Regulatory Coordination Plan](#) and the [Regulatory Coordination Issues Tracking Table](#), for Tilbury Phase 2 the EAO concludes that there would be no adverse residual effects on the employment and economy VC for the following reasons:

- The workforce for the Project is expected to be primarily sourced from Metro Vancouver;
- Tilbury Phase 2 is anticipated to generate positive effects on local and Indigenous employment and income, as well as contribute to increasing local, provincial, and national economic growth and government revenues;

- Mitigation and enhancement measures outlined in the Revised Application, including commitments to ongoing engagement and collaboration with local and Indigenous communities to ensure access to meaningful employment, training opportunities, and related support; and
- With the implementation of the mitigation and enhancement measures identified, no measurable adverse residual effects on employment and economy are anticipated.

If issued, the EA Certificate will require FortisBC to develop and implement a First Nation and Local Economic Inclusion and Monitoring Plan as Condition 17 to further support these outcomes.

No additional characterization of residual effects was completed for employment and economy.

#### 17.9.8 Cumulative Effects Assessment

The Revised Application and the EAO's assessment determined that the Project would not result in residual adverse effects to employment and economy. As no residual effects were identified for the employment and economy VC, a cumulative effects assessment was not warranted.

#### 17.9.9 Conclusion

The EAO is satisfied that Tilbury Phase 2 would not have significant adverse residual or significant cumulative effects on the employment and economy VC. The extent of significance for federal effects to the health, social, and economic conditions of Indigenous peoples are found in [Appendix 15](#). This conclusion considers the information and analysis presented in this section; the views of the TAC, First Nations, and FortisBC; the proposed provincial Table of Conditions including, Condition 16; and federal Key Mitigation Measures and Follow-up Programs under the IAA for the health, social, and economic conditions of Indigenous peoples ([Appendix 2](#)).

The EAO also acknowledges that Tilbury Phase 2 would contribute to a number of positive effects to employment and the economy in the region, including:

- Increased regional employment;
- Increased regional economic activity (e.g., the gross domestic product);
- Increased government revenues in the form of taxes and royalties;
- Economic potential for regional businesses, including opportunities for increased revenues, and opportunities for establishing new businesses; and
- Increased consumer spending from direct, indirect and induced workforce.

## 17.10 Land and Resource Use

### 17.10.1 Summary

Land and resource use was identified as a VC for the Tilbury Phase 2 LNG Expansion Project (Tilbury Phase 2 or Project) environmental assessment due to the potential for effects from the Project on the surrounding area. The assessment of land and resource use considered effects to private property, agriculture, tenure and licenced resource use, public land and resource use, parks and protected areas, and visual quality.

The key issue raised by reviewers was potential effects to Indigenous peoples' use and enjoyment of lands and tenures. This included how First Nations perspectives and knowledge were incorporated into the assessment, their abilities to exercise rights near the Project, and the effectiveness of mitigation measures.

The EAO has proposed that the proposed Certificate Condition 12 (CEMP) and Condition 13 (OEMP) to require consultation on the implementation of mitigation measures proposed by FortisBC (Proponent). The EAO has also proposed Condition 3 (Document Development) which will require a schedule for evaluating the effectiveness of mitigation measures included in the CEMP and OEMP.

The EAO assessed potential effects on land and resource use based on the Proponent's assessment, proposed mitigation, and Certificate conditions. While some residual effects—such as changes to tenure use and visual quality—were identified, they were not considered significant. Cumulative effects from Tilbury Phase 2 in combination with other projects were also assessed and found not to be significant.

### 17.10.2 Assessment Boundaries

The spatial boundaries for the land and resource use assessment include the following:

- The Project Footprint – the area directly disturbed by the project activities;
- Local Assessment Area (LAA) – The land and resource use LAA includes the boundaries of Delta, B.C. and Richmond, B.C., in a 5-km radius from Tilbury Phase 2's footprint, directly north and across the Fraser River. The LAA includes a section of the lower Fraser River from east of Annacis Island to east of Kirkland Island and includes Westham Island.
- Regional Assessment Area (RAA) – The land and resource use RAA includes the boundaries of Metro Vancouver (METRO VAN)

There are three temporal boundaries used for Tilbury Phase 2 land and resource use assessment which are: Construction (3-6 years); Operation (40+ years); and Decommissioning (2 years).

Project components and anticipated duration of activities are described in detail in [Section 1.2](#) (Project Description and Schedule) of this Report.

### 17.10.3 Existing Conditions by Proponent

The assessment of land and resource use conditions was completed using a combination of desktop reviews, information gathered through engagement activities, and available and approved Indigenous knowledge. It also incorporated visual and sensory elements that influence how land and water are experienced and valued.

These conditions are those most likely to interact with Project activities and contribute to potential effects on land and resource use, as discussed in [Section 7.11.4](#) of the Revised Application.

#### Project Location and Land Use Context

The Project is located on Tilbury Island in Delta, B.C., within METRO VAN. The Project Footprint lies on private land owned by FortisBC. Tilbury Island is zoned for industrial use, and includes warehouse operations, manufacturing, cement production, and marine terminals.

Surrounding land uses include agriculture, conservation and recreation, and urban development. Across the Fraser River in Richmond, similar industrial, agricultural and urban uses are present.

#### Cultural and Recreational Significance

The Fraser River, adjacent to the Project Footprint, supports commercial marine transportation, commercial, Indigenous and recreational fisheries, and boating and other recreational activities. The river holds deep cultural and economic importance for First Nations. However, cumulative effects from urbanization and industrialization have altered the landscape and the river and reduced access to traditional lands and resources. First Nations continue to assert rights to fishing, hunting, and cultural practices, though these are increasingly constrained by development and regulatory pressures. First Nations consistently expressed concerns with potential effects to fisheries and fishing rights related to the project and surrounding development, as well as to the Historic Indigenous Village Site.<sup>1</sup>

#### Visual Resources and Landscape Setting

The visual landscape includes a mix of natural and industrial features—foreshore vegetation, the Fraser River, industrial infrastructure, and distant mountain views. Existing visual quality was assessed from publicly accessible Key Observation Points (KOPs), with sensitivity to visual change rated as low to moderate. Areas with residential, recreational, or Indigenous cultural use had higher sensitivity. Indigenous nations emphasized that views are integral to cultural identity and well-being, with Tsawwassen First Nation highlighting the importance of landscape to social and human health.

#### Lighting and Nighttime Conditions

Existing lighting from nearby industrial facilities contributes to varying levels of nighttime brightness. While most KOPs showed low light trespass typical of rural or industrial areas, one KOP on Tilbury Island exhibited a high level of brightness due to street and facility lighting. Skyglow from Metro Vancouver also affects nighttime visibility across the area.

#### Sensory Environment

- **Air Quality:** Generally good, although localized Nitrogen dioxide (NO<sub>2</sub>) and Particulate Matter (PM) levels are elevated due to industrial activity and traffic. Odour complaints in the area have been linked to nearby waste and composting facilities.
- **Ambient Sound:** Noise sources include road traffic, industrial operations, and marine vessels. Sound levels near the Project range from 58–62 dBA (urban) to 53–57 dBA (suburban), depending on proximity.
- **Surface Water Quality:** The Fraser River has high sediment loads and low visibility, affecting navigation and recreation. Water quality is influenced by natural erosion, agricultural runoff, and treated municipal wastewater discharges.

Changes to sensory conditions—particularly noise, light, and air quality—have been identified by Indigenous Nations as affecting current use and cultural health.

#### Land Tenure and Use Designations

The LAA includes 633 active Crown tenures, including:

- Industrial leases and marine navigation reserves;
- Cultural significance tenures (e.g., Historic Indigenous Village Site across the river);
- Utility and pipeline rights-of-way (e.g., FortisBC, BC Hydro);
- Transportation corridors (roads, rail);
- Marine tenures (wharves, float homes, marinas); and

- Environnemental tenures (parks, conservation lands).

#### Planning and Regulatory Context

The Project is subject to municipal permitting and BCER guidelines, including those addressing visual impacts and lighting. The EAO has assessed the Project's consistency with applicable land use plans in [Appendix 11](#) (Consistency of the Project with Land Use Plans).

#### 17.10.4 Potential Project Effects by Proponent

FortisBC considered changes to land and resource use activities would occur due to Tilbury Phase 2, including from Project components (e.g. height of the LNG Storage Tank and Totally Enclosed Ground Flare (TEGF)) and activities (e.g., increased traffic, temporary road closures, increased light scatter), and the interaction of effects in other VCs such as acoustic and air quality could interact with land and resource use. FortisBC's assessment considered effects to the following land and resource subcomponents:

- **Private Property:** Construction and operational activities could impact air quality, generate noise and odors, increase light pollution and cause temporary disruption to property access.
- **Agriculture:** Agricultural areas around the Project site consist of crops and some livestock operations within 2km radius. Noise and odour effects are expected to be minimal, and dust from construction activities and vehicle traffic is expected to remain localized with limited offsite effects.
- **Tenures and Licensed Resource Use:** Air emissions, noise, and light from the Project could affect the sensory experience at the Historic village site across the Fraser River particularly if long-term occupation of the tenured site occurs in the future. Construction and Operation may cause temporary disruptions to access due to traffic along River Road and other routes, especially during peak construction periods.
- **Change to the Use and Enjoyment of Public Lands and Water:** The use of public lands, waters, and resources in the LAA includes both consumptive uses, such as fishing, hunting, and gathering, and nonconsumptive uses, such as boating, walking, bicycling, and wildlife viewing. The Project has the potential to affect the quality of experience for people engaged in activities on public lands and waters. The effects pathways include potential sensory effects from the Project's air emissions (including odours), noise, and light, as well as changes in access to public areas.
- **Parks and Protected areas:** Increased traffic during construction may cause delays along River Road, which could affect access to Deas Island Park and Dow Delta Bar Fishing Park.
- **Visual Quality:** Construction and Operation will alter views from nearby public viewpoints and areas along the Fraser River. Visual changes during the day will occur during Construction from temporary visibility of equipment, lighting, and activities and in Operation from the LNG Storage Tank and Totally Enclosed Ground Flare. At night, lighting at the project site may be seen. Visual effects will be more pronounced from the Historic village site across the Fraser River.

#### 17.10.5 Proposed Mitigation Measures by FortisBC

FortisBC identified mitigation measures for land and resource use in [Table 7.11-6](#) of the Revised Application, which include:

- Implement a documented, regular inspection and maintenance program to ensure all equipment is in proper working order;
- Notify Indigenous nations whose traditional territories overlap with the project, as well as stakeholders, before the commencement of construction;
- Develop and implement a communications process with adjacent businesses;

- There will be no waterborne deliveries of modular components or construction materials to the project site, and no MOF will be required;
- Use of TEGF technology to reduce noise and light from flaring;
- Lighting for the Project will be designed in a manner that is consistent with the Light Control Best Practices Guideline (BCER 2024);
- Develop and implement a refuelling and spill response plan to be incorporated into the CEMP;
- Develop erosion and sediment control measures in consultation with Indigenous nations and a QP to manage surface water and sediment deposition;
- Implement soil-management practices to manage the introduction and spread of invasive Noxious plant species;
- Develop dust-control measures to be described in the CEMP to limit particulate matter emission during the construction phase;
- Communicate project activities, safety measures, and emergency response measures to Indigenous nations, the public, and stakeholders through different media and forums;
- Receive, record, investigate, and follow-up on odour and noise complaints from Indigenous nations, the public, and adjacent businesses;
- All compressors will be enclosed to attenuate noise to a level consistent with the BCER noise regulations;
- Develop mitigation and contingency measures through engagement with a QP to manage acoustic disturbance to human and wildlife receptors;
- Develop and implement a vehicle idle reduction policy that focuses on reducing noise and vibration emissions from construction vehicles. These measures are to be incorporated into the CEMP; and
- Implement all construction-related air emission mitigations and compliance requirements as outlined in the CEMP and Environmental Management System.

#### 17.10.6 Key Issues Raised

Based on a review of the Application and with feedback from the TAC, participating Indigenous nations, and the public, the following key issues related to the assessment of the land and resource use VC for Tilbury Phase 2 were identified.

##### 17.10.6.1 Potential Effects and Impacts to Indigenous Rights

Quw'utsun Nation raised concerns regarding inadequate recognition of their interests and integration of First Nation perspectives, rights, traditional practices, governance and stewardship related to the land and resource use VC, particularly as it relates to the Historic Village site directly across the river from the project site. FortisBC notes that there is language in the Revised Application regarding future planning for the Historic Village site by Indigenous nations. In addition, the Revised Application includes updated text regarding the Quw'utsun Nation Declaration for Reconciliation for the site and the Cultural Significance tenure (the tenure is the site of the historic Indigenous village) identified by Quw'utsun Nation as an important place for conducting resource harvesting activities, cultural practices, and economic participation.

Many Indigenous nations also expressed concerns about air pollution and excess noise from existing development in the area and the project. FortisBC noted that the Historic Village site has been included in the air and noise assessments, at the request of Quw'utsun Nation and other First Nations, due to its cultural importance as well as a receptor site for the visual quality, and for the assessment of effects to ambient air quality and noise.

Numerous First Nations, including Cheam First Nation, Kwantlen First Nation, Katzie First Nation, k'wik'əłəm First Nation, x'wəθk'əyəm, TWN, Quw'utsun Nation, the STSA, Semiahmoo First Nation, Snuneymuxw First Nation, and Tsawwassen First Nation, raised specific concerns regarding the potential effects of the project on First Nation access to the site, or areas close to the site for harvesting and cultural practices.

These concerns are situated within an already severely constrained baseline for utilizing traditional resources in the Lower Mainland region, largely due to the cumulative impacts from past and present industrial projects and activities. This high level of existing development and industrialization means that First Nations engaged in land and water based cultural practices are particularly disproportionately affected by subsequent minor changes in the environment, including effects on fish and fish habitat which are foundational to cultural practices.

FortisBC believes that the mitigation measures are sufficient to mitigate the potential effects from the Project on land and resource use, and it will engage with First Nations in the development of related management plans.

The EAO proposed that, if issued, the Certificate includes Condition 3 (Document Development) which outlines requirements for mitigation effectiveness evaluations and adaptive management. Condition 3 is applicable to Conditions 12 (CEMP) and 13 (OEMP), which will require the implementation of the mitigation measures identified in the Revised Application applicable to land and resource use, as well as measures to address visual quality.

### 17.10.7 The EAO's Characterization of Residual Effects

After considering the proposed mitigation measures and conditions, the information contained in the [Joint Permitting/Regulatory Coordination Plan](#) and the [Regulatory Coordination Issues Tracking Table](#), the EAO concludes that the Project would result in the following residual adverse effects on the land and resource use:

- Changes to use of tenures and licensed resource uses.
- Change to visual quality of the landscape.

The EAO's characterization of the expected residual effects of the Project on land and resource use is summarized below in Table 62, as well as the EAO's level of confidence in the effects determination (including their likelihood and significance).

Table 62: Summary of Residual Effects for Land and Resource Use

| Residual Effect                                      | Assessment Rating*                                                                                                                                                                                                                                                                     | Significance and Rationale                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Changes to use of tenures and licensed resource uses | Context (resilience): Low<br>Magnitude: Low<br>Extent: Local<br>Duration: Medium-term<br>Frequency: Regular<br>Reversibility: Reversible<br>Affected Populations: Disproportionate<br>Risk (likelihood and consequences): Moderate<br>Uncertainty: Low<br>Importance: Moderate to High | <b>Not significant</b><br>Land and resource use has been severely affected by industrial development on Tilbury Island and surrounding areas. A First Nation historical site is in Richmond, B.C., on Lulu Island's shoreline, across the Fraser River from the project site. This historical First Nation village that has been identified as an important location to First Nations, and it represents an area of Indigenous value.<br>The receiving environment is already stressed due to industrial development, indicating potentially lower resilience to further land and resource use loss or alteration.<br>Increased light will be noticeable at the Historic Village site; however, the residual effect is expected to be mostly adjacent to existing disturbance, which will be mitigated and of low magnitude.<br>The effects are considered reversible and will cease when the Project is decommissioned.<br>Effects on land and resource use would be disproportionately experienced by First Nations. |

| Residual Effect                                                                                                                   | Assessment Rating*                                                                                                                                                                                                                                                                                                                   | Significance and Rationale                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|                                                                                                                                   |                                                                                                                                                                                                                                                                                                                                      | <p>The likelihood of the effect is medium, as mitigation is expected to be effective, and the consequences are moderate due to the medium-term duration and low magnitude. Therefore, the overall risk is moderate.</p> <p>Uncertainty is low. The link between changes in use of tenure and licensed resources is well understood, and the proposed mitigation measures are expected to be moderately to highly effective.</p> <p>Importance is moderate to high as land and resource use is linked to the exercise of protected Indigenous rights and the maintenance of cultural integrity. The potential for changes to tenure and licensed use was not identified as a concern by local communities and residents</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Change to visual quality of the landscape                                                                                         | <p>Context (resilience): Low</p> <p>Magnitude: Low</p> <p>Extent: Local</p> <p>Duration: Medium-term</p> <p>Frequency: Continuous</p> <p>Reversibility: Reversible</p> <p>Affected Populations: Disproportionate</p> <p>Risk (likelihood and consequences): Moderate</p> <p>Uncertainty: Low</p> <p>Importance: Moderate to High</p> | <p><b>Not significant</b></p> <p>The Project area has low resilience to further changes due to the Tilbury LNG facility and other industrial activities that impact on key viewing locations associated with residential, recreational, and First Nations cultural use, which are integral to land use activities</p> <p>Residual effects after the application of proposed mitigation measures would generally create a minor degree of visual contrast with the existing landscape and a change from existing perceived lighting conditions, that would be characteristic of the existing, predominately industrial, landscape character.</p> <p>Existing and expected projects, industrial activities, transportation, and other activities contribute to the visual alteration of the landscape in the LAA. While the Project will be visible in the LAA it is not dissimilar to existing infrastructure on Tilbury Island. The residual effect is expected to be mostly adjacent to the Project Site, and directly across from the Fraser River, and is of low magnitude.</p> <p>The effects are considered reversible when the Project is decommissioned.</p> <p>Effects on land and resource use would be disproportionate, affecting both First Nation communities, residents and recreational users.</p> <p>The likelihood of the effect is medium, as mitigation is expected to be effective, and the consequences are moderate due to the medium-term duration and low magnitude. Therefore, the overall risk is moderate.</p> <p>Uncertainty is low. The link between changes in visual quality is well understood, and the proposed mitigation measures are expected to be moderately to highly effective</p> <p>Importance is moderate to high; while not a primary concern for local residents, this rating acknowledges that visual effects are disproportionately experienced by First Nations and are intrinsically linked to cultural integrity.</p> |
| * Note: Criteria and assessment ratings are defined in <a href="#">Appendix 3 - Residual Effects Characterization Definitions</a> |                                                                                                                                                                                                                                                                                                                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

### 17.10.8 Cumulative Effects Assessment

The assessment of a designated project must consider any cumulative effects that are likely to result from the Project in combination with other physical activities that have been or will be carried out.

The following pathways were assessed further to assess cumulative effects to land and resource use in [Section 7.11.5](#) of the Revised Application:

- Change to the use of tenure and licensed resource use; and
- Change to the visual quality of the landscape.

Table 7.11-9 of the Revised Application provides a full accounting for all the projects and activities considered in the cumulative effects assessment that may interact with Tilbury Phase 2. These projects and activities include T1B, TMJ, Delta Grinding Facility Project, natural hazards (e.g. flooding), and climate change.

Tilbury Phase 2 is located primarily within a heavily disturbed industrial landscape, where the effects of industrialization are widespread and expected to persist. Ongoing pressures from other projects and the effects of climate change are also likely to contribute to the decreased accessibility and use of land and resources to the full extent possible and change the visual quality of an already highly impacted industrial zone.

Given the footprint and scope of Tilbury Phase 2, any residual effects related to land and resource use are expected to be low in magnitude and would occur mainly during the Construction and Operation phases of the project. The Construction phase potentially has an increased level of impact due to the overlap with periods of activity from other projects in the region. Tilbury Phase 2, TMJ, and Delta Grinding Facility will likely cause associated changes to air contaminants and sensory conditions due to project-related lighting. The magnitude of the effects associated with these interactions may shift as the various projects transition from Construction to Operation phases.

The RAA continues to experience long-term cumulative effects on land and resource use from ongoing and reasonably foreseeable industrial and transportation activities, including reduced accessibility, changes to visual quality, and other pressures typical of a heavily industrialized landscape; see local government and port authority land use plans, [Appendix 11](#). These cumulative conditions reflect decades of development and are expected to persist irrespective of Tilbury Phase 2 (see Section 17.10.3 Existing Conditions by Proponent). The incremental contribution of Tilbury Phase 2 to this broader cumulative context is expected to be minor, with residual effects largely limited to the Construction and Operation phases and reversible upon decommissioning.

Accordingly, based on the documented existing industrial and transportation context of the RAA and the limited magnitude of Project residual effects, Tilbury Phase 2 is not predicted to cause an adverse cumulative effect on the Land and Resource VC when considered in combination with past, present, and reasonably foreseeable future projects and activities.

The EAO acknowledges that effects to First Nations' rights and interests are closely linked to existing and proposed land use activities. More information about the predicted cumulative effects to each First Nation's rights and interests due to Tilbury Phase 2 can be found in their respective sections of this Report.

#### 17.10.9 Conclusion

The EAO is satisfied that Tilbury Phase 2 would not have significant adverse residual or significant cumulative effects on the land and resource use VC. The extent of significance for federal effects on the current use of lands and resources for traditional purposes are found in [Appendix 15](#). This conclusion considers the information and analysis presented in this section; the views of the TAC, First Nations, and FortisBC; the proposed mitigation measures identified in the provincial Table of Conditions including, Condition 3 (Document Development), Condition 12 (CEMP) and Condition 13 (OEMP).

## 17.11 Infrastructure and Services

### 17.11.1 Summary

The Infrastructure and Services VC was selected to represent the potential interactions of the Project components and activities with local and regional infrastructure. The assessment identified adverse effects of Tilbury Phase 2 on the Infrastructure and Services VC and developed proposed mitigation measures to reduce or avoid these effects, ensuring Tilbury Phase 2's interaction with community infrastructure and services does not lead to significant negative impacts on people and communities in the area.

The assessment considered two main subcomponents: community infrastructure and services and transportation infrastructure subcomponents. These included potential effects related to the availability and cost of housing and accommodation, the demand on healthcare, recreation, education and childcare, the demand on emergency response services, effects on domestic water supply, landfills and recycling facilities, transportation infrastructure and safety, and effects on dikes and other flood protection systems.

The key issues raised by reviewers include Tilbury Phase 2's potential impacts on traffic and transportation infrastructure, and housing availability and affordability.

To address these concerns, the EAO proposed Condition 12 CEMP and Condition 16 (First Nation and Local Economic Inclusion and Monitoring Plan).

The EAO concluded after the implementation of mitigation measures and proposed conditions no significant adverse effects to infrastructure and services are expected from Tilbury Phase 2.

### 17.11.2 Assessment Boundaries

The spatial boundaries for the assessment of effects on infrastructure and services included:

- The Project Footprint, which is the area directly disturbed by Project activities, including associated physical works and activities.
- The Local Assessment Area (LAA): includes Delta, Richmond, and the shoreline from the western edge of Garry Point Park to Shoal Point on Annacis Island.
- The Regional Assessment Area (RAA): includes the boundaries of Metro Vancouver.

The temporal boundaries for Infrastructure and Services include the Construction (3-6 years), Operation (40 plus years), and Decommissioning (2 years) Phases of Tilbury Phase 2.

Tilbury Phase 2 components and the anticipated duration of activities are described in detail in [Section 1.2](#) (Project Description and Schedule) of this Report.

### 17.11.3 Existing Conditions by the Proponent

The existing conditions for the Infrastructure and Services VC were described in [Section 7.12](#) and [Appendix R](#) of the Revised Application by the Proponent and are summarized here.

Utilities across the LAA and RAA include critical infrastructure such as water supply, sewage systems, electrical power, natural gas, and communication networks. These utilities vary in capacity and coverage, with some areas relying on municipal services while others depend on private systems like wells and septic tanks. The assessment indicates that the infrastructure is generally adequate to meet current demands.

Housing in Metro Vancouver is limited and unaffordable. Population growth and rising real estate prices make living costs high. Affordability issues disproportionately affect vulnerable groups, including seniors and those on public assistance. Short-term accommodation (hotels, motels, Bed and Breakfast (B&B)s, campgrounds) has declined since the early 2000s despite rising demand.

Short-term rentals (Airbnb, VRBO) are increasing, especially in Vancouver, raising concerns about competition with long-term housing.

The transportation network within the Project area includes provincial highways (Highway 17, 17A, 91, and 99) and major municipal roads such as River Road and Ladner Trunk Road. Access to the Tilbury Phase 2 site in Tilbury Island from River Road is primarily via Hopcott Road, with MacDonald Road providing an alternative route to the west.

Traffic data collected in June 2022 for River Road between MacDonald St. and Hopcott Road revealed an average weekday two-way traffic volume of approximately 16,040 vehicles per day. Parking is limited to private lots, a few public spots, and permitted roadside areas, including Hopcott Road. Large trucks often park along Tilbury Road.

Currently, healthcare and social services are experiencing challenges due to a shortage of family doctors. Access to primary care is highly constrained in Delta and Metro Vancouver, with an aging population expected to add to an increase in demand for healthcare. Lack of access to family doctors puts pressure on walk-in clinics and emergency services, leading to delayed diagnoses.

There are concerns regarding the current capacity of emergency response services due to the area's large land area, increase in population, emerging health issues (opioid crisis), and traffic congestion.

In terms of waste management, the region is served by a combination of municipal collection services, regional landfills, and transfer stations. The capacity of these facilities is considered sufficient for current needs, with no extensive capacity issues reported. However, the future growth and potential impacts of Tilbury Phase 2 on waste generation and management are noted for further consideration.

The educational services are not currently experiencing demand constraints. However, childcare services in the LAA and RAA are identified as being inadequate to meet current demand, with a very limited supply of spaces available. Tilbury Phase 2 related employment could potentially increase demand for childcare, but not beyond the existing constraints.

#### 17.11.4 Potential Project Effects by Proponent

The activities associated with the Construction, Operation, and Decommissioning Phases of Tilbury Phase 2 have the potential to interact directly and indirectly with two subcomponents of the Infrastructure and Services VC, community infrastructure and services and transportation infrastructure.

The community infrastructure and services subcomponent considers potential effects on the capacity of municipal and regional facilities and services. These facilities and services include housing and accommodation, health care and social services facilities, emergency response services, domestic water supply, sewage/water treatment facilities, utilities, landfills and recycling facilities, community recreational facilities, and educational services and facilities, including childcare.

The transportation infrastructure subcomponent considers potential effects associated with roads and traffic, including potential changes in road access, increased traffic, and parking changes. No potential effects are expected on sewage/water treatment facilities and utilities as no additional sewage/water treatment and power or other utilities are required for Tilbury Phase 2.

The effects pathways were identified during engagement with the TAC, First Nations, and the public during the EA process. Table 63 below summarizes potential effects and effects pathways by project phase, as identified in the Revised Application.

Table 63: Potential Effects, Indicators and Effect Pathways for Infrastructure and Services Identified in the Revised Application

| Potential Effect                                                     | Effect Indicator                                                                   | Project Phase                    | Potential Effects and Effect Pathways as Identified in the Revised Application                                                                                                                                                     |
|----------------------------------------------------------------------|------------------------------------------------------------------------------------|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Increase in demand for housing and accommodation                     | Availability and cost of housing and accommodation                                 | Construction and Operation       | Movement of workers into Tilbury Phase 2 area for construction and operation activities could potentially increase the demand for housing and accommodation, resulting in rising prices and reduced affordability                  |
| Decreased capacity in the delivery of healthcare and social services | Availability of Healthcare and Social Services                                     | Construction and Operation       | Workers moving temporarily to the Project site may require services from walk-in clinics or local healthcare providers, adding to existing constraints of access to primary care.                                                  |
| Increase in demand for use of recreational facilities and parks      | Availability of recreational facilities and parks                                  | Construction and Operation       | Workers relocating with their families could potentially increase the demand for the use of recreational facilities and parks.                                                                                                     |
| Increase in demand for education and childcare services              | Availability of education and childcare services                                   | Construction and Operation       | The number of people requiring education and childcare may increase with employment and the influx of workers from outside the Project area, contributing to existing demand for childcare services, especially for shift workers. |
| Reduced capacity of emergency response services                      | Number of requests for emergency response services                                 | Construction                     | Potential safety incidents, including malfunctions, accidents, and worker injuries could increase the demand for existing community emergency resources such as the police, fire, and ambulance services.                          |
| Increase in demand for portable water                                | Capacity of domestic water supply                                                  | Construction                     | Demand of water for one-time hydrostatic testing of the LNG tank, dust control and concrete during construction could potentially impact water supply in the Project area.                                                         |
| Reduced capacity of landfills and recycling facilities               | Capacities of landfills and recycling facilities                                   | Construction and Decommissioning | Generation of construction waste and decommissioning waste could put a strain on the existing landfill condition and recycling facilities.                                                                                         |
| Increase in demand for transportation infrastructure                 | Volume of traffic, wear and tear on road infrastructure, limited access to parking | Construction                     | Increase in vehicle movement due to movement of materials, equipment, and workers could potentially lead to an increase in traffic volume, road delays, and limited access to parking.                                             |
| Potential effect on flood protection infrastructure                  | Potential effects to dikes and other flood protection infrastructure               | Construction                     | Potential effects of wake to dikes and other flood protection infrastructure.                                                                                                                                                      |

### 17.11.5 Proposed Mitigation Measures by the Proponent

FortisBC identified mitigation measures applicable to infrastructure and Services in [Table 7.12-18](#) of the Revised Application and committed to their implementation through Tilbury Phase 2 design, procedures, and management plans. Mitigation measures identified include:

- Waste management mitigation measures will be developed and implemented as part of the CEMP. The CEMP will identify appropriate local waste management, recycling, compost, and segregation measures. Waste management will minimize use of municipal waste facilities, if practical. To the extent that use of local landfills is part of that plan, the Tilbury Phase 2 team will engage with them during development of the plan. Non-hazardous solid waste will be recycled, re-used, or collected in a central secure area onsite and then disposed of in a licensed waste receiver facility. Hazardous liquid and solid waste will be collected and stored and transported in accordance with applicable regulations or requirements.
- Measures to encourage the use of multi-passenger vehicles and offsite areas will be developed with the contractors and included in the CEMP, where applicable and appropriate, given the scope of work taking place and construction activities underway.
- Traffic management mitigation measures will be developed and incorporated into the CEMP and OEMP. Contractor personnel will comply with road-use and safety requirements outlined in the CEMP and OEMP, applicable Municipal and Provincial traffic regulations, including truck routes and approved access routes.
- Contribute to the maintenance of roads, as required by applicable permits, such as the Delta Development Permit;
- Ensure there are no waterborne deliveries of modular components or construction materials to the project site, and that no Marine Offloading Facility will be required or utilized;
- Develop emergency response measures to prevent and manage emergencies, including complete onsite fire control and response systems independent of Delta Fire and Emergency Services (DFES). Additionally, FortisBC will maintain an Emergency Response Plan (ERP) with procedures, training, and response plans developed alongside the local, fire, police, and medical services and BCER. The ERP will be tested annually in accordance with the requirements of the BCER. These emergency response measures will be incorporated into the CEMP
- Provide onsite emergency health services to meet or exceed WorkSafeBC requirements.
- Implement worker health and safety educational approaches, including mental well-being, as described in the CEMP to avoid project-related incidents;
- Encourage the use of local and regional human resources in design, planning, construction, restoration, and operation, to the extent practical
- Support local training initiatives and opportunities to support development of project -relevant skills
- Conduct testing and treatment of hydrostatic test water prior to discharge to the Delta storm sewer and ensure contact water captured in sumps is measured for field parameters prior to release into onsite drainage ditches
- Communicate project activities, safety measures, and emergency response measures to Indigenous nations, the public, and stakeholders through different media and forums.
- Contribute to the maintenance of roads, as required by applicable permits (Delta Development Permit).

As part of the substituted process, the EAO has identified KMMs for effects within federal jurisdiction to inform the IAAC's draft potential federal conditions. The KMMs related to the Infrastructure and Services VC are outlined in [Appendix 2](#).

### 17.11.6 Key Issues Raised

Based on a review of the Revised Application and with feedback from the TAC, participating Indigenous nations, and the public, the following key issues related to the assessment of the Infrastructure and Services VC for Tilbury Phase 2 were identified.

#### 17.11.6.1 Traffic and Transportation Infrastructure

Delta, Richmond, xʷməθkʷəyám, and Ministry of Transportation and Transit (MoTT) provided comments relating to transportation and transportation infrastructure.

Delta expressed concern about the potential impacts to parking in the area during construction and roadways during construction, while MoTT provided feedback on route selection and timing, and also identified that consultation should occur with them and the Highway 17 Concessionaire on traffic management plans.

FortisBC stated that mitigation measures would be developed as part of the CEMP relating to traffic management, which will include consultation with Delta and MoTT.

The EAO and Delta identified that a Highway Use Permit may also be required from Delta for the moving of oversized loads, traffic impacts and lane closures related to Tilbury Phase 2.

xʷməθkʷəyám noted concerns regarding changes of access due to road traffic to access to Dow-Delta Bar Fishing Park and Deas Island Regional Park. FortisBC identified that impacts to the parks were considered in [Section 7.11.4.1](#) of the Revised Application.

If issued, the Certificate will require FortisBC to develop and implement a Traffic Management Plan as part of Condition 12 (CEMP) which requires the creation of a CEMP. The CEMP will require consultation with First Nations, MoTT, and Delta, and approval by the EAO, prior to the commencement of construction.

#### 17.11.6.2 Housing

Reviewers identified concerns regarding potential effects of workers arriving from Metro Vancouver being needed for Tilbury Phase 2, and impacting the housing supply or local services, particularly during Construction which has the highest number of expected workers.

FortisBC indicated that it believes it can source workers from the local area and does not anticipate a change in demand for housing and accommodations as a result of Tilbury Phase 2. FortisBC identified support for local training initiatives and regional employment as a mitigation measure to reduce strain on housing, childcare, and healthcare services.

The EAO has proposed that if issued, the Certificate should include Condition 16 (First Nation and Local Economic Inclusion and Monitoring Plan) requiring the development of a First Nation and Local Economic Inclusion and Monitoring Plan to support involvement of First Nation and local employment in Tilbury Phase 2, and to minimize the potential for workers being required from outside of Metro Vancouver. The plan will also include monitoring and reporting requirements to support the ability of First Nations, local governments, training providers, and the Province to maximize positive and decrease potential adverse effects of Tilbury Phase 2.

Also, the EAO notes that provincial government is implementing measures to encourage the expansion of the provincial housing supply. This includes "[Homes for People: An action plan to meet the challenges of today and deliver more homes for people, faster](#)" that was announced on April 3, 2023, and the [Housing Supply Act, 2022](#).

### 17.11.7 The EAO's Characterization of Residual Effects

After considering the proposed mitigation measures and proposed conditions, and the information contained in the [Joint Permitting/Regulatory Coordination Plan](#) and the [Regulatory Coordination Issues Tracking Table](#), the EAO concludes that Tilbury Phase 2 would result in no residual effects for several Infrastructure and Services pathways, and negligible residual effects for the remaining pathways. For the purposes of this assessment, a negligible residual effect is one that does not result in a measurable change from existing conditions, or results in no observable change at all at the scale of the Local or RAA.

Tilbury Phase 2 is not expected to have an impact on the following potential effects, and therefore are not need carried forward for further assessment:

#### No Residual Effects

- Housing availability and cost: The number of workers expected to relocate to Metro Vancouver is very small, and no discernible changes to availability, affordability, or disproportionate impacts on vulnerable subpopulations are anticipated.
- Health care and social services: The small number of relocating workers is not expected to affect access to primary care, specialist care, or social services within the region.
- Recreation facilities and parks: Given the wide availability of urban recreation amenities and the absence of identified cultural and limited public use near the Project footprint, no increase in demand is expected.
- Education and childcare services: Regional systems have sufficient capacity to absorb any incidental demand; no changes to availability, affordability, or access for existing users are anticipated.
- Emergency response services: Tilbury Phase 2 includes onsite first aid, emergency response capabilities, and fire protection systems designed to operate independently of municipal services, avoiding measurable demand on police, fire, or ambulance response.
- Dikes and flood protection infrastructure: The removal of waterborne delivery and the MOF eliminates barge traffic, wake, and prop-wash interactions; no pathway remains for effects to shoreline stability or dike integrity.
- Sewage/water treatment and other utilities: No new or expanded utility or treatment capacity is required, and no interaction with these systems is expected.

#### Potential Negligible Residual Effects

- Domestic water supply
- Landfill and recycling facilities
- Transportation infrastructure and safety

The EAO's characterization of the potential residual effects of the Infrastructure and Services VC is summarized below in Table 64, as well as the EAO's level of confidence in the effects determination (including their likelihood and significance).

Table 64: Summary of Residual Effects for Culture

| Residual Effect                                                                                                                     | Assessment Rating*                                                                                                                                                                                                                                                                       | Significance and Rationale                                                                                                                                                                                                                                                  |

| * Note: Criteria and assessment ratings are defined in <a href="#">Appendix 3 - Residual Effects Characterization Definitions</a> . |                                                                                                                                                                                                                                                                                          |                                                                                                                                                                                                                                                                             |

### 17.11.8 Cumulative Effects Assessment

The assessment of a designated project must consider cumulative effects that may result from Tilbury Phase 2 in combination with other past, present, and reasonably foreseeable future projects and activities. For the Infrastructure and Services VC, only the following residual pathways were carried forward: Domestic water supply, Landfill and recycling facilities, and Transportation infrastructure and safety. Reasonably foreseeable projects in the Local and RAAs include the Tilbury Marine Jetty (TMJ), the Fraser River Tunnel Project (FRTTP), and the Delta Grinding Facility (DGF).

Tilbury Phase 2's water interaction is limited to a single hydrostatic test of the LNG tank ( $\approx 95,000$  cubic meters ( $m^3$ )), undertaken under municipal permits with controlled discharge and testing prior to release. There is no material operational water demand beyond standard domestic use by staff. Given the one-time nature, permitting controls, and the scale of Metro Vancouver's potable supply network, Tilbury Phase 2's contribution to any cumulative draw on domestic water is not measurable. Concurrent or overlapping construction from TMJ, F RTP, or DGF would not materially change this conclusion, as those projects rely on routine municipal supply and do not introduce large, discrete potable demands of the same magnitude within the same short window.

Project construction (and eventual decommissioning) generates typical industrial waste streams managed through the CEMP with diversion and disposal at licensed regional facilities. Relative to Metro Vancouver's established solid waste system, Tilbury Phase 2's incremental volumes are small and absorbed within existing capacity. While TMJ, F RTP, and DGF may each produce construction wastes, these are staggered in time and dispersed across multiple receivers, with each project applying its own diversion plans. In aggregate, the combined contribution does not demonstrably change regional landfill performance or lifespan.

During peak periods of the Construction Phase, Project trucking raises total volumes by less than 1 percent of overall traffic ( $\approx 5$  percent of commercial vehicles during peak weeks) on designated truck routes (e.g., River Road/South Fraser Perimeter Road (SFPR)), with effects managed through a Traffic Management Plan under the CEMP/OEMP. Regional baselines already reflect heavy goods movement in the Tilbury/Lower Fraser corridor. While F RTP construction will contribute substantial corridor activity and DGF/TMJ will add intermittent industrial traffic, these occur on arterials designed for goods movement and are subject to dedicated traffic management and staging. Against this background, Tilbury Phase 2's incremental trucking remains minor, short-term, and reversible, and does not alter network performance or safety trends.

Considering the limited magnitude and duration of Tilbury Phase 2's residual effects, the capacity and management practices of regional systems, and the mitigation applied to reasonably foreseeable projects in the area, the EAO concludes that Tilbury Phase 2 is not predicted to cause adverse cumulative effects on Domestic water supply, Landfill and recycling facilities, or Transportation infrastructure and safety.

#### 17.11.9 Conclusion

The EAO is satisfied that Tilbury Phase 2 would not have significant adverse residual or significant cumulative effects on the Infrastructure and Services VC. The extent of significance for federal effects on the current use of lands and resources for traditional purposes are found in [Appendix 15](#). This conclusion considers the information and analysis presented in this section; the views of the TAC, First Nations, and FortisBC; the proposed mitigation measures identified in the provincial Table of Conditions including, Condition 12 (CEMP), which requires the creation of a CEMP and Condition 16 (First Nation and Local Economic Inclusion and Monitoring Plan) which requires the development of a First Nations and Local Economic Inclusion and Monitoring Plan.

## 17.12 Archeological and Heritage Resources

### 17.12.1 Summary

Archaeological and Heritage Resources include fossils, cultural materials (e.g., campsites, culturally modified trees), historical structures, and burial sites. These non-renewable resources are vulnerable to land-altering activities and hold value for Indigenous communities, the public, and stakeholders.

FortisBC (the Proponent) assessed potential project impacts of Tilbury Phase 2 LNG Expansion Project (Tilbury Phase 2 or Project) to archaeological and heritage resources through a review of provided Indigenous knowledge, desktop reviews of recorded historic and paleontological sites, and Archaeological Impact Assessments under the *Heritage Conservation Act*. Key risks include disturbing previously unidentified sites during construction or decommissioning.

Reviewers also provided comments on the Archeological Chance Find Management Guidelines (CFMG) ([Appendix S](#) of the Revised Application), noting the need for clearer procedures on Ancestral Remains, and discussions for the buffer zone size in the event of chance finds.

As outlined in the [Joint Permitting / Regulatory Coordination Plan](#), pre-1846 archaeological sites are protected under the *Heritage Conservation Act*, which requires permits for site investigation or alteration. To address key issues raised on archaeological and heritage resources, and implement mitigation measures identified in the Revised Application, the EAO has proposed Condition 15, requiring the development and implementation of a Chance Find Protocol.

Based on the assessment, mitigation measures, proposed condition, and permitting requirements, the EAO concluded there would be no significant adverse effects. As no residual effects were anticipated, cumulative effects were not assessed, and no potential cumulative impacts from other projects were identified.

### 17.12.2 Assessment Boundaries

The spatial boundaries for the archaeological and heritage resources assessment included:

- Project Footprint – defined as the area directly disturbed by project activities;
- The Local Assessment Area (LAA): the Project Footprint, which contains areas of proposed and potential ground disturbance, plus a 100-metres buffer around the Project Footprint.
- The Regional Assessment Area (RAA): the area of the LAA and the south arm of the Fraser River from the proposed Project Footprint, downstream to Sand Heads, upstream to Annacis Island, and extending 1 km inland from the north and south shores of the river.

The temporal boundaries for Archaeological and Heritage Resources include the Construction (3-6 years), Operation (40 plus years), and Decommissioning (2 years) phases of Tilbury Phase 2.

Project components and anticipated duration of activities are described in detail in [Section 1.2](#) (project description and schedule) of the Report.

### 17.12.3 Existing Conditions by Proponent

The existing archaeological and heritage resources conditions in the region were assessed in [Section 7.13](#) of the Revised Application by the Proponent and are summarized here. A desktop review identified one previously recorded archaeological site (DgRs-17) (the historic Indigenous village site<sup>1</sup>) within the RAA. DgRs-17 is located within 1 km of Tilbury Phase 2 on Lulu Island, directly across the Fraser River from the Project Footprint. It contains precontact heritage resources consisting of surface fire-broken rock, subsurface lithics, and a fishing weir. The review indicated there are no recorded archaeological sites within the LAA.

DgRs-17 is known as a cultural site of high significance to several Indigenous nations. The Revised Application noted sources referencing the site and information about the site was received from xʷməθkʷəy̓əm, Quw'utsun

Nation, Ts'uubaa-asatx, Tsawwassen First Nation, TWN, Kwantlen First Nation, Semiahmoo First Nation, and Stó:lō communities. First Nations also shared that when there is a village site on one side of a river, there is often a related site on the other side, which could include the location of Tilbury Phase 2. Quw'utsun Nation indicated a desire to re-establish permanent use of the historic Indigenous village site.<sup>65</sup>

Two Archaeological Impact Assessments conducted under the *Heritage and Conservation Act* (permits 2013-0332 and 2020-0137) were conducted that included areas of the current Tilbury LNG facility, the Tilbury Phase 2 project area, and the Tilbury Marine Jetty (TMJ) project area. Nine First Nations were involved in the Archaeological Impact Assessments through the issuance of their own permits or authorizations. The Archaeological Impact Assessments did not identify any archeological and heritage resources in the LAA.

The Project area contains bedrock with fossil potential. However, the Revised Application notes that these materials lie 200 to 1,000 metres below modern sediments and would not be affected by Tilbury Phase 2 components or activities.

#### 17.12.4 Potential Project Effects by Proponent

The Revised Application identified the following potential effects to archaeological and heritages sites or resources during the construction and decommissioning of Tilbury Phase 2:

- Construction and decommissioning works could lead to ground disturbance of previously unidentified archaeological and or heritage resources.

#### 17.12.5 Proposed Mitigation Measures by Proponent

In addition to the avoidance of archaeological and heritage resources, and legislative requirements, the following are the mitigation measures proposed by the Proponent:

- Prohibit the collection of heritage resources by project personnel on the site.
- If archaeological and/or heritage resources are identified during construction and decommissioning activities, then the project archaeologist will develop and implement appropriate mitigation measures through engagement with regulators and participating Indigenous nations, and in accordance with the site-specific Archaeological Chance Find Management Guide.
- Notify Indigenous nations whose traditional territories overlap with the project before commencement of construction, as well as stakeholders within the project area.

#### 17.12.6 Key Issues Raised

Based on a review of the Application and with feedback from the TAC participating Indigenous nations, and the public, the following key issues related to the assessment of the archaeological and heritage VC for Tilbury Phase 2 were identified. Comments were also provided on CFMG which is in [Appendix S](#) of the Revised Application.

##### 17.12.6.1 Chance Find Protocol

xʷməθkʷəyám, TWN, Ts'uubaa-asatx and BCER provided comments on the CFMG.

xʷməθkʷəyám identified that if Ancestral Remains were present, it would be inappropriate to take photographs. TWN recommended that CFMG should indicate that the Proponent should be responsible for all additional costs regarding the disturbance, removal, ceremony, specialty analysis, and reburial of any Ancestral Remains, and requested that the CFMG be updated to include fragmentary bone, salmon vertebrae, and sturgeon scutes.

---

<sup>65</sup> See Section 3.1 for naming and jurisdictional context regarding the Historic Indigenous Village Site.

xʷməθkʷəyám, TWN and BCER provided comments related to buffer zones for chance finds. TWN also identified the need for the CFMG to include First Nations communities' guidelines and requirements for Ancestral Remains.

Ts'uubaa-asatx identified a lack of confidence in relying in a Chance Find Protocol as the primary mitigation measure for Archeological and Heritage Resources.

FortisBC's view that a 50 metre buffer is appropriate given the size of the site, committed to update the CFMG based on xʷməθkʷəyám's comments relating to photographs, and committed to considering TWN's comments and requests and discuss with the Nations when revising the plan prior to the start of construction.

The EAO recommend the CFMG be required for Tilbury Phase 2 as part of Condition 15. FortisBC will be required to consult with First Nations and the BCER on an updated version of the CFP which, along with consultation logs, must be submitted to the EAO prior to the commencement of construction.

#### 17.12.7 The EAO's Characterization of Residual Effects

After considering the proposed mitigation measures and conditions proposed, the information contained in the [Joint Permitting/Regulatory Coordination Plan](#) and the [Regulatory Coordination Issues Tracking Table](#), the EAO concludes that the Project would not result in residual effects on the archaeological and heritage resources valued component for the following reasons:

- The current conditions of the Project Footprint and potential for interactions between Project activities and archaeological and heritage resources is well understood with Archaeological Impact Assessments having been conducted at the Project Footprint;
- The required chance finds procedure would help mitigate effects to any sites that are discovered during Construction and Decommissioning; and,
- Any pre-1846 archaeological sites discovered would be protected under the *Heritage Conservation Act* and permits would be required for inspection, investigations, and alterations of these sites.

Therefore, no additional characterization of residual effects was completed for archaeological and heritage resources.

#### 17.12.8 Cumulative Effects Assessment

The Revised Application and the EAO's assessment determined that the Project would not result in residual adverse effects to terrain, soil quality, or soil quantity. As no residual effects were identified for the archaeological and heritage resources valued component, a cumulative effects assessment was not warranted.

#### 17.12.9 Conclusion

The EAO is satisfied that Tilbury Phase 2 would not have significant adverse residual or significant cumulative effects on the Archeological and Heritage Resources VC. The extent of significance for federal effects are found in [Appendix 15](#). This conclusion considers the information and analysis presented in this section; the views of the TAC, First Nations, and FortisBC; the proposed Mitigation Measures identified in the provincial Table of Conditions, including Condition 15.

## 17.13 Culture

### 17.13.1 Summary

Culture was identified as a VC for the Tilbury Phase 2 LNG Expansion Project (Tilbury Phase 2 or Project) due to its significance to First Nations the public, and stakeholders. The Fraser River, central to both Indigenous and non-Indigenous communities, has been used since time immemorial by Indigenous peoples for harvesting, transportation, trade, and spiritual practices. The area contains historic fishing camps, settlements, and cultural sites. Continued access to these resources is vital for preserving intergenerational knowledge and cultural heritage.

Reviewers raised concerns about potential impacts on Indigenous cultural practices, ways of life, and significant sites—affecting cultural continuity, intergenerational knowledge transfer, and community well-being. Additional concerns included the limited integration of Indigenous Knowledge in the assessment and insufficient consideration of cumulative effects and the ongoing impacts of colonialism on Indigenous culture.

If issued, the EAO has proposed that the Certificate include Condition 12 (CEMP) and Condition 13 (OEMP) which would require a Holder implement the mitigations measures identified in the Revised Application applicable to culture. The development of both plans will require consultation with First Nations.

After reviewing the proposed mitigation measures and conditions, the EAO concluded there would be no significant residual or cumulative effects on culture.

### 17.13.2 Assessment Boundaries

The spatial boundaries for the culture assessment includes the Project Footprint, the LAA and the RAA, as described below:

- The Project Footprint is the area directly disturbed by project activities, including the associated physical works and activities;
- The Local Assessment Area (LAA) includes the City of Delta, and largest LAA of the VCs that may interact with potential direct effects on the culture VC; and
- The Regional Assessment Area (RAA) includes the boundaries of Metro Vancouver and the largest RAA for other VCs that may interact with potential indirect or cumulative effects on the culture VC.

The temporal boundaries for culture include the Construction (3-6 years), Operation (40+ years), and Decommissioning (2 years) phases of Tilbury Phase 2.

Project components and anticipated duration of activities are described in detail in [Section 1.2](#) (Project Description and Schedule) of this Report.

### 17.13.3 Existing Conditions by Proponent

An overview of existing culture conditions was provided in [Section 7.14.3](#) of the Revised Application. This section provides a description of existing conditions of the aspects of culture most likely to be affected by the Project.

The Project is located on a brownfield site owned by FortisBC at the Tilbury LNG facility in Delta, B.C. The site is part of Metro Vancouver, a regional district that is comprised of 21 municipalities, one treaty First Nation, and one electoral area. The LAA includes Tsawwassen First Nation lands and xʷməθkʷəyám Indian Reserve No. 4, a 57.2-hectare reserve within the Agricultural Land Reserve, leased to a private farmer.

### 17.13.4 Cultural History and Identity

The Fraser River and surrounding lands, including Tilbury Island, have been used by local First Nations since time immemorial for habitation, sustenance, and cultural practices. The area contains several culturally significant sites,

including spiritual sites, fishing camps, and harvesting areas. Tilbury Island was traditionally used for hunting and gathering, and an historic<sup>66</sup> Indigenous village of high significance lies just across the river.

Kinship ties, social networks, and harvesting protocols fostered cooperation among First Nations, creating a cultural and social continuum of villages and resource sites. Fishing remains central to Indigenous identity, with knowledge passed through generations, reinforcing social bonds and stewardship responsibilities. Indigenous communities maintain a sacred duty to protect land, water, air, and resources for future generations.

The Fraser River delta also attracted European and Asian settlers for its agricultural and fisheries potential, shaping the cultural identity of Delta's communities—Ladner, Tsawwassen, and North Delta. While agriculture continues, land use is shifting toward industrial and urban development, especially along the river's south arm. Salmon fisheries have declined significantly.

Despite these changes, the Fraser River remains culturally vital to many First Nations, supporting fishing and serving as a key travel route.

### 17.13.5 Governance and Stewardship Systems

Governance and stewardship systems were included as cultural indicators because they reflect the socio-environmental values and priorities of the communities they represent. Changes in policy direction or decision-making structures are used as measurable parameters. For both First Nations, and non-First Nation municipal governments, their cultural identity and core values are deeply intertwined with their approach to land and resource management, including climate action and GHG reduction plans.

For First Nations environmental stewardship is deeply rooted in culture, worldview, and a sacred responsibility to both ancestors and future generations. This connection is reflected in their governance and climate plans.<sup>67</sup>

For municipal governments in the Local and RAAs, environmental stewardship and climate action are core cultural values, embedded in governance through specific plans and frameworks:

- Delta views the Fraser River's natural environment as central to its cultural identity. Its OCP promotes ecological protection and stewardship education, while its climate goals, net-zero by 2050 and a 45 percent emissions reduction by 2030, reflect a deep cultural commitment to sustainability;
- Richmond's OCP frames environmental health as essential to the city's long-term well-being. Its climate strategies, including a 50 percent emissions reduction by 2030 and net-zero by 2050, are integral to its cultural vision of sustainability; and
- Metro Vancouver's Climate 2050 and Ecological Health Frameworks reflect a regional culture that values nature, ecosystems, and intergenerational environmental responsibility. These plans guide efforts to reduce emissions and conserve ecological health as part of the region's identity.

### 17.13.6 Customs, Beliefs and Values

Cultural identity is deeply shaped by customs, beliefs, and values, especially for Indigenous communities, where cultural practices are closely tied to specific places and local ecosystems. The assessment focused on two key cultural dimensions: access to culturally significant lands and waters and the quality of those places and resources. These factors directly affect the ability of communities to carry out cultural activities, sustain traditional practices,

---

<sup>66</sup> See [Section 2.1](#) for naming and jurisdictional context regarding the Historic Indigenous Village Site

<sup>67</sup> See [Appendix 5](#) for more information about the predicted effects to each First Nation rights and interests because of Tilbury Phase 2 may be found in their respective sections of this Report and the Indigenous Peoples' Cultural Heritage and Current Use of Lands and Resources for Traditional Purposes, as assessed under the IAA, are considered in [Appendix 15](#).

and pass on knowledge. Section 11 of the Revised Application provided additional detail on Indigenous perspectives.

