Subject: Noise Monitoring New Polaris – June 2026

1 Introduction

1.1 Background

Baseline noise monitoring was conducted by Core Geoscience Services Inc. (CoreGeo) at the New Polaris Project site from June 11 to June 17, 2026, and at Cranberry Island from June 12 to June 16, 2026 to characterize summer acoustic conditions at the mine development, and assess the acoustic impact of the proposed Taku River barge. This monitoring event is a continuation of the baseline noise monitoring conducted by CoreGeo at the New Polaris Project site in October 2025 and March 2026.

The monitoring was undertaken in response to recommendations from members of the Technical Working Group (TWG), including the Taku River Tlingit First Nation (TRTFN), who identified the absence of empirical baseline noise data as a key information gap in the environmental assessment process.

1.2 Objectives and Scope of work

The objectives of the baseline noise monitoring were to:

- Establish quantitative existing acoustic conditions at the Mine/Camp area and at Cranberry Island— to provide a defensible reference for future project-related noise assessments.
- Evaluate the effect of the barge on the acoustic environment at Cranberry Island, as part of a test run in anticipation of the Project's requirements for barge transportation.
- Characterize typical and peak noise levels using standard acoustic indicators (LAeq, LA10, LA50, LA90, LAFmax, LCeq, and LCFmax) and evaluate the contribution of low-frequency sound (LCeq–LAeq).
- Document temporal and meteorological influences on ambient sound, including wind speed, precipitation, and diurnal variation, to ensure data representativeness and identify potential sources of variability.
- Support ongoing engagement with TRTFN and the TWG by providing transparent, high-quality data suitable for incorporation into environmental modelling and assessment of potential project effects on sensitive receptors and wildlife.

2 Methods

Noise monitoring was conducted in accordance with the New Polaris Baseline Noise Monitoring Workplan (CoreGeo, 2025) to ensure consistency with recognized best practices and guidance (ISO 1996-2:2017; BC ENV 2018) and with prior monitoring events. The methods were designed to generate representative, high-quality data suitable for establishing baseline acoustic conditions and supporting future noise modelling and effects assessment.

2.1 Monitoring Locations

Two locations were selected to represent distinct acoustic environments within the Project area (see Figure 1):

- **Mine Site/Camp Area:** Located near the existing camp and mine infrastructure to characterize acoustic conditions during summer site activities and provide continuity with the monitoring completed at this location in October 2025 and March 2026.
- **Cranberry Island:** Located on Taku River along the anticipated barge transportation route. The location was selected to evaluate the influence of the barge test run while also characterizing existing acoustic conditions representative of the Taku River corridor. The monitor was positioned away from known local sources of interference, such as the helicopter landing pad and generator.

2.2 Instrumentation and Configuration

Noise levels were measured using Sonitus EM2030 environmental sound level monitors, which provide high-resolution continuous logging and are suitable for unattended long-term environmental applications. The instruments were configured as follows:

- Logging interval: 1-minute averages
- Weightings: A-weighted and C-weighted measurements (LAeq, LCeq)
- Time response: Fast (LAF, LCF)
- Parameters recorded: Leq, L10, L50, L90, LAFmax, LCFmax, Peak(C), and one-third octave-band spectra
- Trigger recordings: 20-second audio recordings captured automatically when A-weighted sound levels exceeded 50 dBA

The instruments were mounted on tripods approximately 1.5 m above ground level (see photo in Figure 2 below).

Although the sound level monitors were intended to record continuously using one-minute logging intervals for the duration of the field program, the dataset from Instrument B was discontinuous, likely due to power-supply or instrument-setting issues. Nevertheless, Instrument B collected more than 81 hours of valid acoustic data between June 11 and 16.

Figure 2. Cranberry Island deployed monitor ("Instrument B")– June 2026

Instrument A was deployed at the New Polaris Project site from June 11 - 17. Instrument B was deployed at Cranberry Island from June 12 - 16 and then moved to the New Polaris Project site from June 16 to June 17.

2.3 Meteorological Data Collection

Weather data from the on-site meteorological station were reviewed to identify periods when adverse conditions may have affected the acoustic measurements. Periods with wind gusts exceeding 5 m/s were flagged and reviewed for potential exclusion in accordance with ISO 1996-2. Periods with precipitation counts exceeding 10 bucket tips per hour were also reviewed.