In the broader Local and RAAs, the cultural landscape reflects a mix of Indigenous and non-Indigenous identities. Over the past 150 years, the region has been shaped by successive waves of settlement and resource use. Activities like fishing, farming, and forestry have played a foundational role in shaping B.C.'s non-Indigenous cultural identity and continue to be culturally significant. These practices support a sense of place and continuity for many communities, particularly in rural and semi-urban areas.

Access to land and water is central not only for traditional harvesting and ceremonial use but also for a wide range of everyday cultural and recreational practices. Both residents and visitors engage in consumptive (e.g., fishing, farming) and non-consumptive (e.g., hiking, birdwatching, boating) uses of land and water that are part of personal, family, and community identity. However, not all groups have equal access. Barriers such as time, cost, and transportation can limit opportunities for outdoor and cultural activities, particularly for lower-income and racialized communities.

In Delta, agriculture is a key part of local cultural identity, with many farms being family-run and supported by local non-profits that help preserve the area's farming and fishing heritage. This connection to land and intergenerational stewardship reinforces community ties and shared cultural values.

Near the Project Footprint on Tilbury Island, several informal trails reflect how local residents engage with the landscape. These include a shoreline path along the northern edge of the island, situated on the dike between the Project Footprint and the Fraser River, as well as trails beside Tilbury Slough and along the eastern flood dike. While not formally recognized as recreational infrastructure, these routes are part of how people interact with and experience the land, contributing to a sense of place and local identity. See [Appendix 6, Section 17.10](#) (Land and Resource Use) more information about potential effects to recreational opportunities.

#### Language and Intergenerational Knowledge Transfer

Language is a vital expression of culture and a key mechanism for passing down knowledge, values, and traditions across generations. For Indigenous communities, language is deeply tied to identity, worldview, and place-based knowledge. Despite the impacts of colonization and assimilation—such as the residential school system—that have led to a decline in traditional languages, many Indigenous peoples continue to rely on oral traditions to sustain cultural continuity.

Intergenerational knowledge transfer is dynamic and community-driven, often occurring through ceremonies, storytelling, and land-based practices. However, disruptions to access or degradation of culturally significant lands and resources can hinder these practices, affecting the ability to maintain and transmit cultural knowledge and responsibilities.

Non-Indigenous communities place high value on intergenerational knowledge transfer, especially regarding local settler history. In Delta, institutions like the Douglas J. Husband Discovery Centre and local heritage societies preserve this history, while Metro Vancouver museums also contribute to cultural understanding.

Language plays a vital role in shaping culture and worldview, serving as a key tool for passing down cultural knowledge. In Delta, Richmond, and Metro Vancouver, ethnocultural diversity is high, with over half the population in Metro Vancouver and nearly half in Delta identifying as racialized. Common non-official languages spoken at home include Mandarin, Cantonese, Punjabi, and Tagalog. For South Asian and Chinese communities in particular, maintaining cultural cohesion and intergenerational knowledge transfer is especially important due to historical and ongoing experiences of racism and exclusion.

### Community, Cultural Cohesion, and Continuity

Communities are built through shared geography, culture, values, and relationships, supported by institutions and events that foster belonging and cultural continuity. In Delta and Metro Vancouver, diverse cultural celebrations—including Indigenous events like National Indigenous Peoples Day and powwows, as well as multicultural festivals such as Pride and Chinese New Year, help strengthen community ties.

However, marginalized groups, particularly in low-income areas, often face discrimination and social segregation. Anti-racism initiatives and local cultural institutions play a key role in promoting inclusion and cohesion.

For Indigenous communities, well-being is deeply connected to cultural identity, language, and stewardship of land and resources. Despite the impacts of colonization, surveys show a strong sense of belonging and community cohesion among Indigenous peoples.

Religious diversity in the region includes large secular populations and major faith groups such as Sikhism and Catholicism. Indigenous spirituality is uniquely rooted in land, ancestry, and traditional practices, often centered in longhouses and sacred sites.

#### 17.13.7 Potential Project Effects by Proponent

For detailed assessments of Indigenous interests, potential effects, and mitigation measures related to cultural, social, and environmental factors, please refer to Section 11 of the Revised Application.

The Revised Application identified the following potential effects to culture during the Construction, Operation, and Decommissioning of Tilbury Phase 2:

- **Change to the ability of municipalities or Indigenous nations to continue to plan and meet planning objectives for GHG emissions:** The Project will generate GHG emissions during Construction, Operation and Decommissioning, which could challenge the GHG reduction plans of First Nations and local governments. For many First Nations, climate action reflects deep cultural responsibilities to protect the land, water, and future generations. Local governments' climate plans also embody community values tied to preserving the environment, sustaining quality of life, and safeguarding the cultural and natural heritage that defines the region. FortisBC's net-zero by 2030 commitment, along with best available practices, is expected to limit these effects. As a result, the Project is not expected to materially hinder local or Indigenous climate goals. Broader alignment with provincial and national targets is discussed in Appendix 12;
- **Change to land and water-based cultural practices:** The Project may affect land and water-based cultural practices for both Indigenous and non-Indigenous people who maintain personal, spiritual, or community connections to the Fraser River and surrounding areas. For Indigenous communities, these practices are closely tied to identity, spirituality, and stewardship responsibilities, and rely on continued access to culturally significant places and healthy ecosystems. Non-Indigenous communities may also engage in cultural or recreational activities community traditions, and local heritage linked to fishing, farming, and settlement history;
- **Physical Changes to Lands, Waters, and Resources:** Project activities such as site preparation, vegetation clearing, infrastructure development, and industrial operations may result in physical alterations that may physically alter landscapes that support cultural practices. Potential effects include:
  - Disruption or degradation of fish habitat, riparian vegetation, and wildlife corridors;
  - Loss or alteration of plant species used for food, medicine, or ceremonial purposes;

- Disturbance of culturally significant sites, including archaeological or spiritual locations; and
- Reduced availability or quality of natural resources essential to traditional harvesting, fishing, and gathering.
- **Access to Cultural Areas:** Construction and industrial operations may limit access to culturally significant sites through:
  - Temporary or permanent restrictions near work zones;
  - Increased traffic or safety concerns affecting travel routes;
  - Disruption of traditional land and water pathways; and
  - Exclusion from areas of cultural importance, due to perceived changes in safety and risk;
- **Sensory Conditions:** Changes to the sensory environment may affect the quality and integrity of cultural experiences. Potential impacts include:
  - Air emissions or dust affecting health and comfort;
  - Noise disrupting ceremonies, storytelling, or quiet reflection; and
  - Visual changes from industrial structures or lighting.

Further details are in [Appendix 6.01, Sections 17.01](#) (Air Quality), [Appendix 6.02, Section 17.02](#) (Acoustic), [Appendix 6.10, Section 17.10](#) (Land and Resource Use), [Appendix 6.14, Section 17.14](#) (Human Health) and [Appendix 7](#) Accidents and Malfunctions of the Revised Application.

- **Change to intergenerational knowledge transfer:** Indigenous Knowledge transfer relies on cultural practices linked to land and water. Sensory disturbances from the Project could lead to avoidance of key sites, such as the historic Indigenous village site, affecting language, stories, laws, and spiritual beliefs that are central to cultural identity;
- **Changes to the Diversity and Use of Indigenous and Non-Indigenous Languages:** Indigenous languages are deeply tied to landscapes and cultural sites, so limited access due to sensory disturbances could reduce the use of certain place names and words. Non-Indigenous languages in the urban project area are diverse, but the Project is expected to have negligible impact on their use; and
- **Changes to cultural cohesion and community continuity:** Shift work and rotational schedules may reduce employee participation in cultural and social activities, affecting cultural identity and social ties. Indigenous employees may face greater challenges balancing work with traditional activities, which could impact family and community connections. Sensory disturbances near the Project Footprint may also affect Indigenous engagement with cultural practices and their sense of place and community cohesion.
- The assessment also considered perceived effects, including how concerns related to safety, risk, industrial presence, and sensory conditions may influence decisions about accessing or engaging in cultural practices, even where physical access remains unchanged and environmental thresholds are met. These perceptions were evaluated as indirect pathways by which the Project could affect cultural experience and use.

### 17.13.8 Proposed Mitigation Measures by Proponent

FortisBC has identified and committed to the mitigation measures outlined in *Table 7.14-17* (Culture – Potential Effects, Mitigation Measures, and Potential Residual Effects) of the Revised Application. Many of these measures are linked to supporting VC sections, including [Appendix 6, Section 17.01](#) (Air Quality), [Appendix 6, Section 17.02](#) (Acoustic), [Appendix 6, Section 17.10](#) (Land and Resource Use), [Appendix 6, Section 17.06](#) (Vegetation), and [Appendix 6, Section 17.14](#) (Human Health). These measures are designed to limit physical and sensory disturbances to culturally important sites, practices, and landscapes; support continued access to land and water; and minimize disruption to intergenerational knowledge transfer and cultural continuity.

The following mitigation measures are particularly relevant to the key issues raised in relation to potential cultural impacts, see *Table 7.14-17* (Culture – Potential Effects, Mitigation Measures) of the Revised Application for all mitigation measures:

- Notify Indigenous nations whose traditional territories overlap with the project before commencement of construction, as well as other stakeholders within the project area;
- Receive, record, investigate, and follow-up on odour and noise complaints from Indigenous nations, the public, and adjacent businesses;
- Prohibit the collection of heritage resources by project personnel and implement the site-specific Archaeological Chance Find Management Guide through engagement with participating Indigenous nations should resources be identified during construction;
- Communicate project activities, safety measures, and emergency response measures to Indigenous nations, the public, and stakeholders through different media and forums;
- Incorporate emissions reduction and control technologies in the project design to ensure compliance with regulatory air quality requirements and industry best practices;
- Where practical, plan construction activities within wildlife habitat or buffers of identified wildlife habitat features during the least-risk timing windows for applicable species. For any work within the buffer zone during a sensitive timing window, consult with First Nations and a wildlife QP and the appropriate regulatory agencies to determine whether additional feature-specific mitigation is required to be incorporated into the CEMP;
- Develop mitigation and contingency measures through engagement with a QP to manage acoustic disturbance to human and wildlife receptors;
- Design project lighting in a manner consistent with the BCER's Light Control Best Practices Guideline;
- Use of Totally Enclosed Ground Flare technology to reduce noise and light from flaring;
- Develop erosion and sediment control measures to manage surface water in consultation with First Nations and a QP and incorporate them into the CEMP to reduce sediment deposition into watercourses or storm sewers;
- Avoid the use of waterborne deliveries for modular components or construction materials and ensure no Marine Offloading Facility is utilized during any project phase;
- Develop emergency response measures including onsite fire control and response systems independent of local services, to be tested annually in accordance with BCER requirements;
- Traffic management mitigation measures will be developed and incorporated into the CEMP and OEMP. Contractor personnel will comply with road-use and safety requirements outlined in the CEMP and OEMP, applicable municipal and provincial traffic regulations, including truck routes and approved access routes;

and

- FortisBC will develop and implement a Net Zero Plan that will utilize technology to ensure the project's direct operational GHG emissions follow government policies and regulations upon commencement of commercial operation.

As part of the substituted process, the EAO has identified KMMs for effects within federal jurisdiction to inform IAAC's draft potential federal conditions. The KMMs related to the culture VC are outlined in [Appendix 2](#).

### 17.13.9 Key Issues Raised

Based on a review of the Revised Application and with feedback from the TAC, participating Indigenous nations, and the public, the following key issues related to the assessment of the culture VC for Tilbury Phase 2 were identified.

#### 17.13.9.1 Effects on Indigenous cultural practices, ways of life, and sites impacting cultural continuity, intergenerational knowledge transfer, and community well-being

x̣ṃəθḳẉəỵ əm, Quw'utsun Nation, Tsawwassen First Nation, S'ólh Téméxw Stewardship Alliance, Ts'uubaa-saatx and TWN expressed concerns for the potential of Tilbury Phase 2 to negatively impact their cultural practices, ways of life, and significant spiritual and ceremonial sites. This includes impacts to specific places, including the Fraser River, its shoreline and the historic Indigenous village site, as well as those areas that are sacred and confidential, or lost or forgotten through colonisation.

x̣ṃəθḳẉəỵ əm identified that Tilbury Phase 2 would impact their use of and connection to culturally important sites due to noise, air pollution, and visual changes. Additionally, the adequacy and specificity of proposed mitigation measures to address these potential adverse effects on culturally significant practices and sites was raised by both x̣ṃəθḳẉəỵ əm and TWN. They noted that these effects could lead to loss of connection to cultural heritage, changes in community cohesion, impacts on cultural practices, intergenerational knowledge transfer, languages, and community continuity.

TWN expressed concern that the assessment does not adequately consider the implications of increased reliance on methane-based energy and the diversion of hydroelectric power to support fossil fuel processing. TWN indicated that, in their view, these factors contribute to uncertainty regarding the Project's potential to hinder local and Indigenous climate goals, and that the available information is insufficient to support the conclusion presented in the Assessment Report

In response, FortisBC noted that the proposed mitigation measures are based on industry standards, professional judgment, engagement with First Nations and regulators, and lessons learned from operating existing facilities. FortisBC also confirmed that the CEMP and Operational Environmental Management Plan (OEMP) will incorporate all proposed and required mitigation measures. These plans will be developed in consultation with First Nations, local governments, and relevant agencies to ensure effective implementation.

To support and enforce these commitments, the EAO has proposed Conditions 12 (CEMP) and 13 (OEMP), which would require the Holder to detail how mitigation measures will be implemented during Construction and Operation. Both conditions will also require measures be implemented to address effects to visual quality.

These processes, both FortisBC's planning and the EAO's enforceable conditions, are key to addressing potential impacts on culturally important sites, practices, and sensory conditions, and support the ongoing exercise of stewardship responsibilities and cultural continuity.

#### 17.13.9.2 Integration and consideration of Indigenous Knowledge and perspectives in the assessment process

x̣ṃəθḳẉəỵ əm and Quw'utsun Nation raised concerns about accuracy and sufficiency of FortisBC's assessment in integrating and considering Indigenous Knowledge and perspectives. x̣ṃəθḳẉəỵ əm identified the lack of consideration for First Nation thresholds in assessing sensory impacts as a specific example of this, as well as their disagreement with FortisBC's determination that decommissioning activities will return the Project site to industrial use. They requested further engagement, as returning the site to industrial use does not align

with xʷməθkʷəy̓ əm's desired future use of the area and objectives for restoration of the Project area to a non-industrial use.

In response, FortisBC committed to meeting Health Canada and BCER standards and to engage with xʷməθkʷəy̓ əm on its concerns regarding potential sensory disturbance. Furthermore, detailed mitigation measures responding to these concerns will be provided in the CEMP and the OEMP and xʷməθkʷəy̓ əm will be engaged during that process. FortisBC also committed to working in close partnership with xʷməθkʷəy̓ əm pursuant to the Tilbury Projects Master Agreement, dated June 14, 2022, including on Decommissioning.

If issued, the Certificate will include Condition 12 for a CEMP that must be submitted and approved prior to construction, and Condition 13 for an OEMP that must be approved prior to Operation. Under these conditions the Holder is required describe how proposed mitigation measures will be implemented and consult with First Nations as part of the plans' development process. The EAO has also recommended, as part of Condition 3 (Document Development) that when baseline information is included in a document to support monitoring of the efficiencies of mitigations that the baseline information include non-confidential First Nation knowledge when provided by a First Nation.

The EAO notes that the Project requires an LNG Facility Permit; or an amendment to the current LNG Facility Permit held for the existing facility. Section 21 of the LNG Facility Regulation has requirements for site restoration after the closure of a facility. This includes the removal of structures used for the operation of the LNG facility, the restoration of the soil structure and drainage patterns to conditions before alteration, and re-vegetation any exposed soils with an ecologically suitable species that promotes the restoration of the wildlife habitat that existed on the area before the energy resource activity was begun and stabilizes the soil if it is highly susceptible to erosion.

#### **17.13.9.3 Consideration of cumulative effects and the historical and ongoing impacts of colonialism on First Nation culture and well-being**

xʷməθkʷəy̓ əm, Quw'utsun Nation, and Tsawwassen First Nation expressed concerns regarding the adequacy FortisBC's assessment of impacts when considering the historical and ongoing context of development and the enduring effects of colonialism. These First Nations also identified the need to account for past and ongoing impacts on First Nation culture and rights as the true baseline, including the cumulative impacts of colonialism, and that Tilbury Phase 2 may perpetuate existing negative impacts and alienation from traditional lands. Alienation from traditional lands is not only a loss of physical access but disrupts cultural practices, knowledge systems, language use, and spiritual connection to place, all of which are central to Indigenous cultural identity and continuity, as described in [Section 7.14.3](#) of the Revised Application. Indigenous laws and stewardship responsibilities are also tied to the ability to access and care for land and waters.

The EAO acknowledges xʷməθkʷəy̓ əm's, Quw'utsun Nation's, and Tsawwassen First Nation's concerns about cumulative impacts they have experienced as a result of historic and ongoing development in the Lower Mainland and beyond. These impacts are reflected in the "Historical Context" and "Existing Conditions" sections of the Revised Application, which aim to situate the Project within the broader context of land use change and associated effects over time.

Under the environmental assessment process, FortisBC is responsible for identifying the potential effects of the Project and determining whether any residual effects are expected after mitigation. Where no residual effect is anticipated, a cumulative effects assessment is not conducted for that particular VC or Indigenous interest. This approach is consistent with the methodology outlined in the AIR and EAO's Policy.

#### **17.13.10 The EAO's Characterization of Residual Effects**

After considering the proposed mitigation measures and conditions proposed, the information contained in the [Joint Permitting/Regulatory Coordination Plan](#) and the [Regulatory Coordination Issues Tracking Table](#), the EAO concludes that the Project has the potential for negligible adverse effects to the following cultural subcomponents:

- Change to land- and water-based cultural practices;
- Change to intergenerational knowledge transfer;
- Change to the diversity and use of Indigenous languages; and
- Change to cultural cohesion and community continuity.

For the purposes of this assessment, a negligible residual effect is one that does not result in a measurable change from existing conditions, or results in no observable change at all at the scale of the LAA or RAA.

Tilbury Phase 2 is not anticipated to change to the ability of municipalities or Indigenous nations to continue to plan and meet planning objectives for GHG emissions and therefore was not carried forward as a residual effect because the Project's committed NetZero plan and associated mitigation measures remove any remaining project level influence on achieving GHG planning objectives, and GHG emissions function as a globally driven cumulative issue shaped primarily by worldwide emission patterns rather than emissions at the scale of this Project.

The EAO's characterization of the potential residual effects of the Project on Culture VC is summarized below in Table 65, as well as the EAO's level of confidence in the effects determination (including their likelihood and significance).

Table 65: Summary of Residual Effects for Culture

| Residual Effect                                   | Assessment Rating*                                                                                                                                                                                                                                                                          | Significance and Rationale                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Change to land and water based cultural practices | Context (resilience): Low<br>Magnitude: Negligible<br>Extent: Local<br>Duration: medium-term<br>Frequency: Irregular<br>Reversibility: Partially reversible<br>Affected populations: Disproportionate<br>Risk (likelihood & consequences): Low<br>Uncertainty: Moderate<br>Importance: High | <b>Not significant</b><br><br>Cultural practices are already heavily constrained by longstanding industrial development along the Fraser River and Tilbury Island. Project effects are limited to sensory pathways (noise, light, visual, air quality), with no new access restrictions or physical disturbance of cultural sites. Mitigation measures for noise, air, lighting, erosion/sediment control, and communication protocols reduce residual effects to a negligible to low magnitude. Effects may be disproportionately experienced by some Indigenous Nations, but no measurable change to overall practice or use is predicted.<br><br>Reversibility is considered partially reversible because, although effects are negligible and limited to temporary sensory changes, and air quality effects some Indigenous users closest to the site may experience short-term disruptions to cultural practice that could persist for a period beyond active project activities before fully returning to baseline. |
| Change to intergenerational knowledge transfer    | Context: Low resilience<br>Magnitude: Negligible<br>Extent: Local<br>Duration: medium-term<br>Frequency: Irregular<br>Affected Populations: Disproportionate<br>Risk (likelihood & consequences): Low<br>Reversibility: Partially reversible<br>Uncertainty: Moderate<br>Importance: High   | <b>Not significant</b><br><br>Project activities occur within a long-industrialized shoreline where cultural use is already constrained; effects are primarily sensory (noise, lighting, visual, air quality) and are addressed through CEMP/OEMP controls and ongoing Nation communications. Linked VCs (fish and fish habitat, vegetation, land and resource use) predict measurable negligible to low magnitude changes to resource availability or access following mitigation, and no new access restrictions or measurable disturbance to cultural sites are anticipated. Any remaining influence would be localized to the industrial setting and medium-term during Construction and Operation. While some First Nation users closest to the site could perceive effects more acutely, the Project is not expected to result in a measurable change in intergenerational knowledge transfer and water based cultural practices. See rationale for reversibility above.                                            |

| Residual Effect                                                                                                                   | Assessment Rating*                                                                                                                                                                                                                                                                                | Significance and Rationale                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Change to diversity and use of Indigenous languages                                                                               | Context: Low Resilience<br>Magnitude: Negligible<br>Extent: Regional<br>Duration: Medium-term<br>Frequency: Irregular<br>Affected Populations: Disproportionate<br>Reversibility: Partially reversible<br>Risk (likelihood & consequences): Low<br>Uncertainty: Low<br>Importance: High           | <b>Not significant</b><br><br>Opportunities for the diversity and use of Indigenous languages in place-based teaching and knowledge sharing are expected to be maintained because the Project does not introduce new barriers to access or alter locations relied upon for cultural practice; pathways are limited to temporary changes in sensory conditions during construction and specific operational events. With standard mitigation (noise and light controls, emissions management, erosion and sediment control) implemented through the CEMP/OEMP and supported by linked Value Component conclusions that do not indicate measurable changes to biophysical resources that support cultural activities, no measurable changes in the use, transmission, or diversity of Indigenous languages is anticipated. Any perceived influence would be local and reversible once activities subside and Operation ceases.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Change to cultural cohesion and community continuity                                                                              | Context: Moderate Resilience<br>Magnitude: Negligible<br>Extent: Regional<br>Duration: Medium-term<br>Frequency: Irregular<br>Affected Populations: Disproportionate<br>Reversibility: Partially-reversible<br>Risk (likelihood & consequences): Moderate<br>Uncertainty: Low<br>Importance: High | <b>Not significant</b><br><br><b>Context:</b> The Project is located in an already industrialized area where existing conditions have reduced the resilience of community cohesion and continuity and therefore rated as moderate.<br><br><b>Magnitude:</b> Effects are limited to indirect sensory pathways (e.g., noise, lighting, visual quality, air quality) and represent a small incremental contribution to existing pressures on cultural continuity and rated as negligible.<br><br><b>Extent:</b> Rated as regional, duration rated as medium-term), and frequency rated as irregular. The Project-related effects are distributed across the broader region, occur over the Construction and early Operation phases, and are intermittent in nature.<br><br><b>Affected Populations:</b> Effects may be disproportionately experienced by Indigenous nations due to the importance of land, water, and cultural practices to community cohesion and continuity.<br><br><b>Reversibility:</b> Some effects may diminish over time but not all, therefore rated as partially reversible in the context of ongoing cumulative industrial influences.<br><br><b>Risk:</b> The likelihood and consequence of effects are considered moderate, reflecting the potential for incremental contributions to existing conditions.<br><br><b>Uncertainty:</b> There is variability in how effects may be experienced across communities and uncertainty in predicting changes to complex social and cultural systems.<br><br><b>Importance:</b> Cohesion and community continuity are of high importance due to their cultural and social significance. |
| * Note: Criteria and assessment ratings are defined in <a href="#">Appendix 3 - Residual Effects Characterization Definitions</a> |                                                                                                                                                                                                                                                                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

### 17.13.11 Cumulative Effects Assessment

The assessment of a designated project must consider cumulative effects that may result from Tilbury Phase 2 in combination with other past, present, and reasonably foreseeable future projects and activities. For the Culture VC, the reasonably foreseeable projects with potential to interact cumulatively with Tilbury Phase 2 include the Tilbury Marine Jetty (TMJ), the Fraser River Tunnel Project (FRT), and the Delta Grinding Facility (DGF), based on their proximity and shared sensory disturbance pathways.

Residual effects of Tilbury Phase 2 on the Culture VC are limited to sensory pathways, including noise, lighting, and visual change and changes in cultural experience. The Project does not result in direct alteration of identified cultural sites, changes to land or water features of cultural importance, or new restrictions to access. Residual effects are characterized as negligible in magnitude, localized in extent, and in some cases temporary in duration. As such, the Project's contribution to changes in cultural experience is limited.

The cumulative effects assessment considers whether these residual effects interact with similar effects from TMJ, FRTP, and DGF in a manner that would materially alter the future condition of the Culture VC. The RAA is already characterized by long-standing industrial and transportation development along the lower Fraser River, resulting in fragmentation of cultural landscapes and ongoing sensory disturbance. These conditions reflect historical and continuing land use patterns and are discussed in Section 1.1.1 Existing Conditions by Proponent, above.

When compared to this existing condition, Tilbury Phase 2 does not materially increase access restrictions, alter culturally important land or water features, or introduce new categories of disturbance. The Project's incremental contribution to regional sensory disturbance is negligible-to-low relative to the established industrial context. While reasonably foreseeable projects may also contribute to ongoing sensory conditions, the combined effect of these activities is not expected to result in a measurable change in the overall cumulative trajectory for the Culture VC beyond what is already occurring.

Mitigation measures, including the Totally Enclosed Ground Flare, emissions controls, and noise and lighting management under the CEMP and OEMP, further limit the Project's residual sensory effects. Ongoing engagement with Indigenous Nations provides an additional mechanism to identify and address concerns should conditions differ from those predicted.

Indigenous Nations have identified concerns regarding cultural continuity, access, and cumulative legacy effects in the Project area. These broader cumulative conditions are acknowledged and are addressed in Section 11 of this Report. At the Culture VC scale assessed in this section, however, Tilbury Phase 2 is not expected to materially alter the existing cumulative cultural condition.

Accordingly, based on the documented existing industrial and transportation context of the RAA and the limited magnitude of Project residual effects, Tilbury Phase 2 is not predicted to cause an adverse cumulative effect on the Culture VC when considered in combination with past, present, and reasonably foreseeable future projects and activities.

#### 17.13.12 Conclusion

The EAO acknowledges that effects to Indigenous rights and interests are closely linked to existing and proposed land use activities. More information about the predicted effects to each First Nation rights and interests because of Tilbury Phase 2 may be found in their respective sections of this Report ([Appendix 5](#)). Indigenous Peoples' Cultural Heritage and Current Use of Lands and Resources for Traditional Purposes, as assessed under the IAA, are considered in [Appendix 15](#).

In addition to Indigenous cultural values, the assessment also considered non-Indigenous cultural practices and identity, particularly those linked to historical land use, agriculture, and community life along the Fraser River. While residents continue to engage in outdoor and community-based activities that contribute to a sense of place, no culturally significant non-Indigenous uses were identified within or near the Project Footprint. Given the existing industrial nature of the site, and the lack of anticipated changes to access or resource use for surrounding communities, the Project is not expected to result in adverse residual effects on non-Indigenous cultural practices or identity.

The EAO is satisfied that Tilbury Phase 2 would not result in significant adverse residual or cumulative effects on the culture VC. The extent of significance for federal effects as it relates to changes to cultural heritage is found in [Appendix 15](#). This conclusion considers the information and analysis presented in this Report section; the views of the TAC, First Nations, and FortisBC; the proposed mitigation measures identified in the provincial Table of Conditions including, Conditions 3 (Document Development), 12 (CEMP), 13 (OEMP), and 14 (Air Quality Management Plan).

## 17.14 Human Health

### 17.14.1 Summary

Human Health was selected as a VC because of its importance to the public, First Nations, the Proponent, and local, provincial and federal governments. FortisBC's assessment of the Human Health VC, used a coupled approach by assessing both environmental and social determinants of health, combined with Indigenous Knowledge.

FortisBC's Human Health Risk Assessment (HHRA) evaluated potential risks to human health by identifying chemicals in air emissions from Tilbury Phase 2 and predicting how Tilbury Phase 2 could alter environmental media, such as air, soil, water, and country foods, that people may be exposed to (see [Appendix J](#) of the Revised Application). This section focuses on the biophysical assessment of the Human Health VC, while social determinants of human and community well-being (e.g., economic opportunities; adequate public services and infrastructure; access to nature; and social connections) are further discussed in Appendix 8 of this Report (Summary of Human and Community Well-being) in the context of social, economic, health, or cultural outcomes.

Under worst case scenario, when combined with the existing Tilbury Phase 1A production and storage expansion (Phase 1A) operations and current background air quality, the proposed Tilbury Phase 2 is expected to result in short-term increases in ambient nitrogen dioxide (NO<sub>2</sub>) concentrations that exceed applicable air quality objectives in limited circumstances and the exceedances are not predicted to overlap any sensitive receptors. All other air contaminants, such as Sulphur Dioxide (SO<sub>2</sub>) and Particulate Matter (PM) remain below health-based thresholds.

In contrast, air quality dispersion modelling for flaring (during commissioning and start-up/shutdown events) shows short-term exceedances of the 1-hour NO<sub>2</sub> air quality objective across large portions of the surrounding community, including homes, daycares, and schools, covering large areas of Richmond, parts of Vancouver, and parts of Delta.

To mitigate adverse air quality effects, FortisBC has committed to using emissions control technology in Tilbury Phase 2's design for normal daily operations. These technologies are expected to lower nitrogen oxides (NO<sub>x</sub>) and to further reduce sulfur oxides (SO<sub>x</sub>) emissions which will help reduce potential health impacts from Tilbury Phase 2. However, short-term flaring events during commissioning or maintenance are considered 'unmitigated' and may still result in temporary exceedances of air quality objectives over a wider area.

The HHRA looked at how Tilbury Phase 2 could affect people's sensory environment, including potential health risks from noise and vibration, as noted in [Appendix 6, Section 17.02](#) (Acoustics) of the EAO's Report, caused by Project activities. In addition, the assessment included a qualitative assessment of how odours from Tilbury Phase 2 might affect human health, and any impacts from odours are expected to be unnoticeable.

The Proponent looked at how Tilbury Phase 2 could affect the social factors that influence health, using a population health approach.<sup>68</sup> This included information from other parts of the assessment, such as Culture, Human and Community Well-being, Employment and Economy, Land and Resource Use, and Infrastructure and Services VCs. In assessing these social determinants of health, FortisBC considered how Tilbury Phase 2 might affect people's health and well-being through changes in things like employment rates, job types, and household income. The Application found that Tilbury Phase 2's Construction, Operation, and Decommissioning would likely have a positive effect on socio-economic status. However, it also noted that shift work could have negative effects on the health and well-being of workers and their families.

---

<sup>68</sup> Population health is associated with socio-economic conditions on a community level and encompasses health inequities, see Appendix A – Human and Community Wellbeing in this Report for effects on the health and wellbeing of sub-populations.

The EAO recommends for conditions related to human health:

- Certificate condition 14 (Air Quality Management Plan) that includes monitoring of air quality through the operational life of Tilbury Phase 2 and an adaptive management approach where air quality standards are exceeded,
- Certificate Condition 12 (CEMP) that includes a management plan for dust, which is relevant to the human health VC,
- Certificate Condition 13 (OEMP) requiring the development and implementation a plan to manage the environmental effects of Tilbury Phase 2 during Operation.
- Condition 18 (Regional Cumulative Effects Initiatives) may require FortisBC to join BC-led or Metro Vancouver-led airshed initiatives.

Given the assessment, the EAO found that there would not be a significant adverse effect to human health and no significant cumulative effects to human health as a result of the effects of Tilbury Phase 2 interacting with the effects of other past, present and reasonably foreseeable future projects and activities.

#### 17.14.2 Assessment Boundaries

The spatial assessment boundaries for the Human Health VC are defined differently for social and environmental determinants of health, as follows:

- Social determinants of health LAA and RAA both include the boundaries of Metro Vancouver; encompassing 21 municipalities, First Nation reserves, and Treaty lands.
- Environmental determinants of health LAA includes the boundaries of the VCs that may affect human health including Air Quality, Acoustic, Soil, Country Foods,<sup>69</sup> Surface Water, and Groundwater.
- Environmental determinants of health RAA includes the boundaries of the VCs that may have indirect or cumulative impacts to human health from Tilbury Phase 2 including Air Quality, Acoustic, Soil, Country Foods,<sup>70</sup> Surface Water, and Groundwater.

The temporal boundaries for Human Health include the Construction (3-6 years), Operation (40 plus years), and Decommissioning (2 years) Phases of Tilbury Phase 2.

##### 17.14.2.1 Data limitations and technical boundaries for the assessment of human health

Administrative and technical boundaries for the Human Health VC assessment are outlined in Sections 7.15.3.2 and 7.15.3.3 of the Revised Application. Key data limitations included a lack of disaggregated health data for nonbinary and gender-diverse individuals, and limited data for immigrant and racialized communities.

Section 11.1.7.5 of the Revised Application identifies limitations in demographic information for many Indigenous nations, with reliance on Census data in the absence of other sources. As noted in Section 11.1.7, limited primary data and the absence of Indigenous Knowledge from some participating Indigenous nations led to a reliance on secondary data. Section 11.1.7.6 also highlights that some of these sources were outdated or incomplete, such as unpublished 2021 Census data or studies over five years old.

<sup>69</sup> The LAA for country foods quality is the combined LAAs for the Vegetation, Fish and Fish Habitat, and Wildlife and Wildlife Habitat VCs.

See previous footnote.

### 17.14.3 Existing Conditions by Proponent

Tilbury Phase 2 is being proposed in an area that is already heavily developed with urban and industrial activity. The current environmental conditions that affect health reflect the long history of development, urbanization, and industrial land use on and around Tilbury Island.

The existing conditions for the Human Health VC, as described in [Section 7.15](#) of the Revised Application, were based on the more detailed [HHRA Technical Data Report \(Appendix J\)](#). This report included the data FortisBC considered relevant to the assessment, including how certain vulnerable groups might be more affected by Tilbury Phase 2.

For more information on environmental factors that influence human health, see the sections on (Air Quality), [Appendix 6, Section 17.02](#) (Acoustic), [Appendix 6, Section 17.03](#) (Surface Water), [Appendix 6, Section 17.04](#) (Groundwater), [Appendix 6, Section 17.05](#) (Soil), [Appendix 6, Section 17.06](#) (Vegetation), [Appendix 6, Section 17.07](#) (Wildlife and Wildlife Habitat), and [Appendix 6, Section 17.08](#) (Fish and Fish Habitat) in this Report. For social factors that affect health, see the sections on [Appendix 8](#) (Human and Community Well-being), [Appendix 6, Section 17.09](#) (Employment and Economy), [Appendix 6, Section 17.10](#) (Land and Resource Use), and [Appendix 6, Section 17.11](#) (Infrastructure and Services).

#### 17.14.3.1 Environmental determinants of Human Health

Environmental determinants of health describe the environmental factors, external to the individual, that influence human health, including physical, chemical, and biological aspects of the environment. In the context of the Project area, these existing conditions are described as follows:

- **Air Quality:** Poor air quality is associated with increased hospital admissions and mortality. Although Metro Vancouver has improved air quality over the past decade through stricter emission standards and policies, challenges remain due to increased wildfire activity, climate change, and industrial operations. For Indigenous peoples, air quality is an essential part of holistic health and well-being. Key air contaminants monitored in the area include NO<sub>2</sub>, sulfur dioxide (SO<sub>2</sub>), carbon monoxide (CO), ozone (O<sub>3</sub>), PM (PM<sub>10</sub> and PM<sub>2.5</sub>), and volatile organic compounds (VOCs), all of which are known to negatively impact human health. See [Appendix 6, Section 17.01](#) (Air Quality) for more detailed information.
- **Sensory Conditions (Noise, Vibration, Odour):** These sensory conditions can adversely affect human health. Noise exposure can lead to hearing loss, sleep disturbances, stress, and related illnesses. Vulnerable populations, such as people with lower socio-economic status, children, elderly, and shift workers, may be more sensitive to noise impacts. Odour can also affect mental health by causing stress, fear, and anxiety. The area around Tilbury Island already experiences high ambient noise levels from industrial and transportation sources and has existing odour-emitting facilities, with noise and odour complaints primarily linked to these local operations. See [Appendix 6, Section 17.02](#) (Acoustic) for more detailed information.
- **Drinking Water:** 98 percent of Delta's drinking water is supplied by Metro Vancouver's reservoirs and meets B.C. Contaminated Site Regulations (CSR) standards, while 2 percent is from groundwater. While monitoring wells within the Project footprint showed arsenic levels above B.C. CSR guidelines, these were below regional background levels. See [Appendix 6, Section 17.05](#) (Soil) and [Appendix 6, Section 17.04](#) (Groundwater), for more information.
- **Soil Quality:** Soil can be a pathway for human exposure to harmful substances through accidental ingestion, inhalation of dust, or the movement of contaminants into the food chain. Dust is a significant concern for First Nation and Indigenous communities, and perceived contamination can influence health behaviors and well-being; for example, members of Tsawwassen First Nation (Tsawwassen) raised concerns about black lesions on crabs, initially attributing them to dust. It was later determined that the lesions were caused by a naturally occurring shell disease, not contaminants. The Project footprint is largely disturbed, with little

native topsoil remaining. A localized area with arsenic contamination will be removed prior to construction. See [Appendix 6, Section 17.05](#) (Soil) for more information.

- **Country Foods:** Country foods, such as plants, fish, and animals, are culturally, spiritually, and nutritionally important to the public, First Nation's and Indigenous peoples. They also support physical activity and social connection. However, consumption of country foods has declined due to colonization, limited access, reduced availability of species, and concerns about contamination. Many Nations engaged on the Project assessment identified links to community health to the ability to fish and emphasizes the importance of marine foods to their health. Ongoing development has had cumulative impacts on species abundance and habitat quality. See [Appendix 6.08, Section 17.08](#) (Fish and Fish Habitat), [Appendix 6.07, Section 17.07](#) (Wildlife and Wildlife Habitat), and [Appendix 6.13, Section 17.13](#) (Culture) for more information.

### 17.14.3.2 Social determinants of Human Health

Social Determinants of Health outlines how societal conditions, external to individuals, influence their health and well-being, encompassing social, economic, political, and cultural factors throughout a person's life. These factors also include experiences of discrimination, racism, and historical trauma, especially relevant for vulnerable groups like Indigenous peoples, racialized communities, women, seniors, youth, and new immigrants.

Key existing conditions include:

- **Socio-economic status** in Delta and Metro Vancouver is generally high, but the benefits are not shared equally. Indigenous peoples, racialized communities, and women continue to face disparities in income and employment. The high cost of living, especially housing and childcare, also contributes to food insecurity among vulnerable populations;
- **Population health status** in Delta shows higher rates of certain chronic diseases, such as asthma, diabetes, and high blood pressure, compared to the provincial average. Indigenous peoples experience a disproportionate burden of illness, including shorter life expectancy, higher rates of chronic and communicable diseases, addiction, and infant mortality. Suicide rates are also significantly higher among Indigenous populations than among non-Indigenous groups;
- **Health practices** reflect broader social conditions. Smoking and alcohol use are more common among Indigenous peoples due to colonial impacts and systemic racism. The overdose crisis in Metro Vancouver has severely affected Indigenous communities, particularly women, while construction workers also show higher drug use rates. Diet and physical activity vary by income and education, with food insecurity rising because of high costs and limited access to traditional foods; and
- **Health services** are not always equitably accessed. Indigenous peoples often face significant barriers to care due to systemic racism, historical mistrust, and a lack of culturally safe services.

### 17.14.4 Potential Project Effects by the Proponent

This section outlines the potential effects of Tilbury Phase 2 on the Human Health VC during Construction, Operation, and Decommissioning. The assessment considers how different groups, such as Indigenous peoples, women, youth, and elders, may experience these effects differently.

The analysis is divided into two parts; environmental determinants of health, which include physical exposures such as air, water, soil, and noise, and social determinants of health, which include socio-economic conditions, health behaviours, and access to services.

#### 17.14.4.1 Environmental Determinants of Health

Potential adverse effects on environmental determinants of health were assessed through the HHRA and related VC studies. The assessment began by identifying Contaminants of Potential Concern (COPCs)—the chemicals, gases, and particles that could reasonably affect human health through project activities. These substances formed the basis of the human health analysis. COPCs are identified in air, water, soil, sediments, and country foods (like fish or berries) to determine if they might interact with people.

Ultimately, the HHRA concluded that several of these pathways presented negligible risks to human health and omitted them from further detailed analysis. Key findings regarding these excluded pathways include:

- **Drinking and Surface Water:** These were excluded because Tilbury Phase 2 is not predicted to adversely affect water quality. Although some arsenic and cobalt were detected in local monitoring wells, these concentrations were found to be within regional background levels, and the primary municipal water supply for the area is sourced far outside Tilbury Phase 2's reach.
- **Soil Quality:** The HHRA determined the risk from soil was negligible because the project footprint consists almost entirely of gravel and asphalt with virtually no native topsoil. While a small, localized area of arsenic-contaminated soil was identified, FortisBC committed to excavating and disposing of this material offsite prior to construction, effectively eliminating the potential for human exposure.
- **Country Foods and Secondary Pathways:** Pathways involving the consumption of fish, vegetation, or wildlife were also determined to pose no increased health risks. The assessment found that project-related acid or nitrogen deposition would not be sufficient to alter the quality or quantity of these traditional food sources.

#### Potential Effects to Health and Well-being Due to Changes to Air Quality

The Tilbury Phase 2 Project is located in a developed, urban, coastal industrial area surrounded by residential, commercial, recreational, and agricultural land uses. Project activities during construction, operation, and decommissioning will generate air emissions that can affect local air quality and, in turn, human health.

COPC for air emissions include criteria air contaminants (CACs) NO<sub>2</sub>, SO<sub>2</sub>, PM (PM<sub>2.5</sub> and PM<sub>10</sub>), CO, and VOCs. These air contaminants are regulated because they can harm human health at elevated levels.

The HHRA evaluated potential health risks by comparing predicted concentrations of these contaminants to health-based thresholds such as Toxicological reference values like the World Health Organization's air quality guidelines. The HHRA also evaluated against the Canadian Ambient Air Quality Standards (CAAQS 2025) and Metro Vancouver Air Quality Objectives (MV AAQO 2025). CAAQS and MV AAQO 2025 are set to protect human health and the environment.

Risk was expressed as a hazard quotient (HQ), where HQ > 1.0 indicates the predicted exposure levels exceed the Toxicological reference values; the level below which health effects are unlikely. An HQ > 1.0 indicates a potential for adverse outcomes, such as increased asthma-related emergency room visits and increased risk of respiratory morbidity from chronic exposure. However, an HQ over 1.0 does not mean adverse health effects will definitely occur; rather, it indicates that such effects are possible and that the exposure level has exceeded a health-based guideline.

The assessment considered sensitive receptors within 5 km radius of the Project Footprint, including homes, schools, childcare facilities, seniors' residences, and the Historic Indigenous Village Site.<sup>71</sup> See Figure 13 below from Figure 3-2 in [Appendix B](#) of the Revised Application.

---

See Section 3.1 for naming and jurisdictional context regarding the Historic Indigenous Village Site

Figure 13: Discrete Sensitive Human Receptors Used in the Predicted Emission Modelling (Source: Air Quality TDR, Appendix B of the Application)

### What do percentile metrics mean?

Percentiles describe how often a certain concentration is reached or exceeded over time. They help us understand whether air quality standards are met under typical and peak conditions. For example:

- 98th percentile means that almost all the time (98 percent of the hours), concentrations are predicted to be at or below this level. Only about 2 percent of hours (175 hours in a year) would concentration be higher. This captures rare but plausible high-concentration conditions, without relying on an extreme outlier.
- 90th percentile means concentrations are at or below this level for 90 percent of the time. About 10 percent of hours (828 hours in a year) could be higher. This reflects more frequent elevated conditions, not just rare peaks.
- 75th percentile means concentrations are at or below this level for 75 percent of the time, with higher concentrations occurring about 25 percent of hours (2070 hours in a year). This represents fairly common upper-range conditions rather than exceptional events

### Construction Phase

Construction activities such as excavation, heavy equipment operation, and truck deliveries will emit CO, NO<sub>x</sub>, SO<sub>x</sub>, PM (PM<sub>2.5</sub> and PM<sub>10</sub>), VOCs, and trace pollutants such as diesel PM (DPM) and polycyclic aromatic hydrocarbons (PAHs).

The HHRA concluded that concentrations of DPM, PAHs, PM<sub>2.5</sub>, PM<sub>10</sub>, VOCs, and CO during Construction would be negligible and unlikely to pose a health risk. Hazard quotients (HQs) for these pollutants were well below the threshold of concern (HQ = 1.0), and background air quality dominates overall exposure. Acute or chronic health effects for sensitive receptors, such as residents, children, elders, and Indigenous communities, are considered unlikely.

Dust generation from earthworks and heavy machinery will occur but is expected to remain within the project footprint. Health risks from dust are limited to occupational exposure scenarios. Contributions of PM<sub>2.5</sub> and PM<sub>10</sub> from construction are predicted to be undetectable against existing background levels.

Mitigation measures for effects from air quality during construction include:

- Vehicle idle reduction policies
- Dust-control measures in the CEMP
- Regular inspection and maintenance of equipment
- Avoidance of waterborne deliveries (no marine offloading facility required)

These measures are expected to be highly effective and implemented immediately. Overall, residual health effects from air quality changes during construction are predicted to be negligible.

### *Flaring*

Non-routine flaring of LNG and other gases are expected to occur during commissioning, start up and shut down, upset conditions and power outages.

VOCs, particulate matter, and carbon monoxide were not carried forward for detailed assessment under non-routine flaring in the HHRA because predicted Project-related increases were negligible, remaining generally below 10% of applicable air quality objectives. As these contaminants do not materially change background conditions or result in exceedances under either Project-only or cumulative scenarios, they were not identified as contaminants of concern driving human health risk during flaring events.

During these non-routine events, operational mitigations are typically bypassed for safety reasons to prevent escalation. Results from the HHRA for each of these events is as follows:

#### **Commissioning:**

- Commissioning includes three activities: LNG tank commissioning, liquefaction train warm commissioning, and liquefaction train cold commissioning, with duration of air emissions approximately 2 weeks, 72 hours, and 144 hours, respectively.
- The highest value, based on the annual 98th percentile of predicted hourly concentrations using background air quality concentrations from years 2013–2015 is 392 µg/m<sup>3</sup> for NO<sub>2</sub> near the Project Footprint, with HQ = 5. Many sensitive receptors could be impacted.
- SO<sub>2</sub> concentrations from Tilbury Phase 2 are expected to remain below the applicable CAAQS and MVAAQO 2025.

#### **Start up and Shut down:**

- Startup and shutdown events are expected to last less than 5 hours and to occur up to five times per year
- Project-related SO<sub>2</sub> and NO<sub>2</sub> concentrations and their geographic extent of concentrations during these events are expected to be the same as those predicted for commissioning

**Upset Conditions:**

- Expected once per year, less than 5 hours and extend into LAA
- Based on the annual 98<sup>th</sup> percentile of predicted hourly concentrations averaged over 2013–2015 under Abnormal Condition without background concentrations are:
  - SO<sub>2</sub> levels are expected to reach 429 µg/m<sup>3</sup> at 98<sup>th</sup> percentile, HQ = 2.3
  - NO<sub>2</sub> levels are expected to reach 278 µg/m<sup>3</sup> at 98<sup>th</sup> percentile, HQ = 3.5

**Grid Power Outage:**

- The frequency of grid power outages is uncertain and was conservatively modeled as 10 hours per year.
- Based on the annual 98<sup>th</sup> percentile of predicted hourly concentrations averaged over 2013–2015 under Abnormal Condition without background concentrations are:
  - NO<sub>2</sub> levels are expected to reach 171 µg/m<sup>3</sup>, HQ = 2.2
  - SO<sub>2</sub> levels are not expected to increase

**Operation**

The Revised Application assessment of the potential effects to air quality from Tilbury Phase 2 includes both the original unmitigated conceptual design for CO, PM<sub>2.5</sub>, PM<sub>10</sub> and VOCs and the preliminary mitigated conceptual design for NO<sub>2</sub> and SO<sub>2</sub> (Appendix B, Updated Air Quality TDR; Section 7.2, Air Quality). In the Revised Application, Section 7.15.5 of the Air Quality section, Operation emissions were modelled within the RAA under the following scenarios:

- **Base Case** – The predicted air concentrations resulting from the existing FortisBC Phase 1A operation and background conditions.
- **Application Case (Base Case + Project)** – The predicted air concentrations resulting from Tilbury Phase 2 during operations with the Base Case.
- **Cumulative Case** – The predicted air concentrations resulting from all reasonably foreseeable projects and activities, such as TMJ, T1B, that may influence future air quality within the RAA, along with Tilbury Phase 2 and Base Case concentrations and is assessed in the Section 1.1.4 Cumulative Effects Assessment (CEA) below.

Unmitigated NO<sub>2</sub> and SO<sub>2</sub> values are not discussed in the context of EAO assessment for Application and Cumulative Case. See Appendix B (Air Quality TDR) of the Revised Application for full details. CO, PM, and VOCs remained below MV AAQO and CAAQS 2025 under the conservative unmitigated scenario; therefore, they were not modelled with mitigation.

**Acute and chronic exposures to NO<sub>2</sub>**

According to the HHRA, short-term (acute) exposure to NO<sub>2</sub> can irritate the lungs, trigger asthma symptoms, and increase emergency room visits for respiratory issues. Long-term (chronic) exposure may lead to reduced lung function, increased risk of developing asthma, and possibly cardiovascular effects.

Under Base Case, when background concentrations are included, the highest short-term NO<sub>2</sub> levels (1-hour levels 87.3 µg/m<sup>3</sup>), represented by the 98<sup>th</sup> percentile, already exceed MV AAQO & CAAQS 2025 (79 µg/m<sup>3</sup>). This percentile means concentrations are above the standard for less than 2 percent of the time (about 175 hours per year), representing infrequent but realistic peak conditions that regulators use to assess short term air quality impacts.

Because the Base Case alone exceeds the standard, Tilbury Phase 2, even after mitigation, will still contribute to exceedances: it adds a small increment of  $0.86 \mu\text{g}/\text{m}^3$  under these peak conditions ( $\text{HQ} = 1.1$ ), extending the area of exceedance to an adjacent business receptor near the Project footprint. However, under more typical conditions, represented by lower percentiles such as the 90th or 75th,  $\text{NO}_2$  concentrations remain below the standards, meaning that for the vast majority of operating hours, air quality meets regulatory objectives. See Air Quality section of the Assessment Report for more details.

For all sensitive receptor locations, during regular operation mitigated  $\text{NO}_2$  emissions HQs were less than 1.0.

Non-routine flaring events can result in short-term (acute) increases in nitrogen dioxide ( $\text{NO}_2$ ) concentrations, with modelling indicating that 1-hour  $\text{NO}_2$  levels may exceed applicable air quality objectives by several times under worst-case conditions, corresponding to acute hazard quotients (HQs greater than 1.0) at some sensitive receptors. These elevated HQs indicate the potential for transient respiratory effects, such as airway irritation or asthma exacerbation, during flaring events. However, flaring is infrequent and short-duration, and the HHRA concludes that while acute effects are possible during these episodic events, they do not translate into sustained or chronic health risk over the life of the Project.

Chronic exposure refers to exposures that occur over extended periods of time, potentially leading to longer-term health effects. Chronic exposure to  $\text{NO}_2$  was also assessed, and while workers near the facility may face a slightly elevated levels of COPC, all business receptors fall below HQ of 1.0 in the mitigated scenario. (HHRA, Appendix J of Revised Application).

EAO notes that for provincially regulated workplaces the *Workers Compensation Act* and Regulation specify the requirements for employers to ensure the health and safety of workers in all work. This includes specific requirements associated with indoor air quality, as well as other requirements that ensure employers consider safety of workers outdoors if for example air quality is affected by high concentrations of PM.

#### *Acute and chronic exposures to $\text{SO}_2$*

For  $\text{SO}_2$ , short-term exposure can also cause breathing difficulties, especially in people with asthma or other respiratory conditions. Children are considered particularly sensitive.

$\text{SO}_2$  levels during operation are expected to increase as a result of Tilbury Phase 2; however, mitigation measures are predicted to reduce maximum  $\text{SO}_2$  concentrations from Project sources by more than 70% across all averaging periods compared to the unmitigated scenario. This reduction is achieved through emission control technologies, resulting in a low-magnitude impact confined to the immediate Project footprint.

All predicted mitigated project concentrations of  $\text{SO}_2$  for the Base Case, and Application Case are below the 1-hour and annual CAAQS and MV AAQO 2025 target for chronic and acute exposure of HQ of 1.0.

#### *$\text{NO}_2$ and $\text{SO}_2$ Mitigation*

FortisBC has committed to implementing emission control technologies during the detailed Design Phase, which are expected to significantly reduce  $\text{NO}_2$  and  $\text{SO}_2$  emissions, as indicated by the results of the preliminary mitigated conceptual model. In addition, broader air quality improvements are anticipated through regional initiatives such as CleanBC. As such, the actual health risks associated with Tilbury Phase 2's  $\text{NO}_2$  and  $\text{SO}_2$  emissions were assessed by FortisBC to be negligible to low, respectively. The EAO notes that emissions associated with non-routine flaring cannot be practically mitigated beyond existing design and safety controls, as these events are required for safe facility operation.

#### *Particulate Matter ( $\text{PM}_{10}$ and $\text{PM}_{2.5}$ )*

Emissions from Tilbury Phase 2 include PM, specifically  $\text{PM}_{10}$  and  $\text{PM}_{2.5}$ , which are known to affect respiratory health and may result in a higher risk of respiratory and cardiovascular disease. The HHRA determined that predicted concentrations for  $\text{PM}_{2.5}$  and  $\text{PM}_{10}$  under the Base Case and Application Case, remain below CAAQS and MV AAQO

2025. Based on these findings, FortisBC concluded that health risks from these concentrations are unlikely to be observable. (Appendix B of the Revised Application).

The HHRA looked qualitatively at potential lung cancer risks from breathing in PM<sub>2.5</sub> and DPM. The assessment found that Project-related PM<sub>2.5</sub> emissions are not expected to lead to any observable increase in lung cancer cases. For DPM, the HHRA noted that construction emissions would be short-term and limited to the Project footprint, which would reduce exposure. As a result, the Revised Application determined that an increase in lung cancer risk from DPM is also considered unlikely.

#### *Volatile organic compounds*

VOC emissions during operation are made up of a mix of volatile compounds and other gases released from fuel combustion, including nitrogen, CO<sub>2</sub>, alkanes, water vapour, and small amounts of benzene, toluene, and xylenes. To assess health risks from VOCs, the HHRA used benzene as a surrogate since it's a common and more toxic component of VOC mixtures. The assessment found that the predicted concentrations of benzene were lower than the Toxicological reference values (HQ=0.09) for the protection of human health. This finding indicated that VOC emissions were unlikely to result in an observable health risk.

#### *Deposition on Land and Water (Impacting Country Foods);*

Some air pollutants, like NO<sub>2</sub> and SO<sub>2</sub>, can transform into substances (sulfates and nitrates) that settle onto soil and water, referred to as deposition. This can affect plants, fish, and animals that people harvest and eat, which is especially important for Indigenous communities who rely on traditional or “country” foods.

There is potential for Tilbury Phase 2 to affect country foods in the LAA and FortisBC considered several direct and indirect routes of exposure through its HHRA. The assessment considered whether contaminants from Tilbury Phase 2 could enter the food chain through soil, water, or air. For example, plants used as foods could grow in contaminated soils or be covered by contaminated dust.

The HHRA found no contamination above health standards in groundwater, drinking water, or soil at the Project site, except for a small area with elevated arsenic, which is expected to be cleaned up before construction (see Section 7.6 of Revised Application?). Sediments are also not expected to be affected by any phase of the project, and Tilbury Phase 2 is not predicted to add contaminants or disturb sediments in a way that could impact food chains or country foods.

The assessment looked at whether airborne pollutants like nitrogen and sulphate could settle on land or water and affect country foods. Modeling showed that any deposition would stay within 100 metres of the facility and occur in areas not sensitive to acidification. Soils and surface waters in these areas are not expected to be significantly affected, and Tilbury Phase 2 is not expected to reduce the quality or quantity of country foods. Because of this, FortisBC did not investigate this pathway further.

#### *Carbon Monoxide*

CO is a gas that can interfere with the way your body delivers oxygen to your organs and tissues because it binds to the hemoglobin in your blood. The HHRA, for the unmitigated Application Case, determined that CO emissions would remain below Toxicological reference values for human health (HQ = 0.097 for 8-hour exposure and 0.042 1 hour).

#### *Sensory Disturbances (Noise, Vibration, Odour):*

The Revised Application identified that Project-related changes in sensory conditions, noise, vibration, and odour, may have direct and indirect adverse effects on Human Health. These disturbances can affect comfort, sleep, stress levels, and overall quality of life, particularly for those living or working nearby. Noise and vibration were assessed in [Appendix 6.02, Section 17.02](#) (Acoustic). Visual effects are addressed in Land and Resource Use [Appendix 6.10, Section 17.10](#) (Land and Resource Use) Potential project effects are as follows:

### Noise and vibration

Potential increases in noise and vibration due to Tilbury Phase 2 project activities and physical works were assessed for potential adverse effects to Human Health.

Figure 14: Receptor Location in the LAA and RAA for the Noise Assessment (Source: Acoustic TDR, Appendix C of the Application)

Due to the industrial nature of the LAA, existing ambient noise levels are already relatively high (between 46.6 and 57.1 decibels). The existing ambient sound level at the receptors was measured and found to be dominated by industrial, road, rail, river, and air transportation activities.

Noise and vibration were modelled by FortisBC and the EAO's assessment on the Acoustic VC focuses on Construction and Operation (mainly due to the addition of equipment such as compressor buildings), as decommissioning noise and vibration would be similar to construction.

The HHRA considered five locations:

- **R1:** Residential receptor located 500 meters from the Project Footprint, representing the closest residential dwelling;
- **R2:** Delta Community Animal Shelter ~220 metres away;
- **R3:** Historic Indigenous village site located 700 metres away;
- **R4:** A residential building in Richmond, 1,800 metres away; and,
- **R5:** Informal pathway next to the project site, 5 metres away. The pathway receptor was evaluated for information purposes and is not formally assessed.

### Construction Noise Assessment

- For receptors R1, R2, R3, and R4, the predicted increase in community annoyance (% Highly Annoyed or %HA) due to the Project's Construction is less than the Health Canada threshold of 6.5 percent change, when compared to baseline;
- Sound levels at Receptor R5 (recreational pathway) may exceed Health Canada's guidelines for daytime construction; however, existing conditions at this site already exceed thresholds for speech interference and annoyance;

- The assessment found low frequency noise (LFN) is expected during loud construction phases. More detailed analysis is planned in the design stage;
- If a Certificate is granted, FortisBC will assess LFN potential during construction, per BCER guidelines; certain activities (e.g., alarms, material dropping) could exceed Health Canada's criteria; and
- Tilbury Phase 2 is not expected to significantly increase sleep disturbances during construction because existing noise levels at residential receptors (R1, R4) already exceed Health Canada's 40 Decibel(s) (A-weighted scale) (dBA) threshold and worst-case cumulative predictive noise increases would be below 1 Decibel (dB).

### Operational Noise Assessment

- LFN from the Project is predicted to be above the Health Canada guidance at R1,3,4, and 5 but below BCER's threshold for at R1 and R4 receptors.
- Daytime sound levels at Receptor R5 may exceed Health Canada's high annoyance guidelines (6.5%) during Operation;
- For Operation (minimum 40 years), FortisBC identified that nighttime noise increases will be minimal and likely undetectable from existing level; and
- FortisBC plans to develop mitigation measures with a QP to manage acoustic disturbances, including at R5 (Appendix A, Table A-1, Revised Application).

### *Potential for disproportionate effects of exposure to noise disturbances*

Section 7.15 of the Revised Application outlines that health effects from noise and vibration may differ across subgroups. Key findings include:

### Vulnerable Populations:

- People with lower socio-economic status (SES) may be more susceptible to noise effects due to fewer resources to adapt their daily lives.<sup>72</sup>
- Children and youth are particularly sensitive to increases in noise.<sup>73</sup>
- In the Roberts Bank Terminal 2 (RBT2) Review Panel Hearing, Tsawwassen has previously reported that industrial noise infringes on their peaceful enjoyment of land and waters, an important aspect of their culture.<sup>74</sup>

### Nighttime Noise and Health:

- Nighttime noise can reduce sleep quality and quantity, especially affecting children, the chronically ill, the elderly, and shift workers.<sup>75</sup>
- Lower SES communities are more likely to be exposed to higher levels of noise pollution.

<sup>72</sup> Berkers, et al. 2021. "The relative effects of self-reported noise and odour annoyance on psychological distress: Different effects across sociodemographic groups?" PLoS ONE. Vol. 16, No. 10.

<sup>73</sup> See Footnote above, Berkers et al.

<sup>74</sup> Port Metro Vancouver. 2019. Review Panel Public Hearing: Roberts Bank Terminal 2 Project. June 1. <https://iaac-aeic.gc.ca/050/documents/p80054/130113E.pdf>.

<sup>75</sup> World Health Organization (WHO). 2010. "Noise." World Health Organization Europe. April 27. <https://www.who.int/europe/news-room/fact-sheets/item/noise>.

- Exposure to noise pollution is associated with poorer early childhood developmental outcomes.<sup>76</sup>

**Recreation and Outdoor Use:**

- Noise and vibration may discourage recreational users from accessing the Fraser River and surrounding lands (Revised Application Section 7.11 – Lands and Resource Use).
- FortisBC's Human Health assessment notes that chronic or cumulative noise exposure may result in people avoiding the area for outdoor or recreational activities, which could impact physical activity and overall well-being (Revised Application Section 7.15.3.5 – Physical Activity).

**Well-Being and Use Behavior:**

- Although overall health effects to users of the Fraser Riverbanks and waterways are not expected, some people may change how they use the area due to noise disturbances.
- At the historic Indigenous village (Receptor R3), predicted project-specific noise levels during Construction and Operation are not expected to exceed the change in %HA health guidelines. The human health VC and Appendix J (HHRA) did not assess sleep disturbance at R3 because it was not considered a residential receptor; however, R3 was assessed for sleep disturbance under the acoustic VC due to its identification as a sensitive receptor. This assessment is important to consider in light of First Nations comments regarding potential future use of the historic Indigenous village site. The World Health Organization sleep disturbance threshold of 40 dBA LN outdoors was used as the threshold for assessing night-time construction noise. Predicted noise levels at R3 are expected to exceed the 40 dBA guideline under ambient conditions (50.4), and the cumulative construction scenario (baseline plus Project) (52.1). The predicted increase in noise between the baseline and cumulative construction scenario was assessed to be 1.7 dBA.

See [Appendix 6.10, Section 17.10](#) (Land and Resource Use) of this Report for the EAO's assessment of potential effects to land and resource use.

**Odour annoyances**

The Revised Application acknowledges that odour annoyance can affect health and well-being, particularly for people living near emission sources. Strong odours or visible haze contribute to the sensory environment within the RAA and LAA and may influence stress or anxiety. For example, very high NO<sub>2</sub> concentrations can produce a noticeable odour and brownish haze.

However, Section 7.15 of the Revised Application determined odour from NO<sub>2</sub> is not expected to affect human health in the LAA because the concentrations that result from Tilbury Phase 2's mitigated emissions are lower than those required to produce a strong odour.

Section 7.15 states that Tilbury Island and nearby industrial areas have multiple potential odour-emitting sources, including the Annacis Island wastewater treatment plant, Vancouver landfill, and Delta composting facility. This makes quantifying odour events challenging.

Section 7.15 also states that the Human Health Risk Assessment did not include a specific odour assessment, and no odour modeling or predictions for Tilbury Phase 2 were available. Odour events are difficult to quantify with continuous monitoring equipment, and odour disturbances are typically recorded by complaints made by the public. As such, FortisBC has committed to mitigation measures, including receiving, recording, investigating, and following up on odour complaints from Indigenous nations, the public, and adjacent businesses.

---

<sup>76</sup> Berkers, et al. 2021. "The relative effects of self-reported noise and odour annoyance on psychological distress: Different effects across sociodemographic groups?" PLoS ONE. Vol. 16, No. 10.

#### 17.14.4.2 Social Determinants of Health

In addition to environmental exposures, Tilbury Phase 2 may influence human health through social, economic, and cultural pathways, collectively known as social determinants of health. These include factors such as income, education, employment, access to health services, and experiences of discrimination or historical trauma.

##### Potential Effect to Health and Well-being Due to Change to Socio-economic Status

The socio-economic status of workers and their families is expected to be positively affected by Tilbury Phase 2 across all phases, including construction, operation, and decommissioning. These benefits would be driven primarily by increases in employment opportunities, the range of employment types, and household income. See [Section 7.10 \(Employment and Economy\)](#) of the of the Revised Application.

##### *Employment Type*

The assessment indicates that many construction and operational jobs would involve shift work or rotational schedules, which are associated with adverse health and well-being outcomes. Evidence links shift work to disruptions in sleep and mental health, increased risks of substance use, workplace and traffic accidents, and broader effects on family and household well-being. These effects may be more pronounced for women and Indigenous workers.

As shift work would be required during both construction and operation, Tilbury Phase 2 could negatively affect the health and well-being of workers and their families. The proponent has committed to implementing mitigation measures to reduce these effects where feasible.

##### *Household Income*

Tilbury Phase 2 is expected to result in increased household income, with most employment opportunities anticipated to be filled by workers from the Lower Mainland. Overall, labour income in B.C. is predicted to increase by approximately 1.194 billion dollars over construction, or about 0.199 billion dollars annually, with an average Construction-Phase income of about 89,400 dollars per worker. During operations, Tilbury Phase 2 is expected to generate approximately 17.2 million dollars per year in direct labour income.

FortisBC has committed to maximizing the positive socio-economic and health benefits associated with this increased income. This includes applying its Human Resource Policy to recruit workers from groups that are traditionally underrepresented in the construction labour force, such as women, Indigenous peoples, and new immigrants, and implementing cultural awareness programs to support respectful engagement with Indigenous peoples.

FortisBC has also committed to working with Indigenous nations to identify economic opportunities and capacity, provide advance notice to support participation, and communicate Project activities and safety information throughout all phases. In addition, FortisBC's Socio-Economic Impact Program and procurement approach are intended to extend benefits beyond Tilbury Phase 2 by creating broader employment opportunities and supporting local, regional, and Indigenous businesses.

FortisBC acknowledged that First Nations may face additional barriers to employment due to the ongoing legacy of colonization affecting education and employment outcomes. While FortisBC encourages contractors to follow its Statement of Indigenous Principles and "Vendor Code of Conduct" policies, it does not require contractors to set Indigenous employment targets, and wages for contracted positions are outside FortisBC's control.

EAO notes that this limited influence over employment outcomes reflects concerns raised by Indigenous nations. Ts'uubaa-asatx and x'məθk'əyəm noted that positive economic effects are difficult to achieve without addressing systemic barriers, highlighted the persistent income gap between Indigenous and non-Indigenous people, and questioned how hiring practices would meaningfully address this disparity.

x̣ṃəθḳẉəỵəm also raised concerns that project employment could conflict with participation in traditional activities, such as fishing, and suggested measures such as paid cultural leave. Cheam First Nation emphasized the need for Indigenous cultural awareness and safety measures to support the hiring, retention, and advancement of Indigenous workers. Quw'utsun Nation raised concern of creating equitable economic opportunities for Nations (such as Quw'utsun Nation) that are geographically distant from Tilbury Phase 2.

Tsawwassen First Nation (Tsawwassen) stated The Nation also asserts that FortisBC has not presented information in the Revised Application to substantiate how positive benefits would be accrued by Tsawwassen or its members and encourages FortisBC to work on addressing this information gap

x̣ṃəθḳẉəỵəm acknowledged that Tilbury Phase 2 could create positive economic opportunities for their members, particularly through employment, procurement, and training commitments set out in the Tilbury Projects Master Agreement. They also recognized that the Agreement provides a framework for shared benefits, skills development, and long-term economic participation, which they view as meaningful if opportunities are accessible and aligned with community needs.

#### Potential Effect to Health and Well-being Due to Change to Population Health Status

Population health describes the overall health of a community and is shaped by social, economic, and physical conditions, as well as behaviors, coping capacity, and access to services. Effects on population health from Tilbury Phase 2 are expected to be indirect, given the many interacting factors that influence health outcomes.

Section 7.15 of the Revised Application finds that population health is predicted to be both positively and negatively affected by Tilbury Phase 2. Positive effects are primarily linked to improved socio-economic status across construction, operation, and decommissioning, which is expected to indirectly support health and well-being. Potential negative effects are associated with factors such as increased substance use and heightened stress or anxiety among a small portion of nearby communities related to perceived safety and environmental risks.

Perceptions of risk, even where actual risks are low, can affect health through stress, anxiety, behavioral changes, and reduced use of recreational or culturally important areas. These effects may be more pronounced for women and racialized communities.

Overall, EAO anticipates that effects on population health related to perceived safety will be negligible, based on Project design, safety standards, operational experience, and proposed mitigation measures, including transparent communication, advance notification of disruptive activities, and a complaint monitoring system.

#### 17.14.5 Mitigation Measures

FortisBC proposed a range of mitigation and enhancement measures to support positive health outcomes and reduce potential negative effects on human health during the Construction, Operation, and Decommissioning Phases of the Tilbury Phase 2 Project. These measures are designed to address both environmental and social determinants of health, and are linked to other VCs such as Air Quality, Acoustic (Noise), Soil, Surface Water, and Employment and Economy.

- Incorporate emissions reduction and control technologies in Tilbury Phase 2 design to ensure compliance with regulatory air quality requirements and industry best practices.
- Develop and implement waste management mitigation measures as part of the CEMP.
- Electrify Tilbury Phase 2 refrigeration and feed gas compression processes to reduce air emissions.
- Require contractors and subcontractors to implement a fit for duty policy consistent with FortisBC's corporate guidelines.
- Receive, record, investigate, and follow-up on odour complaints from Indigenous nations, the public, and adjacent businesses.

- Final noise mitigation measures for project equipment will be engineered based on detailed noise specifications and incorporated into Tilbury Phase 2.
- Promote awareness of local and regional business opportunities.
- Offer support for FortisBC employees suffering from substance use.
- Implement shift schedules that take into consideration the health and safety implications of shift work.
- Implement FortisBC's Human Resource Policy to recruit workers for Tilbury Phase 2, targeting groups that are traditionally underrepresented in the construction labour force.
- Develop dust-control measures to limit PM emission during the construction.
- Develop mitigations to manage acoustic disturbance to human and wildlife receptors.
- Develop erosion and sediment control measures to manage surface water to reduce sediment deposition into watercourses or storm sewers.
- Develop emergency response measures to prevent and manage emergencies, including complete onsite fire control and response systems independent of Delta Fire and Emergency Services.
- Develop and implement a vehicle idle reduction policy that focuses on reducing noise and vibration emissions from construction vehicles.
- All compressors will be enclosed to attenuate noise to a level consistent with the BCER noise regulations.

For a full list of mitigation and enhancement measures, refer to Table 7.15-14 in the Human Health section of the Revised Application.

In addition to the provincial conditions including Condition 12 (CEMP) which requires the creation of a CEMP, and Condition 14 (Air Quality Management Plan) requiring an Air Quality Management Plan. As part of the substituted process, the EAO has identified KMM for effects within federal jurisdiction to inform IAAC's draft potential federal conditions. The KMM related to the health, social, and economic conditions of Indigenous peoples under the IAA are outlined in [Appendix 2](#).

#### **17.14.6 Key Issues Raised**

Health-related feedback on FortisBC's Revised Application was received through public responses to the EAO's engagement survey, open houses, and letter submissions from non-government organizations during Application Review. These included concerns about increased risks to human health from potential malfunctions and accidents at the project site, increased health risks due to flaring, Tilbury Phase 2's indirect health impacts from climate change, and changes in social determinants of health. For more information related to FortisBC's climate change resilience assessment, see Section 8 of the Revised Application.

During Application Review members of the TAC raised the following key issues related to the assessment of Human Health for Tilbury Phase 2.

##### **17.14.6.1 Human health and air emissions, mitigation controls and scenarios**

Concerns about air emissions and their potential impacts on human health were raised by several reviewers. Vancouver Coastal Health requested FortisBC consider human health risks from emissions during initial start-up of the Tilbury Phase 2 Facility or upset conditions. FortisBC responded by explaining that emissions during these phases are expected to be rare, brief, and low in frequency. To assess worst-case impacts, Fortis modelled continuous upset emissions over a three-year period.

Health Canada, Fraser Health Authority, Vancouver Coastal Health Authority, xʷməθkʷəy̓əm, TWN and Quw'utsun Nation expressed concern over the lack of detail regarding air emission mitigation measures. FortisBC stated these mitigation measures would be developed as part of detailed design, based on permitting, regulatory requirements and available technology. Health Canada requested more detailed information on the types of technologies and their potential to reduce emissions, particularly for Oxides of nitrogen (NO<sub>x</sub>) and Oxides of Sulphur (SO<sub>x</sub>) as well as on commissioning and start-up procedures. FortisBC responded that Appendix P of the Revised Application (Tilbury Phase 2 LNG Expansion Best Available Technology (BAT) Study) outlines the emissions control technologies being considered and their known effectiveness in reducing emissions, and additional information on procedural details was not available. FortisBC also revised the Application to include a mitigated scenario for air quality.

Fraser Health Authority suggested that the conditions of approval specify the use of best available technology, minimum required emission reductions, and air quality monitoring, to be developed in consultation with Metro Vancouver, local governments, First Nations, and health authorities. FortisBC responded that a mitigated scenario, based on the final design, will be modelled as part of Metro Vancouver's air emissions permitting process, which includes engagement with regional health authorities to address health concerns.

Quw'utsun Nation raised specific concerns about ensuring safe emission limits are defined using the proposed technologies and questioned whether Metro Vancouver's permitting process adequately considers the concerns of First Nations. Quw'utsun Nation also requested specific information on the mitigation measures and safe limits to ensure First Nations' interests have been appropriately considered.

FortisBC responded with updated modelling that used mitigated operational scenario (Appendix L), and that future mitigation measures are expected to further reduce any potential risk identified, resulting in no disproportionate health effects expected for Indigenous peoples.

FortisBC has committed to meeting relevant air quality standards once Tilbury Phase 2 begins operation. Health Canada supported this commitment and recommended that FortisBC include details on which air quality standards for which pollutants will be used.

Health Canada also suggested a condition that includes monitoring to verify predicted impacts, supports adaptive management if predictions are exceeded, and requires regular reviews to ensure best practices and available technologies are used to minimize emissions.

EAO also notes that flaring, including during start-up and upset conditions, at gas facilities in B.C. is regulated under permitting requirements set by the BCER. Permit holders must follow regulations and detailed operational guidelines to minimize emissions and protect air quality and public health, including mandatory monitoring, reporting, and, where applicable, notification to nearby residents and the BCER of non-routine flaring events. While the regulatory framework requires operators to quantify and report flaring activity, it does not, in itself, require continuous ambient air quality monitoring of criteria air contaminants (CACs) specifically for flaring emissions, unless such monitoring is imposed as a condition of an LNG facility permit or required under another applicable regulatory instrument. In response to concerns about potential air quality impacts associated with flaring, EAO added an ambient air quality monitoring condition, that requires monitoring, reporting, and adaptive management during the first five years of operation. EAO also added a condition for monitoring and reporting of the use of the flare during the life of the Project.

The EAO is of the view that potential effects to human health from air emissions from Tilbury Phase 2 has been sufficiently assessed in the Revised Application, and any residual effects would be adequately addressed through the current air quality guidelines, future air quality and flaring permitting requirements, and provincial Condition 14 (Air Quality Management Plan) requiring an Air Quality Management Plan that will include consultation with First Nations and technical advisors as part of a technology selection process.

#### 17.14.6.2 Changes in socio-determinants of human health, including Indigenous health and well-being and disproportionate effects

Participating Indigenous nations, including xʷməθkʷəyám, TWN and Quw'utsun Nation, advocated for more meaningful inclusion of Indigenous Knowledge and perspectives in the assessment. They advocated for the integration of Social Determinants of Indigenous Health (SDIH) – a psychosocial approach to health assessment, which includes the impacts of colonialism (both historic and on-going), self-determination, and community perceptions of risk. Additional concerns were raised about the limited consideration of cultural determinants of health, mental health and wellness, food security, proximity to the historic First Nation Village Site, the cultural significance of traditional harvesting practices, and barriers to accessing health services. xʷməθkʷəyám requested that the Proponent commit to monitoring health and well-being using metrics, indicators, and methods developed by xʷməθkʷəyám, and called on FortisBC to acknowledge the insufficient consideration of cultural determinants of health in the current assessment.

FortisBC responded that their assessment included an analysis of human health that goes beyond the SDIH model, and the SDIH model is explicitly considered in Section 13 of the Revised Application. FortisBC is also of the view that perceptions of potential risks from Tilbury Phase 2 and associated health consequences would not be substantively different from perceptions of potential risk and associated health consequences occurring today from the existing Facility.

EAO's assessment and conclusions on Malfunctions and Accidents, included further discussion on real and perceived safety risks, which relate to psychosocial concerns raised by some reviewers, see [Appendix 7](#) of this Report. Also see [Appendix 5](#) related to Indigenous interests. The EAO considers this issue identified and sufficiently addressed through the following Conditions:

- Condition 10 (Community Feedback Process) sets up a process to receive and respond to issues raised by First Nations, their members, and the public during Construction, Operation and Decommissioning Phase;
- Condition 13 (OEMP) requires a plan to manage Project environmental effects during operation;
- Condition 14 (Air Quality Management Plan) requires a plan to manage air quality effects from Tilbury Phase 2; and
- Condition 16 (First Nations and Local Economic Inclusion and Monitoring Plan) requires a plan to support economic participation of First Nations and local communities, including employment, contracting, and training strategies.

#### 17.14.7 The EAO's Characterization of Residual Effects

After considering the comments received from the public, non-government organizations, participating Indigenous nations, and members of the TAC, FortisBC's responses, proposed mitigation measures and conditions, the information contained in the [Joint Permitting/Regulatory Coordination Plan](#) and the [Regulatory Coordination Issues Tracking Table](#), the EAO concludes that Tilbury Phase 2 would result in the following residual adverse effects on Human Health for the following reasons:

- Health and well-being effects associated with inhalation of COPC during operation; and
- Exposure to shift work may have direct and indirect adverse effects on the health and well-being of workers and their families.

The EAO also concludes that Tilbury Phase 2 has the potential to result in positive changes to the socio-economic statistics through changes in employment rates, employment types, and household income. See Table 7.15-12 in [Section 7.15 Human Health](#) of the Revised Application on the predicted effects of Tilbury Phase 2 for more information on this and other potential positive effects of Tilbury Phase 2.

The EAO's characterization of the expected residual effects of Tilbury Phase 2 on Human Health is summarized below, as well as the EAO's level of confidence in the effects determination (including their likelihood and significance). The EAO's characterization considers the adverse residual effects after mitigations, as well as the efficacy of those proposed mitigations.

Table 66: Summary of Residual Effects for Human Health

| Residual Effect                                                              | Assessment Rating*                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Significance and Rationale                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Human Health from Air Quality<br><br>Health impacts from Inhalation of COPCs | Context (resilience): Low to Moderate<br><br>Magnitude: Low to High<br><br>Extent: Local<br><br>Duration: Long-term<br><br>Frequency: Regular, Irregular, Continuous<br><br>Reversibility: Partially reversible<br><br>Affected Populations: Disproportionate for sensitive receptors, may have more pronounced health risks.<br><br>Identified sub-groups:<br><ul style="list-style-type: none"> <li>• Onsite workers; and</li> <li>• Offsite workers (business receptors)</li> </ul> Risk (Likelihood x consequence): Moderate<br><br>Uncertainty: Moderate to High<br><br>Importance: High | <p><b>Not significant</b></p> <p>The airshed has low to moderate resilience because existing NO<sub>2</sub> concentrations are elevated and other concentrations remain below thresholds. While this increases vulnerability, background levels of COPC, including NO<sub>2</sub>, have been declining, and SO<sub>2</sub> has dropped significantly due to low-sulphur marine fuel requirements.</p> <p>The mitigated proposed Project is predicted to have a negligible (NO<sub>2</sub>) to low-magnitude (SO<sub>2</sub>) effect on air quality compared to existing conditions. The potential residual effect to the health and well-being of mitigated emissions is therefore conservatively predicted to be low magnitude (see Section XX, Air Quality). However, during flaring the HHRA showed a HQ of 5, which is rated as high magnitude.</p> <p>For the mitigated Application Case, maximum predicted air concentrations for SO<sub>2</sub> and NO<sub>2</sub> occur at the facility fence line, and NO<sub>2</sub> marginal exceedances of health-based limits are limited to the immediate vicinity of the property boundary, with no exceedances predicted at any sensitive receptor location. However, Tilbury Phase 2 will increase NO<sub>2</sub> and SO<sub>2</sub> levels beyond the property line throughout the LAAs and RAAs, though these contributions are not in exceedance of health-based limits for sensitive receptors. Additionally, flaring could increase NO<sub>2</sub> concentrations across sensitive receptors throughout the local area of assessment.</p> <p>Predicted increase of health and well-being effects include endpoints that may or may not be irreversible (such as cardiovascular issues, airway hyperresponsiveness, asthma requiring emergency room visits, hospitalization).</p> <p>Exposure to air contaminants is expected to be continuous throughout the Construction, Operation, and Decommissioning Phases of Tilbury Phase 2. Flaring will occur regularly during yearly commissioning, and other flaring events are unpredictable, or irregular.</p> <p>The likelihood of an adverse effect occurring is medium likelihood of occurring, given the variation in conceptual modelling. There is a moderate consequence of a residual effect due to negligible to the low to high magnitude and local extent. Therefore, the risk of an adverse effect occurring to human health as a result of Inhalation of Contaminants of Potential Concern is rated as moderate.</p> <p>Uncertainty is moderate to high because the HHRA relies on conceptual emissions modelling and an incomplete project design. Final emission-reduction technologies have not been selected, and limited information is available on the effectiveness of planned mitigation measures. These details are expected to be refined through permitting, which may or may not introduce additional mitigation or monitoring requirements, adding further uncertainty to the predicted outcomes.</p> <p>This residual effect on human health has high importance and has been identified as an interest to First Nations, government agencies, members of the public, and non-government organizations.</p> |

| Residual Effect                                                                                                                   | Assessment Rating*                                                                                                                                                                                                                                                                                                                        | Significance and Rationale                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Human Health and employment type<br>Health impacts from shift work                                                                | Context (resilience): Medium, but low for certain sub-populations<br>Magnitude: Negligible to low<br>Extent: Regional<br>Duration: Long-term<br>Frequency: Continuous<br>Reversibility: Partially reversible<br>Affected Populations: Disproportionate<br>Risk (Likelihood x Consequence) Low<br>Uncertainty: Moderate<br>Importance: Low | <p><b>Not significant</b></p> <p>In Metro Vancouver, many sectors, including healthcare, transportation, manufacturing, and construction, rely on shift work or rotational schedules. While the region's urban workforce generally shows medium resilience to the health impacts of shift work, disparities persist among certain sub-populations. Indigenous peoples, women, and individuals with lower education levels are more likely to experience reduced resilience due to social determinants of health, such as income inequality, limited access to health services, and cultural obligations. These factors can amplify the risks associated with shift work, including sleep disruption, stress, and related health outcomes.</p> <p>The proposed mitigation measures are expected to reduce the potential residual health effects to a negligible magnitude and are unlikely to be discernable from health effects occurring under existing conditions for the majority of the workforce or may be detectable at a low magnitude for some workers, such as more vulnerable population subgroups.</p> <p>Health effects associated with shift work extend across the Regional Area of Assessment, acknowledging that health effects may extend beyond Tilbury Phase 2 site to where workers and their families reside.</p> <p>These health impacts are expected to occur continuously across the Construction, Operation, and Decommissioning Phases, with the greatest effects anticipated during Construction due to higher employment and more frequent shift work.</p> <p>Certain chronic health impacts, such as sleep disorders and stress-related conditions, may persist beyond employment and require on-going management, especially for vulnerable individuals. Therefore, the effects are considered partially reversible and to last long-term.</p> <p>Adverse health effects may be experienced by all shift workers and their families. However, female and Indigenous workers, and those with lower education levels, are expected to be disproportionately affected due to increased socio-economic vulnerability and reduced access to protective resources. These effects can extend beyond the individual, indirectly impacting families and households.</p> <p>The likelihood of an adverse effect is considered medium. While FortisBC's HR policies provide some mitigation, these policies do not consistently apply to all contractors, which may limit their effectiveness. Given the negligible to low magnitude of potential health effects and the positive socio-economic benefits from increased employment, the consequences are minor. Overall, the residual risk is assessed as low.</p> <p>Uncertainty is considered moderate with links between shift work and adverse health effects well understood.</p> <p>The importance of health effects from shift work is considered low, as no parties, Indigenous nations, or TAC members, raised it as a specific concern. However, broader issues around social determinants of health and culturally relevant monitoring were highlighted, particularly for Indigenous well-being. This indicates that while shift work itself was not a priority issue, addressing related impacts through culturally informed strategies and meaningful consultation remains important.</p> |
| * Note: Criteria and assessment ratings are defined in <a href="#">Appendix 3 - Residual Effects Characterization Definitions</a> |                                                                                                                                                                                                                                                                                                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

### 17.14.8 Cumulative Effects Assessment

The current conditions of human health within the RAA, including historical context that provides context for existing conditions, are previously described Section 7.15 of the Revised Application and in Existing Conditions by Proponent and Potential Project Effects by the Proponent sections above ([Section 17.14.3](#)) and considered in the Section [17.14.7](#) of the EAO's Characterization of Residual Effects assessment.

FortisBC's Revised Application identified 5 potential future projects or activities that would have potential to impact cumulatively with Tilbury Phase 2 (see Table 7.15-16 in Revised Application):

- T1B Expansion (proposed);
- TMJ (in permitting);
- Delta Grinding Facility (being assessed);
- RBT2 (procurement); and
- Climate Change.

Of these, T1B, TMJ, and the Delta Grinding Facility are expected to overlap spatially and temporally with Tilbury Phase 2 during construction and operation, contributing to increased emissions of COPC and elevated ambient concentrations. RBT2 was excluded from the Human Health CEA due to its distance (16 km) and limited overlap with Tilbury Phase 2's residual effects.

FortisBC assessed two primary pathways for cumulative effects on human health (see Table 7.15-17 in Revised Application):

- Ambient COPC concentrations during operation, particularly NO<sub>2</sub> and SO<sub>2</sub>; and
- Health and well-being effects from shift work, including sleep disruption, mood and gastrointestinal issues, and mental health impacts.

FortisBC also considered cumulative interactions related to climate change, which were raised during public and stakeholder engagement (see Section 7.15.6.3). FortisBC acknowledged that climate change is contributing to complex and interrelated effects in the RAA, including sea level rise, flooding, wildfires, extreme temperatures, and drought. These events can damage infrastructure, disrupt livelihoods, and cause physical and mental stress, particularly among vulnerable populations. These effects are expected to continue for the foreseeable future. The Climate Change Resiliency Assessment (Appendix G) outlines how these effects may alter environmental and social determinants of health and well-being over time.

Air contaminants from existing conditions, including emissions from the existing facility and Phase 1A, were also considered in the CEA.

#### 17.14.8.1 Health Impacts from Increase COPC Concentrations

The RAA for air quality includes a section of the Fraser River with intensive industrial and commercial activity, significant NO<sub>2</sub> and SO<sub>2</sub> emissions, heavy vessel traffic, and ongoing shoreline development. Elevated ambient concentrations of these contaminants can increase respiratory health risks, including airway hyperresponsiveness, asthma requiring emergency care, and hospitalization.

As outlined in Section 7.15 of the Revised Application, under the Cumulative Case scenario, exceedances of the 1-hour NO<sub>2</sub> MV AAQO and the 2025 CAAQS are predicted at certain sensitive receptors—including residential areas and an Indigenous Village Site, even after mitigation measures for Tilbury Phase 2 are applied. These exceedances are primarily attributable to background levels, and other anticipated regional developments.

The predicted effect is classified as high in magnitude ( $HQ = 2.04$ ). Predicted 98<sup>th</sup> percentile 1-hour  $NO_2$  exceedances are expected across the full three-year modelling period (2013-2015) when all background percentile levels (98<sup>th</sup>, 90<sup>th</sup>, and 75<sup>th</sup>) are included, indicating that elevated concentrations are not isolated events but reflect a persistent, ongoing effect.

Annual  $NO_2$  exceedances are limited to a small area over water near the TMJ facility.

Although current background  $NO_2$  levels are elevated, they are expected to decline with regional emission reduction efforts, including CleanBC initiatives, low-sulphur fuel regulations, and adoption of cleaner technologies such as electric tugboats and BC Ferries' hybrid diesel-electric vessels.

For  $SO_2$ , cumulative concentrations during operation are predicted to remain below MV AAQO and CAAQS 2025 across the RAA, except under rare 100<sup>th</sup>-percentile background conditions. Annual averages are expected to remain below regulatory thresholds. While cumulative effects may slightly increase ambient  $SO_2$  along the Fraser River and its northern bank, concentrations are still predicted to remain within applicable limits.

Cumulative increases in CO, PM, and VOCs are not expected to exceed MV AAQO and CAAQS 2025 anywhere within the RAA, with no predicted health impacts.

Overall, Tilbury Phase 2 and other foreseeable developments may contribute additional  $NO_2$  and  $SO_2$  emissions to existing ambient conditions, which could increase exposure to these contaminants, elevating respiratory health risks to some degree. However, ongoing reductions in background COPC levels and FortisBC's proposed emission control technologies are expected to reduce these cumulative increases over time. Because specific control technologies have not yet been finalized, the EAO has a moderate level of confidence in the CEA.

Cumulative effects from inhalation of potential contaminants of concern may occur within the RAA, given high-magnitude effects ( $HQ > 1$ ) at some sensitive receptors throughout the life of Tilbury Phase 2. Tilbury Phase 2's incremental contribution to these cumulative concentrations is expected to be low magnitude, with most of the cumulative conditions attributable to other foreseeable projects and elevated background levels that will continue into the future. Therefore, Tilbury Phase 2 is not expected to cause a significant cumulative impact to human health from increased COPC concentrations.

#### **17.14.8.2 Health Impacts from Shift Work**

FortisBC noted that cumulative health effects from shift work because of Tilbury Phase 2 are likely, especially among vulnerable groups such as women, Indigenous peoples, and those with lower education. Risk depends on prior exposure, schedule patterns, and socio-demographic factors. Many foreseeable projects will also involve shift work. Associated cumulative health impacts include sleep disruption, mood and gastrointestinal issues, mental health challenges, and increased substance use, which can extend beyond workers to affect families.

These effects are considered low in magnitude, moderate risk, and partially reversible. FortisBC expects the greatest impacts during the Construction Phase, when shift work is most frequent. Because many factors influence health impacts from shift work across the population and other projects, there is low confidence in predicting cumulative effects due to shift work.

To mitigate potential for cumulative effects to health and well-being from shift work, FortisBC has committed to implementing shift schedules that take into consideration the health and safety implications of shift work, including providing educational resources to understand the health and safety implications.

Additional measures to reduce impacts on human health and well-being from shift work will be implemented through Condition 16 (First Nation and Local Economic Inclusion and Monitoring Plan). In addition, the Condition 03 (Document Development Condition) would apply to the First Nation and Local Economic Inclusion and Monitoring Plan, which includes evaluation of adaptive management and mitigation effectiveness requirements.

While there may be moderate cumulative effects, due to shift work that are not significant, these are largely the result of existing and future regional activities rather than the incremental contribution of Tilbury Phase 2.

#### 17.14.9 Conclusion

The EAO is satisfied that Tilbury Phase 2 would not cause significant adverse residual or cumulative effects on the Human Health VC. The extent of significance for federal effects to the health, social, and economic conditions of Indigenous peoples is found in [Appendix 15](#) and federal Key Mitigation Measures and Follow-up Programs under the IAA for the health, social, and economic conditions of Indigenous peoples ([Appendix 2](#)). This conclusion considers the information and analysis presented in this section; the views of the TAC including First Nations, as well as the public, non-government organizations, and FortisBC; the proposed Mitigation Measures identified in the provincial Table of Conditions relevant to Human Health and federal Key Mitigation Measures and Follow-up Programs under the IAA for the health, social, and economic conditions of Indigenous peoples ([Appendix 2](#)).

## 18.0 APPENDIX 7 RISKS OF MALFUNCTIONS AND ACCIDENTS

### 18.1 Background

Malfunctions and accidents were assessed due to their importance to First Nations, marine and roadway users, the public, and to meet provincial<sup>77</sup> EA and federal<sup>78</sup> impact assessment requirements. Unplanned events that could arise from malfunctions or accidents associated with Project-related activities may result in effects to environmental, economic, social, cultural, heritage, and health VC, GHG, and Indigenous interests.

According to the EAO's Effects Assessment Policy,<sup>79</sup> a malfunction is considered a failure of a device, piece of equipment, or a system to function as intended and an accident is an unexpected occurrence or unintended action. This section considers potential malfunctions and accidents, identifies the mechanisms that would be implemented during design, construction, and operation to mitigate the impacts of these potential events throughout the life of Tilbury Phase 2, and assesses the potential effects of these events throughout the life of the project.

### 18.2 Assessment Methods

The assessment focused on credible malfunctions and accident scenarios that could occur during the construction and operation of Tilbury Phase 2 that could result in an adverse effect to a VC and Indigenous interests. FortisBC (or the Proponent) identified the scenarios based on similar projects, input from industry experts, and feedback from the TAC and First Nations. FortisBC's assessment is in [Section 9](#) of the Revised Application.

The Proponent assessed the residual effects of malfunctions and accidents on VCs by assigning risk scores using a risk matrix that considers likelihood and consequence outlined in (Table 67).

---

<sup>77</sup> Section 25(2)(c) of the Act requires that the risks of malfunctions or accidents be considered in every assessment.

<sup>78</sup> Subparagraph 22(1)(a)(i) of the IAA specifies that the assessment of a designated project must take into account the effects of malfunctions and accidents that may occur in connection to the Project.

Note: ≤ = less than or equal to

A preliminary Quantitative Risk Assessment (QRA) was conducted by the Proponent to inform the application; however, it was not included in the Application itself and was not reviewed by environmental participants. QRA aims to identify and evaluate the potential consequences and likelihood of malfunctions and accidents to establish a risk rating and inform effective mitigation strategies. The review of facility siting and layout including results of the QRA is addressed in BCER's permitting process for LNG facilities.

An inventory of materials that could be located on the Project Footprint (e.g. natural gas, solvents, mixed refrigerants, diesel fuel, other chemicals) was included in the Revised Application.

FortisBC manages the security and integrity of its utility assets through multiple layers of protection, aligned with Canadian Standards Association Z246.1-17 (security management for petroleum and natural gas industry systems). This includes, but is not limited to, incorporating physical security elements in design, and monitoring the security environment. FortisBC's preliminary risk assessment, in combination with an assessment of the security environment in the Lower Mainland has assessed the risk of terrorism as negligible. Therefore, as per Section 9.0 of the AIR, accidents and malfunctions from intentional acts of terrorism or force majeure are beyond the scope of the assessment.

## 18.3 Potential Project Effects and Proposed Mitigations

### 18.3.1 Summary of Potential Project Effect

The Proponent assessed the potential effects from malfunctions and accidents on VCs and Indigenous interests in [Section 9](#) of the Revised Application, which is summarized in Table 9.10-1. Malfunctions and accidents that could occur during Construction, Operation, and Decommissioning of Tilbury Phase 2 were considered under the following scenarios:

- **Loss of Containment of LNG without Ignition**

A loss of containment of LNG without ignition can cause extreme cold temperatures. Contact with LNG in this state can potentially result in frostbite to humans in the immediate vicinity of the release. In the unlikely event of an LNG vapour cloud forming and migrating offsite to adjacent riparian areas there may also be impact to wildlife and vegetation.

The rapid vaporization of LNG after release could displace oxygen, posing hypoxia and asphyxiation hazards to individuals and wildlife directly exposed to the displaced oxygen. A release could also lead to temporary restricted access zones affecting land and resource use, Indigenous interests, and local economy by temporarily interrupting agricultural, cultural, recreational, and economic activities near the Project footprint.

It could also alter perception of safety for some individuals, resulting in avoidance of the Project area, impacting their ability to practice their rights, even after the incident has been assessed and addressed.

Due to LNG's physical characteristics such as rapid evaporation and quick dispersion in the environment, no long-term environmental effects are expected from a loss of containment, however the consequence for human health is considered critical due to the potential effects of cold exposure and asphyxiation.

- **Fire or Explosion, including Loss of Containment of LNG with Ignition**

A loss of containment of LNG and other flammable materials could result in a jet fire, vapour cloud flash fire, or vapour cloud explosion.

- For a jet fire, a high-pressure release of flammable liquid or gas that ignites immediately, producing a torch-like flame, the vulnerability zone where second-degree burns could occur to unprotected human skin has been conservatively estimated to extend approximately 150 metres from the puncture site.
- For a vapour cloud flash fire, a sudden ignition of a dispersed hydrocarbon vapour cloud that burns back through the cloud, a large, sustained release could allow a hydrocarbon vapour cloud to migrate offsite. If it encounters an ignition source under the right conditions, the resulting flash fire could reach nearby properties (e.g., Varsteel, Seaspan) and riparian areas north to the Fraser River and south to Tilbury Slough, before atmospheric mixing dilutes the methane below its Lower Explosive Limit.

- The potential downwind extent of a flammable vapor cloud explosion, an ignition of a confined or partially confined vapour cloud that generates a pressure wave, during average weather conditions, is approximately 290 metres with the largest credible release of LNG.

Such events would cause temporary and localized air emissions and noise, potentially burning or damaging vegetation and wildlife habitat at the Project Footprint edges, and lead to temporary restricted access zones for land use and cultural practices lasting days or weeks. Critically, a fire or explosion could potentially injure or cause death to individuals within the Project Footprint, those using adjacent land, and at nearby businesses. Beyond the physical harm, death and temporary access restrictions, this scenario could cause psychological and emotional stress for some Indigenous people, potentially impacting their mental health and leading to long-term effects on Indigenous nations' perception of safety near the Project.

- **Release of hazardous materials**

A release of hazardous materials, such as hydrocarbons or refrigerants, resulting from equipment failure or error could contaminate soil, groundwater, and surface water. This contamination could potentially harm vegetation and wildlife habitat, lead to injury or death of fish and aquatic organisms in affected water bodies like the Fraser River and cause long-term effects on biotic communities and bioaccumulation.

Direct exposure to hazardous materials could affect human health during cleanup and remediation activities through inhalation or dermal contact, though risks from contaminated food or water are considered remote. A release would also likely require a temporary restricted access zone, briefly interrupting local employment, land and resource use, infrastructure, and cultural practices.

The worst-case scenario for a hazardous material release involves approximately 800 tonnes of heat transfer medium, the largest volume of hydrocarbons stored onsite, being released due to equipment failure, operator error, or mishandling. Such an event could lead to contamination of soil, groundwater, and surface water, potentially causing death or long-term effects on fish, aquatic organisms, wildlife, and human health through direct exposure or bioaccumulation. Spills and leaks of hazardous materials, such as diesel, hydraulic fluids, and lubricants, released from construction and operation equipment could cause localized soil contamination with minor impacts on surface water, groundwater, vegetation, wildlife, and fish if the material migrates offsite.

- **Terrestrial Vehicle Collision**

A terrestrial vehicle collision during construction could result in a loss of human life, a fire or explosion, or a hazardous material release. A release of hazardous materials resulting from a project-related vehicle collision could contaminate soil, groundwater, and surface water, potentially harming vegetation, wildlife, and fish in affected areas like the Fraser River or Tilbury Slough. The potential effects also mirror those from a fire or explosion, it could lead to temporary localized air emissions and noise, burning or damaging of vegetation and wildlife habitat at the Project Footprint edges, and potentially injuring or killing wildlife directly exposed. Such an event would likely lead to temporary restricted access zones lasting days or weeks, briefly interrupting local employment, land and resource use, infrastructure, and cultural practices.

For Indigenous interests, effects are linked to impacts on these VCs and human health. For example, a collision, particularly one resulting in a fire or explosion or hazardous material release, could necessitate a temporary restricted access zone, interrupting recreational activities, cultural practices, or economic activities by Indigenous people members using the Project area.

- **Emergency Facility Shutdown**

An Emergency Facility Shutdown (ESD) requires depressurization through flaring, which could result in audible noise and temporary, short-term releases of air contaminants such as carbon monoxide, sulfur dioxide, and nitrogen dioxide. Despite the potential for elevated air emissions to temporarily exceed certain

thresholds, the short duration (hours) and infrequent use of the Totally Enclosed Ground Flare (TEGF) mean flaring is not anticipated to cause a direct risk to human health.

Flaring could potentially lead to bird mortality, particularly during start-up, though population-level effects are not expected as these effects could be reversed in a breeding season. Potential effects on Indigenous interests are linked to impacts on wildlife, air quality, acoustic environment, and human health VCs, however, the short-term nature and low risk to these VCs mean flaring is not anticipated to significantly affect recreation or wildlife resources for Indigenous people.

Table 68: Risk Assessment of potential hazards identified Tilbury Phase 2

| Scenario                                                         | Likelihood                                                                                                                                                                                                                           | Consequence       | Risk = Likelihood x Consequence                                                                                                                                                                                                                         |

|                                                                  | Rare – Air Quality, Wildlife and Wildlife Habitat, Human Health, Indigenous Interests                                                                                                                                                |                   |                                                                                                                                                                                                                                                         |

\*As originally proposed Tilbury Phase 2 would have included waterboard delivery of project components during the Construction Phase. As that delivery method is no longer proposed and will not be used for Tilbury Phase 2 it has not been included in this assessment.

The EAO considers the risk assessment for Tilbury Phase 2 to be conservative because where a range of potential consequences to a VC is predicted, the more conservative consequence is reported for the final risk assessment score. The likelihood of an incident can be influenced by several factors, including how effective the mitigation measures are. The EAO's analysis and conclusions are outlined in Table 69 in [Section 18.5](#) below.

### 18.3.2 Proposed Mitigations Measures

The Revised Application states that Tilbury Phase 2 would include multiple prevention and response measures to meet B.C.'s regulatory requirements for LNG projects. These measures are intended to lower the risk of malfunctions or accidents and help manage or reduce impacts if one were to occur.

Mitigation and monitoring measures proposed by the Proponent that would be implemented to prevent and respond to malfunctions and accidents, required through other permitting and approvals, are described in the [Joint Permitting/Regulatory Coordination Plan](#) for Tilbury Phase 2.

Project design plays a key role in reducing risk and effects of malfunctions and accidents. Tilbury Phase 2 would be designed in accordance with applicable legal requirements, B.C. Building Code, regulatory requirements under the ERAA and its Regulations, oversight by BCER and Technical Safety BC, Canadian Standards Association (CSA) Z276 (LNG — production, storage, and handling) and any other applicable standards outlined in Section 9.1.2 of the Application. Project design will include engineering controls to prevent or contain spills. The design would also include safety shutdown systems that detect fire or gas, secondary containment systems, and emergency shutdown systems.

The Proponent identified the following relevant mitigations to reduce or avoid adverse residual effects listed in Table A-1. Summary of Mitigation Measures of the Revised Application. These include:

- The project will be designed to the Provincial regulations and applicable standards for LNG production, storage, and handling.
- The project site will be designed to promote drainage toward the Delta storm sewer system. Stormwater draining from paved parking areas will be captured and treated in oil-water separators to remove sediments and oil or grease before discharge into the Delta storm sewer.
- Contact water will be collected with the use of containments and impoundments and measured for field parameters before being released to the onsite drainage ditches that flow into the Delta storm sewer.
- The project will be designed with containments that halt potential hazardous material spills from leaving the Project Site.
- The project will have an emergency generator to provide electric supply for critical loads in the event of a site-wide power failure.
- The project will follow comprehensive equipment maintenance schedules consistent with the Provincial regulation for testing the LNG tank and piping. LNG facility operators will be trained in operational procedures and environmental emergency response and compliant with industry standards.
- The project will be designed to meet the applicable seismic design standards in CSA Z276 (LNG — Production, Storage, and Handling).
- The project will be designed and built in compliance with applicable fire prevention codes and standards.
- The project will select appropriately licensed transportation providers in good standing, appropriately maintained equipment, and licensed operators as required.
- Develop emergency response measures to prevent and manage emergencies, including complete onsite fire control and response systems independent of City of Delta Fire and Emergency Services.

- Maintain an Emergency Response Plan with procedures, training and response plans developed alongside the local, fire, police, and medical services and BCER. The ERP will be tested annually, as per the requirements of the BCER. These emergency response measures will be incorporated into the CEMP and OEMP.
- The ERP will include prescribed responses during loss of containment of LNG.
- Coordinate with first responders to verify response plans are effective and ready throughout the life of the project. The project will make the opportunity available for emergency responders to participate in emergency exercises throughout the life of the project.
- The Project Footprint will have onsite emergency fire control and suppression systems independent of the Municipal fire department.
- The project stormwater management system will be connected to the Delta storm water sewer system.
- The Quantitative Risk Assessment for the project will be updated to meet BCER permitting requirements once detailed engineering has been completed.
- Traffic management mitigation measures will be developed and incorporated into the CEMP and OEMP.
- Contractor personnel will comply with road-use and safety requirements outlined in the CEMP and OEMP, applicable Municipal and Provincial traffic regulations, including truck routes and approved access routes.
- A refuelling and spill response plan will be developed and implemented for the Project.
- The mitigation measures described in the CEMP during loss of containment of LNG will be implemented.
- There will be no waterborne deliveries of modular components or construction materials to the project site, and no MOF will be required.
- The Project will be designed in a manner that reduces the potential for a vehicle to collide with key infrastructure.
- Use of TEGF technology to reduce noise and light from flaring.

## 18.4 Key Issues Raised

Based on a review of the Application and with feedback from the TAC, participating Indigenous nations, and the public, the following key issues related to the assessment of the Malfunctions and Accidents were identified.

### 18.4.1 Worst credible accidental release of LNG

Quw'utsun Nation requested specific details regarding the worst credible accidental release of LNG, including the volume, plume size with combustible concentrations, and how far it might travel offsite under average wind conditions.

The Proponent's view is that LNG's physical characteristics, such as rapid evaporation and being lighter than air when gaseous, limit the migration of an uncontrolled release and make interaction with adjacent properties unlikely.

### 18.4.2 Effects of fire fighting on fish habitat

Quw'utsun Nation raised concerns about the lack of identification of potential interaction between a loss of containment resulting in fire and fish and fish habitat. They argue that subsequent reference to mitigation measures to prevent firefighting waste from migrating offsite implies such potential interaction should have been identified.

The Proponent's view is that the implementation of engineering controls can prevent firefighting wastes from migrating offsite, effectively containing environmental effects and avoiding interaction with fish habitat. Engineering

controls such as berms, catch pits and drain shutoffs, for example have proven to be highly effective at containing wastes generated during firefighting and preventing contamination of surface water.

The EAO notes that, if approved, the Project must be constructed and operated consistent with [Fisheries Act](#) and the [Canadian Environmental Protection Act](#), which can require pollution prevention controls and restrict hazardous substance releases into fish and fish habitat.

#### 18.4.3 Engagement on emergency communication protocol

xʷməθkʷəyám and Snuneymuxw First Nation requested information on the engagement plan that outlines specific steps, timeline, process, and methods for ensuring meaningful engagement on the emergency communication protocol, committing to co-developing culturally appropriate communication.

FortisBC has committed to engage and collaborate with xʷməθkʷəyám and Snuneymuxw to develop an emergency communication protocol, should a Certificate be issued.