3 Results

3.1 Meteorological Data Summary

Hourly meteorological data recorded by the on-site weather station during the June noise monitoring program are summarized in Table 1.

Conditions were generally favourable for noise monitoring, with low wind speeds and minimal precipitation on most days. Hourly mean wind speeds remained below the 5 m/s screening threshold referenced in ISO 1996-2. Wind gusts exceeded 5 m/s during 12 one-hour intervals. Because the hourly meteorological data did not identify the precise timing of individual gusts, the one-minute acoustic data recorded within these intervals were reviewed for elevated sound levels potentially attributable to wind. Based on this review, 24 one-minute records were removed from the Cranberry Island dataset and three were removed from the Mine Site dataset.

Precipitation was assessed using the weather station's rain-count data, which were generally low during the monitoring period, with a mean of 0.84 counts per hour. Rain counts exceeded 10 during three one-hour intervals. The corresponding acoustic data were reviewed; because sound levels were not elevated relative to surrounding periods, no acoustic records were excluded on the basis of precipitation.

Overall, meteorological conditions were suitable for representative ambient noise monitoring and support the validity of the retained dataset.

3.2 Noise Data Summary

Between June 11 - 17, 2026, a total of 81 hours of sound level data were collected at the Mine Site by Instrument A, with 29 hours of duplicate recordings when Instrument B was moved alongside Instrument A. 93 hours of sound level data were collected at Cranberry Island by Instrument B between June 12 – 16.

Data segments associated with field staff during instrument deployment and retrieval were identified through the triggered audio recordings or elevated sound levels and excluded from analysis. All remaining data were retained and considered representative of ambient baseline conditions at the time of monitoring.

3.2.1 Cranberry Island

The barge GPS track was reviewed, and monitoring periods during which the barge was in the vicinity of the Cranberry Island noise monitor were identified and compiled separately. A total of 173 one-minute intervals, equivalent to approximately 2.9 hours, were classified as periods when the barge was in the area. The remaining 5,369 one-minute intervals, equivalent to approximately 89.5 hours, were classified as periods when no barge was in the area.

Table 2 summarizes the mean one-minute A-weighted and C-weighted acoustic indicators for the two periods, together with the highest one-minute maximum fast-response sound levels (LAFmax and LCFmax) recorded during each period. The parameters include the equivalent continuous sound level (Leq), percentile sound levels (L10, L50, and L90), and maximum fast-response sound levels. Complete monitoring results are provided in Appendix A.

Table 2: Noise Monitoring Results Summary (dB), Cranberry Island with and without barge in the area, June 2026

	Barge in the Area	**No Barge in the Area**
Count	173	5369
LAeq	46.1	46.1
LA10	47.6	47.6
LA50	45.2	45.1
LA90	43.7	43.7
LAFmax	83.2	89.2
LCeq	58.4	57.3
LC10	58.8	57.9
LC50	58.1	57.1
LC90	57.7	56.6

	Barge in the Area	No Barge in the Area
LCFmax	87.2	91.8
LCeq – LAeq	12.2	11.3

The A-weighted results were essentially unchanged between the two periods. LAeq and LA10 were identical, while LA50 differed by only 0.1 dB and LA90 was unchanged. These results indicate that the barge did not measurably affect the typical broadband A-weighted sound environment at Cranberry Island when the data were averaged across the identified periods.

The C-weighted indicators were approximately 0.9 to 1.1 dB higher when the barge was in the area. The LCeq − LAeq difference also increased from 11.3 dB without the barge to 12.2 dB with the barge. This suggests a small increase in lower-frequency sound during barge passage, consistent with the expected acoustic character of a marine vessel; however, the magnitude of the difference was modest.

The highest recorded A- and C-weighted maximum sound levels occurred when the barge was not in the area: 89.2 dBA and 91.8 dBC, respectively, compared with 83.2 dBA and 87.2 dBC when the barge was present. This indicates that the most prominent short-duration noise events recorded during monitoring were attributable to other environmental or local sources rather than the barge. Because these values represent individual maxima, they should not be interpreted as representative of typical conditions during either period.