The BCER provided additional information about the timing and requirements for Emergency Response Plans:

Core Emergency Response Plans outline set processes, policies, procedures and the Incident Command System (ICS), and detail corporate communications and information policies. They are used as an overarching document for all areas of a permit holder's operations. Core plans are essential for the construction of new facilities. FortisBC maintains a current Core ERP. Additionally, a site-specific or supplemental plan must be updated before introducing any process fluids. The current Tilbury ERP could be revised and resubmitted for application to Tilbury Phase 2.

All ERPs must comply with the [Emergency Management Regulation](#) (EMR) and the CSA Z246.2.

[Section 13](#) of the Emergency Management Regulation requires permit holders to engage with parties, including First Nations, to provide and request information prior to submission of the Emergency Response Plan for operations. Section 13 also outlines minimum communication requirements for permit holders, including notifying First Nations under certain circumstances, during emergencies.

A full-scale exercise will be required before Tilbury Phase 2's operations commence should a Certificate and permits be issued. To support this, the Emergency Response Plan must be submitted well in advance, not only to ensure regulatory compliance, but also to guide and inform the design and execution of the exercise.

The EAO has proposed, that if issued the Certificate should include as part of Conditions 12 (CEMP) and 13 (OEMP) requirements to describe how the mitigation measures identified in the Revised Application applicable to Malfunctions and Accidents will be implemented, and require an emergency communication protocol which outlines how the Holder will communicate with First Nations during emergencies.

#### 18.4.4 Effects of shift from MOF on road traffic

xʷməθkʷəyám is concerned that removing the MOF and shifting transport to road introduces new hazards and cumulative effects, particularly from increased traffic and potential hazardous material spills, which they feel are not accounted for. xʷməθkʷəyám requests a cumulative risk evaluation for road transportation risks and collaboration on mitigation measures.

The Proponent states that the assessment considered the shift to road transport and potential effects like terrestrial vehicle collisions, with mitigation measures proposed.

The EAO notes that, as per the AIR, cumulative effects assessments are not required as part of the Malfunctions and Accidents assessment, and that cumulative effects would be assessed in any related VC assessment if residual effects from Tilbury Phase 2 are anticipated.

If a Certificate is issued, the EAO has proposed that a Traffic Management Plan be required for Tilbury Phase 2 as part of Condition 12 (CEMP), to manage effects associated with the transportation of the materials during Construction by identifying preferred transportation routes, that would require consultation with the Ministry of Transportation and Transit, the City of Delta, and First Nations.

#### 18.4.5 Classification of Risks

x̱m̱əθḵw̱əy̱əm disagrees with the risk assessment, noting that the risk assessment downplays the potential consequences of rare but severe accidents, such as LNG containment loss, by categorizing their impact as "low," which they say failed to adequately reflect significant effects on VCs and x̱m̱əθḵw̱əy̱əm rights, and overlooked risk perception. x̱m̱əθḵw̱əy̱əm requests a revision to the risk assessment framework to treat likelihood and consequences as distinct factors, giving greater weight to severe, long-term consequences.

FortisBC's perspective is that the risk classification is appropriate based on expertise, mitigation, and long history of operating LNG facilities at the site, stating their matrix does treat likelihood and consequence distinctly and accounts for severe to low likelihood events.

The EAO understands that FortisBC's assessment follows industry norm and acknowledges that there are different understandings of risk, risk tolerance, and rating systems between FortisBC, the EAO, permitting agencies, and x̱m̱əθḵw̱əy̱əm, particularly regarding the extent of the potential impacts on Indigenous interests.

### 18.5 The EAO's Assessment and Conclusions

The EAO's characterization of the expected risks of Tilbury Phase 2 malfunctions and accidents to the VC assessed is provided below in Table 69, after considering proposed mitigation measures, regulatory requirements, and Certificate conditions. The federal Key Mitigation Measures and Follow-up Programs under the IAA for malfunctions and accidents are found in [Appendix 2](#).

Table 69: Summary of Potential Risks of Malfunctions and Accidents to Valued Components

| VC                   | Risk Rating                                                                                                                                                                               | Rationale                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Human Health         | High - for Loss of Containment of LNG with or without Ignition, Fire or Explosion, Terrestrial Vehicle Collision<br><br>Low - for Hazardous Material Release, Emergency Facility Shutdown | The likelihood of a loss of containment of LNG without ignition event is assessed as rare because of the Project design measures, training, and emergency planning that will be implemented to mitigate such incidents. However, the overall risk rating for human health is considered high due to the potential critical consequences of such events.<br><br>A fire or explosion, while considered a rare event, could have critical consequences such as injury or death to individuals onsite and at nearby businesses, leading to a high-risk level rating.<br><br>Similarly, the likelihood of a terrestrial vehicle collision is considered rare with critical consequences and therefore a high-risk level because it could lead to fire or explosion and release of hazardous material. The Project will employ appropriate procedures, measures, and safety standards to minimize the potential of Project-related collisions.<br><br>There is a remote likelihood that a release of hazardous materials could also lead to the contamination of drinking water and food. The risk level for such incidents is considered low because the Project Footprint does not have drinking water wells, and food is not harvested from within the Project Footprint and therefore of minor consequence to human health.<br><br>The likelihood of Emergency Facility Shutdown is considered rare with low consequences due to the short duration and infrequent use of flaring, resulting in low-risk rating for human health. |
| Indigenous Interests | Medium - for Fire or Explosion<br><br>Low - for Loss of Containment of LNG                                                                                                                | The likelihood of fire or explosion is considered rare with moderate consequences due to the well-established global approach to designing, maintaining, and safely operating LNG facilities, the Proponent's extensive experience with its existing Tilbury facility, and the                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | without Ignition, Hazardous Material Release, Terrestrial Vehicle Collision, Emergency Facility Shutdown                                                                                                   | <p>extensive regulatory oversight ensuring the highest design and operational standards, resulting in an overall medium risk level rating.</p> <p>A loss of containment of LNG without ignition is a rare event that is not expected to directly affect Indigenous interests as the Project Footprint will be closed to the public. However, this event could potentially result in temporary restricted access to adjacent areas, impacting cultural, recreational, and economic activities and potentially affecting linked VCs such as wildlife, vegetation, culture, land use, and human health. These potential effects are expected to be localized and short-term with normal access restored within hours or days resulting in a minor consequence for Indigenous interests, and an overall low risk level.</p> <p>The potential consequences of terrestrial vehicle collisions are rated moderate with remote likelihood of the event occurring, resulting in a low level of risk assessment. The Project will implement traffic management mitigation measures to reduce the potential for Project-related vehicle collisions.</p> <p>While short-term flaring is not expected to directly affect Indigenous interests, it could indirectly impact them by adversely affecting other VCs such as wildlife and wildlife habitat, air quality, acoustics, and human health, all of which are linked to Indigenous interests. The likelihood of an emergency facility shutdown is considered rare, with low consequence, resulting in a low risk level rating.</p> |
| Air Quality   | Low - across all assessed incident types including Loss of Containment of LNG without Ignition, Hazardous Material Release, Fire or Explosion, Terrestrial Vehicle Collision, Emergency Facility Shutdown. | <p>Loss of LNG containment without ignition would have insignificant air quality effects since natural gas is non-toxic and impacts would be short-term. This event is assessed as low risk because of its rare likelihood and minor consequences.</p> <p>Condensate releases would have minimal air quality effects because most would remain liquid, resulting in minor consequence, and ultimately, low risk level.</p> <p>Rare hazardous spills on land could temporarily affect air quality, but with mitigation and design standards, the impact would be insignificant and minor consequence, resulting in low risk level.</p> <p>In rare fires or explosions, pollutants like particulate matter and carbon monoxide may be released, but air quality is expected to meet B.C. standards and effects would be reversible. Prevention measures reduce the likelihood and consequences of effects and therefore keep the risk level low and insignificant.</p> <p>Transportation incidents could cause short-term, localized air quality effects, especially if a fire occurs. Although vehicle collisions have moderate consequences, their remote likelihood and traffic management reduce the risk to low.</p> <p>Unplanned shutdowns causing flaring may emit pollutants briefly. While emissions could exceed local standards, the short duration and rare occurrence keep air quality risk low.</p>                                                                                                                                                           |
| Acoustic      | Low - for Fire or Explosion, Terrestrial Vehicle Collision, Emergency Facility Shutdown scenarios.                                                                                                         | <p>In the event of a fire or explosion, noise would be audible nearby but brief, lasting seconds. The impact on the acoustic environment is low, and the likelihood of such event is considered rare with an overall low risk.</p> <p>A vehicle collision that could ignite fuel and cause fire or explosion would produce short, audible noise near the accident. The impact on the acoustic environment is low, and the likelihood of such event is considered remote with an overall low risk level.</p> <p>The totally enclosed ground flare (TEGF) during an emergency shutdown would be audible on-site, to nearby projects, and the Fraser River area. B.C. noise regulations don't apply in emergencies. Given the remote, short-term nature of these events, and the low consequence of acoustic impact, the risk is considered low.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Surface Water | Low - for Hazardous Material Release, Terrestrial Vehicle Collision                                                                                                                                        | <p>Containment measures will be in place to prevent hazardous material releases, but if they reach the Fraser River or Tilbury Slough, surface water and sensitive marine areas could be affected. With Project controls, the likelihood of hazardous material release is rare with minor consequences on surface water, resulting in reduced risk level to low.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| VC                            | Risk Rating                                                                                                                                                                     | Rationale                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|                               |                                                                                                                                                                                 | A vehicle collision near water or connected storm drains could release hazardous materials, posing a risk to surface water. However, the risk is low with minor consequences and rare likelihood, given the small material volumes and emergency response measures in place.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Groundwater                   | Low - for Hazardous Material Release, Terrestrial Vehicle Collision                                                                                                             | <p>The Project includes controls to prevent the release of hazardous materials and mitigate potential effects, reducing the likelihood of groundwater contamination to rare with minor consequences and overall low risk rating.</p> <p>The likelihood of a terrestrial vehicle collision resulting in groundwater contamination is considered rare with minor consequences and overall low level of risk because of planned preventive and management measures.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Soil                          | Low - for Hazardous Material Release, Terrestrial Vehicle Collision                                                                                                             | <p>A hazardous material release could risk soil quality in the Project area, with potential consequences rated as minor. The likelihood of such event is rare with the risk level reduced to low through Project design and proven operational practices used at the existing Tilbury LNG facility.</p> <p>Vehicle collisions could spill fuel or hazardous materials, potentially harming soil quality. Soil remediation would limit these effects, resulting in minor consequences. With mitigation measures in place, the likelihood of collisions affecting soil quality is low, resulting in an overall low risk.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Vegetation                    | Low - for Fire or Explosion<br>Low - for Loss of Containment of LNG without Ignition, Hazardous Material Release, Terrestrial Vehicle Collision                                 | <p>Fire or explosion at the Project Footprint is expected to have moderate consequences due to limited vegetation on site and the rare likelihood of such event happening. The risk score for this potential interaction is medium.</p> <p>A loss of containment of LNG without ignition is a rare event that could affect the minimal vegetation on the Project Footprint. A migration of an LNG vapour cloud towards the Fraser River or Tilbury Slough, could potentially damage the riparian vegetation due to its freezing temperature. These effects are expected to be localized and short-term (1 to 3 years), resulting in a minor consequence and low overall risk level.</p> <p>A fire or explosion from a vehicle collision could damage vegetation and wildlife habitats near the Fraser River and Tilbury Slough. The extent of damage depends on fire spread and emergency response. Effects are considered low risk, as safety measures will help reduce collision likelihood to remote and the consequence is moderate.</p>                                                                                                                                                                                                                                              |
| Wildlife and Wildlife Habitat | Medium - for Loss of Containment of LNG without Ignition, Fire or Explosion<br>Low - for Hazardous Material Release, Terrestrial Vehicle Collision, Emergency Facility Shutdown | <p>Loss of LNG containment without ignition resulting in an offsite vapour cloud could potentially cause freezing, hypoxia, or asphyxiation, leading to serious harm or death to wildlife. This effect is expected to be limited to the immediate area around the release with a rare likelihood of occurrence and resulting in a low risk.</p> <p>Noise from a fire, explosion, or vehicle collision could disturb wildlife near the Project Footprint. A fire at the site's edge could damage vegetation and harm animals, though it is expected to be quickly extinguished. The risk is considered medium with rare likelihood and moderate potential consequences.</p> <p>Soil or water contamination from hazardous material releases could indirectly affect wildlife and habitats near sensitive areas like the Fraser River and Tilbury Slough. With Project control measures in place, the likelihood of such occurrence is expected to be rare with minor consequences, resulting in a low risk Level.</p> <p>While the consequences of an emergency shutdown are considered minor, birds could be fatally affected if they come into contact with the ground flare. The effects on wildlife and habitat are considered low risk with low consequences and rare likelihood.</p> |

| Fish and Fish Habitat  | Low - for Hazardous Material Release, Terrestrial Vehicle Collision                                                                                    | <p>The implementation of control measures is expected to reduce the potential of hazardous materials reaching fish and fish habitat to a rare likelihood and minor consequence, resulting in an overall low risk level.</p> <p>A terrestrial vehicle collision near a waterbody could lead to leaks and spills that enter fish habitat, potentially harming fish and damaging fish habitat. However, the likelihood of such an event is considered rare with low consequences, resulting in low-risk rating.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Employment and Economy | Low - for Loss of Containment of LNG without Ignition, Hazardous Material Release, Fire or Explosion, Terrestrial Vehicle Collision                    | <p>Loss of LNG containment without ignition could result in establishing a temporary restricted access zone until the source is identified and resolved. This localized and short-term (hours or days) restriction could affect economic activities. The likelihood of such event is considered rare with minor consequence, resulting in a low risk level.</p> <p>Similarly, a temporary restricted access to the Project area due to a release of hazardous material could lead to a short-term impact on employment and the local economy. The likelihood of such event is considered rare with low consequences because normal operations could be restarted within days or weeks after hazardous materials have been contained and cleaned up, resulting in an overall low risk level.</p> <p>A hazardous material release could cause a temporary shutdown and restricted access to the Project area, briefly impacting employment and the local economy. The consequence is low as operations would likely resume within days or weeks after cleanup, and the likelihood is rare, leading to a low level of risk.</p> <p>Due to traffic management and other mitigation measures that will be implemented, the likelihood of a vehicle collision is considered remote with minor potential consequences, resulting in a low-risk rating.</p> |
| Land and Resource Use  | Medium - for Fire or Explosion<br><br>Low - for Loss of Containment of LNG without Ignition, Hazardous Material Release, Terrestrial Vehicle Collision | <p>A fire or explosion at the Project Footprint could lead to temporary restricted access to nearby areas including the Fraser River, potentially impacting recreation, cultural practices, and the perception of safety. This potential risk level is medium due to the consequence being moderate, and proposed project controls reducing its likelihood to rare.</p> <p>A Loss of Containment of LNG without Ignition is a rare event that could lead to a temporary restricted access zone for recreational, cultural practices, and economic activities until the source is identified and addressed. This potential effect is expected to be of minor consequence due to it being localized and short term, resulting in an overall low risk level.</p> <p>A rare hazardous material release could result in temporary restricted access on-site and potentially to areas near the Fraser River. The potential effect of such event is expected to have low consequence with an overall low risk level.</p> <p>The potential effects of terrestrial vehicle collision are considered low risk because the Project's plans for traffic management and emergency response measures will reduce the likelihood of Project-related collision to remote and is considered to be of minor consequence.</p>                                          |

| VC                          | Risk Rating                                                                                                                                             | Rationale                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Infrastructure and Services | Low - for Loss of Containment of LNG without Ignition, Hazardous Material Release, Fire or Explosion, Terrestrial Vehicle Collision                     | <p>A loss of containment of LNG without ignition is considered a rare event that could cause localized and short-term effects on access for activities, with potential consequences assessed as minor and the overall risk level rated as low.</p> <p>A release of a large amount of hazardous materials could adversely affect the infrastructure on the Project Footprint. The likelihood of such an event is considered rare because of the Proponent's experience and implementation of operational and safety standards, resulting in low consequences and overall low risk rating.</p> <p>Fire or explosion is a rare event that could damage onsite infrastructure. While emergency services may be needed, the Project's independent onsite fire control and suppression systems is expected to manage the incident, resulting in a low consequence on infrastructure and services and an overall low risk level.</p> <p>A collision of vehicle with infrastructure housing flammable material could cause fire or explosion, potentially damaging infrastructure within the Project Footprint. While a worst-case offsite accident might potentially damage public facilities, the Project's traffic management measures are expected to reduce the likelihood of such collisions to remote and minor consequence, resulting in an overall low risk level.</p> |
| Culture                     | Medium - for Fire or Explosion<br><br>Low - for Loss of Containment of LNG without Ignition, Hazardous Material Release, Terrestrial Vehicle Collision) | <p>A rare fire or explosion incident could lead to restricted access and damage to places of cultural significance, impacting cultural activities. The potential effects of fire or explosion is expected to be moderate consequence resulting in a medium risk level with the implementation of emergency response measures.</p> <p>Loss of containment of LNG without Ignition is considered a rare event with minor consequence that could lead to a temporary restricted access zone. This restricted access would have localized and short-term effects, resulting in a low risk rating.</p> <p>A release of hazardous materials is considered a rare event could lead to temporarily restricted access to areas like the Fraser River, impacting cultural practices. Normal access is expected within days or weeks with a low consequence, resulting in an overall low risk level.</p> <p>Similarly, a remote terrestrial vehicle collision event could cause hazardous material release or fire/explosion preventing cultural activities within the Project area, but the potential effect is considered minor consequence, resulting in a low risk level due to small material volumes and emergency response measures.</p>                                                                                                                                    |

The EAO is satisfied that the potential accidents and malfunctions associated with Tilbury Phase 2 have been adequately identified, assessed, and mitigated for this environmental assessment.

## 19.0 APPENDIX 8 HUMAN AND COMMUNITY WELL-BEING

### 19.1 Summary

As required by the Act<sup>80</sup> and the IAA<sup>81</sup> the assessment must consider how different people and communities may experience project effects in different ways. Some individuals or population groups may be more vulnerable to negative impacts, while others may be better positioned to benefit.

To support this, FortisBC used a GBA Plus approach to identify population groups that may be affected differently by the project and to help shape mitigation measures by analyzing how various social identity factors intersect to shape experiences and outcomes, particularly within the context of power dynamics and systemic inequalities. A GBA Plus approach looks at how identity factors – such as gender, age, race, disability, education, ethnicity, economic status, language, religion, sexual orientation, Indigeneity, or where someone lives – can influence how people experience project effects.

FortisBC applied GBA Plus, where disaggregated information was available, across economic, social, cultural, and health topic areas by describing existing conditions and identifying potential effects on diverse population groups, including women, youth, Elders, racialized persons, and First Nation Peoples. Additional analysis was included for VCs, where residual effects may occur. GBA Plus was also applied in sections of the application specific to individual First Nations, including disaggregated information on community health and proposed effects management or enhancement strategies.

Methods included desktop research and analysis of secondary sources, and targeted socio-economic engagement to address information gaps. The assessment was also informed by engagement with First Nations and feedback gathered during four comment periods and virtual and in-person open houses.

After considering KMMs, follow-up programs, potential Certificate conditions, and regulatory requirements, the EAO concludes that significant adverse effects on human and community well-being or distinct populations are unlikely. This conclusion reflects the analysis in this and related sections, and input from the TAC, First Nations, and the Proponent.

### 19.2 Existing Conditions by the Proponent

Situated in Metro Vancouver, the region is characterized by metropolitan areas, industrial and agricultural lands, rural areas, and conservation lands. Since time immemorial, First Nation peoples have inhabited and continue to use and occupy the lands and waters in this region. The area has transformed from being largely resource-based to becoming a densely populated urban centre. The increasing population in the region combined with limited land available for residential use creates pressure to densify existing urban areas. First Nation Peoples are disproportionately affected by competing land uses, particularly in the context of historical and ongoing loss of access to their traditional lands, waters, and resources.

Gender –based violence against First Nation women, girls, and two-spirit, lesbian, gay, bisexual, transgender, queer, questioning, intersex, asexual, and all other sexual orientations and genders (2SLGBTQIA+) people is well-documented in Vancouver's Downtown Eastside and throughout Canada. First Nation women are more likely to experience discrimination than non-First Nation women.

Metro Vancouver ranks as the most expensive region in Canada for maintaining a basic standard of living, with both homeownership and rental costs remaining high. These rising costs disproportionately impact vulnerable

---

<sup>80</sup> Section 25(2)(d) of the Act requires that every assessment consider the disproportionate effects on distinct human populations, including populations identified by gender.

<sup>81</sup> Paragraph 22(1)(s) of the IAA specifies that the assessment of a designated project must take into account the interaction of sex and gender with other identify factors.

populations, including low-income individuals, seniors, families with children, women, First Nation Peoples, and newcomers. Even small increases in the cost of basic needs can significantly affect these groups.

In background research conducted by FortisBC, residents also identified several pressing community concerns beyond affordability. These include access to health care, traffic congestion, homelessness, industrial pollution (air and water), and public safety. These issues reflect broader challenges tied to infrastructure and public services, which are central to community well-being.

Population growth and demographic shifts have placed increasing pressure on Metro Vancouver's infrastructure, particularly in housing, transportation, and health care. Unfortunately, public services have not consistently kept pace with this demand. The region is projected to grow by 34.3 percent between 2020 and 2041, which will likely intensify existing strains. Without adequate investment and planning, these pressures may further disadvantage First Nation Peoples, seniors, people with chronic health conditions, low-income families, and diverse population groups who are more vulnerable to gaps in service capacity.

Before European contact, First Nation Peoples in what is now Metro Vancouver lived in deep relationships with the land and waters, guided by principles of respect and reciprocity. The environment provided food, medicine, shelter, and clothing, and in return, communities maintained sustainable practices. Social systems were rooted in extended families, clans, and nations, offering strong social support. Gender roles were clearly defined but flexible, with each person valued for their contributions to community well-being.

Today, First Nation Peoples in the region continue to experience the lasting impacts of colonization. These include the loss of access to traditional lands and resources, forced relocations, and the intergenerational trauma caused by residential schools. Many First Nations communities still face challenges such as overcrowded housing, limited access to clean water, and inadequate sanitation infrastructure. Despite these systemic barriers, First Nation communities continue to demonstrate resilience, cultural continuity, and a strong sense of identity and belonging.

Metro Vancouver is highly diverse, with racialized groups making up 54.5% of the population in 2021—with Chinese (19.6 percent), South Asian (14.2 percent), and Filipino (5.5 percent) populations being the largest. About 2.4 percent identified as First Nation, making it the third-largest urban First Nation population in Canada.

Culture plays a key role in community well-being and cohesion. Delta's identity continues to be shaped by culturally diverse forces, including influences of First Nation nations, early settler-colonizers, and immigrants to the Lower Mainland, which collectively contribute to the region's multiculturalism. Furthermore, Delta's identity, in relation to the Project site, is reflected through a blend of strong cultural diversity, high-socio-economic stability, and a defined geographical character that balances extensive agricultural and conservation of lands with established industrial areas.

Ethnocultural segregation is most visible in low-income areas, within Metro Vancouver, some data pointing to neighbourhoods in Richmond having high proportions of working poor families. These segregated low-income areas are geographically contained within the broader Metro Vancouver region that comprises the Projects study area. Metro Vancouver is where many recent immigrants live, often leading to weaker community ties. In contrast, First Nation communities report strong belonging despite language loss from colonization. Community cohesion and social connectedness are foundational to First Nation culture and community well-being.

### 19.3 Potential Project Effects and Proposed Mitigations by the Proponent

The four primary areas where FortisBC identified potential project effects are the overrepresentation of men in employment opportunities, visual impacts associated with First Nation land and resource use, human health impacts associated with air quality and shift work, and social divisions associated with the project.

These areas are supported by information provided in related Appendices: particularly the [Appendix 6, Section 17.09](#) (Employment and Economy), [Appendix 6, Section 17.10](#) (Land and Resources Use), [Appendix 6, Section 17.13](#) (Culture), and [Appendix 6, Section 17.14](#) (Human Health).

While the project is expected to provide 6,200 jobs over the six-year construction period (peaking at 600 onsite workers during construction), FortisBC does not anticipate residual adverse effects to infrastructure and services or culture VCs as the labour force will largely come from Metro Vancouver.

#### 19.3.1.1 Employment and Economic Opportunities

Employment and economy are directly relevant to community well-being as they relate to the ability of families and individuals to provide for their needs and thrive in their communities. Improved income security allows individuals and families to avoid difficult decisions, such as relocating to find work or more affordable housing, thereby enhancing their quality of life. Increased income from employment can also contribute to increased quality of life for First Nation community members and families, supporting not only economic stability but also cultural revitalization and well-being.

As provided by FortisBC, Tilbury Phase 2 is anticipated to result in increased employment income, skills training, contracting and procurement. Men may be better positioned to benefit from Tilbury Phase 2-related employment opportunities as the majority of people employed in engineering and trades-related occupations are male. To promote equitable distribution of proposed Project benefits, FortisBC has policies on hiring practices and contracting to support underrepresented groups.

Positive residual effects for First Nation workers are anticipated through increased employment, enhanced opportunity, and a potential improvement of social conditions. Employment income, education and skills training, procurement opportunities, and First Nation Government revenue are anticipated as positive effects. First Nation members with a trades certificate and experience in the construction sector would be most likely to benefit from direct employment with Tilbury Phase 2. However, increased participation in the wage economy may reduce participation in traditional non-wage economies. Workers engaged in proposed Project construction might otherwise be engaged in resource harvesting or related economic activities, resulting in lost opportunity.

Overall, FortisBC expects economic opportunities to positively benefit workers and their families by providing improved income security. FortisBC does not anticipate other adverse impacts to the labour market, opportunities for traditional economic activities, business revenues, property values, cost of living, or impacts caused by track traffic. Further information is available in employment and economy VC (Appendix 7.10).

#### 19.3.1.2 Visual impacts associated with First Nation land and resource use

First Nation Peoples may be disproportionately affected by visual changes to the landscape, particularly where these changes occur in areas with ongoing cultural use or deep historical and spiritual significance. The Fraser River is a culturally important area used by many First Nations for fishing, harvesting, and other social and cultural practices. Visual impacts in this area — especially at culturally significant sites — are directly relevant to First Nation well-being.

A historic village site located across the Fraser River from Tilbury Phase 2, known as ʔəqtinas (also referred to as Tl'uqtinus, Tl'ektines, or Tl'eqtines), holds high cultural significance for several Nations, including xʷməθkʷəy̓əm, Quw'utsun Nation, Ts'uubaa-asatx, Tsawwassen First Nation, TWN, Kwantlen First Nation, Semiahmoo First Nation,

and Stó:lō communities.<sup>82</sup> This site may experience noticeable visual effects during both daytime and nighttime viewing conditions due to project lighting and infrastructure. Views from the Fraser River may also be affected, resulting in potential visual impacts for First Nation Peoples whose cultural and spiritual connections to the landscape are deeply tied to its natural features.

These effects are especially concerning given the cumulative context. First Nation Peoples near Tilbury Phase 2, including those on Tilbury Island, have already experienced restricted access to land and water due to urban development and government regulation. Visual impacts from the Project add to these ongoing pressures. Disruptions to important views, cultural sites, and sensory conditions may weaken connections to place, interfere with cultural continuity, and affect community well-being.

Lighting associated with the Project is required for safety and security, as described in [Appendix 6, Section 17.10](#) (Land and Resource Use). Lighting will be designed in line with BCER's Light Control Best Practices Guideline, the International Commission on Illumination's Guide on the Limitation of the Effects of Obtrusive Light from Outdoor Lighting Installations, and the City of Delta's municipal zoning bylaws. Further information on mitigation and effects is available in Section 7.11.

#### **19.3.1.3 Human health impacts associated with air quality and shiftwork**

Human health is closely linked to overall community well-being, as it shapes population health outcomes that are influenced by social determinants such as income, education, housing, and access to services.

Persons with sensitivities to air quality may be disproportionately impacted by the project – particularly on-site workers and businesses that are directly adjacent to the site. The Project will incrementally contribute to nitrogen dioxide (NO<sub>2</sub>) and sulphur dioxide (SO<sub>2</sub>) during operation, which are common air pollutants formed by the burning of fossil fuels. FortisBC anticipates that with mitigation measures, effects will be negligible to low-magnitude compared to existing conditions, with emissions being concentrated near the Tilbury Phase 2 footprint during normal Operation.

Women, First Nation Peoples, and persons with lower education levels may be disproportionately impacted by the effects of shiftwork due to systemic barriers that limit access to stable, flexible, and higher-quality employment opportunities. Identified by FortisBC, shiftwork can cause adverse health impacts associated with sleep, mood, gastrointestinal health, and mental health. This can subsequently lead to increased risk of chronic disease, substance use, motor vehicle accidents, sleep disorders and negative impacts to relationships and within household environments such as domestic violence due to social isolation. FortisBC expects negligible impacts for the overall workforce that may be detectable at low magnitude for some workers. To mitigate the negative effects of shiftwork, FortisBC proposed flexible work schedules that take into consideration these impacts of shift work such as fewer shifts of the same type, forward rotations or self-scheduling, as well as providing information about the health and safety implications of shift work to the workforce. In addition, as described in the revised Application (Human Health VC, Section 7.15), FortisBC has committed to workplace conduct policies, cultural awareness training, reporting and complaint mechanisms, and emergency response planning intended to prevent and mitigate potential risks related to gender-based violence and worker safety throughout the Project lifecycle.

#### **19.3.1.4 Social division associated with the project**

Community and cultural cohesion are the sense of belonging, trust, and cultural and social connectedness people may have to one another. Community cohesion in the area is strong for both First Nation and non-First Nation persons. Changes to culture has the potential to affect the well-being of people and communities in that it influences a sense of community and cultural cohesion.

---

See Section 3.1 for naming and jurisdictional context regarding the Historic Indigenous Village Site

FortisBC recognized that social divisions may be intensified in local communities if there is strong public opposition to the Project, particularly in relation to climate change; whereas others may favour the benefits of the Project. FortisBC will continue to engage the public and other interested parties throughout the remaining phases of the project to seek input, answer questions, and address potential concerns. FortisBC will also work directly with First Nation nations and governments to maintain transparency, ensure compliance, and seek and address feedback.

## 19.4 Key Issues Raised

### 19.4.1.1 Use and enjoyment of surrounding environments including participation in traditional activities

Reviewers and the public raised concerns regarding the Projects' impacts to the surrounding environment and the subsequent impacts to its use and enjoyment. Cheam First Nation noted concerns regarding increased truck traffic, particularly its impacts on neighbouring businesses, and the ability for First Nation persons to continue to participate in traditional economic activities (e.g. fishing) while supporting First Nation employment, training, and contracting opportunities. TWN raised concerns regarding potential residual effects to harvesting and subsistence activities, cultural use areas, and the overall impacts to First Nation health and well-being – which can include mental, socio-cultural, spiritual, and emotional health due to impacts on cultural values.

Public comments on human and community well-being spoke to concerns regarding public health and safety, air quality, and enjoyment of and impacts to local environments. However, the comments received did not speak to disproportionate impacts to different population groups. These comments were responded to as part of the [Tilbury Phase 2 LNG Expansion Project Application Review Public Engagement Report](#), and the topics are considered in their respective VC sections.

FortisBC will be implementing a range of policies and management plans to help mitigate impacts associated with the project, many of which will be developed in collaboration with First Nation nations and other levels of government. Particularly, trucks associated with the project will follow designated routes and mitigation measures to reduce impacts from the project will be incorporated into the CEMP. No residual effects are anticipated for businesses adjacent to the project (also refer to [Appendix 6, Section 17.11](#) (Infrastructure and Services VC), which speaks to transportation).

FortisBC does not anticipate additional impacts from the project on First Nation persons' participation in traditional versus wage economies compared to existing conditions. FortisBC will be requiring detailed First Nation participation plans during contractor bid processes, which are inclusive of economic and workforce opportunities, and will continue to engage directly with First Nation nations on economic opportunities.

Refer to respective sections for further discussion on impacts to the use and enjoyment of surrounding environments for both First Nation and non-First Nation communities. Particularly, see sections specific to each First Nation.

### 19.4.1.2 Social divisions particularly in relation to climate change

xʷməθkʷəyám noted how risk perception contributes to social divisions, and how First Nation communities are more likely to perceive heightened risks. TWN further describes how First Nation peoples are disproportionately impacted by climate change: including reduced access to shorelines, and reduced access to cultural practices and fishing and harvesting opportunities. Disproportionate impacts to First Nation peoples result in greater perceptions of risk for future projects.

Climate impacts were also cited during the public comment periods as a key concern. While the assessment focusses on the impacts of the Project itself, the overarching social narrative regarding climate change and risk tolerance is evident in issues raised; the real and perceived risks associated with climate change introduce a social division between those who support the project and those who do not.

The Project's contribution to GHG emissions were assessed in [Appendix 12](#), of this report.

#### The EAO's Assessment and Conclusions

The following VCs were assessed by the EAO as having potentially disproportionate effects on different populations:

- Infrastructure and services;
- Land and resource use;
- Acoustic;
- Air quality;
- Employment and economy;
- Human health;
- Vegetation;
- Fish and fish habitat;
- Marine use; and
- Wildlife and wildlife habitat.

### 19.5 The EAO's Conclusion

After considering proposed KMMs and follow-up programs, Certificate conditions (which would become legally binding if a Certificate is issued), and federal and provincial regulatory requirements, the EAO concludes that significant adverse effects on overall human and community well-being are unlikely, certain diverse population groups may remain at heightened risk, highlighting the need for ongoing attention to equity, inclusion, and culturally responsive mitigation and monitoring efforts. This conclusion considers the information and analysis presented in this and related sections, as well as the views of the TAC, First Nations, and the Proponent.

## 20.0 APPENDIX 9 SUMMARY OF EFFECTS ON BIOPHYSICAL FACTORS THAT SUPPORT ECOSYSTEM FUNCTION

### 20.1 Background

This section summarizes the potential effects that Tilbury Phase 2 would have on biophysical factors that support ecosystem function.

Ecosystem function relates to the different physical, chemical, and biological components of an ecosystem (for example, vegetation, water, soil, atmosphere, and biota) and how they operate and interact with each other within and across ecosystems. The function of an ecosystem depends upon the long-term integrity of its physical, chemical, and biological elements.

Biophysical factors that support ecosystem function were assessed by FortisBC through the VC framework and then summarized in [Section 12](#) of the Revised Application.

### 20.2 Potential Project Effects and Proposed Mitigations by the Proponent

Tilbury Phase 2 has the potential to affect biophysical factors that support ecosystem function through the following pathways:

#### Habitats Supporting Ecosystem Function

FortisBC expects the collective residual effects on Vegetation and Wildlife and Wildlife Habitat from Tilbury Phase 2 to be negligible, as there would be no measurable effect on habitats supporting ecosystem function on the ecosystem or lower Fraser River scale. Due to the highly developed nature and the existing disturbance levels of the area, FortisBC predicts a low magnitude of residual effects to wildlife habitat for species at risk, but that these effects to habitats supporting ecosystem function would occur in the Tilbury Phase 2 Project area regardless. The cumulative effects of commercial and industrial activities in the lower Fraser River may be amplified by climate change. This amplification could affect habitat suitability and wildlife resiliency to environmental stressors.

#### Habitat Patches

Due to the highly fragmented nature of the Project Footprint and surrounding area, FortisBC does not anticipate any new barriers to species movement or negative effects to migration routes or ecological corridors as a result of Tilbury Phase 2. FortisBC does not anticipate Tilbury Phase 2 causing any new habitat fragmentation, or creating any habitat disturbance along the Fraser River or Tilbury Slough.

#### What are the biophysical factors that support ecosystem function?

Biophysical factors that support ecosystem function can be grouped into the following ten categories:

1. habitats supporting ecosystem function
2. habitat patches
3. natural disturbance regime
4. structural complexity
5. hydrologic or oceanographic patterns
6. nutrient cycling
7. purification services
8. biotic interactions
9. population dynamics
10. genetic diversity.

These biophysical factors can vary in their contribution to ecosystem function and may be affected by potential project impacts at a landscape or watershed level, ecosystem level or ecological community level. Biophysical factors are assessed at the level that coincides with the potential effect.

### Natural Disturbance Regime

FortisBC does not anticipate interaction of flooding, such as fluvial and tsunami flooding, with Tilbury Phase 2 due to its flood construction level, and existing infrastructure including dikes along the Fraser River and a flood gate at Tilbury Slough. The storm sewer that drains the site has been updated to accommodate runoff from the current site and adjacent properties with allowance for increased rainfall. Additionally, FortisBC considered climate change and the associated trends of severe weather events, as well as potential flooding and seismic events into the project design. FortisBC does not expect Tilbury Phase 2 to contribute to the existing natural disturbance regime in the Project area.

### Structural Complexity

Tilbury Phase 2 would be located in a highly industrialized area with limited vegetation and is dominated by nonnative and invasive species. Prior to the Tilbury Phase 2 Construction phase, vegetation will be removed by other construction activities located at the site.

Climate change has the potential to influence structural complexity in the Tilbury Phase 2 area, such as through the suppression of natural vegetation growth and spread of invasive species. FortisBC predicts a low-magnitude of effects on adjacent habitat of species at risk, and due to concerns raised in the Application and Development phase, FortisBC plans to utilize existing areas of disturbance and avoid vegetation clearing and habitat fragmentation in the Tilbury Phase 2 design. Therefore, with the proposed mitigation measures, limited existing structural complexity, and incremental residual effects, FortisBC does not anticipate any effects to structural complexity as a result of Tilbury Phase 2.

### Hydrologic or Oceanographic Patterns

FortisBC predicts negligible effects of Tilbury Phase 2 to surface water and groundwater and no change to hydrologic patterns or flow due to existing drainage ditches and the existing impermeable surface of the Tilbury Phase 2 site along with no expected changes to water discharge volume into the Fraser River or Tilbury Slough.

### Nutrient Cycling

Tilbury Phase 2 would be located in an area of previous and existing industrial land use with little to no topsoil, and therefore the effects on soil quality are anticipated to be negligible. Additionally, no residual effects to surface water discharged into Delta storm sewers is anticipated due to erosion and sediment control measures. Overall, FortisBC does not expect Tilbury Phase 2 to have any changes to nutrient flow in, out, or through the ecosystem.

### Purification Services

FortisBC anticipates interaction between purification services and the [Appendix 6, Section 17.01](#) (Air Quality VC), [Appendix 6, Section 17.03](#) (Surface Water VC), and [Appendix 6, Section 17.06](#) (Vegetation VC). The Tilbury Phase 2 Construction phase will have a low magnitude of contribution to CAC concentrations in the Project Footprint, and the Operation Phase effects will be negligible for NO<sub>2</sub>, and low-magnitude from increased SO<sub>2</sub>. With the proposed mitigation measures, including design measures to reduce GHG emissions, FortisBC expects an overall low magnitude of effect of SO<sub>2</sub> and therefore no anticipated adverse effects to ecosystem function. FortisBC completed an assessment of the Project Operations phase's air emissions and the potential for acidification and eutrophication effects and concluded that aquatic and terrestrial environments are not susceptible for both surface water and soil. With the implementation of mitigation measures, the residual effects of runoff on surface water quality are not expected. Additionally, the Tilbury Phase 2 Construction phase and Operation phase would not interact with wetlands or riparian habitats.

### Biotic Interactions

Tilbury Phase 2 would have negligible to low effects on invasive species, with no significant impact on biodiversity or ecosystem function. Invasive species are already present on the site, and implementing weed and pest management procedures during construction and operation will help control their spread. The project is unlikely to alter predator-prey dynamics due to limited infrastructure for perching sites. The site is within a heavily industrialized area with significant past habitat loss, and climate change is expected to further affect wildlife habitat. However, FortisBC does not anticipate Tilbury Phase 2 to have significant impacts on wildlife movement, as existing barriers already limit ground movement in the area, and mitigation measures will be in place to minimize any effects.

Species within the Tilbury Phase 2 area are expected to be resilient to human disturbances, with some level of habituation to existing urban and industrial impacts. The project is not expected to have residual effects on keystone species that could alter ecosystems. The introduction or spread of invasive plants and the temporary alteration of wildlife habitat for species at risk are considered to have negligible to low impacts. These changes are unlikely to affect predator-prey dynamics, harm wildlife populations, or reduce genetic diversity in vegetation or wildlife.

Tilbury Phase 2 is not expected to interact with the following pathways:

- Population dynamics; and,
- Genetic diversity.

### Cumulative Effects

The residual effects of Tilbury Phase 2 are expected to have cumulative effects on the biophysical factors that support ecosystem function. These cumulative effects are described in detail in the cumulative effects assessment for each biophysical VC that supports ecosystem function as assessed for Tilbury Phase 2 ([Appendix 6, Section 17.01](#) Air Quality VC, [Appendix 6, Section 17.06](#) Vegetation VC, [Appendix 6, Section 17.07](#) Wildlife and Wildlife Habitat VC, [Appendix 6, Section 17.08](#) Fish and Fish Habitat VC, and [Appendix 6, Section 17.03](#) Surface Water VC).

### Mitigation Measures

FortisBC plans to implement mitigation measures, applicable to biophysical valued components described in [Appendix A](#) of the Revised Application.

### Positive Effects and Enhancement Measures

No positive effects or enhancement measures were identified by FortisBC.

## 20.3 Key Issues Raised

Many Nations raised issues regarding biophysical factors that support ecosystem functions, specifically anticipated construction related truck traffic to the Tilbury Phase 2 site and to Tilbury Slough and Fraser River. First Nations emphasized lack of mitigation measures for fish and fish habitat, surface water, and air quality, and that removing waterborne delivery is not a sufficient mitigation measure on its own. FortisBC assessed the potential effects of alternative construction delivery scenarios and found that truck delivery would result in only a negligible increase over existing non-project truck traffic during construction.

## 20.4 The EAO's Assessment and Conclusions

This section presents the EAO's conclusions on the potential positive and negative effects from Tilbury Phase 2 on biophysical factors that support ecosystem function.

## Proposed Provincial Conditions and Federal Key Mitigation Measures

[Appendix 2](#) of this Assessment Report outlines the identified KMMs under the IAA related to the [Appendix 6, Section 17.01](#) (Air Quality VC), as it relates to the health, social, and economic conditions of Indigenous Peoples, and the [Appendix 6, Section 17.07](#) (Wildlife and Wildlife Habitat VC) as it may pertain to migratory birds, species at risk, and Indigenous use of traditional lands and resources under the IAA.

The following provincial conditions and that address effects to biophysical factors that support ecosystem function:

- Condition 10 (Community Feedback Process) creates a process to address issues raised by First Nations and their members or citizens, and the Public during Construction and Operation.
- Condition 11 (Greenhouse Gas Emissions and Net-Zero Plan) requires the development, implementation, and periodic update of a plan to achieve net-zero GHG emissions by 2050, including interim milestones and annual offsetting of residual emissions starting in 2030.
- Condition 12 (CEMP) requiring the development and implementation a plan to manage the effects of Tilbury Phase 2 during Construction and Decommissioning, including requirements to surface water quality management plans for both Construction, and Decommissioning phases.
- Condition 13 (OEMP) requiring the development and implementation a plan to manage the effects of Tilbury Phase 2 during Operations, including a surface water management plan for Operation Phase.
- Condition 14 (Air Quality Management Plan) requiring the development and implementation of a plan to manage the effects of Tilbury Phase 2 on air quality.
- Condition 17 (Dry Street Sweeping Report) requiring FortisBC to submit a Report on the effectiveness Dry Street Sweeping to mitigate the effects of 6-PPDQ on fish within eighteen months of a Certificate being issued.

## Residual Effects

After considering the proposed provincial conditions and federal KMMs, the EAO characterizes the following effects on ecosystem function from Tilbury Phase 2, as shown in Table 70.

Table 70: Effects on Ecosystem Functions

| Ecosystem Function                     | Assessment Rating                           | Rationale                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------------------------|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Habitats Supporting Ecosystem Function | Negligible to low, localized and reversible | Due to existing development and disturbance in the Project Area, residual effects to habitats supporting ecosystem function such as vegetation and wildlife, are predicted to be negligible to low in magnitude. Climate change may amplify cumulative effects which could affect habitat suitability and wildlife resilience, thereby decreasing support for ecosystem function, however, the exact nature of that amplification is difficult to predict. |
| Habitat Patches                        | Low magnitude, local and reversible         | Impacts to habitat patches would be low magnitude and localized due to the existing conditions of the Project Footprint and surrounding area.                                                                                                                                                                                                                                                                                                              |
| Natural Disturbance Regime             | No effects                                  | Tilbury Phase 2 is not expected to alter the natural disturbance regime.                                                                                                                                                                                                                                                                                                                                                                                   |

| Ecosystem Function                   | Assessment Rating                                  | Rationale                                                                                                                                                                                                                                                                                               |
|--------------------------------------|----------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Structural Complexity                | Low magnitude, localized and permanent             | Habitat loss, including clearing during construction, may have an effect on structural complexity, but this is predicted to be localized, and low magnitude due to the existing conditions in the project area. Additionally, climate change may have an effect on structural complexity in the future. |
| Hydrologic or Oceanographic Patterns | Negligible, localized and short term               | Effects to surface water and groundwater and predicted to be negligible. Effects from project activities to water flow, hydrologic patterns, and water discharge volume are not expected.                                                                                                               |
| Nutrient Cycling                     | No effects                                         | Due to existing conditions in the project area and the predicted effects of the Project, no residual effects to nutrient cycling are expected.                                                                                                                                                          |
| Purification Services                | Low magnitude, localized and partially reversible. | The Construction and Operations phases will have a low magnitude effect on air quality within the project footprint, with negligible to low contribution to CAC concentrations and increase SO <sub>2</sub> .                                                                                           |
| Biotic Interactions                  | Negligible, localized and short term               | The heavily industrialized nature of the Project area has significant past habitat loss, and it is not anticipated that Tilbury Phase 2 will measurably impact the existing conditions or alter biotic interactions.                                                                                    |

### Conclusion

After considering the information provided by FortisBC in the Revised Application, the views of the TAC, First Nations, and the public, the proposed provincial conditions and federal Key Mitigation Measures, the EAO concludes that there would be a low magnitude of effects on biophysical factors that support ecosystem function. The EAO is satisfied that effects on these factors would be appropriately mitigated and minimized to the extent possible for the Project.

## 21.0 APPENDIX 10 EFFECTS ON CURRENT AND FUTURE GENERATIONS

### 21.1 Background

Both provincial and federal legislation require that assessments consider how projects affect current and future generations.

Under the Act, this means looking at positive and negative project effects on current and future generations on environmental, economic, social, cultural, and health values, as well as Indigenous interests that may interact with the project.

Subparagraph 22(1)(a)(iii) of the IAA specifies that the assessment of a designated project must take into account the result of any interaction between changes to the environment or to health, social or economic conditions. The extent to which Tilbury Phase 2 LNG contributes to sustainability, defined as “the ability to protect the environment, contribute to the social and economic well-being of the people of Canada and preserve their health in a manner that benefits present and future generations,” is a federal requirement as per paragraph 22(1)(h) of the IAA and is discussed in more detail in [Appendix 15](#).

This appendix provides information to help decision-makers, First Nations and the public understand whether the environment, people, and communities would be better or worse off as a result of Tilbury Phase 2. The analysis synthesizes all components of the effects assessment to offer insight into Tilbury Phase 2’s overall sustainability—specifically, how it may protect the environment, support a strong economy, and promote the well-being of British Columbians and their communities.

### 21.2 Potential Project Effects to Current and Future Generations

This section provides an overview of the EAO’s assessment of potential project effects to current and future generations. It is informed by [Section 14](#) of the Revised Application and the EAO’s assessment of VCs in [Appendix 6](#) of the EAO’s Report. This assessment focuses only on residual effects, those persisting after mitigation, that matter for current and future generations.

#### 21.2.1 Positive Effects

Tilbury Phase 2 is expected to deliver benefits for both current and future generations. The proponent stated that Tilbury Phase 2 is expected to produce LNG with one of the lowest carbon intensities in the world, primarily using hydroelectric power; however, this outcome depends on external factors beyond the proponent’s control.

Tilbury Phase 2 aligns with B.C.’s climate objectives, including the CleanBC strategy and the provincial energy action framework, by committing to net-zero carbon emissions by 2030 and supporting carbon neutrality by 2050. Design measures also

#### What is considered a current and future generation?

25 years is generally considered representative of a single generation however the Act does not assign a specific numerical value to the term. Generally, effects on current generations would be felt within the next 25 years, while effects on future generations would be felt 25 years and beyond.

FortisBC stated that the project would help displace higher-carbon fuels such as coal and diesel, reducing greenhouse gas (GHG) emissions and air pollutants. However, the EAO determined these claims are too uncertain due to factors beyond the project’s control, such as global market conditions and user behavior. As a result, displacement benefits have not been included as a benefit for current or future generations.

incorporate resilience against extreme weather, flooding, and seismic events, ensuring long-term sustainability.

From an energy perspective, Tilbury Phase 2 will strengthen the resilience of the Lower Mainland's energy system. The addition of an LNG storage tank will provide an emergency backup supply for customers, reducing the risk of widespread outages and ensuring continuity during supply disruptions. Expanded liquefaction capacity will meet growing demand for cleaner energy, supporting both local and global energy transition to lower carbon energy.

Economically, Tilbury Phase 2 will generate the following benefits:

- Tilbury Phase 2 could create more than 6,200 full-time equivalent (FTE) person-years of employment during construction and more than 100 FTE jobs during operation.
- Once operational, the facility will support approximately 600 FTE jobs and contribute nearly 500 million dollars annually to the provincial Gross Domestic Product (GDP) and almost 600 million dollars to Canada's GDP.
- Training programs and apprenticeships will prepare youth and underrepresented groups for future employment opportunities, while inclusive hiring policies have the potential to result in equitable access for Indigenous peoples and other communities.

### 21.2.2 Residual Adverse Effects

The EAO reviewed potential adverse effects of Tilbury Phase 2 on both current and future generations. These effects were assessed across key valued components (VCs), considering their duration, magnitude, and reversibility. Current generation impacts are generally short-term and occur during construction, while future generation impacts are associated with long-term operational activities and cumulative effects. A full assessment of each VC is in [Appendix 6](#), of the EAO's Assessment Report. Table 71 below summarizes these potential residual adverse effects by category and generational scope.

Table 71: Residual effects to current (construction) future generations (operation and decommissioning phase unless noted)

| VC           | Potential Residual Effect                                                                                                                                                                                                                                            | Duration                                               | Magnitude         | Reversibility        |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------|-------------------|----------------------|
| Air Quality  | Increase in ambient Criteria air contaminant (CAC) concentration during site preparation and project construction and increase in ambient Nitrous Oxide (NO <sub>2</sub> ) Sulphur Dioxide (SO <sub>2</sub> ), and other CAC concentrations during Project operation | Medium-term (construction to decommissioning phase)    | Negligible to low | Reversible           |
| Human Health | Health impacts from Inhalation of Contaminants of Potential Concern (COPCs) and shiftwork impacts                                                                                                                                                                    | Long-term (construction to past decommissioning phase) | Negligible to low | Partially Reversible |
| Acoustic     | Increase in noise and vibration levels during construction and increase in noise levels during operation.                                                                                                                                                            | Medium-term (construction to decommissioning phase)    | Negligible to low | Fully Reversible     |

| VC                            | Potential Residual Effect                                                                                                                                                      | Duration                                            | Magnitude         | Reversibility        |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------|-------------------|----------------------|
| Wildlife and Wildlife Habitat | Loss or alteration of habitat and increased wildlife health and mortality risk                                                                                                 | Medium-term (construction to decommissioning phase) | Negligible to low | Reversible           |
| Land and Resource Use         | Change to visual quality of the landscape and changes to use of tenures and licensed resource uses                                                                             | Medium-term (construction to decommissioning phase) | Low               | Reversible           |
| Vegetation                    | Introduction or spread of invasive plant species                                                                                                                               | Medium-term (construction to decommissioning phase) | Negligible to low | Reversible           |
| Infrastructure and Services   | Effects to domestic water supply, landfill and recycling facilities and transportation infrastructure and safety                                                               | Medium-term (construction to decommissioning phase) | Negligible        | Fully Reversible     |
| Culture                       | Change to land and water based cultural practices inter-generational knowledge transfer, diversity, use of indigenous languages and cultural cohesion and community continuity | Medium-term (construction to decommissioning phase) | Negligible        | Partially Reversible |
| Fish and Fish Habitat         | Reduced fish habitat quality increased risk to fish health injury and mortality and changes in fish distribution                                                               | Medium-Term (construction to decommissioning phase) | Negligible        | Fully Reversible     |
| Surface Water                 | Change in water quality and quantity in Tilbury Slough                                                                                                                         | Medium-Term (construction to decommissioning phase) | Negligible        | Partially Reversible |

### 21.3 Potential Project Effects to Indigenous Current and Future Generations

The existing Tilbury LNG facility is private property, largely composed of gravel and paved areas, infrastructure, and equipment laydown areas, with minimal vegetation and little to no wildlife habitat value; vegetation is mostly confined to ditch lines and spoil piles and is dominated by non-native and invasive species. Public access to Tilbury Phase 2 is limited, though the Fraser River dike to the north is used by the public. In the broader Project area, past and present environmental degradation, industrial development, and land-use changes have impacted the traditional harvesting practices and access to and use of cultural sites by the Indigenous Nations assessed.

FortisBC assessed the effects of Tilbury Phase 2 on First Nations in [Section 11](#) of its Revised Application, and the EAO and First Nations conducted their assessments in [Appendix 5](#) of the Assessment Report. The summary below outlines potential effects on First Nations for both current and future generations

Broadly speaking Tilbury Phase 2 could have potential effects on Indigenous interests, including harvesting and subsistence activities, cultural use sites and areas, social and economic conditions, and Indigenous health and well-being.

The EAO recognizes that these interests are interconnected and may overlap, and this is reflected in the individual Nation sections of the Assessment Report where more detailed analysis is provided (see [Appendix 5.01](#) to [Appendix 5.21](#)). Impacts can vary among Indigenous communities, some may experience greater magnitude effects, others minimal or none.

The following summary outlines the anticipated effects to current and future generations in each of the four core Indigenous interest areas based on available information and engagement with Indigenous Nations.

- **Harvesting and Subsistence Activities**

Tilbury Phase 2 is not expected to significantly affect harvesting or subsistence activities. The footprint contains little to no vegetation or wildlife habitat, and fishing access to the Fraser River will remain unchanged. Minor visual or other sensory (noise, psychological) changes may occur, but these are anticipated to either have negligible (not measurable) to low magnitude effect on harvesting experiences, see First Nation sections in [Appendix 5](#).

- **Cultural Use Sites and Areas**

Potential effects on cultural sites are predicted to be non-existent to negligible. The project footprint is on private industrial land and is not known to be used for ceremonies or cultural practices. Archaeological assessments found no heritage resources within the footprint, and mitigation measures will prevent disturbance to nearby sites. Minor visual changes may occur, but these are expected to either have no or negligible (not measurable) effect on cultural experiences.

- **Social and Economic Conditions**

Tilbury Phase 2 could generate positive outcomes by creating employment and contracting opportunities for Indigenous Nations, which may benefit both their current and future well-being. FortisBC has committed to fair and accessible hiring practices and training programs. Agreements with some participating Indigenous Nations include benefit-sharing arrangements, which could support long-term economic development.

- **Indigenous Health and Well-being**

As noted in the Human Health section, and individual First Nation sections in Appendix 6 Tilbury Phase 2 may have implications for the well-being of current and future generations of Indigenous peoples through its interaction with existing health vulnerabilities, mental health pressures, and factors that affect cultural practices and the intergenerational transfer of knowledge. The Human Health Risk Assessment, [Appendix J](#) of the Revised Application, concluded that contamination of country foods is highly unlikely. Noise is predicted to remain within regulatory limits, except for areas close to the fence line of the Tilbury Phase 2 site and mitigation measures will address potential concerns. Under worst case conditions, Project emissions could cause air concentrations within 50 metres of the Project Footprint to exceed regulatory thresholds. Shiftwork-related health impacts may occur for workers but are considered negligible to low magnitude.

## 21.4 Proposed Mitigation Measures, Federal Key Mitigation Measures, Provincial Conditions and Permitting

This section provides an overview of measures designed to avoid, reduce, or manage potential adverse effects on current and future generations, as well as Indigenous interests. These measures are drawn from multiple sources and reflect commitments at the regional, federal, provincial, and project levels:

### 21.4.1 Proponent Mitigation

[Appendix A](#) of the Revised Application includes a comprehensive list of mitigation measures that FortisBC will be required to implement should a Certificate be issued. The following summarizes key mitigations addressing issues of concern for present and future generations:

- **Air Quality**  
Tilbury Phase 2 will electrify refrigeration and feed gas compression processes to reduce CAC and GHG emissions. Emission reduction and control technologies will be incorporated into the design to meet regulatory requirements. Dust-control measures will be implemented during construction, and a vehicle idle reduction policy will help limit emissions. Regular inspection and maintenance programs will ensure equipment operates efficiently, and odour complaints will be tracked and addressed.
- **Fish and Fish Habitat**  
Mitigation focuses on preventing contamination and sedimentation. Measures include collecting and testing water that comes into contact with processing equipment before discharge, implementing erosion and sediment control plans in consultation with First Nations and QPs, and designing drainage systems with oil-water separators. Hydrostatic water used to test the LNG storage tank will be treated before release, and there will be no waterborne deliveries to avoid disturbance in aquatic habitats.
- **Climate Change and GHG Emissions**  
Tilbury Phase 2 will electrify major processes to reduce emissions and implement fugitive emissions management through design and operational controls. A Net-Zero Plan will guide compliance with government policies, and carbon offsets will be pursued when feasible. Additional strategies include exploring renewable fuels, waste heat recovery, and carbon removal.
- **Human Health**  
Mitigation measures address air quality, noise, odor, and safety. Waste management plans will minimize environmental and health risks, and emergency response plans will include fire control systems and annual testing. Noise mitigation will be engineered into equipment design, and dust-control measures will reduce particulate exposure. Health and safety programs will cover shift work impacts, substance use support, and fit-for-duty policies. Onsite emergency health services will meet or exceed WorkSafeBC standards.
- **Indigenous Interests**  
Engagement is integrated throughout mitigation planning. First Nations will be consulted on air quality management, erosion and sediment control, wildlife timing windows, and contingency measures for wildlife interactions. Indigenous employment and contracting opportunities will be promoted, with cultural awareness programs and fair hiring practices aligned with FortisBC's Indigenous Principles. Communication plans will ensure timely updates on project activities, safety measures, and emergency response.

### 21.4.2 Provincial Conditions

If issued, the Certificate will establish binding conditions that strengthen and expand upon the proponent's commitments. The complete set of conditions is provided in the Certificate Table of Conditions. Key conditions include:

- **Air Quality**

The Holder must develop and implement an Air Quality Management Plan under the direction of a QP. This plan must detail mitigation measures (including electrification and emissions control technologies), including a report that details the air mitigation technology selection process, and provide updated air quality modeling. Tilbury Phase 2 will be subject to enforceable emission limits, stack testing, and monitoring under Metro Vancouver's Air Quality Management Bylaw, with results assessed against provincial and federal standards and reported to Metro Vancouver and provincial datasets.

- **Fish and Fish Habitat**

A Dry Street Sweeping Report must be prepared to evaluate its effectiveness in mitigating 6PPD-Quinone (6-PPDQ) impacts on fish and fish habitat. If effective, this measure must be incorporated into the CEMP. The CEMP must also address erosion and sediment control, spill prevention, and water quality management, including hydrostatic testing protocols aligned with B.C. Water Quality Guidelines.

- **GHG Emissions and Climate Change**

The Holder must implement the Net Zero Plan included within the Revised Application throughout Construction, Operation, and Decommissioning, updating it every five years in consultation with the Ministry of Energy and Climate Solutions, Environment Climate Change Canada (ECCC), Metro Vancouver, and First Nations. Starting in 2030, residual emissions must be offset through the retirement of B.C. Offset Units in the B.C. Carbon Registry. Annual reporting to the EAO and the Ministry of Energy and Climate Solutions is required to demonstrate compliance.

- **Human Health**

Human health considerations are embedded in multiple plans, including the CEMP and Operational Environmental Management Plan (OEMP). These plans must address dust management, noise control, waste management, and spill prevention. Emergency response measures and onsite health services are required to meet or exceed WorkSafeBC standards. Air quality monitoring under the Air Quality Management Plan also supports health protection by ensuring compliance with ambient air quality standards.

- **Indigenous Interests**

Conditions require engagement and inclusion measures. The Holder must consult First Nations during the development of all major plans (CEMP, OEMP, Air Quality Management Plan, Chance Find Protocol, and Net-Zero Plan). A First Nation and Local Economic Inclusion and Monitoring Plan must be implemented to prioritize Indigenous hiring, training, and procurement opportunities, with bi-annual reporting during construction and annual reporting during early operations. Cultural awareness programs and consultation records must be maintained and shared with the EAO.

### 21.4.3 Certified Project Description

The Certified Project Description defines the physical and operational scope of Tilbury Phase 2 and incorporates design elements that serve as inherent mitigations. These features are intended to minimize environmental and community impacts through engineering controls and best practices. A full description of these components can be found in Schedule A of the Certificate, should one be issued. Key design-based mitigations include:

- **Totally Enclosed Ground Flare**

The Certified Project Description specifies the use of a totally enclosed ground flare system for vapour management. This design reduces light and noise emissions compared to conventional elevated flares, minimizing visual and acoustic disturbance to nearby communities and wildlife. It also improves combustion efficiency, reducing criteria for air contaminants and odour impacts.

- **Electric-Drive Refrigerant Compressors**  
Liquefaction trains will utilize electric-drive refrigerant compressors rather than gas-fired units. This design choice aligns with mitigation commitments to reduce GHG emissions and improve air quality by eliminating combustion-related pollutants such as NO<sub>2</sub>, SO<sub>2</sub>, and particulate matter.
- **Air Cooling Systems**  
The inclusion of air-cooling systems, rather than water-intensive cooling towers, reduces water consumption and removes thermal discharge risks to aquatic environments, supporting mitigation for fish and fish habitat.
- **Safety and Emergency Systems**  
Integrated fire detection and suppression systems, along with emergency backup generators, are designed to prevent and manage accidental releases or malfunctions. These systems reduce risks to human health and safety and limit potential environmental contamination.

#### 21.4.4 Permitting Processes

If a Certificate is issued, subsequent permits and authorizations will establish detailed technical requirements that complement and enforce mitigation measures identified in the EA process. These permits are administered under provincial, federal, and municipal legislation and are designed to prevent or minimize adverse effects on air quality, fish and fish habitat, GHG emissions, human health, and Indigenous interests. A full list of applicable permits and regulatory processes is outlined in the [Joint Permitting/Regulatory Coordination Plan](#). Key permitting mechanisms include:

- **Air Quality**  
An EMA permit, administered by Metro Vancouver, will authorize and set conditions on air emissions sources. This process requires updated emissions modeling, justification of equipment selection, and consideration of BAT policies. Conditions will include monitoring and reporting requirements aligned with CAAQS and Metro Vancouver objectives, ensuring compliance and minimizing cumulative air quality impacts.
- **Greenhouse Gas Emissions**  
While no permit is required, reporting obligations under the GIRCA will apply if emissions exceed regulatory thresholds. These requirements enforce transparency and support provincial climate targets, complementing the Net Zero Plan commitments under the Certificate.
- **Human Health and Community Well-being**  
Noise and vibration controls may be addressed through LNG Facility Permit conditions under the ERAA and municipal bylaws. Emergency preparedness requirements under BCER's [Emergency Management Regulation](#) and federal [Environmental Emergency Regulations](#) will mandate contingency planning, exercises, and communication protocols to protect workers, nearby communities, and Indigenous nations.
- **Indigenous Interests and Cultural Resources**  
Site alteration permits under the [Heritage Conservation Act](#) may be required if archaeological resources are encountered. These processes include consultation with First Nations and adherence to cultural heritage protection standards. Additional engagement obligations are embedded in emergency planning and LNG facility permitting for Tilbury Phase 2.

#### 21.4.5 Federal Recommended Measures

See [Appendix 2](#)

## 21.5 Key Issues Raised

### 21.5.1 Climate change

During the public comment period, the EAO heard many concerns about climate change and intergenerational equity. Many participants argued that expanding LNG infrastructure would lock in substantial GHG emissions for decades, primarily methane, a gas far more potent than carbon dioxide, contradicting B.C.'s climate targets and Canada's commitments, and delaying the transition to renewable energy.

As outlined in the [Appendix 12](#) Greenhouse Gas Emissions of this report, key issues included whether the characterization of LNG as "lower-carbon," and the credibility of the proponent's Net-Zero Plan. The proponent stated that upstream emissions were assessed using federal guidance and that LNG meets provincial intensity benchmarks. They also stated that Tilbury Phase 2 is designed to achieve an emissions intensity of about 0.016 metric tonne(s) of carbon dioxide equivalent (tCO<sub>2</sub>e) per tonne of LNG, well below the provincial benchmark of 0.16, and among the lowest globally. The proponent has committed to being net-zero for GHG emissions upon commercial operation by 2030 in accordance with Provincial legislation.

The EAO notes that downstream emissions, those from end-use combustion, are largely outside the scope of the EA. Though the EAO did not rely on FortisBC's global emissions analysis when determining project benefits, the EAO recognizes that emissions could contribute positively or negatively to global GHG levels and climate change depending on how and where the LNG is ultimately used.

The EAO proposes a certificate condition requiring a credible Net-Zero Plan with five-year updates and consultation with First Nations, Metro Vancouver, and other government agencies. With these conditions and regulatory requirements, the EAO concluded Tilbury Phase 2 would not cause significant adverse effects on GHG emissions, though residual effects remain due to the cumulative nature of climate change.

### 21.5.2 Impacts to First Nation rights

Some First Nations raised concerns that the assessment does not adequately address long-term and cumulative impacts on their rights, culture, and aspirations for future generations.

Tsawwassen First Nation (Tsawwassen) identifies cumulative effects as a key issue, noting that longstanding and ongoing pressures in the lower Fraser River diminish opportunities to exercise Treaty rights and cultural practices, with implications for both present and future generations.

TWN emphasized that the methodology overlooks cumulative effects and perpetuates degraded conditions, increases impacts of climate change, negatively impacts cultural continuity, and knowledge transfer. TWN disagrees with the EAO's policy that cumulative effects are only assessed where residual effects (after mitigation measure have been applied) are predicted, arguing this approach ignores the full impact on the exercise of their rights. TWN requested a comprehensive cumulative effects assessment (CEA) using a pre-contact baseline to avoid "shifting baseline syndrome." They stated that even small residual effects may infringe on their ability to restore their way of life in industrialized areas and act as barriers to future aspirations.

Ts'uubaa-asatx notes that the Revised Application frequently uses terms such as "potential negative effects" and references to contributions to "existing and ongoing cumulative effects." While common in regulatory language, this phrasing can unintentionally minimize the real and ongoing impacts Ts'uubaa-asatx experiences today. These effects are not merely potential, they stem from the lasting legacy of colonization, dispossession, and displacement from their traditional lands and territories. Ts'uubaa-asatx emphasizes that any assessment of project impacts must clearly recognize this context and avoid language that obscures the lived realities of cumulative impacts on their Rights, culture, and way of life.

Quw'utsun Nation disagreed with the temporal scope of the assessment, noting that impacts should be considered across seven generations, not a single generation (~25 years). Quw'utsun Nation asserted that Tilbury Phase 2 perpetuates colonial exclusion from their territory and undermines plans to re-establish residential use at Tl'uqtinus, the Historic Indigenous Village Site<sup>83</sup>. Industrial development next to land intended for cultural and residential revitalization creates barriers, such as noise, pollution concerns, and safety risks, that conflict with these plans and prevent the Nation from restoring community presence, reinforcing patterns of exclusion.

Quw'utsun Nation also highlighted disproportionate climate change impacts on Indigenous communities and challenged conclusions regarding health and well-being, stating that any negative effect hampers their ability to achieve the highest attainable standard of health and access to country foods.

x<sup>w</sup>məθk<sup>w</sup>əyám raised concerns about the sensitivity of their rights in an already industrialized area and the inadequacy of mitigation for sensory disturbances. x<sup>w</sup>məθk<sup>w</sup>əyám stressed that impacts should be assessed from a pre-colonization baseline, not the current degraded state. They disagreed with conclusions that noise and light effects would be negligible and requested co-development of mitigation measures to address sensory impacts, which they view as directly linked to cultural values and rights.

Kwantlen First Nation disagreed with the proponent's conclusion of no residual effects and raised concerns about further cultural disenfranchisement in areas of importance, including Tilbury Island.

The STSA maintained that FortisBC's characterization of residual effects differs substantially from their own assessment using the Stó:lō Cultural Model. While FortisBC agreed to include both perspectives, the STSA noted that reconciliation of these differing views remains unresolved.

### 21.5.3 Air Quality

TAC members, including Tsawwassen, Quw'utsun Nation, x<sup>w</sup>məθk<sup>w</sup>əyám, TWN, Metro Vancouver, Vancouver Coastal Health, Fraser Valley Health, and the Richmond, raised concerns about potential exceedances of NO<sub>2</sub> standards, the age of background monitoring data, and whether flaring during commissioning/start-up was fully assessed. Several noted that exceedances of NO<sub>2</sub> objectives could occur for a meaningful portion of the year, including near a Richmond retirement residence.

FortisBC's initial modelling used a conservative no-mitigation scenario but with the commitment to incorporate emissions control technology and meet air quality regulatory requirements and included flaring across Construction, Operation and Decommissioning. In response to comments, FortisBC completed additional modelling using a conceptual mitigated design and provided information on expected performance of proposed emissions controls. The updated results show that Tilbury Phase 2's incremental contribution is small in the context of regional concentration, and predicted concentrations under the mitigated scenario remain below CAAQS 2025 and Metro Vancouver Ambient Air Quality Objective (AAQOs) 2025 at all sensitive receptors.

Cumulative effects and uncertainty in the accuracy of the air quality characterization of effects were also central concerns. First Nations and Metro Vancouver emphasized that existing industrial and transportation sources already influence air quality and community health along the Fraser River, and some questioned the treatment of culturally important areas and decommissioning in the CEA. The EAO recognizes these perspectives and notes that Metro Vancouver's air permitting process, along with Conditions 14 (Air Quality Management Plan) and 18 (Regional Cumulative Effects Initiatives), will require detailed design, monitoring and performance testing to confirm mitigation and support broader airshed management.

<sup>83</sup> See Section 3.1 for naming and jurisdictional context regarding the Historic Indigenous Village Site

#### 21.5.4 Project benefits

While the majority of publicly received comments expressed concerns about climate change and intergenerational impacts, a small number of participants provided supportive feedback. These submissions noted that LNG could serve as a cleaner alternative to coal and oil, contribute to energy security, and create jobs and skills development opportunities. Some also highlighted potential economic benefits and the importance of expanding energy projects to reduce reliance on U.S. imports and tariffs.

x̣ṃəθḳẉəỵəm acknowledged that Tilbury Phase 2 could create positive economic opportunities for their members, particularly through employment, procurement, and training commitments set out in the Tilbury Projects Master Agreement. They also recognized that the Agreement provides a framework for shared benefits, skills development, and long-term economic participation, which they view as meaningful if opportunities are accessible and aligned with community needs.

### 21.6 The EAO's Analysis and Conclusions

This section presents the EAO's conclusions on the potential positive and negative effects from Tilbury Phase 2 on current and future generations.

Tilbury Phase 2 is expected to provide economic benefits for current and future generations through job creation, training opportunities. It will also provide increased resilience of the Lower Mainland's energy system. Construction will generate thousands of direct and indirect jobs, while Operation will support long-term employment and contribute positively to provincial and national GDP. Commitments to inclusive hiring and benefit-sharing agreements with Indigenous nations may enhance social and economic well-being for some communities.

Environmentally, Tilbury Phase 2 is designed to operate with one of the lowest carbon intensities globally, (approximately 0.016 tCO<sub>2</sub>e per tonne of LNG under the net-zero policy), supported by electrification. These measures align with provincial climate objectives and the Net-Zero New Industry Policy. However, the EAO notes that downstream emissions, those from end-use combustion—are outside the scope of this assessment but could contribute positively or negatively to global GHG levels depending on market conditions. Residual effects from incremental air emissions, noise, and habitat alteration during Operation are predicted to be low to negligible with mitigation.

The EAO acknowledges concerns raised by First nations regarding cumulative effects, shifting baselines, and intergenerational impacts on rights, culture, and aspirations. First Nations emphasized that even small residual effects compound existing degradation and colonial harms, limiting restoration goals and cultural continuity. While Tilbury Phase 2 footprint is on an industrial site with limited direct interaction with harvesting or cultural use areas, sensory disturbances and cumulative effects remain key issues. Conditions requiring engagement, co-development of mitigation measures, and implementation of a Net-Zero Plan with five-year updates are intended to address these concerns.

After considering proposed mitigation measures, permitting requirements, provincial conditions, and key federal mitigation measures, the EAO concludes that Tilbury Phase 2 would generally have positive effects on employment, training, and economic opportunities for current and future generations. Residual adverse effects on air quality, acoustic environment, and human health are predicted to be negligible to low and reversible after the decommissioning of Tilbury Phase 2. Tilbury Phase 2 design and regulatory conditions, including electrification and a credible Net-Zero Plan, will minimize GHG emissions, though cumulative climate change effects remain a global concern.

With respect to Indigenous interests, the EAO recognizes that some nations view any additional impact as significant due to cultural and historical context. While the EAO considers any residual effects on rights and cultural practices to be not significant, provincial conditions requiring engagement, benefit-sharing, and cultural awareness programs aim to reduce these impacts. Overall, the EAO concludes that, with implementation of mitigation measures and certificate conditions, Tilbury Phase 2 is unlikely to result in significant adverse effects on current and future generations, including both First Nations and non-First Nations communities.

## 22.0 APPENDIX 11 CONSISTENCY WITH LAND USE PLANS

### 22.1 Consistency with Land Use Plans

As part of the assessment the consistency of Tilbury Phase 2 LNG Expansion Project (Tilbury Phase 2 or Project) with Land Use Plans must be considered.<sup>84</sup> Land use planning sets the strategic direction for sustainable resource stewardship and management of lands and waters that meets economic, environmental, social, and cultural objectives. Land use planning sets high-level direction and helps define 'what' can occur 'where' on the land base.

### 22.2 Land Use Plans

Consistency with the land use plans was assessed in [Table 7.11-3](#) of the Revised Application. A total of 31 land use plans were reviewed as part of the analysis. The Revised Application indicated that Tilbury Phase 2 is located within, or may interact with 16 of these land use plans including:

#### 22.2.1 Provincial Government Land Use Plans

The *Lower Fraser Sustainable Resource Management Plan*<sup>85</sup> (2013) includes six Land Units in the Lower Fraser, including the Fraser Valley South Landscape Unit, which the Project is subjected to. 96.7 percent of the Fraser Valley South Landscape Unit is excluded from the planning area reflecting that the plan is intended to be applicable to only Crown Land, though some Crown tenures exist within and near the LAA. The Project Footprint and most of the Land and Resource Use LAA lie on private land on Tilbury Island, with minimal overlap with Provincial Crown Lands. With mitigation measures in place and no in-water activities required, the Project is consistent with the Plan.

#### 22.2.2 Local Government and Port Authority Land Use Plans

Metro Vancouver's *Regional Growth Strategy*<sup>86</sup> (RGS: 2025) outlines land use policies to support infrastructure such as water, waste, transportation, housing, and air quality. It also aims to protect conservation and recreation areas, encourage sustainable development, safeguard agricultural viability, and preserve the industrial land supply. As Tilbury Phase 2 is in a regionally designated industrial area, it is consistent with Metro Vancouver's RGS.

Delta's OCP<sup>87</sup> (Bylaw No. 8400: 2024), outlines long-term policies and land use designations that guide decisions on housing, development, services, and infrastructure. Industrial lands, located at River Road East, Tilbury Industrial Park, Annacis Island, and Roberts Bank, are key to local employment. Delta prioritizes supporting existing industries, encouraging redevelopment, and promoting environmental sustainability. The Project is consistent with the OCP.

Richmond's *Official Community Plan*<sup>88</sup> (Bylaw No. 9000: 2012), outlines policies for sustainable land use, mobility, infrastructure, and ecological networks. The Project is outside of Richmond's OCP and is consistent with the use of the nearest designated areas (industrial and agriculture).

<sup>84</sup> Section 25(2)(g) of the Act requires the consistency with any land-use plan of the government or an Indigenous nation if the plan is relevant to the assessment be considered.

<sup>85</sup> Government of British Columbia (B.C.). 2013. Lower Fraser Sustainable Resource Management Plan. Accessed June 17, 2025. [https://www2.gov.bc.ca/assets/gov/farming-natural-resources-and-industry/natural-resource-use/land-water-use/crown-land/land-use-plans-and-objectives/southcoast-region/chilliwack-lu/chilliwack\\_lu\\_lowerfraser\\_plan\\_jan2013.pdf](https://www2.gov.bc.ca/assets/gov/farming-natural-resources-and-industry/natural-resource-use/land-water-use/crown-land/land-use-plans-and-objectives/southcoast-region/chilliwack-lu/chilliwack_lu_lowerfraser_plan_jan2013.pdf)

<sup>86</sup> Metro Vancouver. 2025. About Metro 2050: Regional Growth Strategy. Accessed June 17, 2025. <https://metrovancouver.org/services/regional-planning/metro-2050-the-regional-growth-strategy>

<sup>87</sup> City of Delta. 2025 Official Community Plan. Accessed June 17, 2025. <https://delta.civicweb.net/filepro/documents/230675/?preview=230456>

<sup>88</sup> City of Richmond. 2012. *Official Community Plan (OCP) Schedule 1 of Bylaw 9000 2041 OCP—Moving Towards Sustainability*. Published 2012. Accessed June 17, 2022. [https://www.richmond.ca/sites/default/files/assets/OCP\\_9000\\_consolidation34181.pdf](https://www.richmond.ca/sites/default/files/assets/OCP_9000_consolidation34181.pdf)

Vancouver Fraser Port Authority's (VFPA) *Land Use Plan*<sup>89</sup> (2020) outlines long-term policies guiding development of lands and waters under its jurisdiction, including the south arm of the Fraser River. VFPA industrial and terminal lands lie directly across from the Project Footprint. Based on the current design, the Project is consistent with the Land Use Plan.

### 22.2.3 First Nations Land Use Plans

Tilbury Phase 2 is located within traditional territories of First Nations. Many of the First Nations whose interests may be affected by Tilbury Phase 2 have developed environmental objectives, plans and targets to help support their governance and stewardship, have implemented land use plans or land codes for reserve or treaty lands, and/or are signatories to land and resource management related agreements (including treaties).

#### xʷməθkʷəyám

The Revised Application considered three land use plans by xʷməθkʷəyám. Of the three plans, two apply to xʷməθkʷəyám reserve and private lands, and do not interact with Project. The third is xʷməθkʷəyám's *Comprehensive Sustainable Community Development Plan*<sup>90</sup> (2018), which is a holistic framework aligning various community goals. The Revised Application indicates that the Project would be consistent with supporting social and economic development. However, it also acknowledges that xʷməθkʷəyám may identify potential adverse impacts related to fishing, employment, community health, and cultural practices.

#### Qu'wutsun Nation, Hul'qumi'num Treaty Group, and their Members

Four Land Use Plans were identified as applicable that are associated with Qu'wutsun Nation, Hul'qumi'num Treaty Group, and member communities of Qu'wutsun Nation or Hul'qumi'num Treaty Group:

- Qu'wutsun Nation's (Cowichan Tribes, Lyackson First Nation, Stz'uminus First Nation, Penelakut Tribe and Halalt First Nation)<sup>91</sup> *Declaration for Reconciliation*, which declares that reconciliation shall be consistent with the following land and resource use objectives: the recovery and restoration of the village and lands at Tl'uqtnus, reestablishing of cultural practices (e.g. harvest fishing), and economic and employment opportunities.
- Hul'qumi'num Treaty Group (whose membership at the time of publication was Cowichan Tribes, Stz'uminus First Nation, Penelakut Tribe, Lyackson First Nation, Halalt First Nation, and Ts'uubaa-asatx) issued *Shxunutun's Tu Suleluxwts: In the footsteps of our Ancestors*, which includes resource management goals and objectives, connections to Tl'uqtnus, and strategies to achieve the resource management objective.
- Ts'uubaa-asatx issued *Lake Cowichan First Nation Policy: South Arm of the Fraser River and Approaches* (2018), which is Ts'uubaa-asatx's consultation process related to the south arm of the Fraser River; and,
- Ts'uubaa-asatx issued *Lake Cowichan First Nation Vision, Goals and Objectives for the South Arm of the Fraser River and Approaches* (2018), which is Ts'uubaa-asatx's vision for clean air, water and land, promoting healthy fish and wildlife populations which will help with re-establishing traditional use and occupancy of the lower mainland.

The Revised Application considered the interaction of the Project with the *Declaration for Reconciliation and Shxunutun's Tu Suleluxwts: In the footsteps of our Ancestors*. FortisBC (the Proponent) states in the Revised Application that it acknowledges that Qu'wutsun Nation's stated goal is to reestablish a permanent residence on Tl'uqtnus lands; however, from FortisBC's perspective, Tilbury Phase 2 is not anticipated to interact with the

<sup>89</sup> Vancouver Fraser Port Authority (VFPA). 2020. *Land Use Plan*. Accessed May 29, 2023. [https://www.portvancouver.com/sites/default/files/2024-08/500\\_POV-Land-Use-Plan\\_FINAL-2.pdf](https://www.portvancouver.com/sites/default/files/2024-08/500_POV-Land-Use-Plan_FINAL-2.pdf)

<sup>90</sup> Musqueam Indian Band. 2018. *Musqueam First Nation Comprehensive Sustainable Community Development Plan*. Accessed June 17, 2025. [https://www.musqueam.bc.ca/wp-content/uploads/2018/10/Musqueam-CCP-Update\\_FINAL\\_Oct2018\\_lowres.pdf](https://www.musqueam.bc.ca/wp-content/uploads/2018/10/Musqueam-CCP-Update_FINAL_Oct2018_lowres.pdf)

Qu'wutsun Nation. 2019. *Roberts Bank Terminal 2 Panel Submission*. Accessed June 18, 2025. <https://iaac-aec.gc.ca/050/documents/p80054/130341E.pdf>

objectives of the *Declaration for Reconciliation*. Table 7.11-3 of the Revised Application explains how changes in noise levels and to the visual landscape as a result of Tilbury Phase 2 are anticipated to be negligible compared to existing conditions and not change the experience of Quw'utsun Nation community members using cultural sites, including Tl'uqtinus. Similarly, air quality effects will be localized to the immediate vicinity of Tilbury Phase 2 Footprint and are not expected to materially affect Quw'utsun Nation's intended use of Tl'uqtinus lands. Given that FortisBC has no intention to utilize Tl'uqtinus lands for the life of Tilbury Phase 2, and there will be no changes to land or water-based access or the physical environment on Tl'uqtinus lands as a result of Tilbury Phase 2, Tilbury Phase 2 is not anticipated to interact with the objectives of the *Declaration for Reconciliation*.

The Revised Application also notes that for *Lake Cowichan First Nation Policy: South Arm of the Fraser River and Approaches (2018)* and *Lake Cowichan First Nation Vision, Goals and Objectives for the South Arm of the Fraser River and Approaches (2018)*, the Project is not anticipated to interact negatively with the policy from FortisBC's perspective. From Ts'uubaa-asatx's perspective, the Project could result in increased use around the Project area, which could in turn contribute to the Lower Mainland becoming increasingly out of reach for Ts'uubaa-asatx members to live and work in the area, thereby negatively interacting with Ts'uuba-asatx's policy. The EAO notes that the effects of the project on the policies are likely consistent with the current conditions – and that from Ts'uuba-asatx's perspective this would continue challenges ongoing challenges accessing land along the Fraser River to exercised Section 35 rights.

### S'ólh Téméxw Stewardship Alliance

The STSA's *S'ólh Téméxw Use Plan and Policy*<sup>92</sup> (2018) guides economic development while minimizing risks to culturally significant areas, including seven heritage zones. The Fraser River is designated a Sensitive Waterway under the plan. The Revised Application indicated that with proposed mitigation Tilbury Phase 2 is not anticipated to interact with the Fraser River as no-water work or water-based activities are proposed as part of the Project. The EAO recognizes that water from the Project site will indirectly enter the Fraser River and has considered effects to Fish and Fish Habitat in Section 7.9 and Surface Water in Section 7.4 of the Assessment Report.

### Tsawwassen First Nation

The Revised Application considered the interaction of Tilbury Phase 2 with five Tsawwassen First Nations' Land Use Plans.

According to the Revised Application, the Project is not anticipated to interact with the Tsawwassen First Nation Land Use Plan (2009) or *Neighbourhood Plan*<sup>93</sup> (2011) as the plans apply to Treaty Lands, which will not be directly impacted by the Project. The Revised Application notes there may be indirect benefits to economic development objectives for Treaty Lands because of the Project.

*Tsawwassen First Nation Strategic Plan 2018-2023*<sup>94</sup> (2018) includes goals for stewardship of lands, water, and resources, including preservation and ensuring the current and future generations to enjoy the benefits of Treaty rights. The Revised Application states that from FortisBC's perspective the project is consistent with Tsawwassen's goals in the strategic plan including capacity funding with opportunities for stewardship studies, cost of energy for Tsawwassen First Nation customers, and economic development and training opportunities. The Revised Application also states that from Tsawwassen's perspective there may be negative interactions with the "The Nation's identity,

including the cultural, spiritual, psychological, emotional and social connection in and around Tilbury Island as a result of Tilbury Phase 2 “

Tilbury Phase 2 interacts with the Tsawwassen First Nation *Final Agreement*<sup>95</sup> (2010), which is the first urban treaty in B.C. The Treaty recognized Tsawwassen jurisdiction over Tsawwassen Lands, defined fisheries allocation areas, hunting rights, and first right of refusal over an additional 278 hectare of lands at Brunswick Point. The Revised Application stated that from FortisBC’s perspective, Tilbury Phase 2 is consistent with the following Tsawwassen Treaty Objectives:

- Healthy Rights – Healthy River,
- Healthy Culture;
- Healthy Relationships, and
- Healthy Future for Future Generations.

The Revised Application stated that from Tsawwassen First Nation’s perspective there may be negative interactions with their Treaty objectives, which include:

1. The continued ability for community members to practice their Rights to harvest fish in the lower Fraser River within Tsawwassen Territory.
2. Impacts to the Nation’s identity, including the cultural, spiritual, psychological, emotional and social connection in and around Tilbury Island because of Tilbury Phase 2.
3. Tsawwassen businesses with similar workforce requirements to Tilbury Phase 2 could experience direct adverse effects by Tilbury Phase 2’s demand for a large construction workforce.

In accordance with Tsawwassen First Nation *Harvest Agreement*<sup>96</sup> (2010), Tsawwassen operates their own fisheries for commercial purposes in approved areas of the river and has guaranteed annual commercial allocation of Fraser River salmon. No changes to commercial fisheries are expected because of Tilbury Phase 2.

### Tsleil-Waututh Nation

The Revised Application considered three land use plans by TWN. Of the three plans, two apply to Burrard Inlet and Indian River Watershed, and do not interact with the Project. The TWN *Land Use Plan*<sup>97</sup> (2018) outlines goals for community and economic development, aiming to create opportunities for economic growth, public spaces, and affordable housing to support future generations. While the Project is not located on TWN reserve or private lands the Project may indirectly support TWN’s economic development goals.

## 22.2.4 Other Land Use Plans

The Fraser River Estuary Management Program’s *A Living, Working River: the Estuary Management plan for the Fraser River*<sup>98</sup> (FREMP 2003) was a long-term, intergovernmental program to coordinate planning, protection, and development in the Fraser River estuary that was discontinued in 2013. The plan for the Fraser River Estuary

<sup>95</sup> Tsawwassen First Nation. 2010a. *Tsawwassen First Nation Final Agreement*. Ottawa: Indian and Northern Affairs Canada. Accessed June 17, 2025. <sup>98</sup> Fraser River Estuary Management Program (FREMP). 2003. *The Estuary Management Plan for the Fraser River: A Living Working River*. Accessed June 17, 2025. <https://www2.gov.gc.ca/library-bibliotheque/281396.pdf>.

provides a framework for integrating the management of human and natural activities in the estuary. The Project is consistent with the objectives of the plan.

### 22.3 Key Issues Raised

Qu'wutsun Nation stated that the Cowichan Nation Alliance *Declaration for Reconciliation* and the *HTG Land Use Plan* were not properly contextualized. Reviewers also provided comments related to land use planning that are addressed in other sections of this Assessment Report, including [Appendix 6, Section 17.10](#) (Land and Resource Use), [Appendix 6, Section 17.11](#) (Infrastructure and Services), and [Appendix 6, Section 17.14](#) (Human Health) VCs.

### 22.4 The EAO's Assessment and Conclusions

The EAO has considered the consistency of Tilbury Phase 2 with the Land Use Plans identified above and listed in [Table 7.11-1](#) of the Revised Application. The EAO has also considered the potential of Tilbury Phase 2 to affect the objectives of the land use plans, strategies and management programs of Metro Vancouver, Delta, Richmond, VFPA, First Nation Land Use Plans, and the Fraser River Estuary Management Program. The EAO has concluded that Tilbury Phase 2 is not expected to have an adverse effect on the overall objectives of these plans.

## 23.0 APPENDIX 12 GREENHOUSE GAS EMISSIONS

### 23.1 Background

This section provides information and an analysis of the direct effects of the GHG emissions from Tilbury Phase 2 as estimated in the Revised Application and the ability for the Governments of Canada and B.C. to meet their legislated emission reduction targets.

Conclusions on how Tilbury Phase 2 affects Canada's ability to meet its environmental obligations and climate change commitments are provided in [Appendix 15: Requirements of the Impact Assessment Act](#). As required under the IAA, the Proponent's Revised Application includes information consistent with ECCC's Strategic Assessment of Climate Change (SACC), including a credible net-zero emissions plan outlining how the Project would achieve net-zero by 2050.

Further, Section 25 of the Act states that every assessment must consider GHG emissions, including the potential effects on the province being able to meet its targets under the [Climate Change Accountability Act](#). The Proponent must also provide a credible plan for Tilbury Phase 2 to achieve net-zero GHG emissions by 2030, as per the [Minister's letter regarding GHG standards](#) and the introduction of the [Net-Zero New Industry Policy](#). In addition to provincial and federal requirements, GHG emissions were identified as a topic to be assessed for Tilbury Phase 2 due to interest from First Nations, the public, and stakeholders.

#### 23.1.1 Regulatory Context

GHG emissions are subject to provincial and federal requirements and guidelines.

The provincial requirements include:

- *Greenhouse Gas Industrial Reporting and Control Act* (GGIRCA) (establishes GHG emission reporting requirements);
- *Climate Change Accountability Act* (previously titled the *Greenhouse Gas Reduction Targets Act*) requires the province to reduce GHG emissions 40 percent below 2007 by 2030, 60 percent by 2040, and 80 percent by 2050. The Minister sets sector targets under the *Climate Change Accountability Act* and has set an oil and gas sector target required to reduce GHG emissions 33 percent to 38 percent below 2007 levels by 2030);
- CleanBC Roadmap to 2030 (comprehensive plan for B.C. to achieve its climate targets and transition to a clean economy);
- New Energy Action Framework builds on the actions outlined in the CleanBC Roadmap for 2030 requires all proposed LNG facilities in or entering the environmental assessment (EA) process to pass an emissions test and develop a credible plan to be net zero by 2030;
- The [Minister's letter to the EAO's Chief Executive Assessment Officer](#), sets out the Province's approach to delivering the CleanBC Roadmap to 2030 commitment and the New Energy Action Framework commitments for all new, large industrial facilities with estimated annual emissions greater than 10,000 tonnes carbon dioxide equivalent to develop a credible plan to achieve net-zero emissions by 2050 (2030 for LNG) and demonstrate alignment with world-leading emission intensity performance; and
- Flaring and Venting Reduction Guideline (BCER regulatory requirements and guidance for flaring, incinerating, and venting at natural gas well sites, facilities and pipelines).

The federal GHG emission requirements applicable to Tilbury Phase 2 include:

- Government of Canada's 2030 Emissions Reduction Plan; and

- *Canadian Net Zero Emissions Accountability Act* (requires national five-year emissions targets to reach net-zero by 2050);
- Greenhouse Gas Reporting Program (facilities that emit more than 10 kilotonnes (kt) CO<sub>2</sub>e annually must report their emissions to ECCC); and
- Strategic Assessment of Climate Change (outlines the GHG emissions and climate change information requirements that proponents must provide).

### 23.1.2 Assessment Boundaries Context

GHG emissions spatial boundaries are not defined because GHGs and climate change are, by nature, both regional and global.

The temporal boundaries of the assessment are the period over which the GHG emissions of Tilbury Phase 2 LNG were estimated and include the Construction, Operation, and Decommissioning Phases of the Project.

## 23.2 Potential Project Effects and Proposed Mitigations

### 23.2.1 Existing Conditions

The table below summarizes the total GHG emissions in 2022<sup>99</sup> for Canada and B.C., along with the emissions specifically from the oil and gas sector. It highlights the sector's contribution to overall provincial and national emissions.

Table 72 Total Greenhouse Gas Emissions by Jurisdiction Compared to Oil and Gas Sector Contributions

| Jurisdiction | Total GHG Emissions                   | Oil & Gas Sector Emissions     | Oil & Gas Share of Total |
|--------------|---------------------------------------|--------------------------------|--------------------------|
| Canada       | 708,000,000 tCO <sub>2</sub> e        | 217,000,000 tCO <sub>2</sub> e | ~30%                     |
| B.C.         | 64,300,000 million tCO <sub>2</sub> e | 15,200,000 tCO <sub>2</sub> e  | ~23.6%                   |

### 23.2.2 Potential Project Effects

The Revised Application considered the activities that would generate direct and indirect emissions during the Construction, Operation, and Decommissioning phases, as well as upstream GHG emissions. Emissions estimates were provided using the methodology outlined in [Section 8](#) of the Application Information Requirements as per SACC requirements and GGIRCA standards. Where the calculations differ, the results using both methodologies are shown.

#### 23.2.2.1 Construction Phase

The Proponent expects direct emissions during the Construction phase to occur from the delivery of materials to the project site, the operation of construction equipment,<sup>100</sup> and commissioning of the flare and vent (Table 73). The annual GHG emissions from these construction activities are 97,979 – 99,385 t CO<sub>2</sub>e

<sup>99</sup> The [National Inventory Report](#) for 2023 was released in April 2025; however, it was not used in the Application. The National Inventory Report indicates that in 2023 Canada's total GHG emissions were 694,000,000 tCO<sub>2</sub>e and Oil & Gas Sector Emissions were 190,000,000 tCO<sub>2</sub>e which represents approximately 27.4 percent of national emissions. The National Inventory Report also provided provincial numbers; however, it is not prepared using GGIRCA methodology.

for the preparation of the site, and assembly of liquefaction module(s) and the above ground tank

Table 73 Emission sources during Construction

| Source                   | CO <sub>2</sub> e (tonnes/year) |
|--------------------------|---------------------------------|
| Onsite Equipment         | 15,666                          |
| Road Delivery and Idling | 1,234                           |
| Commissioning - Flare    | 79,929                          |
| Commissioning - Venting  | 2,550                           |
| <b>Total</b>             | <b>99,379</b>                   |

### 23.2.2.2 Operation Phase

During the Operation phase, pre-mitigation direct emissions include emissions from thermal oxidizers, heat medium-fired heaters, flaring, and fugitive emissions. Indirect emissions will result from the electricity used during the Operation phase, which will be acquired from the electrical grid. The Proponent estimated that direct and indirect emissions will be between 178,095–181,953 tCO<sub>2</sub>e per year using SACC methodology and 192,943 tCO<sub>2</sub>e per year under GGIRCA methodology (Table 74).

Table 74 Total Direct and Indirect GHG Emissions from Tilbury Phase 2 during Operation phase per year

| Source                                       | Annual CO <sub>2</sub> e (tonnes/year) <sup>101</sup><br>SACC Calculation | Annual CO <sub>2</sub> e (tonnes/year)<br>GGIRCA Calculation |
|----------------------------------------------|---------------------------------------------------------------------------|--------------------------------------------------------------|
| Hot Oil Heater                               | 126,209                                                                   | 126,357                                                      |
| Thermal Oxidizer                             | 39,439                                                                    | 39,477                                                       |
| Flare                                        | 11,274                                                                    | 12,434                                                       |
| Fugitive Emissions                           | 1,035                                                                     | 1,035                                                        |
| Acquired Energy (Electricity) <sup>102</sup> | 138–3,996 <sup>103</sup>                                                  | 13,640                                                       |
| <b>Total direct and indirect emissions</b>   | <b>178,095–181,953</b>                                                    | <b>192,943</b>                                               |

### 23.2.2.3 Decommissioning Phase

The Proponent estimates that direct GHG emissions from decommissioning will be 2,841 tCO<sub>2</sub>e. This was based on the construction emissions and ratio of expected decommissioning to construction costs. There is some uncertainty in the estimate as equipment and transportation emissions due to the potential for lower emissions from equipment and vehicles during decommissioning due to technological change (e.g. increased use of zero emission vehicles). Emissions during Decommissioning by source are outlined in Table (75).

<sup>101</sup> Totals may not add up due to rounding.

<sup>102</sup> When electricity from the BC Hydro electrical grid is used, annual average GHG emissions from acquired energy use ranges from 962–2377 tCO<sub>2</sub>e per year from the period of 2027 to 2050. Commissioning emissions are not included in the annual average.

<sup>103</sup> As noted in Table 49: Electricity Intensity Factors and Acquired GHG Emissions from Electricity in Appendix N of the Revised Application emissions are estimated to be 3,996 tCO<sub>2</sub>e in 2028 and decrease to 138 tCO<sub>2</sub>e in the 2042–2068 time frame.

Table 75 GHG Emissions from Tilbury Phase 2 during Decommissioning

| Source                              | CO <sub>2</sub> e <sup>104</sup> |
|-------------------------------------|----------------------------------|
| Onsite Equipment and Transportation | 1,014                            |
| Decommissioning - Flare             | 1,827                            |
| <b>Total</b>                        | <b>2,841</b>                     |

### 23.2.3 Impacts of Tilbury Phase 2 on provincial and federal emission reduction efforts

The Proponent expects that Tilbury Phase 2 would have one of the lowest GHG emissions intensity of any LNG facility in the world during the Operation Phase. The Proponent estimated the project is anticipated to have a pre-mitigation emission intensity of 0.072 tCO<sub>2</sub>e/tLNG under the SACC methodology and 0.077 tCO<sub>2</sub>e/tLNG under the GGIRCA methodology; and a post mitigation emissions intensity of 0.011 tCO<sub>2</sub>e/tLNG under SACC methodology and 0.016 tCO<sub>2</sub>e/tLNG under GGIRCA methodology.

The estimated direct and indirect GHG emissions from Tilbury Phase 2 during Operation compared to provincial and federal oil and gas sector and total emissions using SAAC methodology are provided in Table 76<sup>105</sup>.

Table 76 Comparison of GHG Emissions from Tilbury Phase 2 during Operation to 2022 Provincial and Federal Emissions

| Inventory <sup>1</sup>                                                                                              | Annual GHG Emissions from inventory (t CO <sub>2</sub> e/yr) | Project total annual emissions as a Relative Percentage |
|---------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------|---------------------------------------------------------|

| B.C. (2022)                                                                                                         | 15,200,000                                                   | 1.269%                                                  |
| Canada (2022)                                                                                                       | 217,000,000                                                  | 0.083%                                                  |
| <b>Comparison of Total Provincial and Federal Emissions from all Sectors in 2022 to Tilbury Phase 2</b>             |                                                              |                                                         |
| B.C. (2022)                                                                                                         | 64,300,000                                                   | 0.28%                                                   |
| Canada (2022)                                                                                                       | 708,000,000                                                  | 0.025%                                                  |

<sup>1</sup>Data sources from [National Inventory Report 1990–2022: Greenhouse Gas Sources and Sinks in Canada Part 3](#).

Under the *Climate Change Accountability Act*, B.C. has set targets to cut GHG emissions by 40 percent below 2007 levels by 2030, 60 percent by 2040, and 80 percent by 2050.

The *Provincial Inventory of Greenhouse Gas Emissions* is published every year and shows province-wide emissions and removals. This inventory is used as the baseline to estimate how much the Tilbury Phase 2 project will add to B.C.'s overall emissions.

Because the inventory is updated annually with new data, the baseline for calculating the project's share of emissions in 2030, 2040, and 2050 will change over time. The inventory includes all emissions covered by B.C.'s legislated economy-wide and sector-specific reduction targets.

<sup>104</sup> Totals may not add up due to rounding.

Provincial numbers are calculated in accordance with GGIRCA methodology and federal numbers in accordance with SACC methodology.

The Proponent estimates that operations emissions with mitigation from the Project represent 0.11 percent, 0.16 percent, and 0.32 percent of B.C.'s 2030, 2040, and 2050 targets, and 2.2–2.4 percent of the 2030 BC sectoral target emissions for the oil and gas sector.

At a policy level, the facility will achieve net-zero emissions on an annual basis over its operating life. However, due to current international GHG accounting and reporting guidelines, emissions reductions from the use of Renewable Natural Gas (RNG) or offsets are not reflected in the Provincial Inventory. As a result, Provincial Inventory emissions may increase due to the Project.

At the federal level, Canada's 2030 Emission Reduction Plan requires a 40-45 percent cut from 2005 levels by 2030, with a target of 443 million tonnes CO<sub>2</sub>e. By 2030, the project is expected to align with Canada's commitments in respect of climate change with the implementation of measures outlined in the Proponent's Net-zero Plan.

Further details on how Tilbury Phase 2 contributes to Canada's ability to meet climate change commitments are in [Appendix 15](#).

### 23.2.4 Strategic Assessment of Climate Change

The Proponent included information in the Revised Application to meet the requirements of the Strategic Assessment of Climate Change (SACC), as outlined in Table 8.3-1. Concordance of Requirements in the Strategic Assessment of Climate Change, which aligns SACC requirements with the application guidelines and technical reports.

This information covered:

- Carbon sinks
- Upstream GHG emissions
- Best available technology and environmental practices
- A credible net-zero emissions plan
- A climate resilience assessment
- An assessment of uncertainty for both quantitative and qualitative data.

The Project will not cause measurable changes to carbon sinks from land use changes. Tilbury Phase 2 will not clear vegetation or wetlands that store carbon, so there will be no loss of carbon storage capacity. This conclusion was based on a review of current site conditions and expected changes, noting that the land will remain industrial with minimal vegetation.

Upstream GHG emissions are emissions from producing, processing, and transmitting natural gas before it reaches the Project. These emissions are outside the Project's scope but were assessed using the methodology in the Strategic Assessment of Climate Change and the Draft Technical Guide (ECCC 2021).

The Proponent estimated upstream emissions at 818,000 tCO<sub>2</sub>e in the first year of operation (2028), decreasing to 792,000 tCO<sub>2</sub>e by 2030 and remaining at that level for the Project's lifetime. The Proponent concluded these emissions may add to Canada's natural gas-related emissions but are not considered incremental at the North American or global export scale. Additional details from ECCC are provided in [Appendix 15](#).

### 23.2.5 Proposed Mitigation Measures by the Proponent

The Proponent proposed the following mitigation measures related to Greenhouse Gas Emissions:

- Electrify the project refrigeration and feed gas processes to reduce project Criteria Air Contaminants (CAC) and Greenhouse Gas emissions.

- Carbon emission offsets through technological or market acquired offsets once regulatory and technical clarity are achieved.
- Implement fugitive emissions management through design and engineering control considerations and effective operational controls.
- FortisBC will develop and implement a Net Zero Plan that will utilize inputs like the Best Available Technology (BAT) and Best Environmental Practices (BEP) to ensure the project's direct operational GHG emissions follow government policies and regulations upon commencement of operation. Commits to using 100% renewable, lower carbon "drop-in" fuels for all combustion needs from the start of commercial operations.
- Explore the use of other technology solutions may include waste heat recovery, carbon removal and utilization, developing technologies, and other offset measures.

### 23.3 Key Issues Raised

Based on a review of the Application and with feedback from the TAC, participating Indigenous nations, and the public, the following key issues related to the assessment of the GHG emissions for Tilbury Phase 2 were identified.

#### 23.3.1 Upstream and Downstream Emissions

Members of the TAC, First Nations, and the public requested consideration of upstream and downstream emissions, including upstream fugitive emissions.

FortisBC stated that upstream GHG emissions were assessed in line with the Strategic Assessment of Climate Change and the Draft Technical Guide, using prescribed methods and data from the Government of Canada and ECCC. Details are provided in [Appendix M](#) of the Revised Application.

The EAO notes that downstream emissions (i.e., those from end-use combustion) are not required within the scope of the assessment under the Act or the IAA. This approach is also consistent with most carbon accounting for industrial facilities. The AIR required the Proponent to describe how the Project could contribute to global emission reductions, and FortisBC provided this analysis. However, due to uncertainty inherent in global emissions modeling, the EAO did not rely on FortisBC's global emissions analysis in its assessment. Instead, the EAO focused on project-level emissions, which can be assessed more accurately and fall within the scope of the environmental assessment. To ensure accountability, the Province requires LNG facilities to report their GHG emissions under the *Greenhouse Gas Industrial Reporting and Control Act* and its regulations, including third-party verification of those reports.

#### 23.3.2 Natural Gas as a Lower Carbon Fuel

Members of the TAC, First Nations, and the public expressed views on FortisBC's characterization of natural gas and the potential benefits of LNG. This includes concerns expressed by the First Nations and the public regarding the FortisBC's characterization of natural gas as a lower carbon fuel, given the GHG emissions, particularly methane, associated with its extraction, processing, and use.

FortisBC states that LNG is a lower-carbon fuel compared to diesel that can be used for trucks, trains and ships, or it can be converted back into natural gas for residential and commercial use.

FortisBC also notes that the baseline emissions intensity of LNG that would be produced at Tilbury Phase 2 would be 0.077 tonnes of CO<sub>2</sub>e per tonne of LNG produced under the GGIRCA methodology, which is relatively low compared to other LNG facilities.

The EAO, after consultation with the Ministry of Energy and Climate Solutions, notes that there is currently no consensus on whether natural gas should be considered a low-carbon or lower-carbon fuel. A conclusion on whether LNG exports lead to global net GHG reductions is uncertain and highly dependent on many variables, such as market conditions, displacement assumptions, and lifecycle emissions. However, the Project's proposed post-mitigation emissions intensity of 0.016 tonnes of CO<sub>2</sub>e per tonne of LNG produced is among the lowest intensities in the world.

### 23.3.3 Ability to Meet Net-Zero Plan Requirements

The EAO received comments from reviewers regarding the ability of Tilbury Phase 2 to operate as a net-zero LNG facility and implement a credible Net-Zero Plan for the construction and operation of the facility. These included questions relating to availability of electricity, technical feasibility of mitigation measures, use of Best Available Technologies (BAT) and Best Environmental Practices (BEP), use of blended natural gas, and availability of RNG and BC Offset Units. Responses to themed comments are outlined in Table 77.

Table 77: Responses to themed comments on the ability of Tilbury Phase 2 to operate as a net zero facility

| Category                                                                                                                     | Response                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Will there be sufficient grid electricity for the Project?                                                                   | FortisBC initiated requests with BC Hydro to upgrade its existing connection to serve the Tilbury LNG Phase 1B expansion. The 230 kV power line would also enable BC Hydro to supply enough electricity to meet the additional capacity needed for Tilbury Phase 2. Additional upgrades to the transmission system are not anticipated.                                                                                                                                                       |
| Will FortisBC acquire RNG for the Project, and if so, how?                                                                   | FortisBC expects to acquire sufficient RNG to be used during Operation from commercially available sources in Canada and the United States. FortisBC currently has 20 supply agreements, with eight additional agreements expected to be delivering RNG by 2030. Additional information is included in <a href="#">Appendix O of the Revised Application</a> .                                                                                                                                |
| Will FortisBC be able to acquire a sufficient quantity of BC Offset Units (BCOU) for the Project?                            | FortisBC expects to purchase up to 39,529 tCO <sub>2</sub> e BC Offset Units on a commercial basis every year during Operation to meet BC Net Zero requirements. FortisBC will present a high-level offset procurement strategy in an updated net zero plan before the start of Project construction.                                                                                                                                                                                         |
| Has FortisBC demonstrated that BATs and BEPs will be implemented as part of the Project to reduce emissions?                 | FortisBC completed a BAT and BEP analysis which forms <a href="#">Appendix P</a> of the Revised Application. Comments about specific technologies and practices were responded to during the Application Review phase of the EA as documented in the Issues Tracking Table and Public Engagement Report.<br><br>Where a BAT that could further reduce emissions is not selected, a rationale for not selecting that technology was discussed.                                                 |
| With technology expected to change throughout the Project's expected operational life how will the Net-Zero Plan be updated? | The Net-Zero Plan will be updated at least every five years during Construction and Operations. The five-year update requirement includes considering current BATs and BEPs.<br><br>As per Section 5.5 of Appendix O of the Revised Application the first update to the Net Zero Plan is expected to be submitted once the detailed engineering design is finalized.                                                                                                                          |
| Will the natural gas blend change over time, for example to contain green hydrogen?                                          | FortisBC is actively exploring the potential of hydrogen as its commitment to a lower-carbon future. The blending of hydrogen into natural gas is currently being studied by Enbridge and the Ministry of Energy and Climate Solutions. While the hydrogen market is still developing, FortisBC cannot commit to one type of hydrogen at this time. FortisBC is required to operate the Project as a net-zero facility and will consider green hydrogen as it becomes commercially available. |

The EAO received advice from the Ministry of Energy and Climate Solutions that the Net-Zero Plan, as outlined in the Revised Application, is a credible plan that meets the requirements of the Net-Zero New Industrial Policy. ECS advised that the Project's projected operational emissions intensity with use of mitigation measures is in line with world-leading LNG facilities. The EAO has proposed that if a Certificate is issued that the implementation of the Net-Zero Plan, including a five-year update cycle and consultation requirements for updates, be required as Condition 11 (Greenhouse Gas Emissions and Net-Zero Plan).