Periods when the barge was not in the area were considered representative of existing acoustic conditions during the June 2026 monitoring period. These data were further separated into daytime and nighttime periods to evaluate diurnal differences in the acoustic environment. Daytime was defined as 7:00 to 22:00, and nighttime was defined as 22:00 to 7:00. Table 3 summarizes the daytime and nighttime results.

Table 3: Noise Monitoring Results Summary (dB), Cranberry Island Daytime and Nighttime, June 2026

	Daytime (7:00 – 22:00)	Nighttime (22:00 – 7:00)
Count	3232	2137
LAeq	46.3	45.7
LA10	47.9	47.1
LA50	45.4	44.7
LA90	43.9	43.4
LAFmax	89.2	85.4
LCeq	56.8	58.2
LC10	57.4	58.5
LC50	56.5	58.0
LC90	55.9	57.7
LCFmax	91.8	87.5
LCeq – LAeq	10.5	12.5

A-weighted sound levels were slightly higher during the daytime, although the differences were small. Daytime LAeq was 0.6 dB higher than nighttime LAeq, while differences in LA10, LA50, and LA90 ranged from 0.5 to 0.8 dB. These results indicate that the typical A-weighted acoustic environment was relatively consistent between daytime and nighttime periods, with only a modest reduction at night.

In contrast, the C-weighted indicators were approximately 1.1 to 1.8 dB higher at night. The LCeq − LAeq difference also increased from 10.5 dB during the daytime to 12.5 dB at night, indicating that low-frequency sound made a somewhat greater relative contribution to the nighttime acoustic environment. The nearby Taku River is a plausible source of this persistent low-frequency energy through flowing water, turbulence, and shoreline wave action. Its contribution may become more apparent at night when other environmental and human-generated sounds diminish. However, the monitoring data do not allow the low-frequency component to be attributed exclusively to the river, as distant vessels, aircraft, wind, and other sources may also contribute.

The highest A- and C-weighted maximum sound levels occurred during the daytime, reaching 89.2 dBA and 91.8 dBC, respectively. This is consistent with greater daytime activity or other short-duration daytime noise events. As these values represent individual maxima, they are not considered representative of typical daytime conditions.

3.2.2 Mine Site/Camp

Acoustic monitoring at the Mine Site/Camp was intended to characterize conditions during the comparatively high level of site activity occurring in June 2026, including drilling and other activities near the mine and camp. Instrument was deployed from June 11 to June 17 while instrument B was deployed next to instrument A on June 16-17 as a QAQC measure. The results were separated into daytime and nighttime periods and compared with the October 2025 and March 2026 monitoring results to evaluate changes associated with seasonal conditions and the level of site activity.

Table 4 summarizes the mean one-minute A-weighted and C-weighted acoustic indicators recorded by each instrument during daytime and nighttime periods, together with the highest one-minute maximum fast-response levels recorded during each period. Complete monitoring results are provided in Appendix A.

Table 4: Noise Monitoring Results Summary (dB), Mine Site Daytime and Nighttime, June 2026

	Instrument A		Instrument B	
	Daytime (7:00 – 22:00)	Nighttime (22:00 – 7:00)	Daytime (7:00 – 22:00)	Nighttime (22:00 – 7:00)
Count	3851	999	1233	535
LAeq	51.2	49.7	52.1	50.9
LA10	52.2	50.4	53.1	51.8
LA50	50.7	49.5	51.6	50.6
LA90	49.8	48.9	50.6	49.8

	Instrument A		Instrument B	
	Daytime (7:00 – 22:00)	Nighttime (22:00 – 7:00)	Daytime (7:00 – 22:00)	Nighttime (22:00 – 7:00)
LAFmax	108.7	72.1	113.7	86.3
LCeq	62.7	60.0	61.3	58.8
LC10	64.0	60.9	62.3	59.7
LC50	62.1	59.8	60.7	58.6
LC90	60.6	58.8	59.5	57.7
LCFmax	108.9	77.2	113.9	91.2
LCeq – LAeq	11.4	10.3	9.1	8.0

The June results show relatively consistent A-weighted sound levels between the two instruments. Daytime LAeq was 51.2 dBA at Instrument A and 52.1 dBA at Instrument B, while nighttime LAeq was 49.7 and 50.9 dBA, respectively. The LA90 is the sound level exceeded during 90% of the measurement period and is commonly used as an indicator of the underlying or residual acoustic environment. Because brief, high-level events affect only a small portion of the monitoring period, they generally have little influence on the LA90. At the Mine Site/Camp, LA90 can be used to characterize the underlying acoustic conditions associated with persistent natural and site-related sources; however, it should not necessarily be interpreted as an undisturbed natural baseline because continuous or frequently occurring site activities may also contribute to the measured level.