## 23.4 The EAO's Assessment and Conclusions

### 23.4.1 Residual Effects

After considering all relevant proposed mitigation measures, the Revised Application, issues raised during the Application Review, the EAO's effects assessment and the information contained in the [Joint Permitting / Regulatory Coordination Plan](#), the EAO concludes that Tilbury Phase 2 would have residual adverse effects due to the Project's GHG emissions.

The Proponent provided its net-zero plan as part of the Revised Application which was reviewed by the TAC and members of the public during the Application Review phase. The EAO proposes Certificate Condition 12 (Greenhouse Gas Emissions Net-Zero Plan) that would require the Proponent's implementation of an approved plan, along with providing updates to the plan every five years, in consultation with additional parties, including First Nations and ECS.

This plan includes an estimation of GHG emissions, consideration of provincial emission reduction targets and schedules, analysis of BATs/BEPs, and an analysis to minimize GHG emissions and an explanation for technologies and measures to be and not to be implemented. This plan would work in tandem with policies and legislation regarding GHGs, including:

- The GGIRCA, which establishes a comprehensive framework for regulating industrial GHGs including emission reporting, offsets, tracking, and compliance;
- The *Climate Change Accountability Act*, which sets GHG emission reduction requirements for the oil and gas sector and the CleanBC Roadmap to 2030; and
- The additional relevant provincial and federal regulatory requirements referenced in Section 23.1.1 (Regulatory Context).

### 23.4.2 Cumulative Effects Assessment

GHG emissions are of concern at any magnitude because of their long-term accumulation in the atmosphere and global extent. The Intergovernmental Panel on Climate Change (IPCC) has produced several scenarios projecting potential global GHG emissions trajectories and the potential effects associated with these emissions levels. As GHGs are inherently cumulative, the EAO did not require the Revised Application for Tilbury Phase 2 to include a cumulative effects assessment for GHG emissions and the EAO did not conduct a cumulative effects assessment for the same reasons. Further, IAAC considers GHG emissions to be inherently cumulative in the context of their potential effects related to global climate change. Consequently, cumulative effects are considered within the analysis of climate change impacts and therefore a separate cumulative effects assessment is not described here.

### 23.4.3 Conclusions

Recognizing the requirements for the Proponent to adhere to the Net-Zero New Industry Policy, the implementation of a net-zero plan, and the assumption that BC Hydro would be able to provide sufficient power to the Project, the EAO is satisfied that Tilbury Phase 2 would not have significant adverse effects on GHG emissions. This conclusion considers the information and analysis presented in this section; the views of the TAC (including the information provided in ECCC's GHG Analysis in [Appendix 15](#)), First Nations, and the Proponent; as well as the proposed conditions identified in the provincial Table of Conditions including Condition 11 (Greenhouse Gas Emission and Net-Zero Plan).

## 24.0 APPENDIX 13 ALTERNATIVE MEANS OF CARRYING OUT TILBURY PHASE 2

### 24.1 Overview of Alternative Means

The assessment of technical and economic alternative means is a required component of every environmental assessment. This includes an evaluation of the best available technologies, potential effects, risks, and uncertainties associated with each alternative. [Section 1.7.5](#) of the Revised Application summarizes the alternatives and options considered by FortisBC (the Proponent).

The Proponent identified and assessed technically and economically feasible alternatives for the Tilbury Phase 2 LNG Expansion Project (Tilbury Phase 2 or Project). Alternatives were initially screened based on expected capital cost, then evaluated using the following criteria:

- Technical feasibility,
- Construction and operation cost,
- Safety,
- Footprint,
- Green House Gas (GHG) emissions,
- Environmental risk,
- Changes to health, social, or economic conditions,
- Gender-Based Analysis Plus (GBA Plus); and,
- Effects to Indigenous interests.

The alternative means of undertaking Tilbury Phase 2 for primary project components and activities, as evaluated by the Proponent, are described in Table 78.

Table 78: Summary of FortisBC's Alternative Means of Undertaking Tilbury Phase 2 LNG Expansion

| Project Components and Activities | Alternatives Evaluated                                                                                          | Selected Alternative and Rationale                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Liquefaction Driver Technology    | <ul style="list-style-type: none"> <li>• Gas-fired compression</li> <li>• Electric-drive compression</li> </ul> | <p>The Proponent identified electric-drive compression to be their preferred liquefaction driver technology option because of the following:</p> <ul style="list-style-type: none"> <li>• Experience operating electric-drive compression at the current and other LNG facilities;</li> <li>• Smaller onsite physical footprint.</li> <li>• 250,000 tonnes of direct CO<sub>2</sub> emissions annually less than a gas-fired compression, potentially avoiding 10 to 15 million tonnes of CO<sub>2</sub> emissions over the 40-year expected Operation phase;</li> <li>• Compression does not produce direct air emissions, therefore would result in lower NO<sub>x</sub> and SO<sub>x</sub> emissions from the Project than gas-fired compression; and,</li> <li>• Electric-drive compression does not have direct air emissions and therefore has a lower impact on Indigenous and marginalized populations.</li> </ul> |
| Cooling Technology                | <ul style="list-style-type: none"> <li>• Air Cooling</li> <li>• Water Cooling</li> </ul>                        | <p>The Proponent identified air cooling as their preferred cooling technology option for the liquefaction process based on the following:</p> <ul style="list-style-type: none"> <li>• Lower construction and operations costs;</li> <li>• No need for an offsite footprint for any system components; and,</li> <li>• No interactions with the Fraser River, no disruptions to Fish and Fish Habitat, and no interactions with riparian areas.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Project Components and Activities           | Alternatives Evaluated                                                                                                                                | Selected Alternative and Rationale                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Flare Technology                            | <ul style="list-style-type: none"> <li>• Multipoint Ground Flare</li> <li>• Totally Enclosed Ground Flare (TEGF)</li> <li>• Elevated Flare</li> </ul> | <p>The Proponent identified Totally Enclosed Ground Flare (TEGF) as their preferred flare technology based on the following:</p> <ul style="list-style-type: none"> <li>• Limited thermal radiation restrictions required;</li> <li>• Although TEGFs can have a larger footprint than other flare types, no or a limited thermal setback is required due to the enclosure;</li> <li>• TEGFs limit the opportunities for flare to interact with wildlife, and have the lowest noise, flame and light related effects compared to other flare types; and,</li> <li>• Least disruption to local residents, property owners, Indigenous peoples, and members of the public.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Material Transportation During Construction | <ul style="list-style-type: none"> <li>• Road Transport</li> <li>• Barge Transport</li> <li>• Combined Road and Barge Hybrid</li> </ul>               | <p>The Proponent identified three means of delivering construction materials, project components, and equipment to the Project Footprint during Construction.</p> <p>Originally, the Proponent proposed the “Combined Road and Barge Hybrid” approach in the DPD which would have resulted in the construction of a material offloading facility and use of barges and trucks to delivery project components and materials to the Project Footprint.</p> <p>After the issuance of the Process Order, the Proponent requested to increase the proposed number of barge movements during construction. Based on feedback on that proposal, the Proponent identified Road Transport as the preferred option for material transportation to be considered as part of the Revised Application based on the following considerations:</p> <ul style="list-style-type: none"> <li>• Lowest capital cost and reduced number of project components as the material offloading facility would not be needed; and,</li> <li>• Least interaction with the Fraser River which is used by First Nations for harvesting, cultural, and economic activities and is home to many species of importance such as salmon.</li> </ul> |

## 24.2 Key Issues Raised

No outstanding Key Issues remain with the submission of the Revised Application.

The EAO acknowledges the extensive discussions that have occurred between First Nations, technical advisors, IAAC, the EAO, and FortisBC about Material Transportation During Construction. These discussions arose as a result of FortisBC’s proposal to increase in the use of barge transportation to deliver materials to the Project Footprint after the end of the Process Planning phase of the EA as an alternative to truck transportation. These discussions contributed to FortisBC’s decision not to construct the MOF and not to barge materials to the Project Footprint. The EAO acknowledges that there was not unanimous agreement between First Nations, technical advisors, IAAC, the EAO, and FortisBC about this approach.

These discussions are noted in [Section 1.5.5.1](#) of the Revised Application.

## 24.3 The EAO’s Assessment and Conclusions

The EAO concludes that FortisBC has adequately assessed alternative means for the Tilbury Phase 2 LNG Expansion Project and components of Tilbury Phase 2’s design.

## 25.0 APPENDIX 14 POTENTIAL CHANGES TO THE PROJECT CAUSED BY THE ENVIRONMENT

### 25.1 Background

Section 25(2)(j) of the Act and paragraph 22(1)(j) of the IAA specify that the assessment must take into account any change to the project that may be caused by the environment. The Revised Application assessed the likelihood of the potential changes to Tilbury Phase 2 that may be caused by the environment based on current and potential future conditions, and their consequences on relevant VCs.

The following environmental effects and processes that have the potential to affect Tilbury Phase 2 and result in changes or effects to the valued components assessed in the Revised Application:

- Climate Change;
- Extreme weather;
- Fluvial, tsunami, and compounded flooding; and,
- Seismic events.

The EAO notes that while the Revised Application assesses the effects of climate change and extreme weather in separate sections, they are combined in this report as they are expected to produce similar effects. How effects to the Project may change as a result of climate change are described by the Proponent in [Section 8 \(Climate Change and Greenhouse Gas Emissions\)](#) and [Appendix G \(Climate Change Resilience Assessment\)](#) of the Revised Application.

### 25.2 Potential Effects and Proposed Mitigations

The potential changes to Tilbury Phase 2 caused by the environment are described in [Section 10](#) of the Revised Application and are summarized here. For each environmental effect, the Proponent reviewed the existing conditions and assessed the potential effects for the life of the project until Tilbury Phase 2 is decommissioned. The Proponent used a risk assessment matrix to determine the degree to which an environmental factor would impact VCs by plotting the intersection of the likelihood of the event against the severity of the event's consequences. For the environmental effects and processes noted above, including how the effects and process may change due to climate change, the Proponent assessed the following:

#### 25.2.1 Climate Change and Project Design

##### 25.2.1.1 Potential Project Effect

The Revised Application considers how climate change may influence environmental conditions and potential effects on the Project.

Changes to four temperature effects or processes are expected to occur:

- The frequency of heat waves and extreme heat are expected to increase,
- Changes in season temperatures the number of Cooling degree days (CDDs) exceeding 200 is expected to increase; and,
- The frequency of extreme cold minimum daily temperatures are expected to decrease.

One change to precipitation effects or processes is expected to occur, specifically the frequency of Short-duration, high-intensity rainfall (events causing local flooding) that results in greater than or equal to 100 mm of rainfall in 12 hours is expected to increase.

Changes to two additional meteorological factors were considered climate change and wind speed. Wind speeds are expected to increase by two to three km/hr. The change in wind speed is not expected to affect the risk assessment

for Tilbury Phase 2. Potential impacts of climate change on Fraser River flooding remain uncertain due to the complexity of influencing variables and limited local data. As a result, fluvial flooding was assessed qualitatively.

### 25.2.1.2 Proposed Mitigations

The Climate Change Resilience Assessment was conducted to identify the potential environmental risks to the Project as a result of climate change, as well as to provide climate data for the proposed Project Area. Tilbury Phase 2, if constructed, must be designed so that its operations would not be significantly impacted due to potential effects of climate change.

The mitigation measures are intended to decrease the likelihood and consequence of the negative effects of the environment on the proposed Project. Design mitigation measures that can be implemented to achieve this goal include hard measures, such as control systems, or soft measures, such as risk assessment frameworks, strategies, and management plans.

The Proponent identified the following criteria and mitigation measures to be incorporated in the design of Tilbury Phase 2 to mitigate the effects of climate change to the project:

- The proposed Project would be equipped with an automated safety system to facilitate safe shutdown and isolation of hydrocarbon-containing equipment during extreme adverse conditions.
- Ditches or culverts will be sized for the peak flow of a one in 25-year return period storm event.
- Design weather conditions (e.g. wind and precipitation) for onshore structures that consider a 1-in-50-year return period in accordance with the B.C. Building Code.
- All critical infrastructure will be located above the 1:200-year flood level, including allowances for sea level rise and freeboard, consistent with Delta's Flood Construction Level bylaw, to avoid flooding.

The Proponent also identified the following Project Design Measures (standards, codes, or regulatory requirements) that would limit the potential effects of the environment on Project infrastructure:

- CSA Z276 (LNG - Production, storage, and handling);
- CSA Z246.2 (Emergency preparedness and response for petroleum and natural gas industry systems);
- CSA Z276 will inform the structural design of LNG components to withstand flood-related forces (e.g., hydrostatic uplift and buoyancy under extreme conditions);
- National Building Code of Canada;
- Liquefied Natural Gas Facility Regulation;
- B.C. Building Code (as applicable);
- Delta bylaws (as applicable); and,
- FortisBC specifications.

### 25.2.2 Extreme Weather Events

#### 25.2.2.1 Extreme Temperature Events

Extreme temperature events have the potential to interact with workers and project equipment or component. The frequency of heat events where the maximum daily temperature is 32°C (Degrees Celsius) or higher is likely to increase to twice a year in the 2050s; while the frequency of extreme cold events where the minimum daily temperature is below -10°C is expected to decrease. Currently the site has operated without any effect on operations with recorded temperatures of 32.8°C in June 2021.

Extreme temperatures can impact human health causing injury or death with heatstroke or frostbite being examples of potential related conditions. They can also result in damage to the Project infrastructure or processes leading to potential structural or equipment failure that can subsequently pose a risk to human and environmental values.

#### **25.2.2.2 Extreme Precipitation Events**

The Revised Application considered extreme precipitation (rain) events that would result in 100 mm or more of rain in a 12-hour period.<sup>106</sup> The frequency of extreme rain events is expected to increase, shifting from about once every 100 years under current conditions to about once every 25 years under future conditions.

Extreme rain and the resulting flooding or pooling of water have the potential to cause a stoppage of outdoor activities, cause damage to project infrastructure in low-lying areas, and overwhelm the onsite stormwater management system which may cause flooding on the project site.

Extreme rain events were identified to have an interaction with the human health valued component, which would occur when personnel are working at height. The risks to human health of workers are expected to change from minor under current climate conditions to high in future climate conditions.

#### **25.2.2.3 Extreme wind event**

The Revised Application considered the effects of potential extreme wind events (e.g. gusts greater than 90 km/hr) on the project. The highest recorded gust near Tilbury Island between 1985 and 2015 was 64 km/hr. Extreme wind events were assessed to be of minor risk to Tilbury Phase under current and future climate conditions.

Extreme wind events can cause trees, shrubs, and loose material (e.g. gravel, other non-attached natural material) to collide with the Project's infrastructure or be deposited within the Project Site. This can cause damage to the external façade of equipment, while airborne materials may also pose a risk to human health. Working at heights becomes increasingly unsafe during extreme wind events, as there is the possibility for serious injury or death to occur.

#### **25.2.2.4 Proposed Mitigations**

The Proponent identified the following measures to mitigate the potential effects of extreme weather events:

- Implement the existing FortisBC work safety policy which will be modified or updated to account for the anticipated increase in frequency of extreme weather events as a result of climate change.
- Utilize programmable logic controllers with an appropriate design standard to withstand higher temperatures (that is, up to 70°C).
- Develop health and safety measures at the project site (for example, halting work at heights during extreme wind events).

### **25.2.3 Flooding Events**

#### **25.2.3.1 Potential Project Effect**

The Revised Application considered the potential effects of fluvial flooding,<sup>107</sup> tsunami related flooding, and compound flood events (combined fluvial and coastal flooding). Qualitative analysis was used in the Revised Application for the assessment of flooding events.

---

<sup>106</sup> The 100mm threshold for the assessment is a higher threshold than recent extreme weather events such as the 2021 atmospheric river event which reported up to 66.2mm of rain over 12 hours; and 99.99 over 24 hours at the Delta Burns Bog Station, and had less rainfall than rainfall than the October 2003 rainstorm event which reported 195.2 mm in 24 hours reported for North Delta, B.C.. These three events did not result in flooding at the current Tilbury LNG facility.

Fluvial flooding is defined as flooding that occurs when water breaches a river's banks.

### Fluvial flooding

A fluvial flooding event due to dike failure or overtopping of the dike could damage infrastructure, halt operation activities, and overwhelm the existing onsite and proposed stormwater management system, causing flooding on the Project Site and posing a risk to workers, rather than the wider community. Severe events may result in a facility shutdown; effects associated with a shutdown procedures are considered as part of Malfunctions and Accidents ([Appendix 7](#)).

Fluvial flood events were considered that correspond to 1:100, 1:200, and 1:500-year floods (i.e., 1 percent, 0.5 percent, and 0.2 percent annual probability events). The scenarios considered the Fraser River peak freshet flow occurring at high tide under current and future sea-level conditions. Future conditions considered sea-level rise at +0.5 metres by 2050 and +1.0 metres by 2100. The Revised Application indicated under present and 2050 scenarios that the Project site would likely not be inundated. In the 2100 scenario with a 1.00 metre of sea-level rise the Project site may be inundated with flood depths up to approximately one metre. The Revised Application states that there are plans to raise the River Road Dike to 5.5 metres above sea level which could mitigate effects to the Project in the 2100 scenario; however, the timing of a dike upgrade is uncertain.

### Tsunami Flooding

Tsunami flooding is flooding that results from a wave of water generated by an earthquake, landslide, or volcanic eruption, or disturbance in the ocean that causes the displacement of large amounts of water.

The Revised Application considered tsunamis associated with the Cascadia Subduction Zone. This included tsunami events occurring off the west coast of Vancouver Island, plate boundary events near Richmond, and large subaqueous block slides on the western fore slope of the Fraser River delta.

If a major tsunami event were to occur off the west coast of Vancouver Island the effects are unlikely to affect the Project. The Metro Vancouver coastline generally, would be sheltered by Vancouver Island with wave height anticipated to have dissipated to between 0.5 metres and one metre along the coast – by the time waves reach the Project site they would likely be at or below this level. A plate boundary event near Richmond could generate a wave with a height approximately 0.5 metres, which would be unlikely to affect the Project. Large subaqueous block slides on the western fore-slope of the Fraser delta could create waves approximately two metres high that would strike the adjacent shoreline shortly after the landslide. No potential effects on the Project were predicted at this wave height.

The Revised Application also considered tsunami flooding cause by a submarine landslide in the Fraser River delta generating a wave of up to two metres. This type of event is not anticipated to affect the Project.

### Compounded Flooding

Compounded flooding occurs when multiple events or scenarios occur at the same time. A convergence of factors could result in a more severe flood event than any single factor scenario (e.g. simultaneous occurrences of high tide, freshet, and extreme precipitation). The Revised Application stated that the likelihood of compounded flooding was low, although cause challenges based on current infrastructure conditions.

#### 25.2.3.2 Proposed Mitigations

To prevent catastrophic failure or LNG release from the liquefaction trains during a flood event, the system would be fully deactivated before floodwater ingress. In such an emergency, combustible material (LNG) within the liquefaction trains would be routed to a totally enclosed ground flare for safe disposal.

The LNG storage tank, which is not pressurized, is designed to remain stable for an extended period even in the unlikely scenario of a catastrophic flood causing both primary and backup power failure. Its large thermal mass and the LNG it contains slow any immediate changes.

If power to the boil-off gas compressors is lost, the LNG surface will gradually begin to evaporate, forming natural gas. As pressure builds, it would be safely vented through pressure relief valves until power is restored.

The Proponent identified the following measures to mitigate the potential effects of Flooding:

- Engineering controls will be put in place to maintain operation of the emergency generator during extreme weather events;
- All critical infrastructure will be located above the 1:200-year flood level, including allowances for sea level rise and freeboard, consistent with Delta's Flood Construction Level bylaw, to avoid flooding;
- CSA Z276 (LNG - Production, storage, and handling);
- FortisBC will apply CSA Z246.2 (Emergency preparedness and response for petroleum and natural gas industry systems) to guide the development of flood-specific emergency preparedness measures;
- Ditches or culverts will be sized for the peak flow of a one in 25-year return period storm event;
- All critical infrastructure will be located above the 1:200-year flood level, including allowances for sea level rise and freeboard, consistent with the City of Delta's Flood Construction Level bylaw, to avoid flooding.; and
- Engineering controls will be put in place to maintain operation of the emergency generator during extreme weather events.
- Two other measures that could mitigate the effects of flooding on the Project were noted in the Revised Application:
- A Section 219 Covenant under the *Land Title* Act in place for the Project Site that sets a minimum industrial building elevation of 2.74 metres above sea level; and,
- Plans, with uncertain timing, to raise the River Road Dike to 5.5m meters above sea level.

#### 25.2.4 Seismic Events

##### 25.2.4.1 Potential Project Effect

The Proponent assessed the risk of seismic events on Tilbury Phase 2 in the Revised Application and reported that there is a moderate risk classification for the effects of seismic. The south coast of B.C., including Tilbury Island, includes active faults and tectonic plate movement and interactions, including the Cascadia subduction zone off Vancouver Island.

The Proponent identified that an earthquake event has the potential to affect the Project's infrastructure through soil liquefaction (liquefaction occurs where water-saturated sands and silts are subjected to a loss in their shear strength), shaking, and vibration. Potential adverse effects of seismic events can include a fire or explosion; hazardous material spill; unplanned facility shutdown, including emergency flaring; process upset; or power outage. These effects are assessed in Malfunctions and Accidents ([Appendix 7](#)).

##### 25.2.4.2 Proposed Mitigations

The Proponent identified the following mitigations measures applicable to seismic events:

- The proposed Project would be equipped with an automated safety system to facilitate safe shutdown and isolation of hydrocarbon-containing equipment during extreme adverse conditions.
- Ditches or culverts will be sized for the peak flow of a one in 25-year return period storm event.
- Design weather conditions (for example, wind and precipitation) for onshore structures that consider a 1-in-50-year return period in accordance with the B.C. Building Code.

- The control room operator will utilize BC's Earthquake Early Warning network alerts, along with on-site seismic instrumentation, to initiate an emergency shutdown if necessary.

The Proponent identified that in addition to seismic design that would comply with provincial and federal codes, standards, and regulations such as the LNG Facility Regulation, National Building Code of Canada 2020 and the 2024 BC Building Code, the following measures mitigate the potential effects of Seismic Events:

- The project will be designed to meet the applicable seismic design standards in CSA Z276.
- Design the Project to meet CSA Z276; the standard outlines the following design levels:
  - Operating Basis Earthquake (OBE)<sup>108</sup> with a mean return interval of 475 years
  - Safe Shutdown Earthquake<sup>109</sup> with a mean return interval of 2,475 years

## 25.3 Key Issues Raised

Based on a review of the Application and with feedback from the TAC, participating Indigenous nations, and the public, the following key issues related to the assessment of the potential changes to the Project caused by the environment for Tilbury Phase 2 were identified.

### 25.3.1 Flooding and the River Road Dike

Reviewers including BCER, xʷməθkʷəy̓əm, and Quw'utsun Nation noted there is a degree of uncertainty in the analysis for flooding event and the condition of the River Road Delta Dike (ID number 45), which includes the area between the Project site and the Fraser River. This included concerns on if the dike could withstand compounded flooding events under current and future climate conditions, as well as the condition of the dike. Concerns about the condition of the River Road Dike include its condition, height, and risks in the event of future breachers.

Delta's River Road Dike is expected to provide partial protection to the project site in event of flooding events. Assessments and reports prepared as part of the Lower Mainland Flood Management Strategy,<sup>110</sup> as well as the Lower Mainland Dike Assessment Final Report,<sup>111</sup> indicate there is a risk that existing infrastructure may not meet current standards or perform as expected under extreme flooding conditions. FortisBC provided additional information as part of the Revised Application, including adding a compounded flooding scenario and additional information and mitigations to address risks associated with flooding.

The Revised Application indicates that critical infrastructure is planned to be elevated to 3.5 metres (current dike crest level with freeboard) as an initial design Flood Construction Level, which is consistent with existing guidelines. This elevation is sufficient under current and mid-century (2050) sea level conditions to prevent inundation at up to 1:500-year flood events. FortisBC is also committed to adaptive flood management. As sea levels rise toward 2100, the proponent will collaborate with local authorities on dike upgrades and site improvements. This staged approach balances near-term feasibility with long-term resiliency. Should the facility operate past 2050, additional flood

<sup>108</sup> An Operating Basis Earthquake (OBE) is a seismic event that a facility is designed to withstand without significant damage, allowing it to continue operation. It represents an earthquake that could reasonably be expected to occur during the facility's operating life, based on regional and site-specific geology. If an OBE is exceeded, the plant is required to shut down for inspection.

<sup>109</sup> A Safe Shutdown Earthquake is the maximum earthquake potential for which certain structures, systems, and components, important to safety, are designed to sustain and remain functional.

<sup>110</sup> Fraser Basin Council. 2023. Lower Mainland Flood Management Strategy. <https://floodwise.ca/flood-strategy/>

<sup>111</sup> Ministry of Forests, Land and Natural Resource Operations. 2015. Lower Mainland Dike Assessment Final Report. [https://www2.gov.bc.ca/assets/gov/environment/air-land-water/water/integrated-flood-hazard-mgmt/nhc\\_final\\_lower\\_mainland\\_dike\\_assessment.pdf](https://www2.gov.bc.ca/assets/gov/environment/air-land-water/water/integrated-flood-hazard-mgmt/nhc_final_lower_mainland_dike_assessment.pdf)

mitigation (e.g. incremental site fill or berms) may be implemented to maintain protection. This ensures that even with 2100 sea-level rise projections, the site's flood risk remains within acceptable levels.

FortisBC identified that there is a Section 219 Covenant under the *Land Title* Act in place for the Project Site that sets a minimum industrial building elevation of 2.74 metres above sea level, which it has committed to exceed for critical infrastructure. They also identified the following design mitigation standard; CSA Z246.2 (Emergency preparedness and response for petroleum and natural gas industry systems) to guide the development of flood-specific emergency preparedness measures.

FortisBC identified that there are plans to raise River Road Dike adjacent to the Project to 5.5 metres above sea level although a timeline has not yet been set to do that. In the absence of a clear timeline there is uncertainty with this is a mitigation, and as the River Road Dike is owned by Delta and can not be upgrade by FortisBC without approval from Delta.

The EAO has proposed Condition 12 (CEMP) and Condition 13 (OEMP) which would require implementation of Fortis proposed mitigation measures. The EAO also proposed a condition requiring that critical infrastructure be constructed to a minimum elevation of 3.5 metres geodetic (Geodetic Survey of Canada datum). Condition 3 (Document Development) would require an implementation schedule and a requirement for including how the effectiveness of mitigation measures will be evaluated – for these mitigation measures that could include a staged approach, for example developing a Trigger Response Plan (TRP) based on changes in river or precipitation levels, to review and enhance flood mitigations at the site based on changes to environmental conditions and / or entering into negotiations with Delta to enhance River Road Dike adjacent to the Project Site. The EAO's Assessment and Conclusions

To address key issues related to the effects of the environment, the EAO has proposed the following conditions related to effects of the environment on Tilbury Phase 2 to the Ministers if a Certificate is issued:

- Condition 12 (CEMP); and,
- Condition 13 (OEMP).

These conditions would require the implementation of the mitigation measures identified in the Revised Application. Both plans would be subject to Condition 3 (Document Development) which includes requirements for ensuring that mechanisms for evaluating the effectiveness of mitigations will in place.

After considering the proposed mitigation measures, Certificate conditions proposed (which would become legally binding in the event that a Certificate is issued), Joint Regulatory / Permitting Coordination Plan, and [Regulatory Coordination Issues Tracking Table](#) the EAO concludes the effects of the environment would not cause a significant adverse effects on Tilbury Phase 2 during Construction and Operation due to the engineering design requirements for Tilbury Phase 2 to withstand the types of extreme weather, flooding, and seismic events occurring nearby during the life of the project under current and future climate conditions.

## 26.0 APPENDIX 15 REQUIREMENTS OF THE *IMPACT ASSESSMENT ACT*

### 26.1 Overview

This section describes how the legislative requirements of the IAA for a substituted process were considered and met by the B.C. Environmental Assessment Office (EAO) for the Tilbury Phase 2 LNG Expansion Project (Tilbury Phase 2; the Project).

#### 26.1.1 The Substituted Assessment Process and Cooperation with British Columbia

On January 20, 2022, the provincial environmental assessment process was substituted for the federal impact assessment process. Under substitution, the provincial assessment process is used to meet the requirements for an environmental assessment under the provincial *Environmental Assessment Act* (2018) and an impact assessment under the federal IAA. This Assessment Report (the Report) is the result of that single substituted assessment process. In addition to informing decision-making under the Act, it will be submitted to the federal Minister of the Environment, Climate Change and Nature to inform federal decision-making, fulfilling the requirements of the IAA, and the conditions for substitution outlined in the [Notice of Substitution Approval under the IAA](#).

When provincial and federal assessments are both required, the [Impact Assessment Cooperation Agreement between Canada and British Columbia](#) (the Cooperation Agreement) provides a framework that facilitates the principle of “one project, one assessment”, and describes the way IAAC and the EAO work together to ensure one efficient and effective assessment process, including for substituted assessments.<sup>112</sup>

#### 26.1.2 Requirements of the *Impact Assessment Act*

An impact assessment under the IAA must:

- consider adverse effects within federal jurisdiction and direct or incidental adverse effects (referred together as “adverse federal effects”) as defined in Section 2 of the IAA (Table 79);
- consider the factors set out under Subsection 22(1) of the IAA (Table 80); and
- determine whether adverse effects within federal jurisdiction are likely to be to some extent significant, and if so, to what extent (Table A).

The requirements of the *Notice of Substitution Approval under the IAA*, which contains additional conditions for the substituted assessment, are listed in Table 81.

#### 26.1.3 Assessing Effects Within Federal Jurisdiction

To meet the requirements of the IAA, the Report must provide a rationale and conclusions regarding adverse federal effects, and specify whether the effects, including cumulative effects, are likely to be to some extent significant, and if so, to what extent.

The EAO carried out the assessment of adverse federal effects in accordance with its Effects Assessment Policy (the Policy).<sup>113</sup> The assessment described in this Appendix includes characterization of residual adverse federal effects which consider the application of federal Key Mitigation Measures, which are those that are important for addressing potentially significant adverse federal effects. The substituted assessment process for Tilbury Phase 2 also relied on provincial mechanisms, such as conditions, permits, and authorizations, to the extent possible, to address certain federal effects. The intent of this is to reduce or avoid duplicative conditions and streamline regulatory requirements. See [Appendix 2](#) for the complete list of Key Mitigation Measures and additional context about the

---

<sup>112</sup> Section 7 of the Cooperation Agreement describes specific provisions for substituted assessments.

See Report [Appendix 3](#) for additional detail about the EAO’s effects assessment methodology.

reliance on provincial mechanisms. The characterization of significance applies only to non-negligible residual adverse federal effects and is completed using similar factors and criteria used elsewhere in the Report for each effect being assessed (e.g., magnitude, geographical extent, timing, frequency, duration, reversibility, uncertainty, and social and ecological contexts) <sup>114</sup>, and standards, guidelines, descriptors or objectives, where they exist.

While the frameworks and language used to describe “significance” are different between the federal and provincial assessment approaches, the conclusions are informed by a common body of scientific information and consideration of Indigenous Knowledge. Where effects to a valued component are negligible, an extent of significance determination is not required because they are no longer captured in the definition of effects in federal jurisdiction.

The criteria for characterizing extent of significance for residual (i.e. following the application of mitigation measures) non-negligible adverse federal effects are listed below:

- **Not Significant:** Effects are sufficiently small that they do not individually or cumulatively have a significant effect on a valued component and generate no or few impacts in social or ecological contexts.
- **Low:** Effects are significant but are low in magnitude, of short duration, infrequent, small in spatial extent, reversible or readily avoided, and to generate few or minor impacts in social or ecological contexts. Mitigation measures will allow baseline conditions to remain largely unchanged.
- **Moderate:** Effects are significant and are moderate in magnitude, of moderate duration, occasionally frequent, possibly/partially reversible, and generate a moderate level of impacts in social or ecological contexts. Mitigation measures may not fully eliminate, reduce, control or offset effects but should enable affected communities to maintain economic and social well-being, and should prevent the diminishment or loss of key components of the environment and its ecological functioning.
- **High:** Effects are significant and are high in magnitude, permanent/long term, frequent, irreversible, and over a large spatial extent or within an area of exclusive/preferred Indigenous use or of ecological/environmental sensitivity. High levels of impacts in social or ecological contexts are expected. There is a high degree of uncertainty in the effectiveness of mitigation measures, or mitigation measures are unable to fully address effects such that valued components are diminished or lost.

Extent of significance determinations for non-negligible adverse federal effects are summarized in Table 79. They are based on the EAO’s assessment of residual effects presented in [Appendix 6](#) and the additional analysis specific to adverse federal effects conducted in this Appendix. The factors outlined in Subsection 22(1) of the IAA (Table 80) do not require a characterization of extent of significance.

#### 26.1.4 Malfunctions and Accidents

The proponent was required to provide an assessment of malfunctions and accidents that could impact valued components and Indigenous interests. The EAO’s assessment of malfunctions and accidents, and their potential effects on areas of federal jurisdiction, is provided in the [Appendix 7](#). None of the identified scenarios were considered likely to occur (i.e., less frequent than once every 10 years); therefore, their predicted effects are not included in the conclusions regarding likely adverse federal effects of the project. However, the potential adverse effects within federal jurisdiction from these unlikely malfunctions and accidents are discussed in the sections below, along with key mitigation measures to reduce their risk and consequences.

---

Criteria and assessment ratings are defined in Appendix 3 - Residual Effects Characterization Definitions.

### 26.1.5 Assessment of Adverse Effects within Federal Jurisdiction

Tables 83 and 84 points to locations in this Report where information about adverse effects within federal jurisdiction under Section 2 of the IAA and the factors set out under Subsection 22(1) of the IAA were assessed by the EAO.

For some adverse effects within federal jurisdiction and Section 22 IAA factors, it was necessary for the EAO to include additional assessment in this Appendix beyond that conducted elsewhere in the Report to adequately assess effects and consider factors.

The following adverse effects within federal jurisdiction were subject to additional assessment in this Appendix:

- [Section 26.2](#) — Fish and Fish Habitat
- [Section 26.3](#) — Migratory Birds
- [Section 26.4](#) — Federal Lands
- [Section 26.5](#) — Assessment of 2(e) and (f) Effects with Respect to Indigenous Peoples of Canada

This Appendix does not assess all adverse effects within federal jurisdiction as some were deemed unlikely and not relevant to the assessment<sup>115</sup>.

The following Section 22 IAA factors were subject to additional consideration in this Appendix:

- [Section 26.7](#) — Considering Environmental Obligations and Commitments in Respect of Climate Change
- [Section 26.8](#) — Considering the Extent to Which the Project's Likely Effects Contribute to Sustainability

Additionally, this Appendix contains an assessment of the Indigenous Knowledge Provided with Respect to the Designated Project ([Section 26.6](#)) and Federal Crown's Duty to Consult and treaty obligations under the *Tsawwassen First Nation Final Agreement* ([Section 26.9](#)).

---

<sup>115</sup> The scope of the assessment did not include effects to the marine environment or international waters because the removal by the proponent of plans for a materials offloading facility (MOF) and barge delivery made such effects unlikely. Specifically the following types of adverse effects within federal jurisdiction were not included: (a)(ii) aquatic species, as defined in subsection 2(1) of the *Species at Risk Act*; (c) a non-negligible adverse change to the marine environment that is caused by pollution and that would occur outside Canada; and (d) a non-negligible adverse change – that is caused by pollution – to boundary waters or international waters, as those terms are defined in subsection 2(1) of the IAA.

The definition of adverse effects within federal jurisdiction under the IAA also includes non-negligible adverse effects of a federal work or undertaking as defined in subsection 3(1) of the *Canadian Environmental Protection Act, 1999*. The project does not include federal works or undertakings and thus no related adverse effects.

The definition of adverse effects within federal jurisdiction under the IAA also includes a non-negligible adverse change to a health, social or economic matter that is within the legislative authority of Parliament that is set out in Schedule 3. There are no other health, social, or economic matters set out in Schedule 3.

### 26.1.6 Direct or Incidental Adverse Effects

Under the IAA, the assessment must include a characterization of the extent of significance, if any, for non-negligible direct or incidental adverse effects that are directly linked or necessarily incidental to a federal authority's exercise of power or performance of a duty or function that would permit the carrying out of the Project (defined as "direct or incidental adverse effects" in Section 2 of the IAA). There are no direct or incidental adverse effects anticipated from any of the identified authorization(s) that have not already been considered in this assessment. As such, the EAO has not provided a characterization of significance for any direct or incidental adverse effects from Tilbury Phase 2.

In addition to the assessment approvals, Tilbury Phase 2 would need one federal permit (compliance-based notification under the *Aeronautics Act*), identified in the [Joint Permitting / Regulatory Coordination Plan](#).

## 26.2 Fish and Fish Habitat

### 26.2.1 Overview

The IAA requires an assessment of non-negligible adverse changes to fish and fish habitat.<sup>117</sup> The EAO has assessed effects to fish and fish habitat, which takes into account the proponent's assessment and key issues raised, in [Appendix 6: Fish and Fish Habitat](#). The EAO determined the residual effects from the Project on Fish and Fish Habitat are negligible in magnitude using the EAO's effects characterization definitions (Appendix 3). Below, the residual and cumulative adverse federal effects were assessed based on the EAO's assessment. The effects to fish and fish habitat within federal jurisdiction were determined to be not significant.

#### Residual Effects

Following the application of the Key Mitigation Measures and provincial mechanisms including conditions, the residual effects to fish and fish habitat stem from reduced fish habitat quality, increased risk to fish health, injury and mortality, and changes to fish distribution and abundance. These residual effects are limited to stormwater quality interactions in Tilbury Slough, localized artificial lighting along the shoreline, minimal air-deposition pathways, and upland construction noise. The residual effects were characterized by the EAO as negligible magnitude, highly localized, and fully reversible.

#### Cumulative Effects

The potential for cumulative effects considered residual effects caused by Tilbury LNG Phase 2 in combination with the potential effects of other past, present, and reasonably foreseeable future projects, as described in [Appendix 6: Fish and Fish Habitat](#). The cumulative effects to fish and fish habitat are considered medium to high in magnitude but localized and reversible. As the Project's contribution of negligible magnitude and reversible residual effects is not predicted to materially change the condition of fish habitat or alter the potential recovery of the Tilbury Slough, the cumulative state of aquatic conditions in the RAA would not be altered.

<sup>116</sup> See s.2(a)(i) of the *Impact Assessment Act*.

### 26.2.2 Malfunctions and Accidents

The EAO assessed the effects of potential malfunctions and accidents on fish and fish habitat in Appendix 7: Risks of Malfunction and Accidents. Potential malfunctions and accidents that could result in effects to fish and fish habitat include spills or accidental releases of hazardous materials to the Fraser River or Tilbury Slough from equipment failure, error, or project-related vehicle collision. See [Appendix 7: Risks of Malfunctions and Accidents](#) for further detail on the accidents and malfunctions, their potential effects, and risk ratings. The EAO's identified, and where appropriate recommended, Federal Key Mitigation Measures for malfunctions and accidents are described in [Appendix 2](#).

### 26.2.3 Key Mitigation Measures for Fish and Fish Habitat

The EAO identified federal Key Mitigation Measures to reduce potential effects to fish and fish habitat. These key mitigation measures are described in full in [Appendix 2](#). In summary, Key Mitigation Measures were identified to control erosion, sedimentation and runoff in the Designated Project area during all phases of the Designated Project; and treat any hydrostatic testing waters, storm water and water discharges from sediment basins.

### 26.2.4 EAO Analysis and Conclusion

Based on the predicted residual effects to fish and fish habitat, which include consideration of the proposed federal Key Mitigation Measures, the EAO concludes that residual and cumulative adverse federal effects to fish and fish habitat are not significant.

## 26.3 Migratory Birds

### 26.3.1 Overview

The IAA requires an assessment of effects to migratory birds to determine if there are non-negligible adverse federal effects. <sup>118,119</sup> The EAO has assessed effects to wildlife, including migratory and non-migratory birds, in [Appendix 6](#), Section 17.7: Wildlife and Wildlife Habitat. This section draws from that assessment to assess effects to migratory birds protected under the *Migratory Birds Convention Act (1994)*.

The assessment considered resident and migratory birds in four categories: forest birds, waterbirds, wading birds and shorebirds, and bird species adapted to human infrastructure. Forest birds largely include passerines and raptors; waterbirds include waterfowl and seabirds; bird species adapted to human infrastructure include those that commonly utilize anthropogenic structures for roosting and nesting. Not all birds within these categories are defined under the *Migratory Birds Convention Act*. A total of 34 bird species were observed during field surveys, of which 24 are protected under the *Migratory Birds Convention Act* as listed below. An asterisk indicates if the bird is also protected under the *Species at Risk Act*.

**Forest birds:** American goldfinch, American robin, Black-capped chickadee, Common yellowthroat, House finch, Marsh wren, Northern flicker, Rufous hummingbird, Savannah sparrow, Song sparrow, Spotted towhee, Tree swallow, Violet-green swallow, White-crowned sparrow, Yellow warbler.

**Waterbirds:** Blue-winged teal, Canada goose, Gadwall, Green-winged teal, Gulls (unspecified), Lesser scaup, Mallard.

**Wading birds and Shorebirds:** Spotted sandpiper, Great blue heron (*fannini* subspecies) \*.

**Bird species adapted to human infrastructure:** None

Migratory birds of provincial or federal conservation concern that were not identified during surveys but have the potential to occur in the Regional Assessment Area, include: American bittern, Band-tailed pigeon\*, Bank swallow\*,

<sup>118</sup> Migratory birds are listed in the Schedule to the [Migratory Birds Convention Act, 1994](#).

See subsection 2(a)(iii) of the *Impact Assessment Act*.

Barn swallow\*, Black swift\*, Brant, Californian gull, Caspian tern, Common nighthawk\*, Green heron, Horned grebe\*, Olive-sided flycatcher\*, Purple martin, Red knot (*rufa* and *islandica* subspecies, *roselaari* type)\*, Red-necked phalarope\*, Yellow rail\*, and Western grebe\*. Of these species, 12 have potential to interact with the Project and were included in the EA (that is, they have low, moderate, or high potential to occur, or confirmed presence within the LAA).

#### Residual Effects

Three potential effects to wildlife, including migratory birds, were identified: loss or alteration of habitat, change in movement (corridors), and change in health and mortality risk. Change in movement was considered to be negligible and therefore not carried forward to the residual effects assessment. See [Section 7.08](#): Wildlife and Wildlife Habitat of the Revised Application for more detail about FortisBC's assessment.

The EAO anticipates that construction will cause indirect habitat loss and changes within the LAA, which is an industrialized zone with limited suitable land for migratory birds. Species in this area are adapted to ongoing human disturbances, but construction may temporarily displace birds during key times such as migration and nesting, reducing habitat effectiveness. The residual effects are expected to be negligible in magnitude for most migratory bird species, with a low rating applied to migratory birds that are also species at risk due to their lower resilience. The residual effects would be localized, medium-term, and reversible.

Direct and indirect residual effects to migratory bird health and mortality could result from wildlife interactions such as vehicle strikes, sensory disturbances, contact with the heat from flaring, and wildlife collisions with Project infrastructure. Altered air, surface water, and soil quality, which could overlap with sensitive timing periods (e.g. migration) for migratory birds, could increase health risk. Given the Project's scope and planned mitigation, the residual effects are expected to be negligible in magnitude for most migratory bird species, with a low rating applied to migratory birds that are also species at risk due to their lower resilience. The residual effects would be localized, medium-term, and reversible.

#### Cumulative Effects

The potential for cumulative effects considered residual effects caused by Tilbury LNG Phase 2 in combination with the potential effects of other past, present, and reasonably foreseeable future projects, as described in Appendix 6: Wildlife and Wildlife Habitat.

The cumulative effects for loss or alteration of wildlife habitat, with respect to migratory birds, were predicted to be high in magnitude, based on the extent of past and existing project activities in a highly industrialised landscape. Habitat disturbance within the region is likely to be exacerbated by climate change and is predicted to persist in perpetuity due to continuous industrial activities in the region and overlap with reasonably foreseeable projects.

Cumulative effects to changes in health and mortality risk to wildlife, with respect to migratory birds, were predicted to be high in magnitude, based on the extent of past and existing project activities in a highly industrialised landscape. Increased health and mortality risk are likely to be exacerbated by climate change and would persist, despite rare to infrequent occurrences, with or without the project due to the continuous and long-term persistence of industrial activities in the broader region and overlap with reasonably foreseeable projects.

The Project's contribution of residual effects to migratory birds and their habitat for both loss or alteration of habitat and change in health and mortality risk are predicted as negligible to low in magnitude, localized, and reversible. The Project's contributions to the cumulative effects are not predicted to materially change the condition of migratory bird habitat or constrain the potential recovery of the RAA.

### 26.3.2 Malfunctions and Accidents

The EAO assessed the effects of potential malfunctions and accidents on migratory birds in [Appendix 7: Risks of Malfunction and Accidents](#). Potential malfunctions and accidents that could result in effects to migratory birds include emergency facility shutdown and depressurization through flaring, leakage or spill during transportation, motor vehicle or trucking accident, or accidental release of contaminants to surface water runoff into the Tilbury Slough. See Appendix 7: Risks of Malfunction and Accidents for further detail on the characterization of risk and potential effects. Federal Key Mitigation Measures for malfunctions and accidents are described in [Appendix 2](#).

### 26.3.3 Key Mitigation Measures for Migratory Birds

The EAO has identified federal Key Mitigation Measures to IAAC to reduce potential effects to migratory birds. These Key Mitigation Measures, including any recommendations from the EAO, are described in full in Appendix 2: Key Mitigation Measures and Follow-Up Programs under the IAA. In summary, Key Mitigation Measures were identified to avoid harming migratory birds or their nests or residences, identify the presence of migratory bird nests, delineate setback distances around nests and residences, and control lighting to mitigate attraction and disorientation.

### 26.3.4 EAO Analysis and Conclusion

Based on the predicted effects to migratory birds, which include consideration of the proposed Key Mitigation Measures, the EAO concludes that residual and cumulative adverse federal effects to migratory birds are not significant.

## 26.4 Federal Lands

### 26.4.1 Overview

The IAA requires an assessment of non-negligible adverse changes to the environment that would occur on federal lands. Examples of federal lands include Indigenous reserves or national parks.<sup>120</sup> The results of the EAO's effects assessments for valued components with the potential to affect federal lands (e.g. air quality, acoustic) have been used to assess effects to federal lands.

#### Residual Effects

No federal lands would be used to carry out Tilbury Phase 2 and the project is not located near First Nation land as defined in Section 2(1) of the *First Nation Land Management Act*. The nearest Indigenous reserve lands are identified in the proponent's Revised Application. The proponent noted that the largest RAA (Metro Vancouver) encompasses 1,892 federal parcels and the closest parcel is 150 metres to the southwest. Directly across the Fraser River from the proposed Project Footprint (approximately 900 metres north) is a complex of federally owned industrial parcels on Lulu Island. The British Columbia Supreme Court, in *Cowichan Tribes v. Canada (Attorney General)*, 2025 BCSC, declared that Quw'ustun Nation holds Aboriginal title to an area which includes this complex of federally owned industrial parcels, managed by the Vancouver Fraser Port Authority. The Court also declared that Canada's fee simple titles to these parcels are invalid. The declaration of invalidity regarding Canada's fee simple lands is suspended for 18 months from the date of the trial decision, August 7, 2025.<sup>121</sup>

There are no direct physical impacts such as vegetation clearing, grading, and other physical activities that would occur on federal lands. The valued components with geographic extents within the RAA that overlap with federal lands and with potential residual effects are air quality and acoustics. See [Appendix 6](#) - Section 17.1 and Air Quality and Section 17.2: Acoustics, for further detail on the characterization of potential effects.

---

<sup>120</sup> See s.2(b) of the *Impact Assessment Act* for more detail on Federal Lands.

The court decision is currently under appeal, including by the provincial and federal governments, the City of Richmond, and First Nations.

### Air Quality

During construction, potential increases in criteria air contaminants (CACs) would be negligible to low in magnitude and localized to the Project Footprint. Effects during construction may extend to the LAA near local truck routes due to increased truck traffic. During operation, incremental contributions to negative air quality from the project would be negligible to low and may extend to the LAA.

After consideration of mitigation measures, emissions of sulphur dioxide, nitrogen dioxide, and other CACs are projected to remain low at the Project Footprint, though aggregate concentrations could increase due to existing ambient conditions and other present and future projects.

### Acoustics

The project's anticipated noise and vibration impacts are minimal, with effects limited to the LAA and considered negligible on federal lands. Overall, these impacts are expected to be minor and reversible, predicted with moderate to high confidence.

### Cumulative Effects

The potential for cumulative effects considered residual effects caused by Tilbury LNG Phase 2 in combination with the potential effects of other past, present, and reasonably foreseeable future projects, as described in [Appendix 6: Air Quality and Acoustics](#).

Cumulative effects from other physical activities and present and foreseeable projects are anticipated to overlap with federal lands within the RAA where the airshed has low resilience to increases in nitrogen dioxide, as well as a moderate to high resilience to increases in other criteria air contaminants. The cumulative effects to air quality from nitrogen dioxide are predicted as high in magnitude, and low to moderate for other criteria air contaminants. These characterizations vary depending on the modelling scenarios. The residual effects from the Project are predicted to be negligible to low in magnitude. The airshed may be able to absorb the small contributions from the Project to the cumulative concentrations, while noting the uncertainty in the cumulative air-quality results and differing modelled scenarios.

There is potential for cumulative effects of a low to moderate magnitude on the acoustic environment for adjacent federal lands given existing and foreseeable projects and moderate resilience to increases under ambient conditions. The Project's contribution to the acoustic cumulative effects on federal lands are predicted to be negligible to low in magnitude, reversible, and short term for construction and potentially long term for operations. The acoustic environment is not predicted to alter based on these negligible to low residual effects of the projects.

Given the negligible to low contribution of Tilbury Phase 2 to these conditions for both acoustics and air quality, the EAO concluded that it is not likely to result in significant adverse cumulative effects.

## 26.4.2 Malfunctions and Accidents

The EAO assessed the effects of potential malfunctions and accidents in Appendix 7: Risks of Malfunction and Accidents. Potential malfunctions and accidents that could result in effects to federal lands through air quality and acoustics include loss of containment of LNG without ignition and an emergency facility shutdown. Federal Key Mitigation Measures for malfunctions and accidents are described in Appendix 7.

### 26.4.3 Key Mitigation Measures for Federal Lands

The EAO has identified federal Key Mitigation Measures to IAAC to reduce potential effects to federal lands. These Key Mitigation Measures, and any recommendations from the EAO, are described in full in Appendix 2: Federal Key Mitigation Measures and Follow-up Programs Under the IAA. In summary, Key Mitigation Measures were identified through provincial and municipal mechanisms to reduce fugitive particulate and dust emissions, and other contaminants of potential concern including nitrogen dioxide, sulphur dioxide, and volatile organic compounds from construction and operation, including the use of Totally Enclosed Ground Flare technology to reduce air quality impacts and noise emissions. FortisBC also committed to implement contingency measures if ambient air quality monitoring for contaminants of potential concern attributable to the project exceed thresholds of the Canadian Council of ministers of the Environment's Canadian Ambient Air Quality Standards or Metro Vancouver's Ambient Air Quality Objectives, whichever is more protective of human health.

### 26.4.4 EAO Analysis and Conclusion

Given the negligible to low magnitude of anticipated effects to air quality and the minimal acoustic effects on federal lands, residual adverse effects on federal lands are not anticipated. The EAO concludes that residual and cumulative adverse federal effects on air quality and acoustic resources that would occur on federal lands are not significant.

## 26.5 Assessment of 2(e) and (f) Factors with Respect to the Indigenous Peoples of Canada

Sections 2(e) and (f) of the IAA require, with respect to the Indigenous peoples of Canada, an assessment of:

- non-negligible adverse impacts — occurring in Canada and resulting from any change to the environment — on the current use of lands and resources for traditional purposes and physical and cultural heritage (current use; CULRTP); and structures, sites or things of historical, archaeological, paleontological, or architectural significance (2(e)), and
- non-negligible adverse changes occurring in Canada on health, social or economic conditions (2(f)).

The EAO's assessment in this section draws on information provided in various sections of FortisBC's Revised Application, and from information provided by Indigenous Nations and the public. Due to the holistic nature of Indigenous culture, current use, and health and socioeconomic conditions, numerous connections are drawn between the two assessment factors. These connections are described in Section 26.5.2: Indigenous Peoples' Current Use of Lands and Resources for Traditional Purposes and Cultural Heritage, and Section 26.5.3: Health, Social, and Economic Conditions of Indigenous Peoples.

### 26.5.1 Assessment Methodology

Potential non-negligible adverse effects to Indigenous peoples were assessed for each individual Indigenous nation in [Appendix 5](#): Detailed Indigenous Nation Assessments. Information in this section builds upon the analysis conducted in Appendix 5 and [Appendix 6](#): Valued Component Assessments of this Report.

The following methodology was used to assess potential non-negligible adverse effects:

- 1) Context about the assessment factor is presented, to further describe the interconnected nature of Indigenous values and draw connections to other VC sections.
- 2) Subcomponents of the assessment factor are identified:
  - a) Potential effects and effect pathways on the subcomponent are identified.
  - b) The potential effects on the subcomponent are characterized.
- 3) Potential effects of malfunctions and accidents on the assessment factor are identified.
- 4) GBA Plus considerations for the assessment factor are outlined.

- 5) Potential cumulative effects on the assessment factor are identified.
- 6) Federal Key Mitigation Measures and Follow-Up Programs as they relate to the assessment factor are considered.
- 7) Conclusions on the significance of potential non-negligible adverse effects to the assessment factor are presented.

#### Identification and Characterization of Effects and Effect Pathways

As described in Section 26.1: Overview, the assessment of adverse federal effects considers non-negligible adverse residual effects following the implementation of mitigation measures. Therefore, potential effects and effect pathways that are considered to be negligible following the implementation of standard mitigation measures are not included. Further information on standard mitigation measures is included in the [Appendix A](#) Mitigation Table of the Revised Application

Non-negligible adverse effects on CULRTP and cultural heritage; and health, social and economic conditions of Indigenous peoples are characterized using terminology described in Section 26.5. In the context of assessing impacts to Indigenous interests, additional criteria must be considered when characterizing effects. These include the degree to which the effects will impact the ability of an Indigenous nation to continue customs, traditions, and practices that are integral to the group's distinct culture; whether the effects of the project will affect the community's ability and systems for self-governance and self-determination; and the effects of the project on sub-populations of a community (including women, Elders, youth, Two-Spirit individuals, and others).

#### Malfunctions and Accidents

A detailed assessment of malfunctions and accidents as they relate to Indigenous interests is included in [Appendix Z](#).

#### Characterization of Significance

As described in Section 26.1.5: Assessment of Effects Within Federal Jurisdiction, this Report characterizes whether adverse federal effects, including cumulative effects, are likely to be to some extent significant, and if so, to what extent.

### 26.5.2 Indigenous Peoples' Current Use of Lands and Resources for Traditional Purposes and Cultural Heritage

Section 2(e) of the IAA requires the assessment of non-negligible adverse effects – occurring in Canada and resulting from any change to the environment – on the current use of lands and resources for traditional purposes, and physical and cultural heritage, including any structure, site or thing that is of historical, archaeological, paleontological, or architectural significance (collectively considered as Cultural Heritage for the purposes of this assessment) as they relate to Indigenous peoples. This section assesses these potential effects from the Project.

Figure 15: The Nested Circle Methodological Approach to Assessing Effects to CULRTP and Cultural Heritage

As illustrated in Figure 15, the assessment of CULRTP (Section 26.5.1) includes the analysis of two subcomponents: (1) quality and quantity of lands and resources and (2) access to lands and resources. The assessment of cultural heritage (Section 26.5.3.1) includes the analysis of two subcomponents: (1) tangible cultural heritage and (2) intangible cultural heritage; and the consideration of health, social, and economic conditions (Section 26.5.4). The figure further illustrates the ways in which subcomponents (CULRTP and cultural heritage) and their sub-factors are interrelated. These interrelations illustrate the foundational importance of the environment to Indigenous peoples' current use of lands and resources and cultural heritage.

### 26.5.3 Changes to Current Use of Lands and Resources for Traditional Purposes - IAA 2(e)(ii)

This section assesses the potential effects of the Project, with respect to Indigenous peoples, on current use of lands and resources for traditional purposes. CULRTP includes current use by Indigenous peoples, uses that are likely to occur in the reasonably foreseeable future and uses that may have ceased due to external factors.

CULRTP includes activities such as the harvesting of resources (including hunting, trapping, fishing, and gathering), accessing and inhabiting the land (including use of trails and travelways and connections), and preferred uses of lands and resources. CULRTP may have tangible values (e.g. wildlife species or traditional plants) and/or intangible values (e.g. ability to experience quiet enjoyment on the land, knowledge transmission, and community gathering).

In the assessment of CULRTP, the EAO organized data according to two identified subcomponents:

- Quality and quantity of resources; and
- Access to lands and resources for traditional purposes.

#### Quantity and Quality of Lands and Resources

The ability to harvest resources is a fundamental component of CULRTP. Changes in the quantity and quality of lands and resources may result in changes to harvesting activities, ability to access locations used for CULRTP, cultural heritage, and well-being. For affected Indigenous Nations, hunting, harvesting, and fishing are culturally important and communal activities where members experience the land and share intergenerational knowledge. The quantity and quality of resources is therefore important to the ability of Indigenous nations to engage in land-based practices and maintain cultural continuity. Potential impact to Indigenous peoples in proximity to the project area include effects to rights to harvest, hunt, and fish for food, social and ceremonial purposes, as described in [Appendix 5: Detailed Indigenous Nation Assessments](#).

The assessment of potential effects to the quality and quantity of resources has been subdivided into the two sub-factors outlined below: A) Species of Importance, and B) Vegetation and plant harvesting resources.

#### *(A) Species of Importance*

The assessment of potential effects from changes to the environment on species of importance considers potential effects on birds and fish resources. While noting that Tilbury Phase 2 activities will be occurring on the existing Tilbury Plant, consideration of these effects reflects the desire expressed by nations including Cheam First Nation, Kw'ikw'əłəm, Kwantlen First Nation, x'w'məθk'əyám (Musqueam Indian Band), Quw'utsun Nation, Snuneymuxw First Nation, the S'ólh Téméxw Stewardship Alliance, S'ÁUTW First Nation, Tsawwassen First Nation, and Tsleil-Waututh Nation to protect culturally important species (including but not limited to: salmon, sturgeon, eulachon, mallard, geese, and deer) and restart harvesting in the future.

The following table provides a summary of how Tilbury Phase 2 activities may result in potential effects to the quantity and quality of species of importance via the key effect pathways.

Table 82: Potential Project Effect Pathways on Quantity and Quality of Species of Importance

| Relevant Phase(s)                               | Effect Pathway                                                                                                                                                                                                                                             | Effect from change to the environment                                                                                                                                                                   |
|-------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Construction, Operation, Decommissioning</b> | Transportation of equipment and materials may result in a decrease of stormwater quality, including an increased seepage of run-off from tires (containing 6-PPD quinone) into waterways resulting in a decrease of fish health and the marine environment | Reduction in fish habitat quality, increased risk to fish health and mortality (especially salmonoids like coho and chinook salmon and steel head trout) and changes in fish distribution and abundance |
| <b>Operation</b>                                | Project emissions (air contaminants, dust, noise, and vibration) may result in deposition of air contaminants into waterways                                                                                                                               | Reduction in fish habitat quality, increased risk to fish health and mortality and changes in fish distribution and abundance                                                                           |
| <b>Construction, Operation</b>                  | Upland construction and operation generating underwater noise which may affect fish health                                                                                                                                                                 | Reduction in fish habitat quality, increased risk to fish health and mortality, and changes in fish distribution and abundance                                                                          |

#### *(B) Vegetation and plant harvesting resources*

The assessment of potential effects from changes to the environment on vegetation and plant harvesting resources considers potential effects on culturally important vegetation.

While noting that Tilbury Phase 2 activities will be occurring on the existing Tilbury Plant, consideration of these effects reflects the desire expressed by *kʷikʷəłəm*, Kwantlen First Nation, *xʷməθkʷəyəm* (Musqueam Indian Band), Quw'utsun Nation, Snuneymuxw First Nation, the S'ólh Téméxw Stewardship Alliance, *SʔÁUTW* First Nation, Tsawwassen First Nation, Tsleil-Waututh Nation, and Ts'uubaa-asatx Nation to protect culturally important vegetation (including but not limited to: wapato, salal, cranberries and blueberries, cattails, and crab apple) and restart harvesting in the future.

The following table provides a summary of how Tilbury Phase 2 activities may result in potential effects to the quantity and quality of vegetation and plant harvesting resources via the key effect pathways.

Table 83: Potential Project Effect Pathways on Vegetation and Plant Harvesting Resources

| Relevant Phase(s)       | Effect Pathway                                                                                                                                                                  | Effect from change to the environment                                                                    |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| Construction, Operation | Project emissions (air contaminants, dust, noise, and vibration) may result in deposition of air contaminants into soil resulting in a decrease in terrestrial ecosystem health | Reduction in quality of vegetation and plant harvesting resources including culturally important species |

The changes in the quality and quantity of lands and resources can change the experience and preferences regarding the practice of harvesting rights and potential effects on the quality, quantity, and availability of resources for Indigenous nations. These changes can also affect harvesting methods and practices (such as timing and seasonality of such methods and practices).

#### Access to Lands and Resources for Traditional Purposes

To engage in current and future use activities, Indigenous peoples must have access to preferred areas associated with traditional practices. Preferred areas often include important locations such as hunting grounds, trapping routes, fishing sites, and key gathering areas. Preferred areas also include sites and locations necessary for intangible elements of current use such as knowledge transmission and spiritual, ceremonial, and cultural practices (e.g., historic camp sites, key gathering sites, and teaching locations). Loss of access to preferred areas may directly affect the ability of Indigenous peoples to engage in current and future use activities. As discussed in Appendix 6 - Land and Resource Use, many Indigenous nations raised concerns about the potential effects of the Project on their access to the site, or areas close to the site for harvesting and cultural practices. Loss of access to preferred areas is further connected to cultural heritage (Section 26.5.3.1), and the Health, Social, and Economic Conditions of Indigenous Peoples (Section 26.5.4).

It is important to note that access to preferred areas is directly connected to the quality and quantity of resources necessary for current use activities in that area (see Table 84). Perceived risk, such as the perceived risk of contaminated resources or community safety, may also result in avoidance of lands and resources. While studies may indicate no biophysical effect to the lands and resources, social avoidance due to perceived risk constitutes a potential effect. This nuance is further discussed in Section 26.5.4 Health, Social, and Economic Conditions.

The following table provides a summary of how Tilbury Phase 2 activities may result in potential effects to accessing lands and resources for traditional purposes, via the key effect pathways. The table also identifies key CULRTP sites within or close to assessment boundaries.

Table 84: Potential Project Effect Pathways on Access to Lands and Resources for Traditional Purposes

| Relevant Phase(s)                        | Effect Pathway                                                                                                                                                                    | Effect                                                                                                                    | Key CULRTP Sites                                                                                                                                                                                                                                                                                                |
|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Construction, Operation, Decommissioning | Discharge of project emissions (air contaminants, dust, noise, and vibration) may result in perceived reduction in the quality of lands and resources necessary to support CULRTP | Actual, functional and/or perceived loss in the ability to access lands and resources necessary to support desired CULRTP | <ul style="list-style-type: none"> <li>Historic Indigenous Village Site<sup>122</sup></li> <li>Historic Ts'uubaa-asatx Nation fishing camp</li> <li>Storied Places, habitation sites, place names, and archaeological sites along the south arm of the Fraser River, Tilbury Island, and Lulu Island</li> </ul> |
|                                          | Sensory disturbance due to dust, noise, vibration, and light resulting in a reduced quality of experience while engaged in the CULRTP                                             |                                                                                                                           |                                                                                                                                                                                                                                                                                                                 |
|                                          | Transportation of equipment and materials may result in increased seepage run-off from tires, resulting in a reduction in the quantity and quality of fish and marine resources   | Functional and/or perceived loss in the ability to access lands and resources necessary to support desired CULRTP         |                                                                                                                                                                                                                                                                                                                 |

### 26.5.3.1 Changes to Cultural Heritage – IAA 2e(i) and 2e(iii)

This section assesses the potential adverse impacts of Tilbury Phase 2 on Indigenous cultural heritage. Cultural heritage includes consideration of both factors IAA 2(e)(i) physical and cultural heritage, and 2(e)(iii) any structure, site or thing that is of historical, archaeological, paleontological or architectural significance. Appendix 5 includes further discussion of cultural heritage for Indigenous nations.

Cultural heritage is holistic in nature and includes physical, emotional, mental, kinship and spiritual components. All elements of cultural heritage are considered valued due to cultural importance and meaning, and their connection to shared memory and collective identity. The assessment of potential effects to cultural heritage has been divided into two subfactors: (1) tangible cultural heritage and (2) intangible cultural heritage.

Physical and cultural heritage, as described by the IAA, includes both tangible and intangible elements. Tangible elements may include specific places or sites necessary to support culture, identity, and the CULRTP; as well as items or objects that are important for sustaining cultural heritage practices such as teaching, ceremony, or spirituality. Intangible elements may include knowledge systems, the transmission of knowledge, beliefs, values, practices, stories, songs, language, laws, and traditions. These elements are not tied to a specific place or item; however, they remain integral to the continuation and resurgence of Indigenous culture.

Comparatively, the assessment of any structure, site or thing that is of historical, archaeological, paleontological or architectural significance, as described under the IAA, includes only tangible elements, for example locations such as burial grounds, historic settlements and camps, and travelways; and items such as pottery, stoneware, tools, and culturally modified trees.

As a result of these distinctions, conclusions to IAA factor 2(e)(iii) any structure, site or thing that is of historical, archaeological, paleontological or architectural significance will be informed by the identified effects and effect pathways to tangible culture. Accordingly, conclusions to IAA factor 2(e)(i) physical and cultural heritage will be informed by the identified effects and effect pathways to both tangible culture heritage as well as intangible cultural heritage.

Potential effects to tangible and intangible cultural heritage are qualitatively evaluated based on descriptors of changes related to valued components.

See Section 3.1 for naming and jurisdictional context regarding the Historic Indigenous Village Site.

### Tangible Cultural Heritage

As described above, tangible cultural heritage includes any structure, site, or thing that is of historical, archaeological, paleontological or architectural significance, as well as some elements of physical and cultural heritage. Sites and structures of significance include mappable locations that are of cultural importance, including those related to the historic use of lands and resources, archaeological sites, and palaeontological sites. Items of significance include artifacts and features that have cultural value such as palaeontological and architectural resources.

Tangible elements of physical and cultural heritage are similar and may include areas and items necessary for practices such as ceremony, spirituality, or knowledge transmission, among others. These land-based practices require a certain quality of sensory conditions to facilitate a spiritual connection to the land. These conditions may include solitude, quiet, and a lack of sensory disruption. Changes and barriers to these conditions and the ability to participate in quiet enjoyment on the land therefore represent potential effects to cultural heritage.

As CULRTP is discussed in Section 26.5.1, this section focuses on potential project effects on archaeological sites, palaeontological sites, and items of cultural significance, as well as potential effects to the conditions necessary to support a spiritual connection to the land.

The following table provides a summary of how project activities may result in non-negligible adverse effects to tangible cultural heritage.

Table 85: Effects Pathways on Tangible Cultural Heritage

| Relevant Phase(s)                        | Effect Pathway                                                                                                                                                                                                       | Effect                                                              |
|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------|
| Construction                             | Site preparation, ground disturbance, and infrastructure development may result in the destruction of artifacts/features of cultural heritage significance                                                           | Direct loss of artifacts/features of cultural heritage significance |
| Construction, Operation, Decommissioning | Discharge of project emissions (air contaminants, dust, noise, and vibration) may result in increased sensory disturbance resulting in a reduced quality of experience, and avoidance of, sites of cultural heritage | Loss of desired access to sites of tangible cultural heritage       |

### Intangible Cultural Heritage

In contrast to tangible cultural heritage, intangible cultural heritage includes elements of physical and cultural heritage that cannot be seen or touched. Intangible cultural heritage is broadly understood as living heritage and is carried forward from generation to generation through the transmission of knowledge, beliefs, and values. Intangible cultural heritage can also be understood as the ability to preserve the historical traditions of culture and to carry them forward into the future in a desired way. This concept is closely tied to cultural identity and is related to the current and future use of lands and resources for traditional purposes (Section 26.5.3), and health, social and economic conditions (Section 26.5.4). The assessment of potential project effects on intangible cultural heritage therefore considers the potential effects to CULRTP, access to sites and items of cultural heritage, consideration of intangible facets such as knowledge transmission, ceremony, spirituality, and governance, stewardship obligations, self-determination, food sovereignty, and the consideration of health, social, and economic conditions.

As potential effects to CULRTP (Section 26.5.1), tangible cultural heritage (Section 26.5.3.1) and health, social and economic conditions (Section 26.5.4) are assessed elsewhere in this appendix, only the overall conclusions are brought forward and considered in the characterization of significance for potential effects to intangible cultural heritage. This section focuses on potential project effect pathways leading to effects to stewardship and governance.

The concept of stewardship and governance relates to the ability of Indigenous nations to self-determine and self-govern. This includes the ability of an Indigenous nation's government to ensure the safety, security, stability, and prosperity of their communities. More broadly, stewardship and governance relate to the practices and systems by which Indigenous peoples are able to manage their lands, resources, and communities.

Stewardship and governance over lands, resources, and communities therefore include the ability to make decisions concerning land use, the ability to engage in and maintain real and desired cultural practices, the ability to maintain cultural identity, the transmission of knowledge, and maintaining and ensuring health, social, and economic conditions.

The following table provides a summary of how project activities may result in non-negligible adverse effects to intangible cultural heritage via the identified effect pathways.

Table 86: Effects Pathways on Intangible Cultural Heritage

| Relevant Phase(s)                        | Effect Pathway                                                                                                                                                                                                                                                                   | Effect                                                                                                                                     |
|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| Construction, Decommissioning            | Transportation of project equipment and materials may result in increased discharge of project emissions (air contaminants, dust, noise, and vibration) that reduce the perceived quantity and quality of culturally important species                                           | Loss of the ability to engage in and maintain desired cultural practices                                                                   |
|                                          |                                                                                                                                                                                                                                                                                  | Loss of the ability to maintain food systems and restore harvesting practices                                                              |
| Construction, Operation, Decommissioning | Discharge of project emissions (air contaminants, dust, noise, and vibration) as well as light and visual disturbances, that may result in a reduction in the quantity and quality of culturally important species resulting in a loss of existing and desired cultural practice | Loss of the ability to engage in and maintain desired cultural practices                                                                   |
|                                          |                                                                                                                                                                                                                                                                                  | Loss of the ability to maintain food systems and restore harvesting practices                                                              |
|                                          | Discharge of project emissions (dust, noise, and vibration) may result in a change to the sensory conditions that are necessary to support CULRTP, resulting in a loss of existing and desired cultural practices                                                                | Loss of the ability to engage in and maintain desired cultural practices                                                                   |
|                                          |                                                                                                                                                                                                                                                                                  | Loss of the ability to maintain cultural identity                                                                                          |
|                                          | Discharge of project emissions (air contaminants) may result in an increase in acute/chronic health effects                                                                                                                                                                      | Loss of the ability to maintain and ensure health, social, and economic conditions                                                         |
| Operation                                | Discharge of project emissions (air contaminants, dust, noise, and vibration) may result in a reduction in mental health due to real and perceived changes to CULRTP                                                                                                             | Loss of the ability to maintain and ensure health, social, and economic conditions                                                         |
|                                          |                                                                                                                                                                                                                                                                                  | Loss of the ability to maintain and ensure health, social, and economic conditions                                                         |
|                                          | Reduced mental health and increased community distress due to real and perceived concerns around climate change                                                                                                                                                                  | Loss of the ability to maintain and ensure health, social, and economic conditions                                                         |
|                                          |                                                                                                                                                                                                                                                                                  | Loss of intergenerational well-being and the ability to make decisions concerning cultural resurgence                                      |
|                                          | Reduced self-governance over matters of governance such as climate change resulting in reduced ability to make decisions concerning land use                                                                                                                                     | Loss of the ability or the delaying in ability to make decisions concerning land use, conduct stewardship planning and cultural resurgence |

| Relevant Phase(s)                        | Effect Pathway                                                                                                                          | Effect                                                                   |
|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------|
| Construction, Operation, Decommissioning | Inability to make decisions about the use of traditional territories and the inability to pursue desired use of traditional territories | Loss of the ability to engage in and maintain desired cultural practices |
|                                          |                                                                                                                                         | Loss of the ability to maintain cultural identity                        |
|                                          |                                                                                                                                         | Loss of the ability to make decisions concerning land use                |

### 26.5.3.2 Malfunctions and Accidents

The EAO assessed the effects of potential malfunctions and accidents on Indigenous peoples' CULRTP and cultural heritage in [Appendix 7](#). Potential risks (likelihood x consequence) of malfunctions and accidents related to cultural heritage are outlined in Table 87 below. Federal Key Mitigation Measures for malfunctions and accidents are summarized in Appendix 7 and described in full in [Appendix 2](#). All scenarios in Table 87 have a likelihood of rare to remote.

Table 87: Potential Risks of Malfunctions and Accidents for CULRTP and Cultural Heritage

| Accident/Malfunction Scenario               | CULRTP                            |        | Cultural Heritage |            |
|---------------------------------------------|-----------------------------------|--------|-------------------|------------|
|                                             | Quality and quantity of resources | Access | Tangible          | Intangible |
| Fire or Explosion                           | Medium                            | Medium | Low to Medium     | Medium     |
| Loss of Containment of LNG without Ignition | Low                               | Low    | Low               | Low        |
| Hazardous Material Release                  | Low                               | Low    | Low               | Low        |
| Terrestrial Vehicle Collision               | Low                               | Low    | Low               | Low        |
| Emergency Facility Shutdown                 | Low                               | Low    | Low               | Low        |

### 26.5.3.3 GBA Plus Considerations

The Project has the potential to cause disproportionate adverse federal effects to Indigenous women, girls, 2SLGBTQI+ people, Elders, and youth with respect to CULRTP and cultural heritage. The following describes the disproportionate effects and provides a characterization of those effects.

- Sensory disturbances may be experienced disproportionately by Indigenous peoples, particularly those with greater sensory sensitivity, participating in cultural heritage practices or when accessing cultural heritage sites.
- Due to potential increases in perceived risk when accessing sites of significance, Indigenous Elders and women may have fewer chances to participate in CULRTP and cultural heritage practices.
- Indigenous youth may disproportionately experience the impacts of diminished intergenerational transfer of knowledge, language, and cultural skills, as they may face reduced opportunities to engage in practices upheld by previous generations.

#### 26.5.3.4 Cumulative Effects

The assessment of potential cumulative effects in the area is analyzed throughout [Appendix 5](#) and [Appendix 6](#). A list of past, present, and reasonably foreseeable future projects and activities in the region is provided in [Section 2.4.5](#). Multiple Indigenous nations emphasized the importance of accounting for the long-term alteration and degradation of the area in which the project is located when assessing cumulative effects. The following list identifies potential cumulative effects on CULRTP and cultural heritage:

- Potential for cumulative effects from emissions and sensory disturbances from air quality, noise, vibration, and visual quality which may have a direct impact on perceived experiences when participating in cultural heritage practice or use of cultural heritage sites.
- Potential for cumulative effects from a reduction in or loss of quality and quantity of lands and resources and culturally important species which may have a direct impact on intergenerational knowledge, cultural transmission, cultural continuation, and food sovereignty.
- Potential for avoidance of the project area and areas associated with past, present, and reasonably foreseeable projects which may have a direct impact on access to cultural use sites.
- Potential for cumulative effects from a reduction in or loss of access disrupting intergenerational knowledge and cultural transmission, connection to place, and Indigenous cultural traditions, laws, and governance systems.
- Potential for cumulative effects from the above effects may impact the future governance and stewardship aspirations of Indigenous nations, such as habitat and wildlife restoration enabling the revitalization of cultural and spiritual traditions and harvesting practice.

#### 26.5.3.5 Key Mitigation Measures and Follow-Up Programs

The federal Key Mitigation Measures to reduce potential effects of the Project on CULRTP and cultural heritage are described in full in [Appendix 2](#): Key Mitigation Measures and Follow-Up Programs under the IAA. In summary:

- Develop and implement measures to prevent or mitigate impacts to sensory conditions including noise, odour, vibration, and visual landscape. Measures include controlling project lighting while meeting health and safety requirements, enclosing all compressors in sealed structures during operation to reduce noise, and a community feedback protocol to respond to noise complaints in a timely manner.
  - Relevant effect pathways and non-negligible adverse effects: sensory disturbance due to dust, noise, vibration, and light resulting in a reduced quality of experience while engaged in the CULRTP, avoidance of sites of cultural heritage, loss of existing and desired cultural practice from reduction in the quantity and quality of culturally important species and reduction in aquatic habitat from underwater noise.
  - Other relevant non-negligible adverse effects: disconnection from lands, enjoyment of lands, maintenance of food systems and restoring harvesting practices.
- Develop and implement measures to prevent or mitigate impacts to health from air quality, such as air contaminants in the airshed or deposition into waterways or soil. Measures include a vehicle idle reduction policy, routine inspections and maintenance of engines and exhaust systems on all mobile equipment and vehicles, measures to reduce fugitive dust by applying suppressants, minimize the quantity of vented and flared gas and duration of flaring events, and enclose all compressors in sealed structures during operation to reduce air emissions.
  - Relevant effect pathways: air pollution (CACs including NO<sub>2</sub>, SO<sub>2</sub>, PM, and VOCs), terrestrial and aquatic ecosystem health from potentially contaminated surface water.

- Relevant non-negligible adverse effects: disconnection from lands, enjoyment of lands, effect to water viable to wildlife and fish habitat.
- Develop and implement measures to prevent or mitigate impacts to surface water, such as seepage from vehicles resulting in reduction of aquatic habitat and fish distribution and abundance, and loss of access to lands and CULTRP. Measures include implementing measures to control erosion, sedimentation and runoff within the Project area, and collecting and treating, as necessary, any water discharges and contact water generated from site preparation activities.
  - Relevant effect pathways: aquatic ecosystem health from potentially contaminated surface water.
  - Relevant non-negligible adverse effects: loss of access to lands and CULTRP, effect to wildlife and fish habitat and water viable to those species.

Due to the holistic nature of CULRTP and cultural heritage, mitigation measures and follow-up programs designed to reduce potential effects to the valued components such as fish and migratory birds will also serve to reduce the potential for adverse federal effects and serve as additional protections to CULRTP and cultural heritage more broadly, even when a specific adverse effect to CULRTP or cultural heritage is not identified.

### 26.5.3.6 Residual Effects Characterization for Indigenous Peoples' Current Use of Lands and Resources for Traditional Purposes and Cultural Heritage

The following table provides a characterization of potential adverse federal effects to current use (IAA 2(e)(ii)) and cultural heritage (IAA 2(e)(i) and 2(e)(iii)). The characterizations are based on the information provided in Section 26.5.3 and the methodology described in [Appendix 3](#): Residual Effects Characterization Definitions. These characterizations take into account the application of the Key Mitigation Measures and Follow-up Programs described above.

Table 88: Summary of Residual Effects Characterization for Indigenous Peoples' Current Use of Lands and Resources for Traditional Purposes and Cultural Heritage

| Residual Effects Characterization <sup>123</sup> | Current Use                                 |                                                        | Cultural Heritage          |                              |
|--------------------------------------------------|---------------------------------------------|--------------------------------------------------------|----------------------------|------------------------------|
|                                                  | Quantity and Quality of Lands and Resources | Access to Lands and Resources for Traditional Purposes | Tangible Cultural Heritage | Intangible Cultural Heritage |
| Magnitude                                        | Low                                         | Low                                                    | Negligible to low          | Low                          |
| Duration                                         | Medium-term                                 | Medium-term                                            | Long-term                  | Long-term                    |
| Frequency                                        | Irregular                                   | Regular/Continuous                                     | Continuous                 | Continuous                   |
| Reversibility                                    | Partially reversible                        | Partially reversible                                   | Reversible                 | Irreversible                 |
| Risk                                             | Low                                         | Low                                                    | Low-to-Moderate            | Moderate                     |
| Uncertainty                                      | Moderate                                    | Moderate                                               | Moderate                   | High                         |
| Importance                                       | High                                        | High                                                   | High                       | High                         |

For further detail on the residual effects characterization, see [Appendix 3](#): Residual Effects Characterization Definition.

### 26.5.3.7 EAO Conclusions on Indigenous Peoples' Current Use of Lands and Resources for Traditional Purposes and Cultural Heritage

As described in Section 26.1: Overview, the Report concludes as to whether adverse federal effects, including cumulative effects, are likely to be to some extent significant, and if so, to what extent. The criteria for characterizing extent of significance for non-negligible adverse federal effects are defined in Section 26.1.3: Assessing Effects Within Federal Jurisdiction.

Based on the predicted effects to Indigenous peoples' current use of lands and resources for traditional purposes (Section 2(e)(ii) of the IAA), the EAO concludes that residual effects are significant to a low extent, and cumulative effects are significant to a low extent.

Based on the predicted effects to Indigenous peoples' physical and cultural heritage (tangible and intangible cultural heritage) (Section 2(e)(i)), the EAO concludes that residual effects are not significant. Given the status of the receiving environment, the cumulative effects are significant to a low extent.

Based on the predicted effects to any structure, site or thing that is of historical, archaeological, paleontological or architectural significance (tangible cultural heritage; Section 2(e)(iii)), the EAO concludes that residual and cumulative adverse federal effects are not significant.

Tsleil-Waututh Nation disagreed with the EAO's conclusion that the effects to CULTRP are not significant and expressed concerns about how the Project would hinder its stewardship obligations, self-determination, food sovereignty, and ability to govern in accordance with its laws. Tsleil-Waututh Nation furthermore views effects of the Project as undermining its intangible cultural heritage by interfering with its ability to exercise stewardship and self-determination towards cultural resurgence, climate governance, and intergenerational well-being.

### 26.5.4 Health, Social or Economic Conditions of the Indigenous Peoples of Canada

Section 2(f) of the IAA requires the assessment of non-negligible adverse changes to the health, social, or economic conditions of the Indigenous peoples of Canada.

As worker health is assessed in [Section 17.14: Human Health](#), this section focuses on Indigenous health outside of the workplace. This includes the health of community members living and using the land outside of the Project Footprint, community health, and health impacts associated with CULTRP.

For this Project, the spatial assessment boundaries for the Human Health VCs are defined differently for the social (including population health) and the environmental determinants of health. For social determinants of health, this includes the LAA and RAA boundaries of Metro Vancouver, which includes 21 municipalities, First Nation reserves, and Tsawwassen First Nation Treaty lands. The spatial boundary for environmental determinants of health includes the LAA boundaries of the VCs that may affect human health including Air Quality, Acoustic, Soil<sup>124</sup>, Country Foods<sup>125</sup>, Surface Water and Groundwater Quality. This spatial boundary also includes the RAA boundaries for VCs that may have indirect or cumulative impacts to human health from the Project including Air Quality, Acoustic, Soil, Country Foods<sup>125</sup>, Surface Water and Groundwater Quality.

Information from across valued components and Detailed Indigenous Nation Assessments was gathered and synthesized to assess these potential non-negligible adverse changes to Indigenous health and well-being according to a holistic framework in Figure 16.

<sup>124</sup> The temporal boundaries for Soil include the Construction (3-6 years), Operation (40 plus years), and Decommissioning (two years) phases of the Project.

The LAA for Country Foods Quality is the combined LAAs for the Vegetation, Fish and Fish Habitat, and Wildlife and Wildlife Habitat VCs.

Figure 16: The Nested Circle Methodological Approach to Assessing Effects to the Health, Social, or Economic Conditions of Indigenous Peoples

As illustrated in Figure 16, the assessment of health, social and economic conditions of Indigenous peoples (Section 26.5.4) includes the analysis of two subcomponents: (1) health and (2) Indigenous well-being. The assessment of health ([Appendix 6, Section 14.12](#)) includes the analysis of potential effects to mental health and physical health, and the consideration of potential effects to cultural heritage (Section 26.5.3.1). The assessment of Indigenous well-being includes the analysis of potential effects to infrastructures and services, employment and economy, economic conditions, and social conditions, and the consideration of potential effects to health. Like Figure 16, this diagram illustrates the foundational importance of the environment to the health, social, and economic conditions of Indigenous peoples.

The assessment of potential effects to Indigenous health, social, and economic conditions necessitates a comprehensive approach that honors and integrates Indigenous Knowledge, values, and traditions. Health, social, and economic conditions are holistic, encompassing spiritual, environmental, cultural, and community dimensions. This perspective underscores the interconnectedness of all aspects of life.

As such, the assessment of potential adverse health, social, and economic effects of a project on Indigenous peoples must include consideration of both biophysical changes, as well as the broader social and economic environments in which people exist. Potential effects must be considered at both a community and Nation-level (e.g., political and economic shifts, and structural factors) and changes occurring at a more individual level (e.g., living, working, and material conditions).

As it relates to Indigenous nations, it is important to recognize the ways in which factors such as the quantity, quality, and access to land, and impacts of colonization intersect with determinants of health, social, and economic conditions in ways that are distinct from non-Indigenous peoples. As such, Indigenous determinants of health often emphasize the interconnections between the land and the spiritual and cultural determinants of health, social, and economic well-being.

In assessing potential effects of the Project on the health, social, and economic conditions of Indigenous peoples, the EAO has considered potential non-negligible adverse changes associated with physical and mental health, employment, the local economy, infrastructure, and community services. Where available, quantifiable information such as economics, employment standards, and census data has been used as a foundation on which conclusions are drawn.

#### **26.5.4.1 Physical and Mental Health Conditions**

The assessment of potential effects on Indigenous physical and mental health considers biophysical changes, such as air quality impacts and mental health related factors, including the ability to carry out CULRTP. Changes in air quality and land use can affect well-being and real or perceived risks associated with being on the land, contributing to cumulative health impacts. Because mental and physical health are closely linked, shifts in mental health may lead to behavioural changes that directly influence physical health outcomes.

Findings from Indigenous Well-being (Section 26.5.4.2) should be considered alongside potential impacts on Indigenous physical and mental health, with cumulative interactions discussed further in Section 26.5.4.5 (Cumulative Effects).

##### **Effect Pathways**

The following table provides a summary of how Project activities may result in potential effects to the physical and mental health conditions of Indigenous peoples, via the key effect pathways identified.

Table 89: Potential Project Effect Pathways on Health and Mental Health

| Relevant Phase(s)                    | Effect Pathway                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Effect                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Construction, Decommissioning</b> | Increased dust generation, diesel particulate matter (DPM) (e.g. excavation, heavy equipment operation, and truck deliveries) resulting in reduction in air quality within the Project Footprint                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Potential acute or chronic negative health effects, such as respiratory irritation or the exacerbation of existing respiratory or other health conditions (e.g., cardiovascular symptoms or irritation related effects)                                                                                                                                                                                                  |
| <b>Operation</b>                     | <p>Decreased air quality due to upset conditions and flaring resulting in elevated NO<sub>2</sub> and SO<sub>2</sub> emissions extending beyond the Project Footprint to areas of close proximity</p> <p>Reduced air quality during project Operation due to emissions of COPCs:</p> <ul style="list-style-type: none"> <li>• NO<sub>2</sub>, SO<sub>2</sub>, PM<sub>10</sub>, PM<sub>2.5</sub> and VOCs: Generated or emitted beyond the Project Footprint to areas of close proximity</li> <li>• DPM: From diesel-powered equipment and vehicles within the Project Footprint</li> <li>• Deposition on land and water: NO<sub>2</sub> and SO<sub>2</sub> settling onto soil and water in the LAA</li> </ul> | <p>Potential increase in the prevalence and/or severity of respiratory symptoms and conditions, resulting in elevated respiratory health impacts</p> <p>Potential adverse health effects from project related air pollutants and deposition, through direct and indirect exposure pathways that may contribute to respiratory or cardiovascular conditions and increase overall health risks for exposed populations</p> |
| <b>All Phases</b>                    | <p>Increased real and perceived changes to CULRTP and cultural heritage may contribute to mental health stress</p> <p>Increased distress related to climate change and greenhouse gas emission concerns may contribute to reduced mental well-being</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                       | <p>Decline in mental health, contributing to broader adverse health impacts</p> <p>Decline in mental health, contributing to broader adverse health impacts</p>                                                                                                                                                                                                                                                          |

#### 26.5.4.2

##### Indigenous Well-being

Indigenous well-being is holistic, encompassing physical and mental health, cultural continuity, and the ability to live in a preferred way. It is shaped by social, economic, and cultural conditions, including participation in CULRTP and tangible and intangible cultural heritage. At a community level, well-being includes considerations of the way people live, work, play, and practice their culture, and/or organize themselves. As such, the information below considers potential effects to social organization/community wellness, economic security and stability, and healthcare services.

This analysis includes a holistic perspective of Indigenous well-being, considering potential impacts to physical health, mental health, social conditions, economic conditions, Indigenous governance systems, and stewardship of lands and cultural heritage. These areas reflect the social determinants of health for Indigenous peoples and influence health and well-being by encompassing health, social, economic, political, and environmental conditions together with the ongoing impacts of colonialism.

Conclusions from sections on health, employment and the economy, and community well-being are carried forward into this analysis; however, full assessments are provided within each respective section.

##### Effect Pathways

The following table provides a summary of how Tilbury Phase 2 activities may result in potential effects to Indigenous well-being, via the key effect pathways identified.

Table 90: Potential Project Effect Pathways on Indigenous Well-being

| Relevant Phase(s)                            | Effect Pathway                                                                                                                                                                                           | Effect                                                                                                                                                                                                                                                                                                              |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Construction, Operation, and Decommissioning | Reduction in the ability to maintain and ensure health, social, and economic conditions as a result of a reduction in stewardship and governance                                                         | Declines in social conditions that reduce quality of life, overall community wellness, and cohesion<br>Reduced ability to engage in and maintain desired cultural practices, including through the degradation of mental health<br>Loss of cultural identity as a result of changes to intangible cultural heritage |
|                                              | Reduction of mental health conditions as a result of real and perceived changes to CULRTP and tangible and intangible cultural heritage resulting in reduced ability to participate in the local economy | Decreased economic stability contributing to reduced overall wellness                                                                                                                                                                                                                                               |
| Construction, Operation, and Decommissioning | Project emissions and contaminants may contribute to negative physical health outcomes and reduce individuals' capacity to engage in daily activities and participate in the local economy               | Decreased economic stability contributing to reduced overall wellness                                                                                                                                                                                                                                               |
|                                              | Project emissions and contaminants may result in adverse health effects—both acute and chronic—that could require medical intervention                                                                   | Increased burden to health infrastructure, resulting in negative health effects                                                                                                                                                                                                                                     |

#### 26.5.4.3 Malfunctions and accidents

The EAO assessed the effects of potential malfunctions and accidents and their risk ratings in [Appendix 7: Risks of Malfunction and Accidents](#). Potential risks on the health, social, and economic conditions of Indigenous peoples (Section 2(f) factors) from malfunction and accidents are outlined in Table 91 below. The federal Key Mitigation Measures for malfunctions and accidents are described in full in [Appendix 2: Key Mitigation Measures and Follow-Up Programs](#) under the IAA.

Table 91: Potential Risks in Relation to Malfunctions and Accidents on Indigenous Health Conditions

| Accident/Malfunction                                             | Health, Social or Economic Sub-component |
|------------------------------------------------------------------|------------------------------------------|
|                                                                  | Physical and Mental Health               |
| Loss of Containment of LNG without Ignition                      | High                                     |
| Loss of Containment of LNG Resulting in Fire or Explosion        | High                                     |
| Release of hazardous materials                                   | Medium                                   |
| Terrestrial Vehicle Collision                                    | High                                     |
| Accident or Malfunction Resulting in Emergency Facility Shutdown | Low                                      |

#### 26.5.4.4 GBA Plus Considerations

Tilbury Phase 2 has the potential to cause disproportionate adverse federal effects to Indigenous women, Elders, children, and 2SLGBTQQIA+ individuals with respect to well-being. The disproportionate effects, and characterization of those effects is provided below:

- Existing population health disparities, including higher rates of chronic diseases, addiction and suicide among Indigenous peoples, may lead to disproportionate health effects from Tilbury Phase 2 project activities, as these pre-existing conditions increase sensitivity due to additional environmental stressors (e.g., noise, air emissions, odors).
- Indigenous Elders and children, particularly those with existing respiratory conditions, may face heightened respiratory risks from project-related emissions or air quality changes, resulting in disproportionate effects compared to other populations.
- Indigenous women may be less likely to obtain project-related employment, as they often carry a disproportionate share of domestic and caregiving responsibilities. Barriers to equitable healthcare access, including systemic discrimination and limited availability of culturally safe services, may reduce the ability of Indigenous peoples to manage or mitigate potential project-related health impacts, leading to disproportionate effects.
- Racism, inequitable treatment, and the lasting effects of past injustices continue to impact the mental, emotional, and physical health of Indigenous peoples. These systemic factors may amplify mental health impacts related to project activities, including noise, odours, CULRTP or culturally significant sites.
- Indigenous 2SLGBTQIA+ individuals may experience reduced access to project-related employment opportunities due to societal discrimination, exclusion, and economic marginalization, leading to disproportionate socio-economic effects.

The risk of disproportionate effects is considered low if policies such as the Proponent's Human Resource Policy and Statement of Indigenous Principles guide inclusive and culturally aware hiring practices. These measures are expected to reduce potential inequalities; however health risks are expected to remain across vulnerable populations.

#### 26.5.4.5 Cumulative Effects

The assessment of potential cumulative effects in the area is described in [Appendix 6: Valued Component Assessment](#) and include consideration of past, present, and reasonably foreseeable activities. The following list identifies potential cumulative effects on the health, social, and economic conditions of Indigenous peoples:

- Emissions of COPCs can degrade air and soil quality, contributing to cumulative impacts on both acute and chronic health outcomes for Indigenous peoples.
- Alterations to soil conditions and the deposition of COPCs may lead to cumulative, long term disruptions to CULRTP. Both real and perceived constraints on CULRTP can have lasting physical and mental health implications, diminish well-being, affect cultural identity, and hinder the intergenerational transfer of cultural knowledge.
- Reduced use or enjoyment of lands, stemming from real or perceived environmental impacts, can contribute to cumulative limitations to land-based activities, cultural practices, and social connection, all of which are vital determinants of physical and mental health for Indigenous peoples. Continued or compounding disruptions to access and use of culturally important places can erode wellness, weaken cultural identity, and reduce community cohesion over time, resulting in lasting cumulative effects.
- Historic and ongoing impacts of colonization, displacement, and discrimination can reduce resilience to health-related stressors. Barriers to accessible health and mental health supports further reduce protective factors, increase population-level vulnerability, and magnify cumulative impacts on Indigenous peoples.

#### 26.5.4.6 Key Mitigation Measures and Follow Up Programs

The federal Key Mitigation Measures to reduce potential effects of Tilbury Phase 2 on the health, social and economic conditions of Indigenous peoples are described in full in [Appendix 2](#): Key Mitigation Measures and Follow-Up Programs under the IAA. This reflects the holistic nature of Indigenous well-being which requires the ability to engage in the CULRTP and participate in cultural heritage activities and adequate health, social, and economic conditions. Mitigation measures designed to support these activities, and the overall physical and mental health of Indigenous nations, will therefore support Indigenous well-being.

- Develop and implement measures to prevent or mitigate impacts to health from air quality, such as air contaminants in the airshed or deposition into waterways or soil, as well as fugitive dust emissions. Measures include a vehicle idle reduction policy, routine inspections and maintenance of engines and exhaust systems on all mobile equipment and vehicles, measures to reduce fugitive dust by applying suppressants, minimize the quantity of vented and flared gas and duration of flaring events, enclose all compressors in sealed structures during operation to reduce air emissions, and a community feedback protocol to respond to air quality complaints and implement corrective actions to reduce exposure in a timely manner.
  - Relevant effect pathways: direct and indirect exposure to air emissions and dust (Inhalation of COPCs from DPM), dust generation from earthworks and DPM, changes to CULRTP, reduced autonomy over health, social, and economic conditions of Indigenous nations.
  - Relevant non-negligible adverse effects: Acute or chronic health effects, disproportionate effects, increased stress and anxiety, disconnect from traditional lands and cultural identity.
- Develop and implement measures to prevent or mitigate impacts to the economic conditions of Indigenous peoples. Measures include promoting safe, respectful and inclusive conduct in the workplace such as developing workplace code of conduct and mandatory cross-cultural awareness training, as well as creating and enhancing opportunities for Indigenous peoples, including Indigenous women and businesses, to obtain and retain employment, procurement or contracting opportunities related to the Project.
  - Relevant effect pathways: reduction in the ability to participate in the local economy from negative physical health outcomes due to project emissions, decline in mental health from disconnection to traditional lands and cultural identity.
  - Relevant non-negligible adverse effects: decreased economic stability contributing to reduced overall wellness.

#### 26.5.4.7 Residual Effects Characterization for the Health, Social, and Economic Conditions of Indigenous Peoples

The following table provides a characterization of potential adverse federal effects to the health, social, and economic conditions of Indigenous peoples (IAA 2(f)). The characterizations use methodology described in [Appendix 3](#): Residual Effects Characterization Definitions. These characterizations take into account the application of the Federal Key Mitigation Measures and Follow-up Programs described above.

Table 92: Summary of Residual Effects Characterization for Health, Social or Economic Conditions of Indigenous Peoples<sup>126</sup>

|               | Physical and Mental Health | Well-being           |
|---------------|----------------------------|----------------------|
| Magnitude     | Low                        | Low                  |
| Duration      | Long-term                  | Medium-term          |
| Frequency     | Continuous                 | Irregular            |
| Reversibility | Partially Reversible       | Partially Reversible |
| Resilience    | Low to Moderate            | Moderate             |
| Importance    | High                       | High                 |
| Uncertainty   | High                       | Low to Moderate      |
| Risk          | Moderate                   | Low                  |

#### 26.5.4.8 EAO Conclusions on Health, Social or Economic Conditions of the Indigenous Peoples of Canada

Based on the predicted effects to the health, social, and economic conditions of Indigenous peoples, which include consideration of the proposed Key Mitigation Measures, the EAO concludes that residual and cumulative adverse effects are significant to a low extent.

## 26.6 Indigenous Knowledge Provided With Respect to the Designated Project

The IAA requires the assessment to consider Indigenous Knowledge provided about the project and identify how Indigenous Knowledge was incorporated into the assessment.<sup>127</sup> The EAO worked with IAAC and Indigenous nations, as outlined in the [Cooperation Agreement](#) and the [Project's Substitution Agreement](#), to support the collection, sharing, and protection of Indigenous Knowledge. Where available and shared by Indigenous nations, EAO described key concerns expressed by Indigenous nations in the assessment of valued components in [Appendix 6: Valued Component Assessments](#) and [Appendix 5: Detailed Indigenous Nation Assessments](#).

Throughout the assessment, the EAO sought regular feedback from Indigenous nations to ensure the proper characterization and inclusion of Indigenous Knowledge and representation of Indigenous interests and concerns. This Indigenous Knowledge was used to inform Project design, the Revised Application, and the Report.

### 26.6.1 Indigenous Knowledge in Impact Assessment

Indigenous Knowledge is a dynamic, holistic, and intergenerational system rooted in the deep, reciprocal relationships Indigenous peoples maintain with the land, waters, animals, and ecosystems. Indigenous Knowledge is often directly tied to the exercise of Aboriginal and treaty rights, including land use for hunting, fishing, gathering,

<sup>126</sup> For further detail on the residual effects characterization, see [Appendix 3: Residual Effects Characterization Definitions](#) of this Report.

See 22(1)(g) and 28(3.1) of the *Impact Assessment Act*.

ceremonial purposes, and other cultural practices. These rights are recognized and affirmed by Section 35 of the *Constitution Act, 1982* and form a legal foundation for the protection of Indigenous ways of life in Canada. Unlike Western scientific paradigms, it emphasizes interconnectedness, oral transmission, stewardship, and relationality. The IAA recognizes Indigenous Knowledge not as static or solely traditional, but as a living system that evolves in response to environmental, social, political, and economic change. By explicitly naming it "Indigenous Knowledge," the IAA affirms its contemporary relevance and central role in Indigenous identities, governance, and well-being. Respectful engagement with Indigenous Knowledge holders must begin early in project planning and continue through decision-making, with recognition that such knowledge is often inseparable from constitutionally protected Aboriginal and treaty rights related to land, culture, and sustenance.

Canada's adoption of the [United Nations Declaration on the Rights of Indigenous Peoples](#) (UN Declaration) in 2021 further reinforces the legal and ethical obligation to integrate Indigenous Knowledge into impact assessments. The UN Declaration upholds Indigenous rights to protect and sustain their cultural heritage, knowledge systems, and spiritual practices, and affirms the principle of free, prior, and informed consent (UN Declaration Articles 18, 19, 25, 32). Aligning the IAA with the UN Declaration calls for a fundamental shift in regulatory approaches—one that respects Indigenous self-determination, co-governance, and legal traditions. Incorporating Indigenous Knowledge is not only a legal requirement but a cultural and environmental necessity that enriches impact assessments through a holistic lens of cumulative impacts and intergenerational responsibility. This integration is vital for advancing reconciliation and creating more just, inclusive, and sustainable environmental decision-making processes.

### 26.6.2 Sources of Indigenous Knowledge

While the EAO has described Indigenous Knowledge made available during the assessment in this Report, the EAO recognizes that knowledge-holders are the only people who can truly define Indigenous Knowledge for their communities. Throughout the assessment process, the EAO and IAAC regularly sought feedback and confirmation from Indigenous nations on the adequacy of the characterization and consideration of Indigenous knowledge within the Report, and representation of Indigenous interests and concerns. Similarly, the proponent worked directly with Indigenous nations to meaningfully include Indigenous knowledge into the project design and Revised Application. Indigenous knowledge was provided in a variety of forms, including:

- Indigenous knowledge studies and reports (identified in [Appendix 15, Section 26.6](#));
- Indigenous engagement (including technical review); and
- Indigenous-led assessments.

Where available and shared by Indigenous nations, the EAO described key concerns expressed by Indigenous nations in the assessment of valued components in [Appendix 6](#). Examples of Indigenous knowledge that were provided to inform the assessment include, but are not limited to:

- Characterization of existing conditions and potential Project effects;
- Identification of species and sites of importance for culture, spirituality, and traditional use;
- Technical review of Project information through an Indigenous Knowledge lens;
- Detailed Indigenous Nation Assessments;
- Detailed 19(4) assessments under the *Act*;
- Recommendations for mitigation measures; and
- Review and co-development of draft potential provincial and federal conditions.

Through the Technical Advisory Committee (TAC), Indigenous peoples applied and submitted Indigenous knowledge through their technical feedback on documents. Application review comments are captured in the [Application Review Issues Tracking Table](#).

### 26.6.2.1 Indigenous Consultation

Throughout the assessment, the EAO and IAAC consulted with potentially impacted Indigenous nations.

#### Collaboration with FortisBC

FortisBC engaged with Indigenous nations to complete Indigenous Knowledge studies and other reports specific to Tilbury Phase 2. Indigenous nations, including but not limited to xʷməθkʷəyám, Quw'utsun Nation, Chawathil First Nation, S'ólh Téméxw Stewardship Alliance (STSA), Tsleil-Waututh Nation, and Tsawwassen First Nation worked directly with FortisBC to include and verify the application of the Indigenous Knowledge studies into the Revised Application. FortisBC engaged with Indigenous groups to review draft Application sections, share information, resolve issues, and provide opportunities to collect existing information related to Indigenous Knowledge.

#### Technical Advisory Committee

The TAC was established to advise the EAO on technical matters related to the assessment and to facilitate review of documents such as the Revised Application and the Report. Indigenous nations were given the opportunity to identify as a participating Indigenous nation, which includes membership in the TAC. The TAC's draft Application review comments are captured in the [Application Review Issues Tracking Table](#).

### 26.6.2.2 Indigenous-led Assessments

xʷməθkʷəyám, Quw'utsun Nation, STÁUTW First Nation, Tsawwassen First Nation, and Tsleil-Waututh Nation completed their own assessments of the impacts of the Project on their rights, interests, and values using their own methodologies. These Indigenous-led Assessments were carried out under Section 19(4) of the Act. Where Indigenous nations did not complete their own assessment, the EAO collaborated with Indigenous nations on the assessment of their Indigenous interests and incorporated Indigenous Knowledge into these assessments. Opportunities for the verification of Indigenous Knowledge was provided to ensure the adequacy of the effects assessment.

The analysis and conclusions from the Indigenous-led Assessments along with the Indigenous nations consent decisions will be included into federal the decision-making materials.

#### Assessment of Impacts of the Tilbury Phase 2 LNG Expansion Project on xʷməθkʷəyám Culture

xʷməθkʷəyám carried out an assessment with respect to the potential residual effects on xʷməθkʷəyám rights (title, fishing, harvesting, hunting, cultural continuity, and health) resulting from the Project, as well as the Tilbury Marine Jetty Project given its physical proximity. The assessment considers residual effects of the Project following the application of mitigation and offsetting measures and will inform xʷməθkʷəyám on whether to provide or withhold consent to the Project. The assessment also provides context for ongoing conversations with the proponent and the Crown regarding consultation and accommodation, as appropriate. xʷməθkʷəyám's assessment serves as a direct means of including Indigenous knowledge into the Report.

#### Quw'utsun Nation Indigenous-led Assessment of the Proposed Tilbury Phase 2 LNG Expansion Project

Quw'utsun Nation carried out an assessment with respect to the potential effects of the Project on Quw'utsun Nation and its Rights, and in accordance with Quw'utsun *Snuw'uy'ulh* (described as including but not limited to law and teachings). The assessment assesses the impacts of the Project on Quw'utsun Rights and way of life through the lens of its culture, its *snuw'uyulh*, its values, its history, and its 2016 Declaration for Reconciliation for the Lands of Tl'uqtinus.

The assessment analyzes the effects of changes to the valued components in the context of Quw'utsun Nation's vision for the future and also includes an economic quantification from the alienation of its lands of Tl'uqtinus and the ecological context for Quw'utsun Nation's relationship to and stewardship of the lands and waters near the Project site.

Quw'utsun Nation characterizes the intention of its Indigenous-led Assessment is to provide a means for them to assess effects on Quw'utsun Nation and its rights through the Nation's own laws, knowledge systems, governance, and decision-making framework.

### **STÁUTW First Nation Assessment Indigenous-led Assessment**

STÁUTW First Nation carried out an assessment with respect to Project's potential impacts on its rights in consideration of existing cumulative effects. STÁUTW's assessment describes the Nation's Douglas Treaty and Aboriginal rights in the context of the proposed Project and existing cumulative effects and includes predicted adverse residual effects and cumulative effects on its rights and interests as well as characterization criteria for these effects. STÁUTW First Nation's assessment serves as a direct means of including Indigenous Knowledge into the Report.