At the Mine Site/Camp, LA90 ranged from 48.9 to 50.6 dBA and was relatively consistent between instruments and between daytime and nighttime periods. The small differences among LAeq, LA10, LA50, and LA90 indicate that the acoustic environment was influenced by persistent or frequently recurring sound, rather than being governed solely by occasional high-level events. Given the activities occurring at the Mine Site/Camp, these LA90 values likely incorporate continuous or recurring site-related sound and should therefore be interpreted as the prevailing background during the June monitoring period, rather than as an undisturbed natural or activity-free baseline.

Sound levels decreased modestly at night. LAeq was approximately 1.2 to 1.5 dB lower at night, while LA90 decreased by approximately 0.8 to 0.9 dB. This limited diurnal variation indicates that the underlying acoustic environment remained relatively consistent and that some continuous or recurring sound sources persisted during nighttime periods.

The largest differences between daytime and nighttime conditions occurred in the maximum sound levels. Daytime LAFmax reached 108.7 dBA at Instrument A and 113.7 dBA at Instrument B, compared with nighttime maxima of 72.1 and 86.3 dBA, respectively. Similarly, daytime LCFmax reached 108.9 and 113.9 dBC. These results indicate that short-duration, high-amplitude events occurred during daytime activities, with the highest event recorded at Instrument B. Because these values represent individual maxima, they are not representative of typical daytime sound levels.

The C-weighted results indicate a measurable low-frequency component. The LCeq − LAeq difference ranged from 7.9 to 11.5 dB and was greater at Instrument A than at Instrument B. The difference was also somewhat greater during the daytime at both locations. This pattern is consistent with contributions from mechanical equipment or other site-related sources containing low-frequency sound; however, source attribution should be supported by field observations or audio records.

The June A-weighted levels were generally similar to, but slightly lower than, the short October 2025 Mine Site dataset, when LAeq was 53.4 dBA and LA90 was 47.7 dBA. In contrast, the June results were substantially higher than those measured during March 2026, when Mine Site LAeq was approximately 26 dBA and LA90 was approximately 25 dBA during both daytime and nighttime periods. June LAeq values were approximately 24 to 26 dB higher than in March, and June LA90 values were approximately 24 to 26 dB higher.

Overall, the three monitoring events demonstrate that the Mine Site/Camp acoustic environment varies substantially with season and the level of activity. March 2026 represented quiet winter conditions with little apparent site activity, October 2025 represented a moderately elevated environment during a short daytime monitoring period, and June 2026 captured a more consistently elevated acoustic environment with pronounced daytime transient events. The June results therefore provide a useful characterization of Mine Site/Camp sound levels during a period of comparatively high activity. Direct comparisons should nevertheless consider differences in monitoring duration, season, instrument location, environmental conditions, and the specific activities occurring during each deployment.

4 Discussion and Recommendations

The June 2026 monitoring results complement the October 2025 and March 2026 datasets by characterizing summer acoustic conditions during a period of comparatively high activity at the Mine Site/Camp and by providing the first measurements at Cranberry Island along the anticipated barge transportation route. Collectively, the three monitoring events capture a broad range of seasonal and activity-related acoustic conditions relevant to the Project.

At Cranberry Island, the comparison between periods with and without the barge indicated no measurable change in the typical A-weighted acoustic environment. The modest increase in C-weighted levels suggests that the barge introduced a small low-frequency contribution, but this did not increase LAeq, LA10, or LA90. The highest maximum sound levels occurred when the barge was not in the area, indicating that other local or environmental events produced more prominent short-duration noise during the monitoring period. The barge test run therefore had a limited acoustic influence at the monitoring location under the vessel operating, distance, and propagation conditions encountered during the test. These results should not be interpreted as representing all future barge movements, which may involve different vessel configurations, loads, speeds, routes, distances from shore, or meteorological conditions.

The periods without the barge provide a useful characterization of existing summer acoustic conditions along the Taku River. The limited daytime–nighttime differences in A-weighted levels indicate a relatively stable acoustic environment. The elevated C-weighted levels and persistent LCeq − LAeq difference suggest an ongoing low-frequency component, for which the nearby Taku River is a plausible contributor through flowing water, turbulence, and shoreline wave action. This component became somewhat more prominent relative to A-weighted sound at night, when other environmental and human-generated sounds were reduced. However, other distant or environmental sources may also have contributed to the measured low-frequency sound.

At the Mine Site/Camp, the three monitoring events demonstrate substantial variation associated with season and the level of site activity. The March 2026 dataset represents near-minimum winter sound levels in the absence of substantial activity, with the Mine Site exhibiting levels comparable to the more remote Flannigan Slough location. The October 2025 results represent a short period of moderately elevated conditions, while the June 2026 results characterize a more consistently active summer environment. The relatively elevated and stable June LA90 values indicate that persistent or frequently recurring site-related and environmental sources contributed to the prevailing acoustic environment. The June results therefore represent existing conditions during active summer work and should not be interpreted as an undisturbed natural baseline.

The March measurements remain useful as a lower-bound characterization of existing sound levels for assessing potential Project effects when background masking is minimal. Some March levels approached the practical lower measurement range of the Sonitus EM2030 under field conditions, approximately 20 to 25 dBA. Nevertheless, their consistency between instruments, locations, and daytime and nighttime periods supports their interpretation as representative of very quiet winter conditions rather than

anomalous instrument behaviour. The October and June datasets provide complementary measurements under progressively more active and seasonally louder conditions.

Overall, the combined monitoring program provides a defensible range of measured existing conditions for the Project area. It demonstrates that remote receptor locations are generally influenced by natural environmental sources, while sound levels at the Mine Site/Camp vary substantially depending on season and the intensity of site activity.

The following recommendations are provided:

1. **Address the remaining Flannigan Slough East data gap:** Complete a full monitoring deployment at this location to strengthen characterization of representative receptors and provide a consistent basis for comparison with Flannigan Slough West and Cranberry Island.
2. **Apply seasonally and operationally representative existing-condition levels:** Retain the March results as representative of quiet winter conditions, the October results as a limited fall snapshot, and the June results as representative of active summer conditions. These datasets should not be combined into a single average that would obscure meaningful seasonal and operational variability.
3. **Document future barge operating conditions:** If additional barge monitoring is undertaken, record vessel type, load, engine operating condition, speed, route, distance from the monitor, and meteorological conditions to support direct comparison among barge movements and assessment scenarios.
4. **Maintain detailed site-activity records:** During future Mine Site/Camp monitoring, document the timing and location of drilling, equipment operation, aircraft movements, and other major activities. Where practicable, review triggered audio recordings to identify the sources of prominent events.
5. **Establish criteria for interpreting very low sound levels:** Define consistent procedures for reviewing Sonitus EM2030 data near the practical lower measurement range, including consideration of instrument self-noise, reduced signal-to-noise ratios, and the interpretation of LCeq − LAeq under low-level conditions.
6. **Continue concurrent meteorological monitoring:** Where practicable, collect meteorological data at a finer temporal resolution so that individual wind gusts and precipitation events can be correlated more precisely with the one-minute acoustic data.
7. **Complete instrument quality-control checks:** Resolve the power-supply or configuration issue associated with the discontinuous Instrument B record and verify power capacity, logging settings, clock synchronization, calibration, and data storage before future deployments.

5 Conclusions

The June 2026 monitoring complements the October 2025 and March 2026 datasets by characterizing active summer conditions at the Mine Site/Camp and existing conditions along the Taku River at Cranberry Island. The barge test run produced no measurable change in typical A-weighted sound levels, although a modest low-frequency contribution was observed. Together, the three monitoring events define a representative range of seasonal and activity-related acoustic conditions and provide a robust foundation for noise modelling and effects assessment.