### **Indigenous-Led Assessment of the Effects of the Tilbury Phase 2 Expansion Project on the Rights of Tsawwassen First Nation**

Tsawwassen First Nation carried out an assessment with respect to the potential effects of the Project on its Treaty Rights as outlined in the *Tsawwassen First Nation Final Agreement*. The assessment focuses on psychosocial conditions that support meaningful rights-based practice and include the often-intangible dimensions that shape the necessary conditions for the meaningful exercise of Tsawwassen's rights and Treaty objectives. The report also identifies recommended measures to reduce residual impacts. Tsawwassen First Nation's assessment serves as a direct means of including Indigenous Knowledge into the Report.

### **Assessment of Impacts of the Tilbury Phase 2 LNG Expansion Project on səliwətał 's Rights and Interests**

Tsleil-Waututh Nation carried out an assessment to assess the Project's potential effects on its rights, title, and interests. The assessment reflects Tsleil-Waututh Nation's own assessment framework, methodologies, legal orders, and knowledge systems and uses scé-len (salmon) as the primary indicator to trace pathways of effects from the Project through environmental effects and impacts to Tsleil-Waututh rights, culture, and governance. The assessment's views, conclusions, characterization of effects, and recommended conditions reflect Tsleil-Waututh Nation's perspectives and serves as a direct means of including Indigenous Knowledge into the Report.

#### **26.6.3 EAO Analysis and Conclusion**

Indigenous Knowledge was incorporated in the assessment through a variety of sources such as Indigenous Knowledge studies and reports, direct engagement with Indigenous nations, and the submission of Indigenous-led assessments. This Indigenous Knowledge was used to inform Project design, the Revised Application, and the Report. Throughout the assessment, EAO engaged with Indigenous nations to ensure the meaningful application of Indigenous Knowledge and sought feedback and confirmation on the adequacy of the characterization of Indigenous Knowledge, and the representation of Indigenous interests and concerns.

### **26.7 Considering Environmental Obligations and Commitments in respect of Climate Change**

This section assesses whether the likely effects of the project may hinder or contribute to Canada's ability to meet its environmental obligations and its commitments in respect of climate change.<sup>128</sup>

---

See Section 22(1)(i) of the *Impact Assessment Act*.

The extent to which the likely effects of Tilbury Phase 2 contribute to Canada's ability to meet these obligations and commitments is also one of the three public interest factors to be considered in decision making under the IAA, should there be a determination that residual adverse effects within federal jurisdiction are likely to be, to some extent, significant.

The term "environmental obligations" refers to Canada's obligations in domestic and international law in relation to protecting the natural environment. In international law, legally binding international instruments (such as conventions) to which Canada is a party can create environmental obligations. "Commitments in respect of climate change" are set out in legally binding and non-binding domestic and international instruments.<sup>129</sup>

Identification of relevant obligations and commitments took into consideration the specific context of the Project, including:

- the potential emissions and discharges from the Project; and
- components of the environment, including potential effects to these components.

Canada's environmental obligations, including those related to species at risk and migratory birds, are discussed in [Appendix 6, Section 17.6](#), while Canada's climate change commitments are discussed in [Appendix 15, Section 26.7](#). The Project's contributions to sustainability with respect to these factors are assessed in [Appendix 15, Section 26.8](#); Considering the Extent to which the Project's Likely Effects Contribute to Sustainability. The assessment considered all Indigenous Knowledge provided in relation to these factors as described in [Appendix 15, Section 26.6](#) — Indigenous Knowledge Provided with Respect to the Designated Project.

### 26.7.1 Environmental Obligations

The following environmental obligations were considered relevant to the project, and therefore were identified in the Application Information Requirements:

Table 93: Environmental Obligations identified in the Application Information Requirements, applicable to the Project

| Environmental obligation                                                                                                                                                                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Convention on Biological Diversity</i> and Canada's supporting national frameworks: Canadian Biodiversity Strategy, Canada's Biodiversity Outcomes Framework and current Biodiversity Goals and Targets for Canada | <p>The <i>Convention on Biological Diversity</i> is an international, legally binding treaty with three main goals: Conservation of biodiversity; sustainable use of the components of biological diversity; and fair and equitable sharing of the benefits arising from the utilization of genetic resources.</p> <p>It encourages actions that will lead to a sustainable future, and covers biodiversity at all levels: ecosystems, species, and genetic resources.</p> <p><i>This Environmental Obligation is applicable to the species at risk and migratory birds identified during the assessment, and to the consideration of Indigenous Knowledge and the application of Gender Based Analysis Plus.</i></p>                              |
| <i>Species at Risk Act</i> (SARA)                                                                                                                                                                                     | <p>SARA provides for the legal protection of wildlife species to prevent them from becoming extinct and to secure the necessary actions for their recovery. SARA requires that an assessment identifies the adverse effects of the project on all species listed in Schedule 1 or their critical habitat and ensures that measures are taken to avoid or lessen the effects on the listed species and its critical habitat and to monitor the effects. The measures must be taken in a way that is consistent with applicable recovery strategies and action plans.</p> <p>SARA is a result of the implementation of the Canadian Biodiversity Strategy, which is in response to the United Nations <i>Convention on Biological Diversity</i>.</p> |

<sup>129</sup> For more information, see [Policy Context: Considering Environmental Obligations and Commitments in Respect of Climate Change under the Impact Assessment Act](#).

| Environmental obligation                                                                                                                                                                                                                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                                                                                                                                                                                                                                | <i>This Environmental Obligation is applicable to the species at risk identified during the assessment.</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Recovery Strategies and Action Plans developed under the <i>Species at Risk Act</i> for all species at risk potentially affected by the Project                                                                                                                                | A Recovery Strategy is a planning document that identifies what needs to be done to stop or reverse the decline of a species. An Action Plan identifies the measures to take to implement the Recovery Strategy for a threatened, endangered or extirpated species.<br><br><i>This Environmental Obligation is applicable to the species at risk identified during the assessment.</i>                                                                                                                                                                                                                                                                         |
| <i>Convention for the Protection of Migratory Birds in the United States and Canada</i> , as implemented in part through the <i>Migratory Birds Convention Act, 1994</i> , and supporting guidance on conservation objectives arising from Bird Conservation Region Strategies | This convention is an international agreement with the objective to protect migratory birds, their eggs, and their nests. The requirements of this convention have legislated components embedded in the <i>Migratory Birds Convention Act, 1994</i> , Migratory Birds Regulations and Migratory Bird Sanctuary Regulations.<br><br>Elements of this convention are also implemented via the North American Waterfowl Management Plan and the <i>Declaration of Intent for the Conservation of North American Birds and their Habitat</i> .<br><br><i>This Environmental Obligation is applicable to the migratory birds identified during the assessment.</i> |

### 26.7.2 Considerations for Migratory Birds

Migratory birds identified during the assessment are protected or supported under *the Convention on Biological Diversity*, the *Migratory Birds Convention Act, 1994*, SARA, and recovery strategies and action plans.

Numerous species of migratory birds are known or likely to occur within the area. Of those identified as likely to occur in the area of Tilbury Phase 2, none have SARA-defined critical habitat in the LAA or RAA. Effects to migratory birds and associated Key Mitigation Measures are discussed in [Appendix 6, Section 17.6](#). The adverse effects of Tilbury Phase 2 on migratory birds are anticipated to be not significant following the application of mitigation measures, recovery strategies and action plans. It is therefore expected that the likely effects of Tilbury Phase 2 will not contribute to Canada's ability to meet its obligations under the *Convention for the Protection of Migratory Birds in the United States and Canada*.

### 26.7.3 Considerations under the *Species at Risk Act*

Identification, mitigation and monitoring of effects to federally listed species at risk potentially affected by projects undergoing impact assessments is required under Section 79 of SARA. The federal species at risk that are likely to occur within the LAA and their status are listed below.

Tilbury Phase 2 is located near marine habitat via the Fraser River estuary; however, no impacts are expected to marine environments or the species that reside in them (e.g. cliff swallow), as a result of FortisBC's measures to avoid waterborne deliveries through the materials offloading facility (MOF) and additional mitigations through avoidance and minimization of potential discharges and spills. No SARA-defined critical habitat has been identified in the LAA or RAA. No listed plant species at risk were observed in the area.

**Special concern species:** Great blue heron, Horned grebe, Western grebe, Red-legged frog, Western toad.

**Threatened species:** Barn owl, Barn swallow (Special Concern – COSEWIC), Western painted turtle (Pacific Coast population).

**Endangered species:** Little brown myotis, Pacific water shrew.

Recovery strategies have been prepared for little brown myotis, Pacific water shrew, barn owl, and western painted turtle. The Project Footprint falls outside the identified critical habitat of the Little brown myotis, Pacific water shrew, and Western painted turtle, which have a low to moderate potential to occur within the LAA.

Two amphibians of special concern, the Red-legged frog and the Western toad, are predicted to have a low potential of occurrence. There is federally designated Critical Habitat for Pacific water shrew within 1.2 kilometres southeast of the project site near the Tilbury Slough, but outside of the Wildlife and Wildlife Habitat RAA, and its suitability is not optimal due to the lack of riparian forest and proximity to industrial development and resulting lower water quality. The Project Footprint and LAA overlaps with Critical Habitat for Barn owl; however, FortisBC indicated Barn owl are moderately likely to occur within the LAA, noting that the area was not suitable to support foraging, nesting, and roosting habitat.

Cheam Nation requested further information about the fish foraging species for the Great blue heron. Quw'utsun Nation and x̱m̱əθḵw̱əy̱əm (Musqueam Indian Band) requested more detailed assessments for species at risk other than birds, such as bats or amphibians, including the types of species-specific surveys, locations, effort/intensity, and timing. The proponent provided further information in the Revised Application regarding the suitability of habitat for these species and clarification of the methods used during field surveys, with additional mitigation measures related to controlled lighting.

The assessment of potential adverse effects to wildlife and associated federal Key Mitigation Measures are discussed in detail in [Appendix 6](#) Wildlife and Wildlife Habitat and [Appendix 2](#). The potential effects assessed include changes in habitat, changes in movement (not carried forward), and changes in mortality risk. Following the application of the identified Key Mitigation Measures and provincial mechanisms including conditions, residual effects to wildlife overall were characterized as negligible to low magnitude and reversible. The EAO is satisfied that the Project would not have significant adverse residual or significant cumulative effects on wildlife and species at risk habitat.

In consideration of the above, it is expected that the likely effects of Tilbury Phase 2 will not contribute to Canada's ability to meet its obligations under SARA.

#### 26.7.4 Canada's Climate Change Commitments

The EAO has assessed the effects of the project's greenhouse gas (GHG) emissions in [Appendix 12](#) – Greenhouse Gas Emissions. This section uses that analysis to inform the assessment of the contribution of the project's likely effects on Canada's ability to meet Canada's current climate change commitments relevant to the project. A list of these commitments is provided in Table 94. The EAO is of the view that the likely effects would not contribute to Canada's ability to meet its commitments in respect of climate change.

Table 94: Canada's Current Climate Change Commitments Relevant to The Project

| Climate change commitment                                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Canada's 2030 Emissions Reduction Plan</a>                                             | The target associated with this Plan was established under the <i>Canadian Net Zero Emissions Accountability Act</i> (described below). Under this plan, Canada must reduce its emissions by 40 to 45 percent of 2005 levels by 2030.<br><br>The current emissions target for 2030 is 443,000,000 tonnes CO <sub>2</sub> e (representing a 40 percent reduction from the 2005 baseline for Canada's GHG emissions). |
| <a href="#">Canadian Net Zero Emissions Accountability Act</a>                                     | This legislated commitment requires five-year emissions targets to demonstrate how Canada will reach its longer-term net-zero goal by 2050.                                                                                                                                                                                                                                                                         |
| <a href="#">Draft guidance for best-in-class GHG emissions performance by oil and gas projects</a> | Current Government of Canada guidance to proponents of new oil and gas projects subject to the IAA, enables them to demonstrate that they will have "best-in-class" low-emissions performance.                                                                                                                                                                                                                      |
| <a href="#">Strategic Assessment of Climate Change (SACC)</a>                                      | The SACC outlines the GHG emissions and climate change information requirements that proponents should provide, with details on calculation protocols provided in the supporting technical guidance documents. The SACC applies to projects assessed under the IAA.                                                                                                                                                 |

#### 26.7.4.1 Canada's 2030 Emissions Reduction Plan

The project would be in operations in 2030, and the provincial Net-Zero New Industry Policy (NZNIP) requires LNG facilities to plan how they will achieve net-zero GHG emissions by 2030. To comply with this policy, the proponent has committed to using renewable fuels for combustion and offsetting the remaining GHG emissions from sources including entrained CO<sub>2</sub>, fugitive emissions and acquired energy use. With these measures in place, the project is expected to reach net-zero GHG emissions in 2030. By meeting the provincial NZNIP by 2030, the project would align with Canada's commitment outlined in the 2030 Emissions Reduction Plan.

#### 26.7.4.2 Canadian Net Zero Emissions Accountability Act

The proponent's net-zero plan prioritizes reducing direct GHG emissions, as the proponent anticipates that the indirect GHG emissions from the use of electricity would decrease as the grid becomes net zero. As noted above, the proponent has committed to reducing and offsetting GHG emissions to achieve net-zero beginning in 2030. As such, the project is expected to align with Canada's commitment outlined in the *Canadian Net Zero Emissions Accountability Act*.

#### 26.7.4.3 ECCC's Supplemental Analysis

Section 6 of the SACC states that IAAC or the lifecycle regulator, with the support of expert federal authorities, will provide supplemental analysis on the project's net GHG emissions in the context of Canada's emissions targets and forecasts. This analysis for the Tilbury Phase 2 LNG Expansion Project prepared by ECCC fulfills this requirement.

#### Greenhouse Gas Emissions

##### *Greenhouse Gas Emissions from the Project*

The proponent estimated the maximum annual GHG emissions for each phase of the project prior to committed mitigation measures in [Appendix N](#) GHG Technical Data Report (TDR). The proponent states in Section 6 of the GHG Net- Zero Plan TDR that the proposed Project is predicted to have a GHG emission intensity of 0.072 t CO<sub>2</sub>e / t LNG, with a possibility to be as low as 0.011 t CO<sub>2</sub>e / t LNG using 100% renewable natural gas. Table 8.5-2 of the Application includes a comparison against seven other Liquid Natural Gas (LNG) facilities, in British Columbia (BC) and outside of Canada. The comparison shows that the proposed Project's projected emission intensity is lower than all the projects in the Table, except for Woodfibre LNG which is in its preconstruction phase in BC with a projected emission intensity of 0.04 t CO<sub>2</sub>e / t LNG. The proponent also projected that the proposed Project's emission intensity will be lower than various LNG benchmarks including the Global benchmark and the Top 5 percent global benchmark.

[Appendix N](#) of the Revised Application states that the proposed Project will not have quantifiable impacts to carbon sinks from land-use changes. The Project site will have similar use without any significant impacts on vegetation both pre- and post-Project, as it is a brownfield site.

##### *Upstream Emissions Related to the Project*

[Appendix M](#) of the Revised Application discusses the upstream emissions related to the proposed Project. The proponent states that the current policy scenario predicts that upstream production will not increase with the addition of LNG export facilities, referring to the Canada Energy Regulator's prediction of a future baseline scenario where global LNG demand will be fed, in part, by Canadian LNG exports.

The proponent presents two scenarios: the Conservative Scenario where upstream emissions are calculated based on maximum annual LNG production and annual emission intensities through 2030 and remaining constant thereafter; and the Net-Zero Scenario which is the same until 2030 but assumes Canada's target to be net-zero by 2050 in a linear decline after 2030.

Table 3 of Appendix M shows the annual upstream emissions ranging between 792,000 t CO<sub>2</sub>e and 818,000 t CO<sub>2</sub>e for the Conservative Scenario, and between 0 t CO<sub>2</sub>e and 818,000 t CO<sub>2</sub>e for the Net-Zero Scenario.

In the qualitative analysis of upstream emissions, the proponent compares the Project Case with a No Project Case.

- The Project Case assumes that all LNG produced will be for export, and renewable natural gas will not be used for exports. However, the proponent states that more than 40 percent of the LNG produced by the Project could be used to meet local demand, especially with the growing local demand for LNG in heavy duty vehicles, according to the demand projected by the Vancouver Fraser Port Authority.
- The No Project Case may result in local and global demand being met by an increase in operations at other facilities. Globally, the proponent states that due to the lack of feed gas to Tilbury from other jurisdictions, it is unlikely that upstream production and emissions would shift to other jurisdictions. Section 3.5.2 of Appendix M states that global demand for LNG is expected to continue to exceed global supply, and the proposed Project's contribution to global supply would be small and unlikely to impact the balance between global supply and demand noticeably.

### *ECCC's Observations*

The proponent has considered the anticipated Project activities that are within the scope of the Impact Assessment that have potential for GHG emissions. The proponent's estimated GHG emissions are adequately calculated and are supported by sufficient information provided in the Application and its supporting appendices. While the Application depicts the *maximum* possible emissions in the range presented by the proponent, the actual GHG emissions are likely lower due to the proponent's commitment to switching to 100 percent renewable fuel for combustion in the operation phase.

Table 8.5-2 of the Application shows that the proposed Project has one of the lowest emission intensities of the domestic and global LNG facilities listed in the Table. If the proposed Project achieves the stated operational GHG emission intensity of 0.072 t CO<sub>2</sub>e / t LNG, or 0.011 t CO<sub>2</sub>e / t LNG using 100% renewable natural gas, ECCC agrees that it would have one of the lowest GHG emission intensity in the sector.

The proponent has adequately presented the quantitative and qualitative analyses of upstream emissions related to the proposed Project. ECCC agrees with the proponent's conclusion that upstream GHG emissions could be fully or partially incremental domestically, but if the LNG demand was to be met by another existing project, it is likely to result in a net global increase in emissions, as the Project is expected to produce one of the least GHG-intensive LNG in the world. ECCC also agrees that if the Project's LNG is used to replace higher emitting fuels such as the ones currently used for heavy duty vehicles or marine vessels, it may contribute to a net decrease in emissions domestically or globally.

### *Net-Zero Plan*

#### *Proponent's Net-Zero Plan*

The proponent's mitigation measures are listed in the GHG Net-Zero Plan TDR ([Appendix O](#) of the Revised Application). The proponent committed to achieving net emissions reductions through the best available technologies and best environmental practices (BAT/BEP) and compliance with federal and provincial regulations, aiming to contribute to Canada's economic development positively and to support Canada in meeting its environmental obligations and climate change commitments. The proponent committed to achieving net-zero by 2030, in line with NZNIP, such that the Project is net-zero at the start of steady-state operations. The proponent states that the proposed Project represents best-in-class emission intensity due to the use of electrically driven compression.

The adoption of additional mitigation measures over the life of the proposed Project will ensure it remains best-in-class and support Canada's goal of net-zero by 2050. The proponent states that the proposed Project is expected to reduce emissions within Canada's largest port from bunkering, and globally by displacing the use of higher emitting fuels.

The Best Available Technology Conclusions of [Appendix O](#) of the *Revised Application* lists the following mitigation technologies for further consideration during the subsequent phases of design:

- Electric drive gas compression
- Gas fuel-fired hot oil heater
- Direct-fire thermal oxidizer
- Ultra-low NO<sub>x</sub> burners
- Totally enclosed ground flare

Appendix O also lists potential additional mitigation measures including:

- Electrification
- FortisBC Clean Growth Pathway
  - Low and zero-carbon vehicles and infrastructure
  - Continued growth of renewable and low-carbon gas
  - Increasing investment in conservation and energy efficiency programs
- Renewable Fuels
- Waste heat utilization
- Upstream removal of entrained CO<sub>2</sub> in process feed
- Offset measures, including carbon capture, utilization, and storage technologies (CCUS) and offset credits

The proponent stated that regardless of which technology is adopted, Tilbury LNG will continue to use 100 percent renewable natural gas for all combustion needs for the operation phase of the proposed Project. The proponent discussed the procurement strategies for renewable natural gas, as well as offset credits for residual GHG emissions from entrained CO<sub>2</sub>, fugitive releases, and electricity use.

#### *ECCC's Observations*

The proponent appropriately considered GHG mitigation technologies and practices, following the BAT/BEP Determination process outlined in the SACC Technical Guide. The proponent's commitment to implement the proposed BAT/BEP measures will contribute to the proposed Project being a comparatively low GHG-emitting LNG facility. With the above information, as well as the information provided by the proponent as a part of the review process, the Net-Zero Plan is deemed to be credible and aligns with the SACC Technical Guide requirements of section 3.5.2. The planned mitigation measures are expected to help the facility maintain its status as a producer of one of the least GHG-intensive LNG in the world, through the continuous improvement process of applying additional mitigation measures as they become feasible.

#### *Climate Change Resilience*

The proponent presented the site-level and regional climate trends for the 2050 time horizon, using the most conservative scenario. The Climate Change Resilience Assessment (CCRA) ([Appendix G](#) of the *Revised Application*) evaluated risks including heat waves, extreme precipitation, unusual wind, and flooding, focusing on impacts to operations, infrastructure and worker safety; Table 8.2-1 of the *Revised Application* shows the adaptation measures

for major risks. The resilience plan emphasizes monitoring, iterative review, and the ability to revise management strategies as climate projections or operational experience change.

#### *ECCC's Observations*

The CCRA aligns with SACC requirements and with best practices as it takes a site-specific, risk-based, and adaptive approach that supports long-term resilience.

#### **Conclusion**

The proponent followed the SACC approach, provided an Upstream Assessment, a Net-Zero Plan and a Climate Change Resilience Assessment, and has sufficiently considered various options to mitigate GHG emissions and risk of climate change in each phase of the proposed Project.

Given that the proponent has committed to achieving net emissions reductions through BAT/BEP, has committed to net-zero emissions by 2030 under BC's NZNIP, and has committed to comply with federal and provincial regulations and permits, ECCC is of the view that the proposed Project will be a low GHG-emitting LNG facility, and is likely to achieve net-zero by 2050, provided it carries out its commitments.

#### **26.7.4.4 Analysis of Uncertainty in the GHG emissions Information:**

The proponent approached the calculation of GHG emissions conservatively, based on the Project's maximum capacity and design flow gas compositions. The proponent identified potential uncertainties in the emissions quantification as the SACC Technical Guide does not include emission factors for LNG liquefaction. In terms of their net-zero plan, the Proponent noted that the procurement of offset credits is subject to considerable uncertainty, given the evolving nature of offset markets, regulatory frameworks, and proposed project parameters.

#### **26.7.5 EAO Analysis and Conclusions**

Based on the analysis of the considerations listed above and the adverse effects of the Project on terrestrial and aquatic environments that may not be fully mitigated, the EAO is of the view that the project would not contribute to Canada's ability to meet its environmental obligations.

Given the Project's Net Zero Plan and considerations above, the Project is expected to align with Canada's commitments in respect of climate change by 2030, when emissions reduction strategies committed to by the proponent are implemented. However, given the project's GHG emissions, the EAO is of the view that the likely effects would not contribute to Canada's ability to meet its commitments in respect of climate change.

### **26.8 Considering the Extent to which the Project's Likely Effects Contribute to Sustainability**

#### **26.8.1 Regulatory Context**

This section assesses the extent to which Tilbury Phase 2's likely effects contribute to sustainability.<sup>21</sup> Under the IAA, sustainability is defined as "the ability to protect the environment, contribute to the social and economic well-being of the people of Canada and preserve their health in a manner that benefits present and future generations."

As per Section 22(1)(h) of the IAA, the assessment must take into account the extent to which the Project contributes to sustainability. The extent to which the likely effects of the Project contribute to sustainability is also one of the three public interest factors considered in decision-making.

The sustainability analysis weighs the balance of positive effects and adverse federal effects. If a project's effects are likely to result in net positive contributions to sustainability, that means the Project is likely to result in positive and lasting equitable effects for present and future generations, and that positive effects include improvements over adverse environmental and socio-economic conditions or trends.

If a project's effects are likely to result in net negative contributions to sustainability (net sustainability losses rather than sustainability gains), that means the project's adverse federal effects or risk of irreversible harm outweigh a project's lasting contributions to sustainability.

### 26.8.2 Approach to determining the extent to which project effects contribute to sustainability

The approach characterizes VC effects and interactions with respect to health, social, and economic well-being for present and future generations, forming the basis for conclusions on the extent to which the Project's likely effects contribute to sustainability (Net Positive or Net Negative). This includes recognizing the precautionary principle to ensure that potential effects are examined carefully, and that uncertainty be clearly acknowledged. Finally, this incorporates a GBA Plus lens to understand how impacts may differ across populations and generations, consistent with a GBA Plus approach.

Key steps of the sustainability analysis are outlined below:

1. Identify the VCs pertinent to sustainability, establish spatial and temporal boundaries.
2. Consider interconnections between the VCs within the context of the human-ecological system associated with the Project.
3. Consider the benefits and costs to the environmental, health, social and economic well-being of present and future generations.

### 26.8.3 Valued Components, Spatial and Temporal Boundaries

VCs included in the sustainability analysis were selected based on their importance to long-term community well-being. The EAO considered Indigenous Knowledge and the values, concerns, and perceptions of risk described by Indigenous peoples, the public, and other Knowledge Holders affected by Tilbury Phase 2. The EAO also considered whether the VCs would experience long-term effects, interactions with other VCs, and the Project's probable effects.

The following VCs were selected based on the considerations above:

- **Air Quality:** Air quality is vital to long-term community well-being as it supports the health, cultural practices, and environmental conditions that Indigenous peoples rely on to sustain their relationships with the long-term community well-being.
- **Employment and Economy:** The Project could affect the economic well-being of Indigenous peoples, which must be considered under the IAA. Economic opportunities and impacts are important for long-term community sustainability.
- **Current Use of Lands and Resources for Traditional Purposes:** The Project may affect present and future land based activities, including tangible values such as plant harvesting and intangible values such as connection to place, knowledge sharing, and community use, as these practices rely on access to sustainable lands and resources. Changes to conditions or availability can influence cultural continuity and overall well-being.
- **Human Health, Human and Community Well-being:** The Project may affect health through changes in air, soil, and sensory conditions, which are closely linked to physical health, mental health, and overall well-being. Indigenous peoples in the LAA and RAA have identified health and well-being as key concerns for their communities and others.

### Spatial Boundaries

For the Project, spatial assessment boundaries for VCs are defined as:

- For social determinants of health (e.g. community well-being, employment, and economy), the spatial boundary includes the LAA and RAA boundaries of Metro Vancouver; 21 municipalities, First Nation reserves, and Tsawwassen First Nation Treaty lands.
- For environmental determinants of health, the spatial boundary includes the LAA boundaries of the VCs that may affect Human Health such as Air Quality, Acoustic, Soil<sup>130</sup>, Country Foods<sup>131</sup>, Surface Water and Groundwater Quality.
- The spatial boundary for environmental determinants of health also includes RAA boundaries for VCs that may have indirect or cumulative impacts to human health from the Project including Air Quality, Acoustic, Soil, Country Foods<sup>125</sup><sup>125</sup>, Surface Water and Groundwater Quality.

### Temporal Boundaries

To account for effects caused by the Project, and to recognize that impacts to individuals can persist after Project activities cease, the temporal boundary for the sustainability analysis was set at 70-80 years. This timeframe includes all the Project phases (Construction 3-6 years, Operation 40+ years, Decommissioning 2 years), plus a 25-year period that reflects one generation of time following the ceasing of activities relating to the Project.

From a sustainability perspective, some project impacts may continue even after activities end, particularly those affecting Indigenous Knowledge, cultural practices, health, and community well-being. While not all valued components will be affected long-term, some impacts could persist across generations. This perspective is consistent with the Seventh Generation Principle, which encourages consideration of potential impacts extending seven generations into the future.

## 26.8.4 Human–Ecological System Interconnections of Valued Components

This section describes the interconnections among VCs within the human ecological system associated with the Project. The analysis examines how changes to system components, functions, and linkages may influence environmental, health, social, and economic conditions, recognizing that these effects emerge through a series of interconnected interactions within the ecological system of the Project Footprint, LAA and RAA respectively.

### *Summary of Assessment*

The Project is located within the existing facility on Tilbury Island in Delta, B.C., and is linked to the health and well-being of Indigenous nations within the Project's RAA and LAA. These areas are urban environments characterized by strong connections between communities and nearby ecosystems, reflecting a complex and dynamic relationship in which people and the environment shape and rely on one another for long-term sustainability (see Figure 99 and 98 above). The following analysis considered the ways in which the Project's activities may influence interconnected systems, including both adverse and positive effects.

<sup>130</sup> The temporal boundaries for Soil include the Construction (3-6 years), Operation (40 years), and Decommissioning (2 years) phases of the Project.

The LAA for Country Foods Quality is the combined LAAs for the Vegetation, Fish and Fish Habitat, and Wildlife and Wildlife Habitat VCs.

Project activities that may adversely impact health through air quality, sensory and soil conditions:

- COPCs air emissions, including NO<sub>2</sub>, SO<sub>2</sub>, PM<sub>10</sub>, PM<sub>2.5</sub>, and VOCs, that may disperse beyond the Project Footprint. Additional decreases in air quality may result from upset conditions or flaring events, which can generate elevated NO<sub>2</sub> and SO<sub>2</sub> air emissions beyond the Project Footprint.
- Deposition of NO<sub>2</sub> and SO<sub>2</sub> onto soils and surface waters within the LAA may also occur.
- Sensory disturbances, including strong odours and visible haze, may be experienced outside of the Project Footprint.

These disruptions may contribute to broader adverse effects such as reduced real or perceived access to areas traditionally used for cultural practices and to sites of cultural significance. Over time, intersecting pressures may affect cultural continuity, land use, mental health, and overall well-being across generations.

In parallel, the Project presents opportunities for socio-economic advancement, with activities that may enhance community well-being and economic resilience through:

- Project related employment may increase household income, with Indigenous people potentially benefiting from both employment and procurement opportunities.
- Training and workforce development associated with the Project may enhance long term skill development and support economic independence.
- Benefit sharing agreements, where they exist, may provide stable and meaningful sources of income for Indigenous nations, and help to support community priorities, strengthen local programs and services, and contribute to long-term economic resilience.

### *Sustainability Analysis*

This analysis examines the Project's anticipated environmental, health, socio-cultural, and socioeconomic effects, with particular attention to how these interactions may influence well-being for different populations.

Overall, the Project is expected to result in medium-term environmental, socio-cultural and health interactions, with potential changes to air quality, including associated shifts in odour, visibility, and soil quality.

Potential health effects may cause respiratory and cardiovascular irritation and exacerbate chronic health conditions. These potential health implications may pose greater risks for vulnerable groups, including children, Elders, people with pre-existing conditions and Indigenous peoples who have a higher prevalence of respiratory illness.

Indigenous peoples may face disproportionate and cumulative health impacts linked to increased exposure from land-based activities and historic and systemic inequities. Factors such as reduced healthcare access and historical trauma can lower resilience to new stressors, while restricted access to mental health supports may compound vulnerability and heighten anxiety, distress, and perceived environmental risks.

Project activities may also contribute to mental distress, particularly for Indigenous people resulting from real or perceived loss of CULRTP, undermined confidence in CULRTP, weakened connection to culturally significant places and increase stress associated with environmental change.

Positive socioeconomic effects may arise through employment, income stability, skill development, and more equitable opportunities, particularly where hiring and procurement practices prioritize Indigenous workers and local businesses.

The extent of these benefits will depend on the effectiveness of Proponent's Human Resource Policy and Statement of Indigenous Principles, inclusive and culturally aware hiring practices, and broader regional affordability pressures. However, economic benefits may be unevenly distributed. Women, Indigenous people, and others facing systemic income inequities may have reduced access to Project-related opportunities, potentially reinforcing existing disparities.

Employment can enhance household income, reduce financial stress, and support social well-being, contributing to long-term socioeconomic stability. Benefit sharing agreements with Indigenous nations may further strengthen community conditions, health, and cohesion. Training and capacity building opportunities can also support long-term skills development and economic independence, creating pathways for future generations.

Considering these interactions, the Project could result in certain socioeconomic benefits, such as additional employment and modest income growth. The Project may also result in uncertain health impacts, including those associated with air quality, sensory and soil conditions. Federal Key Mitigation Measures may reduce adverse physical and mental health effects and shorten their duration; however, they may not fully eliminate these negative impacts over the long term.

## 26.8.5 Environmental, health, social and economic well-being of present and future generations

This section considers how the Project's positive outcomes and potential adverse federal effects on environmental, health, social, and economic well-being may change over time, considering not only the immediate impacts but also the implications for future generations beyond the Project's operational lifecycle.

### *Summary of Assessment*

Indigenous peoples have identified a range of interconnected elements as essential to their well-being, emphasizing the deep relationship between people, the environment, cultural practices, and resource use.

Although Project activities are confined to the existing Tilbury Plant site, the assessment also reflects Indigenous nations' perspectives on future use of culturally important lands and resources within the RAA and LAA, specifically those of the x<sup>w</sup>məθk<sup>w</sup>əyám, Quw'utsun Nation, Tsleil-Waututh Nation, and Ts'uubaa-asatx.

Table 95: Positive and adverse effects on the well-being of Indigenous Peoples

| Positive effects on the well-being of Indigenous Peoples and local communities <sup>1</sup>                                                                                                                                                                                                                                                                                                                                                                            | Adverse effects on the well-being of Indigenous Peoples and local communities <sup>2</sup> :                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> <li>Economic benefits may include increased spending at local businesses, Indigenous procurement opportunities, and additional Indigenous government revenues where benefit sharing agreements are in place.</li> <li>Potential positive outcomes for Indigenous nations include employment and income gains, education and skills training, and more inclusive hiring for Indigenous and other underrepresented groups.</li> </ul> | <ul style="list-style-type: none"> <li>Acute or chronic health effects, including respiratory irritation and the exacerbation of existing conditions, may disproportionately affect Indigenous peoples due to higher prevalence of respiratory illness and elevated health vulnerabilities. These impacts may also disrupt cultural practices and intergenerational knowledge transfer, with Elders being particularly affected.</li> <li>Project activities may disrupt cultural practices and knowledge transfer when perceived or actual health risks, along with changes in air quality, sensory conditions, and soil quality, interfere with participation in CULRTP and ties to culturally significant places.</li> <li>The Project may contribute to adverse mental health outcomes for Indigenous peoples—now and in future generations—through employment related stress and concerns about climate change, with barriers to healthcare exacerbating vulnerability and increasing anxiety, distress, and potential substance misuse risks.</li> </ul> |

### *Sustainability Analysis*

The Project may have implications for the well-being of current and future generations of Indigenous peoples through its interaction with existing health vulnerabilities, mental health pressures, and factors that affect cultural practices and the intergenerational transfer of knowledge.

Indigenous nations may have constrained opportunities to meaningfully engage in CULRTP, both current and in future, as a result of Project activities situated within an area already heavily industrialized and altered by past development. Environmental changes and perceived contamination risks may reduce participation in cultural and land-based activities, creating challenges for cultural continuity, resilience, and traditional knowledge practices.

Conversely, the Project may enhance the long-term well-being of Indigenous peoples by providing economic benefits, expanding Indigenous procurement, offering inclusive employment and training opportunities and benefit sharing agreements that support household stability and community prosperity across generations. However, access to these opportunities may vary, especially for vulnerable groups, which could affect how broadly benefits are realized. Employment related pressures may also affect mental health and may extend into future generations.

Overall, the Project presents potential benefits alongside possible health and environmental impacts. With the application of key mitigation measures, adverse effects are expected to be limited although some uncertainty remains, making the effective implementation of these measures important.

#### **26.8.6 Proponent Analysis and Conclusion**

FortisBC states that the Project would deliver meaningful benefits, including a more resilient energy system capable of supplying a low carbon energy source, improved affordability, and enhancements to community infrastructure. As outlined in Figure 15.21 and subsections 15.2.2 and 15.2.3 of the Revised Application, FortisBC notes that these benefits extend beyond low carbon energy supply, contributing to climate resilience, community well-being, and positive economic outcomes through employment, skills training, contracting opportunities, and broader regional prosperity.

#### **26.8.7 Key Mitigation Measures and Follow Up Programs**

The sustainability analysis considered federal Key Mitigation Measures and how they address effects to valued components that inform the sustainability principles. The federal Key Mitigation Measures are described in full in Appendix 2: Key Mitigation Measures and Follow Up Program Under the IAA.

#### **26.8.8 EAO Conclusion**

The summary of assessment and the sustainability analysis above were used to inform the determination, taking into account the balance between positive and adverse federal effects, the interconnections among valued components within the human–ecological system, and how effects on the environmental, health, social, and economic well-being of Indigenous peoples may change over time. These are as follows:

- **Positive effects on current and future generations from increased economic opportunities:** The Project is expected to enhance economic well-being through increased employment, income stability, procurement opportunities, and benefit sharing (where existing), contributing to stronger and more resilient Indigenous communities. It may also support long-term skills development, reduce financial stress, and promote intergenerational economic independence, although outcomes will depend on equitable access to opportunities.

- **Adverse federal effects on health and well-being conditions of Indigenous people:** Project emissions (e.g., NO<sub>2</sub>, SO<sub>2</sub>, PM, VOCs), odours, and potential soil deposition may degrade environmental quality and increase risks of respiratory and cardiovascular illness, disproportionately affecting Indigenous peoples due to cumulative exposures and existing vulnerabilities. Sensory disturbances, limited access to culturally significant lands, and perceived climate and environmental risks may contribute to stress, anxiety, and adverse mental health outcomes, potentially undermining cultural continuity, traditional land use, and the intergenerational transfer of knowledge. These impacts may be further intensified by systemic barriers to healthcare, exacerbating overall health and well-being effects, particularly for vulnerable groups.

Overall, the Project is unlikely to make meaningful, long-term contributions to the sustainability of human–ecological systems for present or future generations. While it may generate some economic benefits that support community well-being and resilience, these benefits are expected to be limited and dependent on the effectiveness of future actions to enhance positive outcomes and mitigate adverse federal effects, including cumulative impacts on the health and social conditions of Indigenous peoples. While acknowledged that potential adverse federal effects, particularly impacts on health, social conditions, and cultural continuity, may also pose ongoing risks, some uncertainty remains about how these impacts may manifest over time. Taking this into consideration, mitigation measures will be required to effectively manage adverse federal effects and enhance positive contributions to sustainability.

Based on conclusions reached through the application of the sustainability analysis, the EAO determined that Tilbury Phase 2's likely effects would contribute to sustainability to a low extent. The EAO is therefore of the view that Tilbury Phase 2's likely effects would result in net positive contributions to sustainability.

## 26.9 Federal Crown's Duty to Consult and Tsawwassen Treaty Obligations

This section assesses the extent to which the substituted assessment process supports Canada's ability to meet its constitutional obligations to Indigenous peoples, including the duty to consult and treaty obligations under the *Tsawwassen First Nation Final Agreement*. If there is a determination that adverse federal effects are likely to be significant, the effects on Indigenous peoples will be considered as a public interest factor in decision making by Canada.<sup>132</sup> This section draws on the information provided by or about potentially affected Indigenous nations in various sections of the Report, including:

- [Section 2](#): Regional and Regulatory Context;
- [Section 6](#): Indigenous Nation Engagement and Summary of Effects;
- [Section 12](#): Notifications of Consent or Lack of Consent by Participating Indigenous Nations;
- [Appendix 5](#): Detailed Indigenous Nation Assessments;
- [Appendix 8](#): Human and Community Well-being;
- [Appendix 10](#): Effects on Current and Future Generations; and
- [Appendix 11](#): Consistency with Land Use Plans.

The information has been used to describe the potential effects of the project on Indigenous peoples from a holistic perspective, considering Indigenous Knowledge described throughout this Report.

<sup>132</sup> Further information on the consideration of effects on Indigenous peoples in the public interest factors can be found in [Policy Context: Public Interest Determination under the Impact Assessment Act](#).

### 26.9.1 The Duty to Consult and Tsawwassen Treaty Obligations

The former federal Minister of Environment and Climate Change approved the substitution of the provincial assessment process for the federal impact assessment on November 29, 2022. As per the [Cooperation Agreement](#) and the [Notice of Substitution Approval under the IAA](#), the EAO conducts the procedural aspects of consultation with Indigenous peoples through the substituted assessment process. However, Canada retains its duty to consult with Indigenous peoples and its treaty obligations under Chapter 15 of the *Tsawwassen First Nation Final Agreement*.

The IAA describes how this duty is to be implemented, including support for coordination action among jurisdictions; fostering reconciliation and working in partnership with Indigenous peoples; and the integration of Western scientific information and Indigenous Knowledge. Consideration of any potential adverse impact on the exercise of the rights of Indigenous peoples that may be caused by the Project is required by the IAA and to fulfill the Crown's constitutional obligation to consult with respect to potential impacts.

Chapter 15 of the *Tsawwassen First Nation Final Agreement* contains obligations related to the assessment that are additional to the requirements of the IAA. Information gathered during the substituted assessment will inform Canada's determination of whether it has met the requirements under Chapter 15 of *Tsawwassen First Nation Final Agreement*.

IAAC collaborated closely with Tsawwassen First Nation throughout the substituted assessment to understand their concerns regarding the Project in relation to the Treaty and how the Project may impact Tsawwassen First Nation's aspirations as stewards of its territory and resources.

Tsawwassen First Nation conducted their own Indigenous-led Assessment according to their own laws, knowledge systems, and decision-making frameworks. The assessment evaluated the potential effects of the Project on the psychosocial conditions that support Tsawwassen's Aboriginal and Treaty rights, as well as Treaty Objectives. Additionally, it focused on mental and emotional well-being, sense of place and identity, and experiences of marginalization within a landscape shaped by sustained industrial transformation.

Tsawwassen's Indigenous-led Assessment concludes the following impacts to Tsawwassen's Aboriginal and Treaty rights and Treaty Objectives:

Residual effects on psychosocial well-being are characterized by high vulnerability, moderate magnitude, long-term duration, and low reversibility. When assessed against Tsawwassen's articulated desired future conditions, including strengthened cultural continuity, stewardship, and confident intergenerational renewal and rights-based practice, the Project contributes incrementally but materially to ongoing strain in a negative direction.

The overall severity of residual psychosocial effects, which translate into effects on Tsawwassen's rights and Treaty Objectives, is determined to be Moderate. The Project does not eliminate the ability of Tsawwassen members to exercise their rights. However, it reinforces cumulative pressures in a landscape where psychosocial thresholds have already been crossed, further constraining the conditions that support confident, future-oriented revitalization of rights-based practices.

IAAC acknowledges and respects Tsawwassen First Nation's leadership in undertaking its own Indigenous-led Assessment and the considerable time and effort taken to provide a thorough analysis of the Project's potential impacts on Tsawwassen First Nation. Tsawwassen First Nation's Indigenous-led Assessment considers not only the environmental effects of the Project, but also the cultural, historical, and cumulative impacts on the exercise of rights. The assessment puts Indigenous perspectives, knowledge, values and laws at the forefront; with Tsawwassen selecting the assessment methods, indicators and thresholds that are most relevant to its community.

Tsawwassen First Nation concludes in their Indigenous-led Assessment that the Project does not eliminate the ability for members to exercise their rights, but it contributes to the cumulative pressures that constrain the practice of

rights in the preferred manner. IAAC is supportive of the assessment conducted by Tsawwassen and acknowledges the conclusions reached by Tsawwassen in the Indigenous-led Assessment.

### 26.9.2 Consultation Principles and Objectives

The objectives of Crown consultation are to meet the duty to consult, uphold the honour of the Crown, and help build long-term relationships based on shared reconciliation objectives. The methods for meeting the legal duty to consult can be different for every project, but are informed by government policies, best practice, and evolving jurisprudence such as:

- [\*Aboriginal Consultation and Accommodation Guidelines\*](#) (Guidelines);
- [\*Principles Respecting the Government of Canada's Relationship with Indigenous Peoples\*](#) (Principles);
- [\*Impact Assessment Agency of Canada's Reconciliation Framework\*](#) (Pathways)
- [\*Building Relationships and Advancing Reconciliation through Meaningful Consultation\*](#);
- [\*Collaboration with Indigenous Peoples in Impact Assessments\*](#)
- [\*Indigenous Knowledge under the Impact Assessment Act\*](#); and
- [\*Considering Community Knowledge under the Impact Assessment Act\*](#).

As described in the documents above, key principles and objectives driving the Crown's Duty to Consult include the following:

- **Respectful:** The process must respect the potential or established Aboriginal or Treaty rights of First Nation, Métis, and Inuit people while engaging in consultation and should demonstrate how the Crown has sought to accurately understand all issues and potential impacts on Indigenous peoples and their rights (Guideline No. 1, No.2, No.3, and No.8; Principle No.5, and No.10). This includes ensuring that Indigenous nations are given opportunities, appropriate to the level of potential impacts on rights, to learn about the project and its potential impacts, evaluate the project, and communicate concerns to the Crown (Guideline No.2, and No. 3; Pathway No.1 and No.4).
- **Meaningful:** The process must clearly reflect that the Crown has made meaningful efforts to understand Indigenous concerns, potential impacts, and identify solutions for accommodation where required (Guideline No.4, and No.8, Principle No.6, and No.7; Pathway No.2, and No.3).
- **Flexible and Responsive:** Through its consultation record, the Crown must demonstrate that the process remained flexible and responsive, and identified means to address potential impacts on Indigenous peoples and their rights (Guideline No.4, No.5, No.7, and No.8; Principle No.6; Pathway No.1, and No.2). Responsiveness must be both meaningful and reasonable, where 'meaningfulness' is measured by sufficiency, quality, and consistency (Guideline No.4; Pathway No.2).
- **Accommodation:** Where appropriate, accommodation should be considered, and commensurate to the degree of seriousness of the potential impact on Indigenous nations and their rights (Pathway No.3, and No.4).

Overall, the process must be accessible, reasonable, flexible and fair, founded in the principles of good faith, respect and reciprocal responsibility, and respectful of the uniqueness of each Indigenous nation.

### 26.9.3 The Tilbury Phase 2 LNG Expansion Project Consultation Process

Throughout the consultation process, each Indigenous nation had opportunities to:

- Evaluate the Project's impacts on Indigenous interests;
- Provide Indigenous Knowledge related to the assessment site and potential impacts to Indigenous rights and interests;
- Conduct studies to support the characterization of potential impacts to Indigenous rights and interests;
- Raise concerns to the proponent, the EAO, IAAC, and Federal Authorities who participated through the TAC; and
- Meaningfully engage in the substituted assessment and consultation process, including on potential federal conditions which are based on the federal Key Mitigation Measures.

Issues raised by Indigenous nations were documented and tracked in the [Application Review Issues Tracking Table](#). This document was regularly updated and shared with Indigenous nations to facilitate discussion.

During the Effects Assessment and Recommendations phase, the EAO and IAAC are pursuing a collaborative approach to consultation with the aim of achieving consensus with Indigenous nations on the draft Report, the proposed provincial conditions, and the potential federal conditions. The EAO and IAAC will hold consultation meetings and/or provide written correspondence to respond to outstanding issues or concerns from Indigenous nations prior to the Decision phase.

The EAO is of the view that, to date, the substituted assessment offered sufficient opportunities and funding to all Indigenous nations to enable them to participate meaningfully in all phases of the process. Indigenous nations received timely information to enable them to understand the Project, the substituted assessment and consultation process, and to evaluate the potential changes to the environment, health, social and economic conditions, and the potential impacts on the rights of Indigenous peoples.

### 26.9.4 Meeting Federal Crown Consultation Objectives

Below is a summary of Detailed Indigenous Nation Assessments from [Appendix 5](#) and a description of how these assessments support meeting federal consultation obligations.

#### 26.9.4.1 Consensus Seeking Under the Provincial EA Process

The EAO sought consensus with participating Indigenous nations at each phase of the substituted assessment and offered the opportunity to submit notifications of consent or lack of consent at the conclusion of the assessment. These notices of consent will be noted in the Report and are provided to decision makers to support both federal and provincial decision making on the Project.

#### 26.9.4.2 Tsawwassen First Nation Final Agreement

Chapter 15 of the *Tsawwassen First Nation Final Agreement* specifies unique provisions for environmental assessments that are in addition to the requirements of the IAA and B.C.'s *Environmental Assessment Act (2018)*. The decision maker must consider the requirements in Clauses 4 and 5 of Chapter 15. Canada's representatives worked collaboratively with Tsawwassen First Nation and B.C. as part of a tripartite government approach, which supported timely information sharing, the discussion of issues relevant to decision-making, and application of Tsawwassen First Nation's treaty rights and interests, while respecting each government's distinct requirements and responsibilities.

### 26.9.4.3 Mitigation Measures and Conditions

During consultation on the draft Report, proposed provincial conditions, and potential federal conditions, provincial and federal representatives indicated the measures proposed to address the concerns and interests of Indigenous nations, as summarized in [Appendix 5](#): Detailed Indigenous Nation Assessments, [Appendix 6](#): VC sections, and in [Appendix 15](#): Requirements of the *Impact Assessment Act*.

### 26.9.5 Issues Outside the Scope of the Project

Indigenous nations also raised concerns about broader issues affecting Indigenous interests that are outside the scope of the assessment and may not fully be addressed by Project-specific mitigation measures, as described below.

#### Federal Assessment Scope

Tsleil-Waututh Nation raised ongoing concerns throughout the substituted assessment process, including in comment submissions and in a letter to IAAC on August 5, 2025, noting that the environmental assessment does not consider the full scope of the Project by omitting marine shipping impacts from the transportation of materials to the project or from shipping the LNG product overseas, and splitting components and activities of the expansion through numerous regulatory reviews.

Tsleil-Waututh Nation indicated that statements provided by the proponent have not been considered in balance with potential impacts of the project beyond the scope of the sustainability analysis, including electricity demands and greenhouse gas emissions (GHG). The proponent described project benefits, including satisfying demand for natural gas, however Tsleil-Waututh argued it did not fully consider the economic impacts on communities—particularly Indigenous communities—related to higher renewable electricity costs and cumulative climate pressures. Tsleil-Waututh also raised concerns about the proponent’s qualitative assessments regarding the global GHG reductions from shipping LNG to overseas markets and using LNG as a beneficial alternative marine fuel. Downstream GHG emissions and components of upstream or Project emissions, such as methane slip, are outside the scope of the assessment, as well as the consideration of GHG emissions or other impacts from shipping and bunkering of ships transporting the LNG product overseas.

More information on these concerns is described in [Section 7.1](#) Greenhouse Gas Emissions, [Section 7.3](#) Project Scope and Aquatic Effects, and [Appendix 5, Section 16.20](#) of this Report.

In responding to these concerns, the EAO worked with IAAC, ECCC, and B.C.’s Climate Action Secretariat to meet with Tsleil-Waututh Nation in October and November 2025 regarding the Strategic Assessment of Climate Change and provincial GHG emission requirements. IAAC also provided a further response in writing to Tsleil-Waututh Nation’s outstanding concerns raised in its August 5, 2025, letter. The EAO and IAAC acknowledge that Tsleil-Waututh Nation continues to have outstanding concerns as identified in this section and in [Appendix 5, Section 16.20](#) of this Report and will continue to work with Tsleil-Waututh Nation through the Effects Assessment Phase to attempt to resolve outstanding issues.

Most Indigenous groups have also raised concerns about splitting components and activities of the expansion through numerous separate regulatory reviews. The EAO and IAAC sought information from FortisBC in Early Engagement and Readiness Decision phases to clarify the relationship and linkages between the project, Tilbury Marine Jetty, and the Tilbury Phase 1 activities. The EAO and IAAC remains of the view that Tilbury Phase 2, the Tilbury Marine Jetty Project and the Tilbury Phase 1 activities are separate projects and have been considered or are being assessed under the appropriate regulatory mechanisms.

#### Cumulative effects in the lower Fraser River

Many Indigenous nations emphasized the significant cumulative effects from industrialization on Tilbury Island, in Tilbury Slough, and in the lower Fraser River. Indigenous nations noted these effects are limiting or preventing the practice of their Rights in these areas, as described in [Appendix 5](#) of this Report. While these impacts were raised in

the context of the Project, Indigenous nations also identified these concerns as more broadly related to the cumulative effects of the region.

The provincial and federal governments remain committed to meaningfully addressing these concerns in partnership with Indigenous nations through the various collaborative initiatives currently underway. Examples include the B.C. Coastal Marine Strategy, which will invest more than \$2.5 million in Indigenous-led marine stewardship initiatives focused on habitat restoration, pollution prevention, and environmental monitoring, and the British Columbia Salmon Restoration and Innovation Fund, which invested \$128.6 million in 97 projects between 2019 and 2024 to support salmon restoration, habitat recovery, sustainable fisheries, climate resilience, and Indigenous participation. Federally, through the Oceans Protection Plan, the Government of Canada is also investing \$1.5 billion to improve marine safety, protect coastal ecosystems, and strengthen Indigenous partnerships through the Cumulative Effects of Marine Shipping (CEMS) Initiative that assess and manage cumulative effects of marine shipping and the Whales Initiative that aims to reduce cumulative impacts on Southern Resident Killer Whales. The Government of Canada is investing an additional \$2 billion over nine years to continue these existing initiatives and to establish 15 new measures to expand ocean protection initiatives to more regions and improve marine safety.

### 26.9.6 The EAO's Analysis and Conclusion

The EAO is of the view that for the purpose of informing federal decision making, the potential impacts of the Project on Indigenous interests have been effectively identified and meaningfully consulted on for each potentially impacted Indigenous nation. Comments received from Indigenous nations on drafts of this Report, and the federal Key Mitigation Measures and Follow-Up Programs were meaningfully considered by the EAO. The EAO notes, however, that a number of Indigenous nations developing their Indigenous-led Assessments do not share this view and continue to have outstanding concern related to the sufficiency of information to inform their own decision-making, prior to providing their own conclusions on the Project.

To inform both federal and provincial decision making on the Project, Indigenous nations may provide input directly to decision makers, including expressions of consent or lack of consent with this Report, the EAO's draft recommendations and the federal Key Mitigation Measures and Follow-Up Programs to inform the Minister's decision.

The EAO is satisfied that through the substituted assessment process, the proposed provincial conditions and other related mechanisms, federal Key Mitigation Measures and Follow-Up Programs will avoid, minimize, or otherwise accommodate for potential adverse effects of the Project on Indigenous interests. The engagement undertaken with Indigenous nations on the Project supports the federal Crown in meeting its duty to consult and broader reconciliation objectives.
